Appendix B Background – Section 4: Reference Case Natural Gas Forecast

Introduction

Appendix B provides additional detailed information related to the construction of the Commercial sector Reference Case. The appendix discusses the following:

- Additional Reference Case Results – Vancouver Island, Inland South & Inland North Regions.
- CEEAM Archetype Summaries – New Buildings.

B1 Additional Reference Case Results

B2 CEEAM Archetype Summaries – New Buildings

This section includes summary profiles of the 64 existing building archetypes constructed for this study. Exhibit 59 presents a table of contents for the CEEAM building profiles that follow.

Exhibit 59 Table of Contents - New CEEAM Building Profiles

COMMERCIAL SECTOR BUILDING PROFILE

EXISTING BUILDINGS:	SIZE:	VINTAGE:	REGION:
Large Office	> 9,300 m² (100,000 ft²)		Lower Mainland

Appendix C Background – Section 5: Efficiency & Alternative Energy Technologies

Introduction

This section includes short narrative descriptions of the energy-efficiency measures examined in this study. The list of measures is reproduced for reference in Exhibit 60 below. For full descriptions of measure baselines, upgrades, as well as the financial, economic and energy analysis, readers are encouraged to review the Measure TRC model Excel file that accompanies this report.

Exhibit 60 Efficiency and Alternative Energy Technologies Included in This Study

Space Heating
- Near-condensing boilers
- Condensing boilers
- Condensing unit heaters
- High-efficiency rooftop units
- Condensing rooftop units
- Infrared heaters
- High-efficiency forced air furnaces
- Absorption heat pumps
- Micro-combined heat & power
- Solar pre-heated make-up air
- Air-to-air heat recovery
- Demand-controlled ventilation
- Demand-controlled kitchen ventilation
- HVLS fans
- Programmable thermostats

Building Envelope
- High-performance glazings
- Super high-performance glazings
- Wall insulation upgrade
- Roof insulation upgrade
- Air sealing

Water Heating
- Condensing DHW boilers
- Condensing tank-type water heaters
- Tankless water heaters
- Drainwater heat recovery
- Low-flow faucet aerators and showerheads
- Low-flow pre-rinse spray valves
- Solar hot water heating

Cooking
- High-efficiency cooking equipment

Whole Building
- New construction – 25% more efficient
- New construction – 40% more efficient
- Recommissioning and advanced building automation (BAS)
- O&M

Space Heating Measures

Near-condensing Boilers

Near-condensing boilers present a significant efficiency gain over a standard-efficiency boiler without some of the additional considerations required for a full condensing boiler while providing a competitive cost.

Condensing Boilers

Condensing boilers provide the highest efficiency option available in today's market with thermal efficiencies reaching as high as 98% depending on conditions.

Condensing Unit Heaters

Relatively new to the market, condensing unit heaters provide a high-efficiency option for high-bay areas that have typically been served by standard-efficiency unit heaters.

HE Rooftop Units

Rooftop units are the most common form of HVAC and new developments such as modulating burners are becoming widely available and can raise the seasonal burner efficiency.

Condensing Rooftop Units

Rooftop units are the most common form of HVAC and condensing burners represent the highest efficiency available in today's market. This market hasn't reached maturity and is typically relegated to the high-energy use 100% outdoor air custom HVAC units.

Infrared Heaters

Radiant infrared heaters can be used as primary heating sources or in applications where supplementary or spot heating is required. Radiant heating systems offer energy savings because building occupants feel comfortable at lower air temperatures in radiantly heated spaces.

HE (Condensing) Forced-air Furnace

Federal legislation now requires that all residential furnaces meet the minimum performance standard of 90% AFUE. However, higher efficiency condensing furnaces are available. These furnaces include more advanced heat exchanger designs that extract more heat from the flue gases before they are exhausted.

Gas-fired (Absorption) HP

Gas absorption heat pumps can offset electricity load, using a natural gas burner as a heat source as opposed to an electrical compressor.

Micro-combined Heat & Power (CHP)

Micro-CHP units, such as Honda's Freewatt, combine natural gas or propane furnaces/boilers along with electrical generators to make the best use of available fuel.

Solar Pre-heated Make-up Air

Solar walls consist of cladding placed on a southern exposure of a building to pre-heat ventilation air, usually for 100% outdoor air applications such as a warehouse.

Air-to-Air Heat Recovery

Heat recovery allows facilities to reduce their energy consumption while maintaining the same ventilation levels, transferring heat from exhaust air to intake air.

Demand-control Ventilation

Ventilation units are typically sized for a peak load to ensure ample service when necessary. However, actual use is usually well below this and over ventilation can occur, using energy unnecessarily to heat this excess air. Demand-controlled ventilation systems use CO_2 sensors to ensure high air quality and minimal costs.

Demand-control Kitchen Ventilation

Kitchen ventilation hoods are typically sized to remove the heat created when all the kitchen equipment is in operation, a condition that occurs only during peak service times. During the downtime, a demand-controlled ventilation system can significantly reduce the excess airflow and reduce energy costs.

High-volume Low-speed Fans

The stratification effect in warehouses or other high-ceiling spaces can cause the area near the roof to be from 6-11°C higher during the heating season, causing occupant discomfort as well as excessive heat loss through the roof. HVLS fans act to reduce this stratification.

Programmable Thermostats

Programmable thermostats can help occupants better control their space temperature while incorporating shutdown/setback abilities.

Building Envelope

High-performance (HP) Glazing

HP glazings refer to a variety of technologies that can be used alone or in combination to provide an array of benefits, including lower energy costs, enhanced daylighting opportunities, reduced heating and cooling loads, and more comfortable spaces. They incorporate one or more of the following:

- Double or triple glazing with a sealed insulating glass unit
- Low-E glass
- Inert gas such as argon or krypton in the sealed unit
- Low conductivity or "warm edge" spacer bars
- Insulated frames and sashes.

Combining some of these features can lead to windows with U-values of 0.32 Btu/hr.ft^2.^{o}F or lower.

Super High-performance (HP) Glazing

Super HP glazings refer to a variety of technologies that can be used alone or in combination to provide an array of benefits, including lower energy costs, enhanced daylighting opportunities, reduced heating and cooling loads, and more comfortable spaces. They incorporate one or more of the following:

- Double or triple glazing with a sealed insulating glass unit
- Low-E glass
- Inert gas such as argon or krypton in the sealed unit
- Low conductivity or "warm edge" spacer bars
- Insulated frames and sashes.

When several of these features are combined, windows with U-values of 0.20 Btu/hr.ft^2.^{o}F or lower are possible.

Wall Insulation Upgrade

Various insulating materials and methods can be used to upgrade wall insulation, including applying rigid polystyrene board to the exterior of a building or installing fibreglass batts between interior wall studs. In addition to superior insulating performance and lower energy costs, the co-benefits include enhanced comfort, noise reduction and reduced HVAC equipment costs.

This measure involves upgrading wall insulation to R-22 (an additional R-10).

Wall Insulation Upgrade

Upgrading insulation on a built-up roofing system typically involves adding additional layers of rigid insulation at the time of re-roofing. This measure involves upgrading roof insulation with the equivalent of two inches of rigid polystyrene (an additional R-10).

Air Sealing

Air sealing is a simple building envelope measure that seals air leakage that arises around doors and windows as a result of building wear.

Water Heating

Condensing DHW Boilers
In larger facilities, domestic water is often provided by a separate boiler with a large insulated storage tank. Condensing boilers can provide large amounts of DHW at a high efficiency.

Condensing Tank Type Water Heaters
Condensing tank-type DHW heaters provide very high efficiency with a compact tank arrangement.

Tankless Water Heaters
Tankless DHW heaters can provide very high efficiency with a very compact tankless arrangement and are a suitable replacement for residential-style DHW heaters used commonly in the Commercial sector.

Drainwater Heat Recovery
For applications like showering, up to 90% of the energy used for water heating is wasted down the drain. Several companies provide products that replace a section of vertical drainpipe with a heat exchanger, harvesting heat and returning it to the hot water tank. This measure assumes that a standard-efficiency natural gas heater is providing all domestic hot water at an energy factor of 0.69.

Low-flow Faucet Aerators and Showerheads
Hand washing contributes a significant portion of Commercial sector building water use and can be considerably reduced through the use of easy to install faucet aerators.

Showers in commercial facilities such as hotels can contribute significantly to domestic hot water loads and efficient alternatives are readily available.

For this measure, a standard-efficiency DHW heater with an energy factor (EF) of 0.69 is used.

Low-flow Pre-Rinse Spray Valves
Pre-rinse spray valves are used in nearly every restaurant and hotel in British Columbia. Low-flow options are an inexpensive way to curtail both water and natural gas use.

Solar HW Pre-heat
Solar water pre-heat is the most efficient renewable technology currently on the market, avoiding the need to convert sunlight to electricity but instead converting directly to heat. Solar thermal systems pre-heat make-up water to an intermediate temperature, reducing the operation of the standard hot water heater.

Cooking

High-efficiency Cooking Equipment
Major cooking appliances include fryers, griddles, ranges and ovens. Most cooking appliances are evaluated in terms of “cooking efficiency,” which is the ratio of energy added to food being cooked to the energy supplied to the appliance during cooking. Cooking efficiency of cooking equipment may be improved in two main ways: 1) increased insulation minimizes heat loss and improves energy performance in the idling state and 2) improved controls may reduce "on time" by sensing the presence of a cooking load and avoiding overheating.

Whole Building

New Construction - 25% More Efficient

High-performance new building construction refers to new high-efficiency buildings that are designed using the integrated design process. Through the application and integration of energy-efficiency technologies and design approaches, high-efficiency buildings that use this process can achieve substantial improvements over conventional new buildings. The co-benefits include lower operations and maintenance costs, and enhanced occupant productivity and health.

New Construction - 40% More Efficient

High-performance new building construction refers to new high-efficiency buildings that are designed using the integrated design process. Through the application and integration of energy-efficiency technologies and design approaches, high-efficiency buildings that use this process can achieve substantial improvements over conventional new buildings. The co-benefits include lower operations and maintenance costs, and enhanced occupant productivity and health.

Recommissioning (RCx) and Advanced Building Automation Systems (BAS)

Recent developments in BAS have unlocked the potential to exploit incremental energy uses in the building such as timed setbacks, automatic temperature resets and better adjustments to changing operating conditions.

Note that this combines BAS and RCx. Many of the general non-BAS related measures are covered in the O&M processes.

Operations and Maintenance (O&M)

While capital equipment replacement typically dominates energy-efficiency spending, O&M upgrades can unlock the potential of these capital expenditures as well as provide significant benefits at low or no incremental cost. These include (but are not limited to):

- Recommissioning time clocks and sensors
- Introducing a regular preventative maintenance program
- Eliminating simultaneous heating and cooling.

Appendix D Background – Section 6: Economic Potential Forecast

Introduction

This appendix provides a detailed mapping of how energy-efficiency measures were applied in the Economic Potential Forecast. Exhibit 61 provides this mapping by region, while Exhibit 62 provides a mapping by sub sector. In both cases, a ✓ symbol indicates that the measure is applied in the region/sub sector.

Appendix E Background – Section 7: Achievable Potential Forecast

Introduction

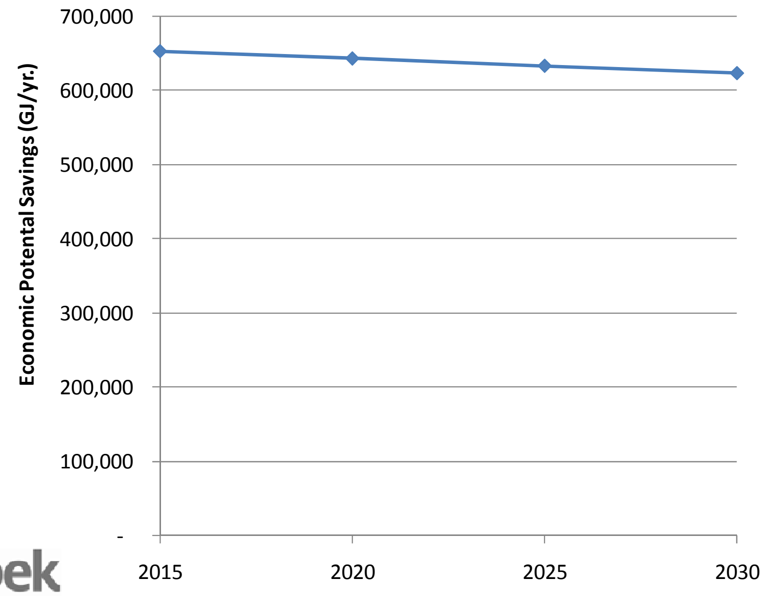
This appendix provides workshop materials from the Commercial sector Achievable Potential workshop conducted on January 26, 2011.

Exhibit 63 through Exhibit 70 show the slides that were prepared before the Achievable Potential workshop to provide participants with background information on each of the measures discussed.

Exhibit 71 through Exhibit 78 show the worksheets that were prepared before the Achievable Potential workshop to provide a structured format in which to record the results of the discussions on each measure. Workshop results and discussion highlights, as recorded during the discussions, are included in the exhibits.

Exhibit 62 Commercial Opportunity Profile, Opportunity 1

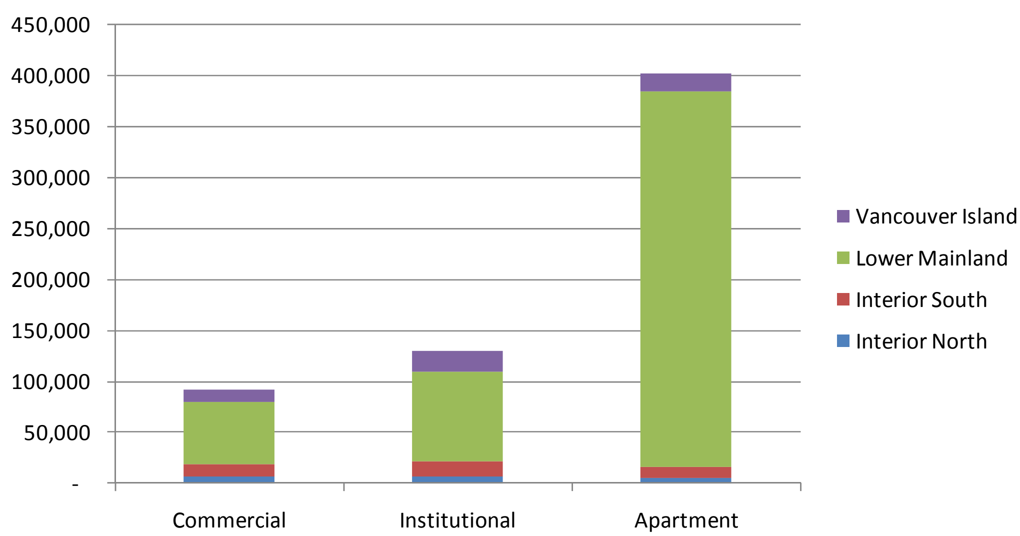
Commercial Opportunity 1: Ultra Low-Flow Fixtures



Marbek

12

Commercial Opportunity 1: Ultra Low-Flow Fixtures



Marbek

13

Commercial Opportunity 1: Ultra Low-Flow Fixtures

- Technology Description
  - Measure involves limiting an existing 8.3 LPM (2.2 GPM) faucet to 3.8 LPM (1 GPM) using an aerator.
- Discussion Sub Sector – Large Apartment, LM
- Typical Application
  - Cost: estimated full cost of $10/$25 installed (aerator/showerhead)
  - Useful life: 5/10 years (aerator/showerhead)
  - Savings: approx 55%/50% of faucet/shower hot water use

Marbek

14

Commercial Opportunity 1: Ultra Low-Flow Fixtures

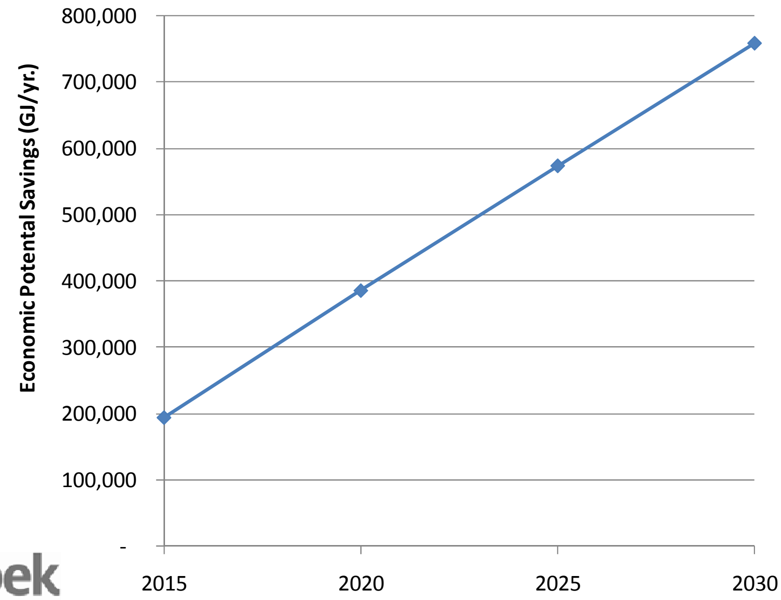
- Financial & Economic Indicators
  - Approx. 10 month simple payback
  - B/C ratio = 4.8
  - Basis of assessment: Full Cost
- Approximate Number of Eligible Participants
  - 135 Large Apartment Buildings
  - Eligible immediately

Marbek

15

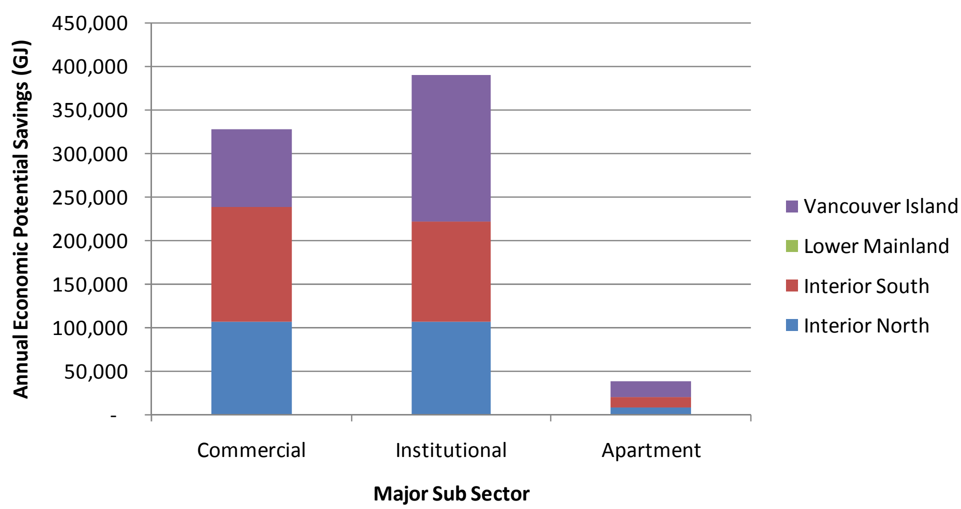
Exhibit 63 Commercial Opportunity Profile, Opportunity 2

Commercial Opportunity 2: Roof Insulation



16

Commercial Opportunity 2: Roof Insulation



17

Commercial Opportunity 2: Roof Insulation

- Technology Description
  - Measure involves upgrading roof insulation to R-20 at time of re-roofing
- Discussion Sub Sector – Medium Office, VI, IN, IS
- Typical Application
  - Cost: estimated at $1/ft^2 of roof (incremental)
  - Useful life: 20 years
  - Savings: approx 50% of heat lost through roof (estimated 8% of space heating load for medium office)

Marbek

18

Commercial Opportunity 2: Roof Insulation

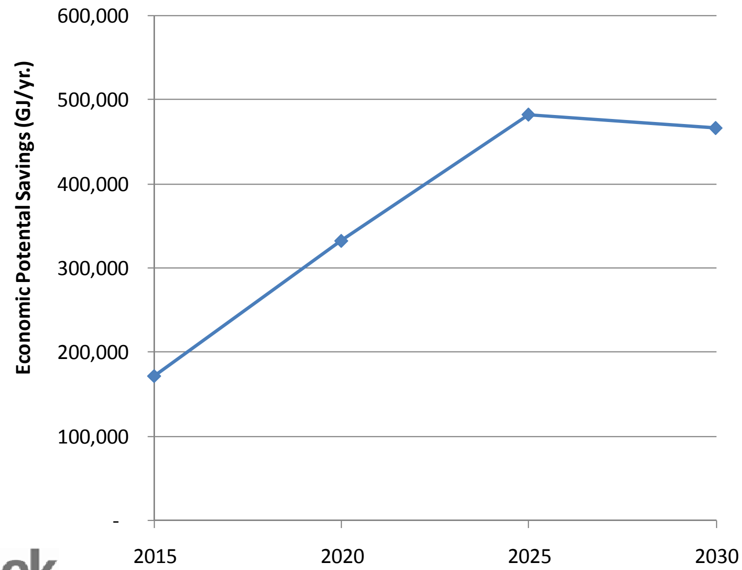
- Financial & Economic Indicators
  - 4.7 – 7.2 yrs simple payback dependent on region
  - B/C ratio = 1.03 - 1.61
  - Basis of assessment > Incremental
- Approximate Number of Eligible Participants
  - 480 roofs total (VI, IS, IN)
  - Approximately 25 sites eligible to 1st milestone year, 2015. 100 sites to 2030 milestone year.

Marbek

19

Exhibit 64 Commercial Opportunity Profile, Opportunity 3

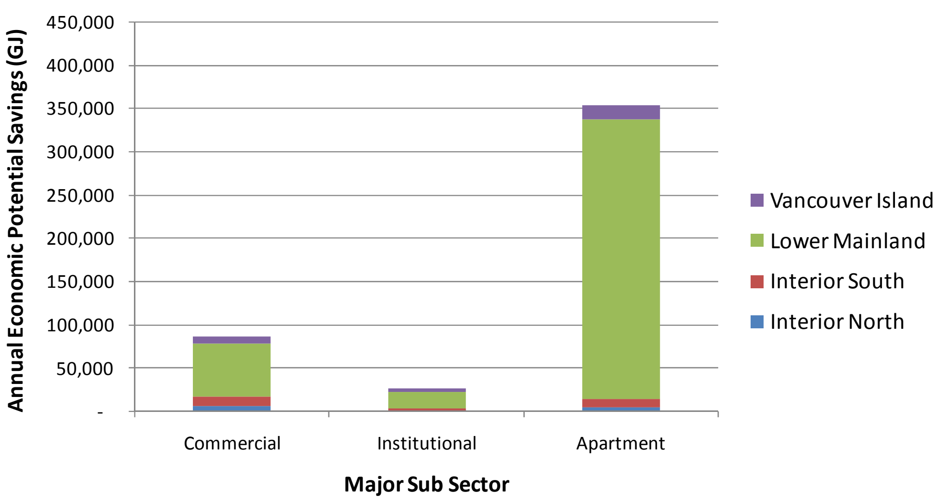
Commercial Opportunity 3: Condensing DHW (Tank)



Marbek

20

Commercial Opportunity 3: Condensing DHW (Tank)



Marbek

21

Commercial Opportunity 3: Condensing DHW (Tank)

- Technology Description
  - Measure involves upgrading to a condensing DHW Boiler at time of equipment turnover
- Discussion Sub Sector – Large Apartment, LM
- Typical Application
  - Cost: estimated at $16/MBH (incremental)
  - Useful life: 15 years
  - Savings: approx 20% of DHW Energy

Marbek

22

Commercial Opportunity 3: Condensing DHW (Tank)

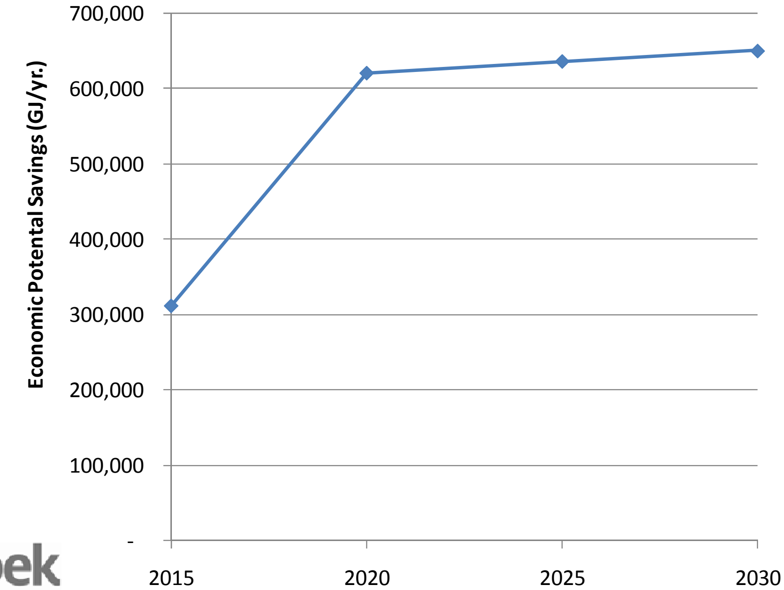
- Financial & Economic Indicators
  - 2.4 – 7.2 yrs simple payback dependent on usage
  - B/C ratio = 0.9 – 2.6
  - Basis of assessment > Incremental
- Approximate Number of Eligible Participants
  - 220 buildings total
  - Approximately 75 Large Apartment buildings eligible by 2015, 220 by 2030.

Marbek

23

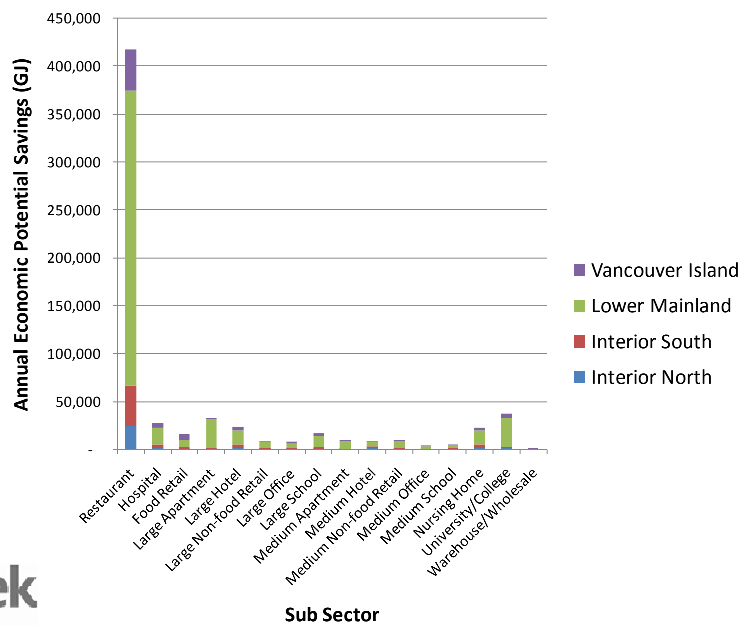
Exhibit 65 Commercial Opportunity Profile, Opportunity 4

Commercial Opportunity 4: HE Cooking Equipment



24

Commercial Opportunity 4: HE Cooking Equipment



25

Commercial Opportunity 4: HE Cooking Equipment

- Technology Description
  - Measure involves upgrading to an HE cooking equipment at time of equipment turnover.
- Discussion Sub Sector – Restaurant, LM
- Typical Application
  - For example: ENERGY STAR fryers
    - Cost: estimated at $1,100/unit (incremental)
    - Useful life: 10 years
    - Savings: approx 22% of Cooking Energy

Marbek

26

Commercial Opportunity 4: HE Cooking Equipment

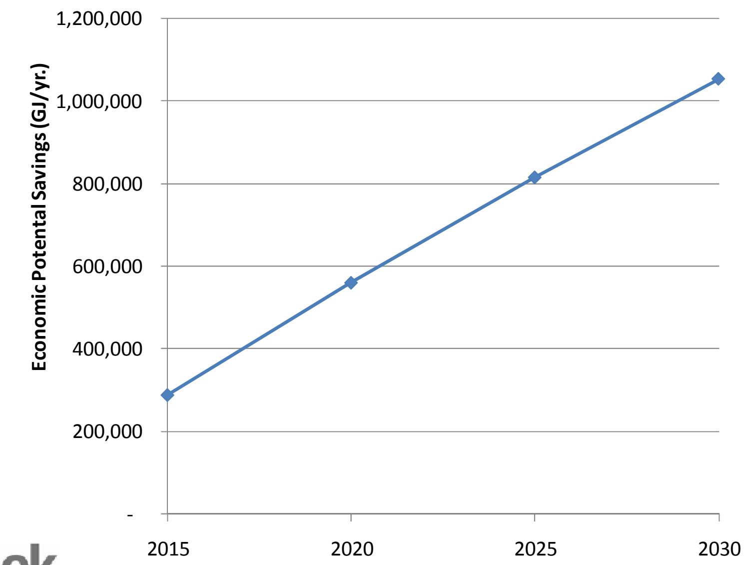
- Financial & Economic Indicators
  - 3.1 yrs simple payback (dependent on usage)
  - B/C ratio = 1.5
  - Basis of assessment > Incremental
- Approximate Number of Eligible Participants
  - 5700 buildings total
  - Approximately 570 buildings eligible yearly (Notionally 3000 pieces of equipment yearly, 14,000 to 1st milestone year – 2015)

Marbek

27

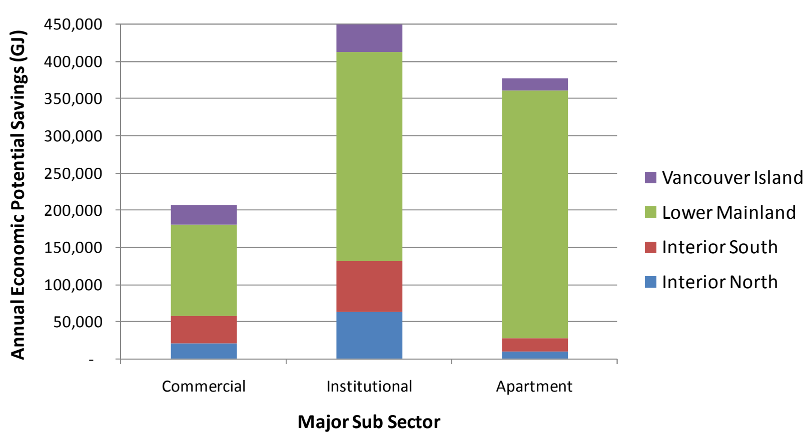
Exhibit 66 Commercial Opportunity Profile, Opportunity 5

Commercial Opportunity 5: HE Boilers



28

Commercial Opportunity 5: HE Boilers



29

Commercial Opportunity 5: HE Boilers

- Technology Description
  - Measure involves upgrading to a condensing or near-condensing boiler at the time of equipment replacement
- Discussion Sub Sector – Large Office, LM
- Typical Application
  - Cost: estimated at $17/MBH and $3/MBH (incremental) for condensing and near-condensing respectively
  - Useful life: 25 years
  - Savings: approx 24% and 15% of Space Heating Energy for condensing and near-condensing respectively

Marbek

30

Commercial Opportunity 5: HE Boilers

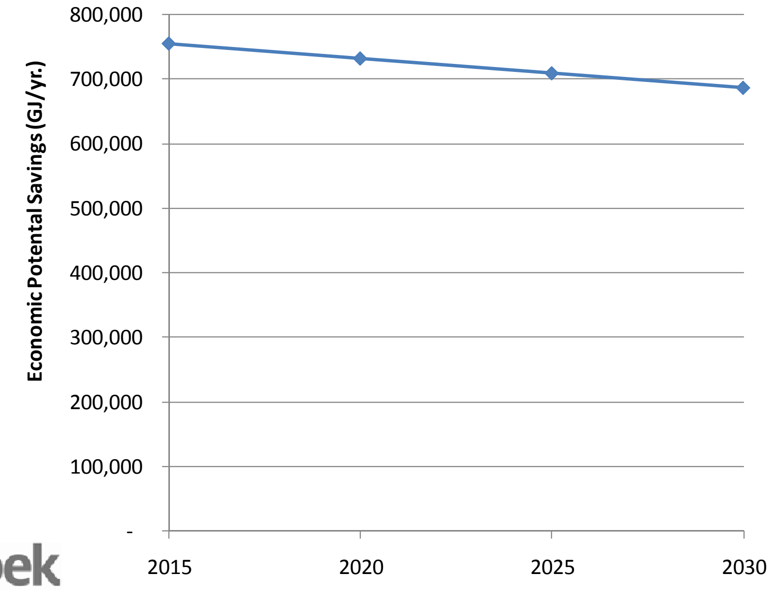
- Financial & Economic Indicators
  - 4.7 / 1.3 yrs simple payback for condensing and near-condensing respectively (dependent on region)
  - B/C ratio = 6.4 / 1.8 for condensing and near-condensing respectively
  - Basis of assessment > Incremental
- Approximate Number of Eligible Participants
  - 480 buildings total
  - Approximately 20 buildings eligible yearly (100 to 1st milestone year – 2015)

Marbek

31

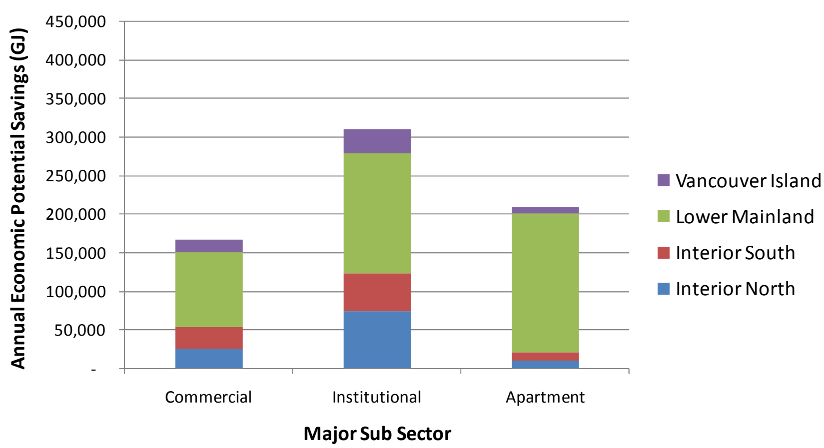
Exhibit 67 Commercial Opportunity Profile, Opportunity 6

Commercial Opportunity 6: Recommissioning



32

Commercial Opportunity 6: Recommissioning



33

Commercial Opportunity 6: Recommissioning

- Technology Description
  - Measure involves applying the retrocommissioning process to an existing building and/or installing an advanced building automation system (BAS)
- Discussion Sub Sector – Large Office, LM
- Typical Application
  - Cost estimated at $0.15/ft^2$
  - Useful life is 15 years (BAS) & 5 years (RCx) respectively
  - Typical savings of 10% of total gas use

Marbek

34

Commercial Opportunity 6: Recommissioning

- Financial & Economic Indicators
  - 1.7 yrs simple payback (dependent on region)
  - B/C ratio = 3.7
  - Basis of assessment > Full cost
- Approximate Number of Eligible Participants
  - 130 buildings total
  - All buildings eligible immediately

Marbek

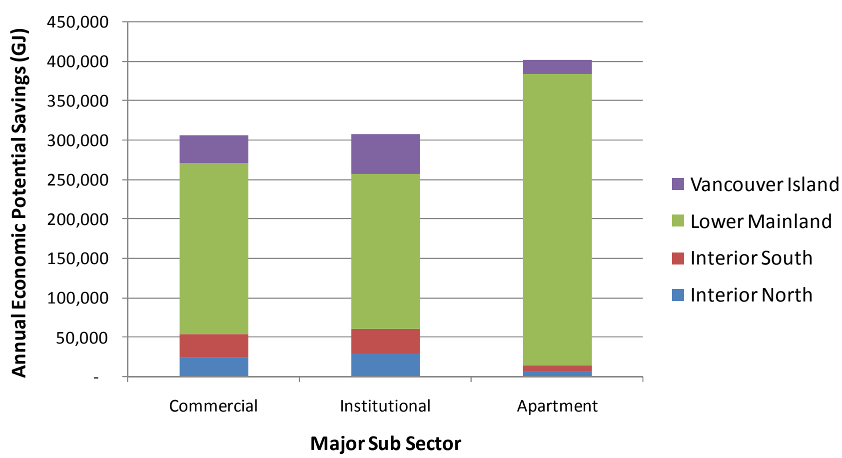
36

Commercial Opportunity 7: O&M Measures



Marbek

37

Commercial Opportunity 7: O&M Measures

- Technology Description
  - Measure involves undertaking the low or no cost measures such as cleaning heating coils, eliminating simultaneous heating & cooling, setback of DHW equipment.
- Discussion Sub Sector – Large Office, LM
- Typical Application
  - Cost estimated at $0.01/ft^2 (mix of no & low-cost measures)
  - Useful life is 1 year
  - Typical savings of 5% of total gas use

Marbek

38

Commercial Opportunity 7: O&M Measures

- Financial & Economic Indicators
  - 3 month simple payback
  - B/C ratio = 1.9
  - Basis of assessment > Full cost
- Approximate Number of Eligible Participants
  - 110 buildings total
  - All buildings eligible immediately

Marbek

39

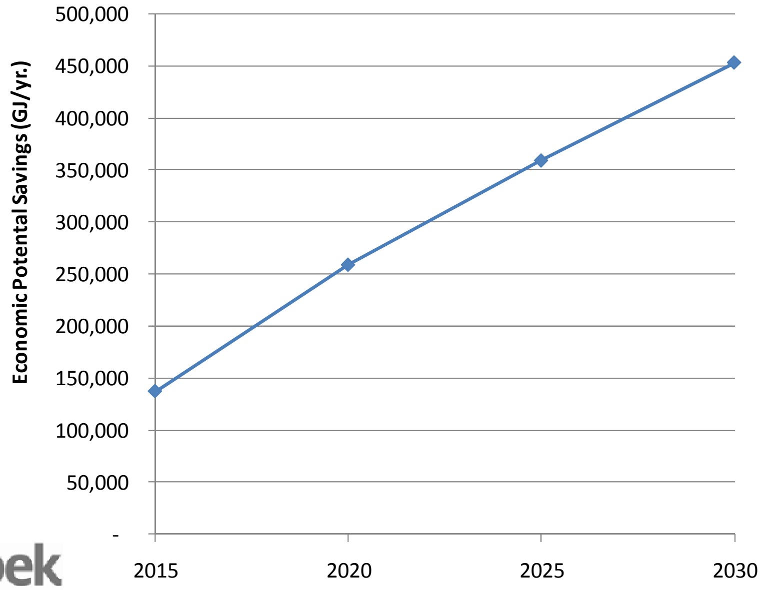
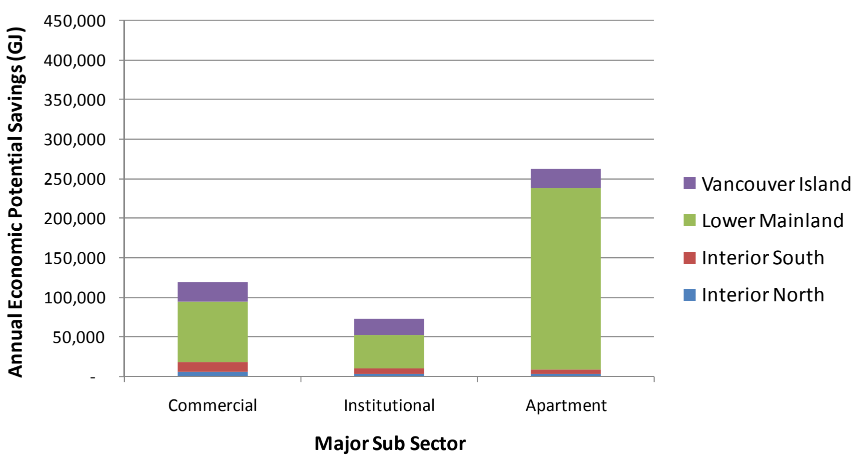
Commercial Opportunity 8: New Construction Measures



Marbek

40

Commercial Opportunity 8: New Construction Measures



Marbek

41

Commercial Opportunity 8: New Construction Measures

- Technology Description
  - Measure involves constructing new commercial buildings using an integrated design process to lower overall energy use. Two measures are examined: 40% better and 25% better than baseline construction.
- Discussion Sub Sector(s) – All, LM
- Typical Application
  - Cost estimated at \$1.50/ft^2 & \$4.50/ft^2 for 25% and 40% respectively
  - Useful life is 30 years

Marbek

42

Commercial Opportunity 8: New Construction Measures

- Financial & Economic Indicators
  - 3.4 & 6.4 year simple payback for 25% and 40% respectively
  - B/C ratios = 5.7 and 3.0
  - Basis of assessment > Incremental Cost
- Approximate Number of Eligible Participants
  - Approx 150 100,000 ft^2 buildings total per milestone period
  - All buildings eligible immediately

C1 -- Ultra Low-Flow Fixtures

General Measure Information				
Approximate Economic Savings Potential (GJ/yr) in 2030	DHW - Low Flow Fixtures	624,000		
Benefit/Cost ratio	ULF Faucet Aerators	7.9		Full
	ULF Showerheads	1.7		Full
Approx. payback (months)	ULF Faucet Aerators	2		
	ULF Showerheads	18		
Sub Sector for Discussion: Fixtures > Large Apartment > Existing > Lower Mainland				
Measure information	Benefit/Cost Ratio	4.8		Full Cost
	Approx. Payback (months)	10		
Approximate Economic Savings Potential (GJ/yr) in 2015		249,700		
Approximate Economic Savings Potential (GJ/yr) in 2030		238,300		
Market Size	Total ft^2 (approx.)	165,932,658		
	Total # of sites	720		Eq. 230,000 ft^2 buildings
	% eligible	19%		Exclude "can't" + current
	# eligible sites by 2015	135		
	# eligible sites by 2030	135		
Participation Rates, by Year (% of Eligible Sites)		**2011-2015**	**2026-2030**	**Curve**
ULF Fixtures	Common Sense	14%	55%	Curve A
	Aggressive	20%	80%	Curve A
Achievable Potential (# Buildings)				
ULF Fixtures	Common Sense	19	74	
	Aggressive	27	108	

Participation Rates for Other Subsectors/Regions (H=higher; L=lower; S=same; N/A=not applicable)			
Large Office	Higher	Hospital	Higher
Medium Office	Higher	Nursing Home	Higher
Large Non-food Retail		Large School	Higher
Medium Non-food Retail		Medium School	Higher
Food Retail		University/College	Higher
Large Hotel	Higher, but not as much as	Large Apartment	
Medium Hotel	Higher, but not as much as	Medium Apartment	Higher
Restaurant			
Warehouse/Wholesale		Vancouver Island	Higher
		Inland North	Lower
		Inland South	Same

Program Implementation Considerations		
Sensitivity to Incentives	(High Medium Low)	
Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•Would have to be a direct install program.
•Ownership patterns are a challenge. In fact, buildings where all suites are rental and the whole thing is owned by one owner, the situation is actually easier than for the strata buildings.
•By 2030 this is an issue but it's not impossible: it's an issue of contacting possibly multiple owners, and the occupants, booking a time to get into the suites, obtaining releases, etc.
•Other challenge is the perception of low-flow fixtures, which are often perceived not to work very well. This is probably more of a challenge for the high-end strata situations than for rental.
•Suggestion of going through the operator/building manager as the delivery agent for the installs.
•Issues with showerheads are largely the same as for aerators.
•Some experience with strata corporations on a fireplace program has been quite positive. Some strata corporations can be a barrier, but some are quite activist on these issues.
•Can also work with the management companies that manage strata buildings on behalf of their corporations.

Notes:
• BCH program has seen increased uptake in recent years, potential for partnership
• Lack of capacity is a barrier (esp. designers)
• Architects, builders inherently conservative.
• Will owner/purchaser/builder occupy?
• Very little demand from consumers. Talk outpacing action.
• Impending hydro rate hikes may drive EE construction (and/or consumer awareness). Especially true in MURBs
• Perception that "green" = more expensive
• Governments quite active despite lack of public uptake (subject to any changes in government/policy environment)
• Significant pushback re: "patchwork" of improved code requirements
• Carbon tax, municipal commitments to carbon neutrality are drivers
• Public sector, Universities etc. building more efficient buildings, but few of them
• Market leaders could bring along the rest of the market. (May have to overpay leaders an underpay followers)
• EE design/build tends to be more time consuming
• Establishment of 3rd party ID labs could overcome many barriers
• Developers tend to lack marketing money, may be a role for TG.
• Dependent on "energy literacy" among consumers.
• Possible partnership with governments: joint incentive, reduction in permitting time (i.e.. fund a staff position to review green permits).

Exhibit 72 Commercial Achievable Worksheet, Opportunity 2

Commercial Sector
C2 -- Roof Insulation

General Measure Information				
Approximate Economic Savings Potential (GJ/yr) in 2030	Space Heating - Roof Insulation	758,000		
Benefit/Cost ratio	Roof insulation	1.2	Incremental	
Approx. payback (years)	Roof insulation	6.2		
Sub Sector for Discussion: Roof insulation > Medium Office > Existing > IN/IS/VI				
Measure information	Benefit/Cost Ratio	1.2	Incremental Cost	
	Approx. Payback (years)	6.2		
Approximate Economic Savings Potential (GJ/yr) in 2015		5,400		
Approximate Economic Savings Potential (GJ/yr) in 2030		20,700		
Market Size	Total ft^2 (approx.)	7,831,858		
	Total # of sites (estimated)	110	Eq. 75,000 ft^2 buildings	
	% eligible	90%	Exclude "can't" + current	
	# eligible sites by 2010 - 2015	25		
	# eligible sites 2025 - 2030	25

	Aggressive	1	18	

Participation Rates for Other Subsectors/Regions (H=higher; L=lower; S=same; N/A=not applicable)			
Large Office	Higher	Hospital	Higher
Medium Office		Nursing Home	Higher
Large Non-food Retail	Higher	Large School	Higher
Medium Non-food Retail	Same	Medium School	Higher
Food Retail	Same	University/College	Higher
Large Hotel	Higher	Large Apartment	Same
Medium Hotel	Same	Medium Apartment	Same
Restaurant	Same		
Warehouse/Wholesale	Same	Vancouver Island	
		Inland North	
		Inland South	

Program Implementation Considerations		
Sensitivity to Incentives	(High Medium Low)	
Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•TG generally has to offer programs throughout the service territory. They can't really offer a program to three regions and exclude the Lower Mainland. Need to check on what the weighted average TRC result is.
•Need to pursue this through relationships with roofers, which TG doesn't currently have. That will require some start-up.
•Need to consider a barrier to do with rooftop equipment and required clearances.
•Need to do it when roof membrane being replaced in most cases.
•Interior may be a bit more difficult than LM/VI.

Large Office	Lower	Hospital	Higher
Medium Office	Lower	Nursing Home	Higher
Large Non-food Retail	Lower	Large School	Higher
Medium Non-food Retail	Lower	Medium School	Higher
Food Retail	Lower	University/College	Higher
Large Hotel	Higher	Large Apartment	
Medium Hotel	Higher	Medium Apartment	Same
Restaurant	Higher		
Warehouse/Wholesale		Vancouver Island	Slightly higher
		Inland North	Same
		Inland South	Same

Program Implementation Considerations		
Sensitivity to Incentives	(High Medium Low)	
Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•Venting is one of the challenges. Some buildings have B-venting through the roof, but mainly that's in 3-4 storey buildings. In high rise, the tanks are likely either in a rooftop mechanical room or a basement. Venting is probably not a big problem there. There currently isn't an option for common venting. If they already have B-vented standard tank type heaters, the vents may be ganged together. You can't do that with the condensing type.
•Cost issues around run length of PVC pipe as well as the type of plastic you are allowed to use. If the exhaust is hotter, the venting material costs four times as much.
•Apartment owner's main concern is reliability. They don't want call-backs on water heater failure.
•Incremental cost can be overcome if the savings are demonstrable and they can be assured of reliability. If they can't, no incentive will overcome the reluctance.
•There are still a lot of contractors who are sceptical of reliability of condensing units. Certainly the condensing tank is more complex and has more parts, and the servicing people are not all knowledgeable enough to service the product properly. The technology is now mature enough that reliability issues have been resolved.
•Partnerships for developing training programs for contractors would be appropriate.
•Typically the target market is going to be the strata corporations.
•Apartment building owners are hard to convince on spending more money upfront. Sometimes they are holding the building mainly because of the appreciating land value, so they're not interested in a lot of investment.
•A lot of strata corporation boards would have very little technical knowledge and might be hard to convince. This amount of expenditure is also probably voted on by the AGM, not just the board.
•The technology is relatively new: 10-12 years into it with water heaters.
•Could the program include provisions for regular servicing of the equipment? Could also have internet connection to the product to do remote monitoring. People who work on condensing boilers could easily take on servicing of condensing DHW tanks, but regular plumbing contractors would not be as far along the learning curve.
•Payback threshold is probably 2-3 years in this subsector.
•Higher cost of servicing the equipment is also a perceptual barrier out there.
•Awareness and availability of product are also issues. They don't have enough track record with their new product to have a sense of how it will go yet. Program was only launched in July.
•By 2020, current proposal is that this efficiency becomes minimum under federal legislation.
•Conversation would be very similar for tankless condensing.

Exhibit 74 Commercial Achievable Worksheet, Opportunity 4

Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•Lot of turnover in the restaurant business.
•Market leaders exist in some of the chains.
•Chains vary by corporate culture. Some are very slow adopters, others quite enthusiastic.
•Quality of the product is an issue with some equipment and chains.
•Program through equipment vendors might work well, particularly if the incremental cost can be covered.
•Some experience offering boiler programs to restaurants suggests that when the participate in that program they are looking for high efficiency cooking equipment as well.
•Lower Mainland might be a bit higher because of trend towards cooking under the public eye (in front).

Program Implementation Considerations		
Sensitivity to Incentives	(High Medium Low)	
Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•Boiler program experience starting to come in.
•There are owners who put in hybrid systems - put in some condensing units, but keep the old one as a peaking unit.
•Earlier on there were contractors who thought the program was foolish because of reliability concerns.
•Now there are lots more advanced contractors who are comfortable with the condensing technology.
•There are lots of installations now where the system design is correct so that you get condensing, but there are still installers who don't know how to do that properly.
•The mild climate means there are lots of periods of the year that are like "shoulder seasons" so that it's possible to use relatively low delivery and return temperatures to ensure condensing occurs.
•Boiler program is going to be segmented by several different building types and by boiler efficiency.
•This technology is heading towards becoming the norm - there are still issues with the industry, but it is coming along.
•Incremental cost doesn't seem to be a huge issue.
•Most of the program experience has been with large institutional, where most owners seem convinced that this is the thing to do, and with large apartment owners, who are pretty convinced that it isn't the thing to do.

Exhibit 76 Commercial Achievable Worksheet, Opportunity 6

Commercial Sector
C6 -- Recommissioning

General Measure Information				
Approximate Economic Savings Potential (GJ/yr) in 2030	RCx and Advanced BAS	690,000		
Benefit/Cost ratio		3.7		
Approx. payback (years)		1.7		
Sub Sector for Discussion: Recommissioning> Large Office > Existing > Lower Mainland				
Measure information	Benefit/Cost Ratio	3.7		
	Approx. Payback (years)	1.7		
Approximate Economic Savings Potential (GJ/yr) in 2015		36,000		
Approximate Economic Savings Potential (GJ/yr) in 2030		33,600		
Market Size	Total ft^2 (approx.)	30,704,593		
	Total # of sites (estimated)	100	Eq. 230,000 ft^2 buildings	
	% eligible	95%	Exclude "can't", N/A, + current

Sensitivity to Incentives	(High Medium Low)	
Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
Commissioning can mean different things to different contractors

benefits & payback clear, but market knowledge is low.

Perception is that not always necessary (by owners) - no immediate incentive/crisis

Site assessment program could be used to determine opportunity for RCx

Overall lack of understanding awareness re: degree of rigor, benefits not always apparent.

May be lack of capacity in the market to deliver service

BCH/Terasen partnership: in discussion.

Current energy specialist program - individuals may be able to promote RCx within organizations.

Split incentives an issue. Leased buildings may be less likely to participate.

Exhibit 77 Commercial Achievable Worksheet, Opportunity 7

Primary Incentive Target	(User, Channel Member, Both)	
Sensitivity to Direct Program Support	(High Medium Low)	
Most Critical Program Support Type(s)	(e.g., Trade Ally Training, Certification, Technical Workshops, etc.)	

Notes:
•most buildings in the CEUS & other walk-through audits show potential savings. Visible problems dealt with most often.
•Most building maintenance staff feel that appropriate maintenance is being undertaken.
•Could this be tied to on site assessments?
•Mobility among building maintenance staff is a barrier
•May fund a building maintenance manual / checklist (specific to each building)
• Fewer on site building engineers, often outsourced to contractors
•May be a larger opportunity in smaller commercial buildings (when unqualified staff are responsible for maintenance)
• Opportunity to educate contractors (& their associations)
•May be an opportunity for contractors to "up-sell" by looking for other issues while on a call.
• May be possibility that contractors undertake unnecessary measures if incented to do so.

Executive Summary

Background and Objectives

This Conservation Potential Review (CPR) provides FortisBC Energy Utilities ("FortisBC") with a comprehensive planning document that the company can use on an ongoing basis to:

- Develop a long-range energy-efficiency strategy
- Design and implement energy-efficiency programs
- Assess the impact of energy-efficiency programs on both peak and annual loads
- Set annual energy-efficiency targets and budgets.

Scope

Sector Coverage: The study addresses three sectors: Residential, Commercial/Institutional[1] and Industrial. In contrast to the 2006 CPR, which excluded FortisBC's (then, Terasen Gas) 300 largest industrial accounts, this CPR includes all of FortisBC's customers.

Geographical Coverage: The study results are presented for the total FortisBC service region and for the five service areas of: Lower Mainland, Vancouver Island, Whistler, Northern Interior and Southern Interior.

Study Period: The Base Year for this study is calendar year 2010. The time period covered by this study is to 2030, with milestones at the intervening years of 2015, 2020 and 2025.

Technologies: The study addresses energy-efficiency, customer behaviour and alternative energy options such as renewable and combined heat and power technologies.

Relation to Previous B.C. CPRs: This study builds on the substantial body of information and modeling work prepared in previous CPR studies conducted for FortisBC (then Terasen Gas) (2006) and BC Hydro (2007). The 2006 FortisBC study was intended to mesh with the BC Hydro study from 2007 and therefore included all customers of either utility, not just FortisBC customers. This study includes only FortisBC natural gas customers because this permitted the study to make better use of the recently completed energy end-use studies.

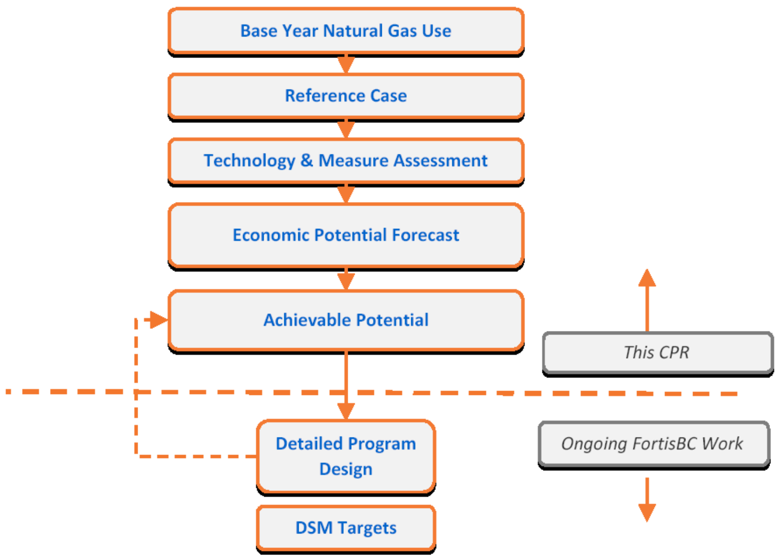
Approach

The detailed end-use analysis of energy-efficiency opportunities in the Industrial sector employed a customized spreadsheet model. Key inputs to the model were the forecast of comfort and process heat requirements per service area, major sub sector, and major end use. Other key inputs were the efficiency of the technologies (natural gas-using equipment) that were currently in place and the efficiency of higher efficiency alternatives that were available.

The major steps involved in the analysis are shown in Exhibit ES 1 and are discussed in Section 2 of this report. As illustrated, the results of this CPR study, and in particular the estimation of Achievable Potential, support on-going DSM planning work. However, it should be emphasized that the estimation of Achievable Potential is not synonymous with either the setting of specific program targets or with program design.

[1] Throughout this report, use of the word "commercial" includes both commercial and institutional buildings unless otherwise noted.

Exhibit ES 1 CPR 2010: Main Analytic Steps



Base Year Natural Gas Use

In the Base Year of 2010, FortisBC's industrial customers consumed approximately 36,456,000 GJ. Exhibit ES 2 and Exhibit ES 3 provide, respectively, additional details on the major end uses and sub sectors where Industrial sector natural gas consumption occurs.

Exhibit ES 2 shows that boilers accounts for approximately 43% of the total industrial natural gas use. Most of the boiler load involves process steam use. Furnaces for air heating large industrial areas account for about 12% of the consumption and another 12% is used in kilns at pulp and paper sites, manufacturing lime for the Kraft pulping process. The remaining natural gas is used in a variety of industrial processes including lumber kilns, coal driers and cement kilns.

Exhibit ES 2 Base Year 2010 – Industrial Natural Gas Consumption by Major End Use – All Service Areas

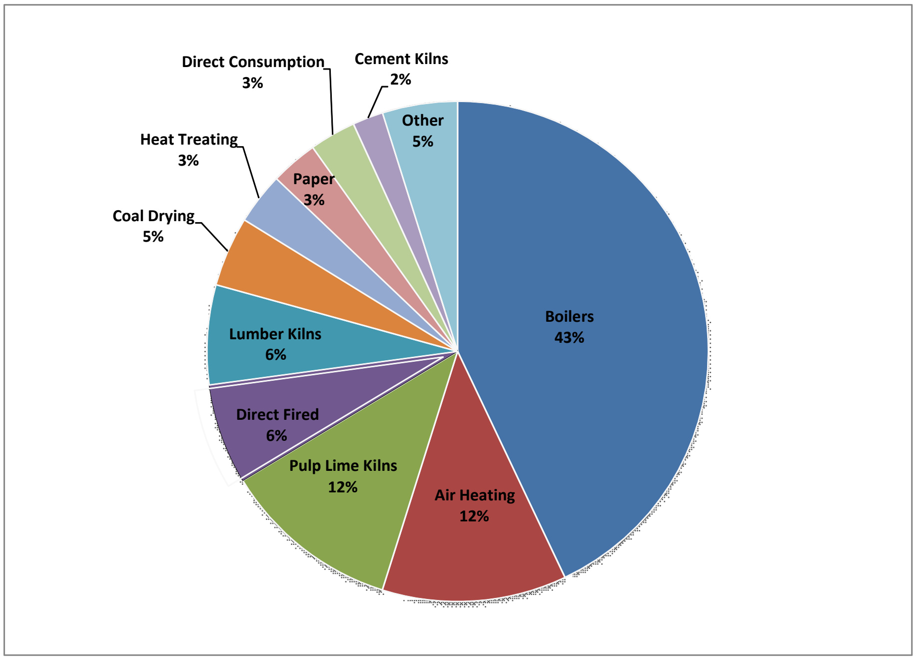


Exhibit ES 3 indicates the distribution among the sub sectors. The Pulp and Paper sector dominates at 32%, followed by Agriculture, Food & Beverage at 12% each, Chemical at 10%, Wood Products at 9%, Mining at 8% and Fabricated Metal at 6%.

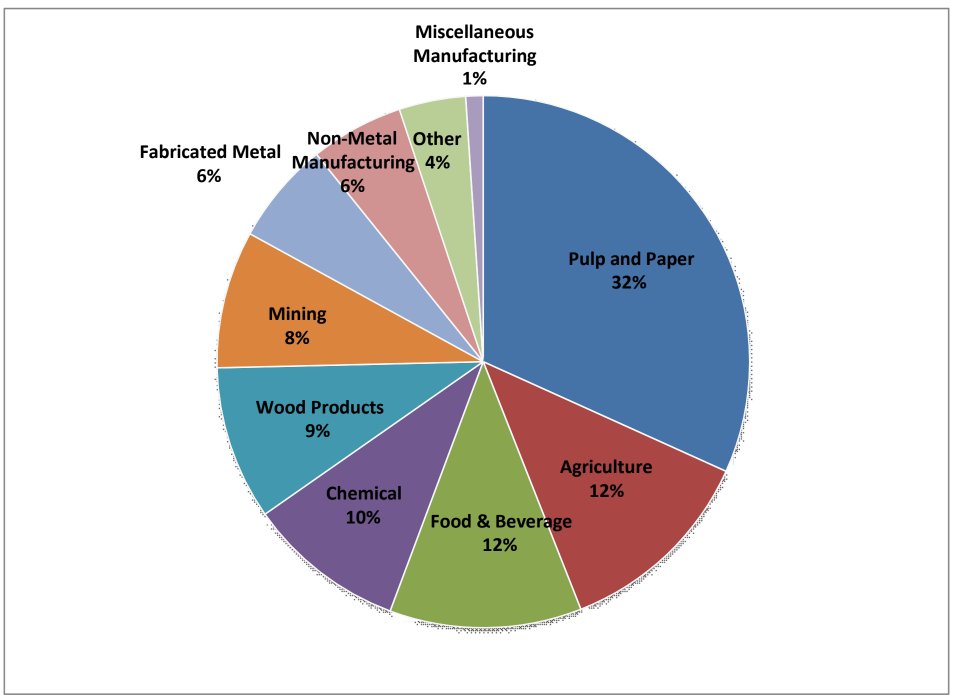
Exhibit ES 3 Base Year Industrial Natural Gas Consumption Distribution of Use by Sub Sector

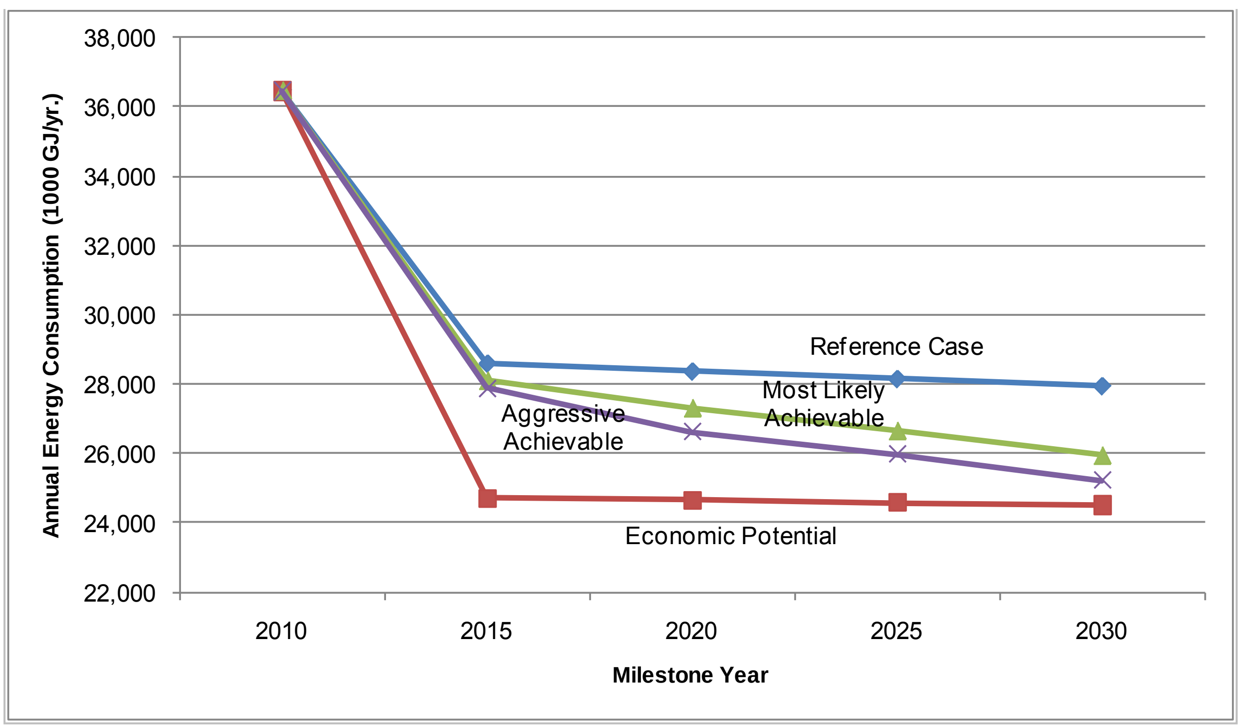


Results and Findings

A summary of the levels of annual natural gas consumption contained in the Reference Case and each of the energy-efficiency forecasts, by milestone year, is presented in Exhibit ES 4 and discussed briefly in the paragraphs below.

Exhibit ES 4 Summary of Forecast Results, Energy Efficiency (TJ/yr.)

Year	Annual Consumption (TJ/yr.)					Potential Annual Savings		
				Achievable			Achievable	
	Base Year	Reference	Economic	Most Likely	Aggressive	Economic	Most Likely	Aggressive
2010	36,456	36,456						
2015		28,594	24,710	28,095	27,880	3,884	500	714
2020		28,367	24,648	27,302	26,621	3,719	1,065	1,747
2025		28,151	24,576	26,646	25,985	3,575	1,505	2,166
2030		27,946	24,506	25,936	25,221	3,439	2,010	2,725



Reference Case

In the absence of continued demand side management (DSM) initiatives, the study estimates that natural gas consumption in the Industrial sector will decline from the Base Year (2010) consumption of approximately 36,546,000 GJ/yr. to 28,367,000 GJ/yr. by 2020 and 27,946,000 GJ/yr. by 2030. This represents an overall decrease of about 23% in the period. The forecast decrease is due to an expected continued decline in the wood products and pulp and paper industry as well as a continuation of the move to wood waste from natural gas. The move to wood waste will be mainly due to the provincial government policy of encouraging a reduction of GHG emissions.

Economic Potential Forecast

Under the conditions of the Economic Potential Forecast, the study estimated that consumption in the Industrial sector would decline to about 24,506,000 GJ/yr. by 2030. Annual savings relative to the Reference Case are about 3,439,000 GJ/yr. or about 12%. The Economic Potential is obtained relatively quickly due to the analysis indicating that, from a strictly economic perspective, most of the inefficient equipment could be replaced by more efficient alternatives within the next five years.

Achievable Potential – Energy-efficiency Scenario

A selection of the natural gas savings opportunities identified in the Economic Potential Forecast was discussed in a full-day workshop. The guided participant discussions provided estimated levels of participation under a *most likely* scenario of program activity and an *aggressive* scenario of program activity. These levels were applied to the Economic Potential savings to estimate the Achievable Potential for these two scenarios. For technologies not specifically discussed in the workshops, participation levels were estimated through extrapolation from the technologies that were discussed. The results are presented in Exhibit ES 5 and Exhibit ES 6 by technology and by milestone year for, respectively, the *most likely* and *aggressive* Achievable Potential scenarios.

Exhibit ES 5 Most Likely Achievable Natural Gas Savings for the Total FortisBC Service Area by Technology and Milestone Year (GJ/yr.)

Technology	2015	2020	2025	2030	2030 Savings Share of 2030 Reference Consumption	2030 Savings Share of Total 2030 Savings
Boilers	256,269	527,267	823,065	1,153,094	9%	57%
Air Heating	88,567	174,994	259,343	341,709	11%	17%
Ovens	470	4,134	6,278	8,748	1%	0%
Heat Treating	1,809	16,439	23,073	29,753	6%	1%
Lumber Kilns	48,534	97,260	140,724	180,165	29%	9%
Veneer Dryers	6,116	12,044	17,723	23,097	1%	1%
Pulp Lime Kilns	2,884	8,117	15,777	25,538	6%	1%
Cement Kilns	6,395	13,015	17,758	21,494	3%	1%
Ore Drying	1,016	2,435	2,639	2,964	0%	0%
Coal Drying	53,356	127,832	110,862	124,497	24%	6%
Direct Fired	34,172	81,391	88,010	98,928	6%	5%
Total	499,589	1,064,929	1,505,251	2,009,988	7%	100%

Exhibit ES 6 Aggressive Achievable Natural Gas Savings for the Total FortisBC Service Area by Technology and Milestone Year (GJ/yr.)

End Use	Technology	2015	2020	2025	2030	2030 Savings Share of Total 2030 Savings	Average B/C Ratio
Coal and Ore Drying	High-efficiency Coal and Ore Dryers	55,388	132,701	116,140	130,425	5%	15 (Coal)
Cement Kilns	High-efficiency Kiln	2,558	23,427	33,149	42,988	2%	9.1
Pulp Lime Kiln	High-efficiency Kiln	7,211	20,293	39,441	63,846	2%	7.0
Direct Fired	Direct-fired Heating- Gypsum and Asphalt	68,344	162,783	176,021	197,856	7%	5.5
Ovens	High-efficiency Ovens	940	8,268	12,555	17,497	1%	5.4
Heat Treating	Heat Treating Furnace with Sequential Firing, High-velocity Burners	3,619	32,879	46,145	59,507	2%	5.4
Veneer Dryers	Advanced Veneer Dryer	9,785	19,271	28,357	36,955	1%	5.4
Air Heating	Radiant Tube Heating	110,709	218,743	324,178	427,137	16%	4.4
Lumber Kiln	High-efficiency Kiln	64,712	129,680	187,632	240,220	9%	4.2
Boilers	Efficient Boilers	373,963	950,508	1,110,661	1,367,177	50%	~4
Process Water Heating	Direct-fired Water Heating	7,988	24,561	50,261	81,010	3%	
Paper Drying	Direct-fired Paper Drying	8,871	23,500	41,621	60,576	2%	
	Total	714,089	1,746,613	2,166,162	2,725,193	100%	

Peak Day Load Impacts – Energy-efficiency Scenarios

The peak day savings associated with each of the Achievable energy-efficiency scenarios were calculated using load factor data provided by FortisBC. The results are summarized in Exhibit ES 7 and Exhibit ES 8. As illustrated, the Achievable peak day savings in 2030 range from a decrease of 16,990 GJ/day (*most likely* scenario) to a decrease of 23,080 GJ/day (*aggressive* scenario) for the total FortisBC service region.

Exhibit ES 7 Peak Day Capacity Impacts – Most likely Achievable Potential, by Scenario, Service Region and Milestone Year (GJ)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	2,197	936	971	110	4,213
2020	4,633	1,963	2,150	227	8,973
2025	6,749	2,978	2,659	328	12,715
2030	9,055	4,064	3,462	409	16,990

Exhibit ES 8 Peak Day Capacity Impacts – Aggressive Achievable Potential, by Scenario, Service Region and Milestone Year (GJ)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	3,250	1,398	1,228	162	6,039
2020	8,064	3,367	2,990	373	14,794
2025	10,003	4,424	3,442	476	18,346
2030	12,544	5,694	4,285	556	23,080

Greenhouse Gas Impacts – Energy-efficiency Scenarios

The natural gas savings associated with each of the Achievable Potential scenarios would also result in a reduction of greenhouse gas (GHG) emissions.[2] As illustrated in Exhibit ES 9 and Exhibit ES 10, by 2030 the GHG reductions are estimated to be in the range of 96,000 to 130,000 tonnes CO_2e per year, depending on scenario.

Exhibit ES 9 Estimated GHG Emission Reductions – Most likely Achievable Potential, By Scenario and Milestone Year (tonnes CO_2e/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	3,250	1,398	1,228	162	6,039
2020	8,064	3,367	2,990	373	14,794
2025	10,003	4,424	3,442	476	18,346
2030	12,544	5,694	4,285	556	23,080

Exhibit ES 10 Estimated GHG Emission Reductions – Aggressive Achievable Potential, By Scenario and Milestone Year (tonnes CO_2e/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	16,809	8,681	7,627	1,159	34,276
2020	41,707	20,903	18,563	2,665	83,837
2025	51,735	27,468	21,374	3,399	103,976
2030	64,876	35,357	26,607	3,969	130,809

[2] GHG impacts are estimated based on an emissions factor of 48 kg of CO_2 e per GJ of natural gas. This is the BC natural gas emissions factor.

Summary of Findings

The study findings indicated that even with a declining load growth there are significant potential cost-effective natural gas efficiency improvements in the Industrial sector. This potential is due to the existence of older inefficient boilers, lumber kilns, lime kilns, and a variety of other industrial process equipment that could be economically replaced. It would be cost effective for this replacement to occur by 2015, but due to other market barriers, it is estimated that in the most likely and aggressive scenarios it will take until 2030 to obtain the savings.

The major barriers constraining faster market penetration include:

- High equipment and installation cost of efficient technologies
- Need to recover investment costs in a short period (payback)
- Lack of product performance information
- Lack of available product.

In the most likely and aggressive Achievable scenarios those energy-efficiency improvements would provide between 2,010,000 and 2,725,000 GJ/yr. of savings in 2030 as well as peak day load reductions of approximately 16,990 to 23,080 GJ.

A variety of efficient boiler technologies account for nearly 57% of the total energy savings in the two Achievable Potential scenarios. The major opportunity involves replacing standard efficiency boilers in the 68-80% efficiency range with condensing boilers in the plus 90% efficiency range. This opportunity is mainly applicable to medium size boilers in the food processing and manufacturing sectors.

For large boilers, such as in pulp mills, and for large process equipment such as cement kilns, lime kilns and coal driers, the most likely opportunities will involve upgrading the equipment with better controls or heat recovery equipment rather than replacing the complete unit. The cost of replacing complete units will usually involve large capital expenditures (often more than $100 million) and there were no sites where it appeared that this type of expenditure could be justified on the basis of simply reducing natural gas use.

Improving the air heating efficiency of large industrial fabrication workspaces is another significant energy saving opportunity. Generally, these spaces are now heated with unit heaters. In some cases, inefficient unit heaters could be replaced with more efficient unit heaters but replacing the unit heaters with gas radiant heaters is a larger opportunity.

APPENDICES (Bound separately)

List of Appendices

1 Introduction

1.1 Background and Objectives

This Conservation Potential Review (CPR) provides FortisBC with a comprehensive planning document that the company can use on an ongoing basis to inform the:

- Development of a long range energy-efficiency and fuel choice strategy
- Design and development of energy-efficiency and fuel choice programs
- Assessment of the impact of energy-efficiency and fuel choice programs on peak versus annual load
- Setting of annual energy-efficiency and fuel choice targets and budgets.

1.2 Study Scope

Sector Coverage: The study addresses three sectors: Residential, Commercial/Institutional and Industrial. In contrast to the 2006 CPR, which excluded FortisBC's 300 largest industrial accounts, this CPR includes all of FortisBC's customers.

Geographical Coverage: The study results are presented for the total FortisBC service region and for the five service areas of: Lower Mainland, Vancouver Island, Whistler, Northern Interior and Southern Interior.

Study Period: The Base Year for this study is calendar year 2010. The time period covered by this study is to 2030, with milestones at the intervening years of 2015, 2020 and 2025.

Technologies: The study addresses energy-efficiency, operations and maintenance (O&M), alternative energy options such as renewable, and combined heat and power technologies.

Relation to Previous B.C. CPRs: This study builds on the substantial body of information and modeling work prepared in previous CPR studies conducted for FortisBC (2006) and BC Hydro (2007). The 2006 FortisBC study was intended to mesh with the BC Hydro study from 2007 and therefore included all customers of either utility, not just FortisBC customers. This study includes only FortisBC natural gas customers because this permitted the study to make better use of the recently completed energy end-use studies.

1.2.1 Data Caveat

As in any study of this type, the results presented in this report are based on a large number of important assumptions. Assumptions such as those related to the current penetration of energy-efficient technologies, the rate of future growth in the economy and specific customer barriers to implementing new energy-efficiency measures. Specific customer barriers include:

- Customer does not have sufficient in-house technical resources to project manage the implementation of projects
- There is uncertainty as to the long-term viability of the operation at the particular site involved
- Customer's technical personnel do not want to risk changing an existing equipment unit that is working reliably even though it is not energy efficient.

Wherever possible, the assumptions used in this study are consistent with those used by FortisBC and are based on best available information, which in many cases includes the professional judgement of the consultant team, FortisBC personnel and local experts. The reader should, therefore, use the results presented in this report as best available estimates; major assumptions, information sources and caveats are noted throughout the report.

1.3 Study Organization

The study has been organized into four[3] areas:

- **Three individual sector reports** (Residential, Commercial and Industrial) that provide an assessment of the technical opportunities for more efficient use of natural gas within each sector.
- **A commercial end-use survey (CEUS)** that provides insight into current natural gas equipment efficiency levels, fuel share and annual consumption levels within key Commercial sub sectors. The CEUS results were used to refine the Commercial sector building archetypes employed in the assessment of technical opportunities.
- **A summary and employment impact report** that brings together the findings of the Residential, Commercial and Industrial sectors, together with an estimate of net job creation and other economic effects attributable to the achievable efficiency activities results within the three sectors.
- **An options paper** that outlines alternative approaches to the assessment of cost-effective levels of DSM activity outside of the California Standard Practice tests.

1.4 This Report

This report presents the Industrial sector results and is organized as follows:

- **Section 2** presents an overview of the study methodology, including a definition of key terms and an outline of the major analytic steps involved.
- **Section 3** presents a profile of Industrial sector Base Year natural gas use in the total FortisBC service area as well as in the five individual service regions.
- **Section 4** presents the Industrial sector Reference Case, which provides a detailed estimate of natural gas use within the total FortisBC service area and each of the five service regions over the study period 2010 to 2030, in the absence of new DSM program initiatives.
- **Section 5** identifies and assesses the economic attractiveness of energy-efficiency, customer behaviour and alternative energy technology options within the Industrial Sector.
- **Section 6** presents the Industrial sector Economic Potential Forecast for the study period 2010 to 2030.
- **Section 7** estimates the proportion of energy savings identified in the Economic Potential Forecast that can realistically be achieved within the study period. Impacts on peak day loads and greenhouse gas emissions are also presented.
- **Section 8** lists sources and references.
- **Section 9** is the Glossary.

[3] A separate Customer Preferences study was prepared in parallel with this CPR. The two studies were, however, implemented in a co-ordinated manner and the results of the Preferences study contributed to the results of this CPR.

1.5 Results Presentation

The preparation of Conservation Potential Reviews involves the compilation and analysis of an enormous amount of market and technology data and a nearly infinite number of ways of organizing and presenting the results. It is recognized that readers will have differing levels of needs with respect to the level of detail that is provided. Consequently, the results of this CPR are presented at three levels of detail.

- **Main report body**. The main body of the report provides a relatively high level reporting of the main steps involved in undertaking each stage the study together with a concise summary of results, including comments and interpretation of key findings. It is assumed that the content and level of detail in the main report body is suitable for the majority of readers who wish to gain an understanding of the potential contribution of DSM options to FortisBC's long-term natural gas requirements.

- **Appendices.** A separate appendix accompanies each major section of the main report. Each appendix provides more detailed information on the methodology employed, including major assumptions or sample calculations as applicable, together with additional levels of results. It is assumed that this presentation is better suited to DSM analysts and managers wishing a more thorough understanding of the study results.

- **Software.** All of the data generated by the study is provided along with the energy end-use and projection model and the Measure TRC model.

  - The energy end-use model for Industrial sector customers in BC builds on the study results and is capable of supporting DSM program design and implementation planning.

  - The measure TRC model is a custom-designed model that provides comprehensive profiles of all of the DSM measures assessed within the study. Because the information is provided is software form, any changes to economic, financial or performance data inputs can be easily accommodated and revised results generated automatically.

2 Study Methodology

This section provides an overview of the methodology employed for this study. More specifically, it addresses:

- Definition of terms
- Major analytic steps
- Key economic inputs
- Analytic models.

2.1 Definition of Terms

This study employs numerous terms that are unique to analyses such as this one and consequently it is important to ensure that all readers have a clear understanding of what each term means when applied to this study. Below is a brief description of some of the most important terms.

Base Year	The Base Year is the starting point for the analysis. It provides a detailed description of "where" and "how" energy is currently used in the existing Industrial sector. Creation of the Base Year required the development of profiles of current natural gas processes and equipment in each Industrial sub sector.
Reference Case (includes Natural Conservation)	The Reference Case estimates the expected level of natural gas consumption that would occur over the study period in the absence of new DSM program initiatives. It provides the point of comparison for the subsequent calculation of "economic" and "achievable" savings potentials. Creation of the Reference Case required the estimation of changes in sub sector production levels and an estimation of "natural" changes affecting energy consumption over the study period.
Technology Assessment	Energy-efficiency and alternative energy options were identified that met the criteria, as outlined in Section 1.2. Technology cost and performance data were compiled relative to the baseline technology and the measure TRC was calculated for each option. The measure TRC calculates the net present value of energy savings that result from an investment in an efficiency or alternative energy technology or measure. The measure TRC is equal to its full or incremental capital cost (depending on application) plus any change (positive or negative) in the combined annual energy and operating and maintenance (O&M) costs. This calculation includes, among others, the following inputs: the avoided natural gas and electricity supply costs, the life of the technology, and the selected discount rate, which in this analysis has been set at 7.4% for the Mainland and 6.9 % for Vancouver Island.
Economic Potential Forecasts	The Economic Potential Forecast is the level of energy consumption that would occur if all equipment and building envelopes were upgraded to the level that is cost effective, from FortisBC's perspective, when using lifecycle costing with the long-run avoided cost of new natural gas supply. All the energy-efficiency and alternative energy options included in the technology assessment that had a positive measure TRC were incorporated into the Economic Potential Forecast.

Achievable Potential The Achievable Potential is the proportion of the savings identified in the Economic Potential Forecast that could realistically be achieved within the study period. Achievable Potential recognizes that it is difficult to induce customers to purchase and install all the energy-efficiency/alternative energy or behaviour options that meet the criteria defined by the Economic Potential Forecast. The results are presented as a range, defined as "Most Likely" and "Aggressive."

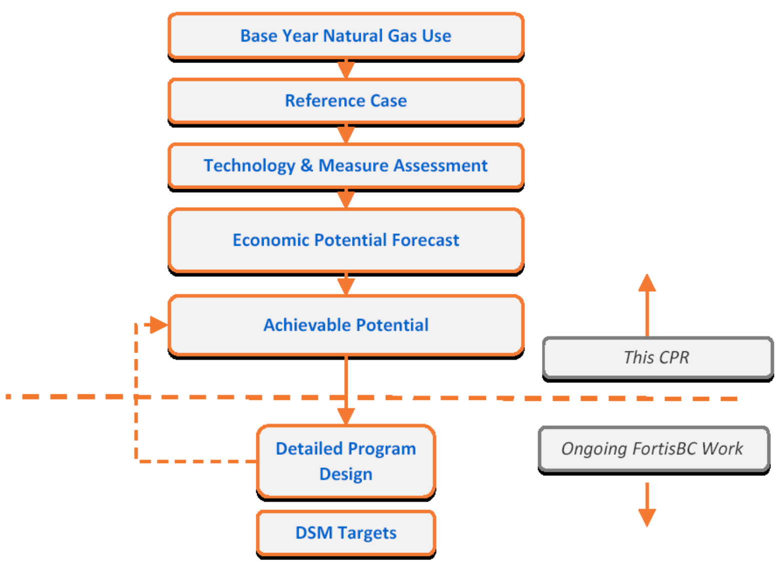
Estimates provided were developed in a workshop involving FortisBC energy-efficiency program personnel, trade allies, selected external experts and the consulting team.

Peak Day Load Impacts Load factors provided by FortisBC were used to derive peak day load impacts from the energy consumption values contained in each of the potential estimates noted above.

2.2 Overview of Approach

To meet the objectives outlined above, the study was conducted within an iterative process that involved a number of well-defined steps, as illustrated in Exhibit 1. At the completion of each step, the client reviewed the results and, as applicable, revisions were identified and incorporated into the interim results. The study then progressed to the next step.

Exhibit 1 CPR 2010: Main Analytic Steps



A summary of the steps is presented below.

Step 1: Develop Base Year Calibration Using Actual FortisBC Billing Data

- Compile and analyze available data on British Columbia's existing Industrial sub sectors.
- Develop detailed technical descriptions of the existing processes and technologies within each sub sector.
- Compile actual FortisBC billing data.
- Create sector model inputs and generate results.
- Calibrate sector model results using actual billing data.

Step 2: Develop Reference Case

- Compile data on forecast levels of output growth in each major sub sector.
- Compile data on "natural" changes in equipment efficiency levels and/or practices.
- Define sector model inputs and create forecasts of energy use for each of the milestone years.

Step 3: Develop and Assess Energy-efficiency and Alternative Energy Options

- Develop list of energy-efficiency and alternative energy measures.
- Compile detailed cost and performance data for each measure.
- Identify the baseline technologies employed in the Reference Case.
- Develop energy-efficiency and/or alternative options for each end use.
- Compile economic data, including current and forecast costs for new supply of natural gas and electricity generation.
- Determine the measure TRC for each energy-efficiency and alternative energy option.

Step 4: Estimate Economic Energy-efficiency and Alternative Energy Potential

- Screen the identified energy-efficiency and alternative energy measures from Step 3 against the economic data.
- Identify the combinations of energy-efficiency measures and building types where the measure TRC is positive.
- Apply the economically attractive energy-efficiency measures from Step 3 within the energy use model developed previously for each sub sector.
- Determine annual natural gas consumption in each sub sector when the economic efficiency measures are employed.
- Compare the consumption levels when all economic efficiency measures are used with the Reference Case consumption levels and calculate the natural gas consumption impacts.

Step 5: Estimate Achievable Savings Potential

- "Bundle" the energy-efficiency and alternative energy options identified in the Economic Potential Forecast into a set of actions.
- Create "Action Profiles" for each of the identified Actions that provide a high level rationale and direction, including target technologies and sub-markets as well as key barriers and a broad intervention strategy.
- Review historical achievable program results and prepare preliminary Action Assessment Worksheets.
- Conduct Achievable Potential workshops involving FortisBC personnel, trade allies and other stakeholders and reach general agreement on *most likely* and *aggressive* range of Achievable Potential.

Step 6: Estimate Peak Day Load Impacts of Economic and Achievable Savings Potential

- Annual energy decreases/increases contained in each of the energy-efficiency/alternative energy scenarios were converted to average daily values based on annual load profile data provided by FortisBC.
- Load factors that correlate "average" to "peak" consumption were provided by FortisBC for each rate class and service region.
- Peak day load impacts were calculated for each of the energy-efficiency and fuel choice scenario results by applying the above load factors.

2.3 Analytical Models

The analysis of the Industrial sector employed a customized spreadsheet model. The model applies appropriate end-use technologies to each sub sector in each service area. The input energy use information and equipment efficiencies are organized by service area, major sub sector, major end use, and technology.

- The service areas are the Lower Mainland, Vancouver Island, Northern Interior and Southern Interior. This study for the Industrial sector did not include any facilities located in Whistler.

- The major sub sectors are:
  - Agriculture
  - Chemical
  - Fabricated Metal
  - Food & Beverage
  - Mining
  - Miscellaneous Manufacturing
  - Non-Metal Mineral Manufacturing
  - Pulp and Paper
  - Wood Products
  - Other, including textiles, construction, and laundries.

This study includes analysis of the interruptible natural gas loads for large customers and the savings measures associated with their process requirements. As a result the Mining and Pulp and Paper sub sectors have been added for the 2010 review, compared to those sub sectors studied previously in the 2006 CPR.

The equipment or devices used to convert natural gas to heating for comfort and process are referred to as technologies. The analytical work involves estimating the number of applications over a certain time period where a standard efficiency technology will be changed out for a higher efficiency technology. Standard generally refers to equipment that is in place at the present time or the technology that is commonly used even though a higher efficiency technology is available.

The average natural gas consumption for June through August provided the basis for the annual process heat load for the industries with process consumption not affected by climate.

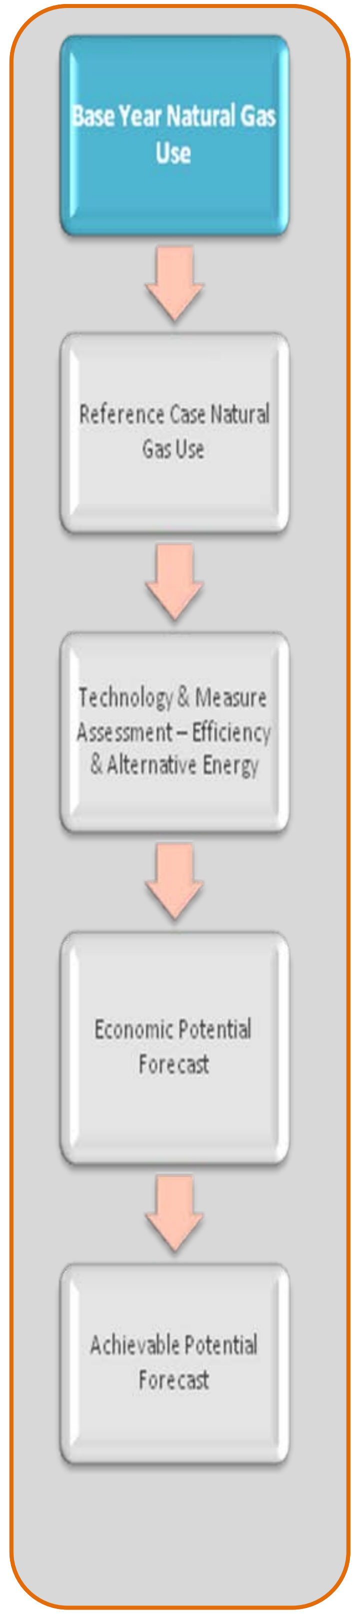
- The model recognizes and tracks efficiency improvements that can be installed on existing equipment (technologies) between milestone years. These improvements include:
  - Controls and high-efficiency burners (bundled standard upgrades)
  - Heat recovery (off of boiler)
  - Insulation – equipment and distribution systems
  - Heat recovery (off of process)
  - Optimized heat balance and control
  - Steam trap maintenance.

- The energy use changes that would occur without utility programs are in the Reference Case. There is a constant rate of improvement applied for each technology that reflects natural rate of equipment replacement and upgrades seen in B.C.'s Industrial sector.
- The natural gas sales are calculated for each sub sector and region along with the useful heat based on the conversion efficiencies of technologies for both comfort and process heating.

The primary input variables affecting the consumption of natural gas, based on industrial process, are:

- Type and efficiency of specific major processing equipment
- Energy consumption and operating hours for heating equipment
- Economic activity levels within each sub sector (useful heat requirement)
- Production processes employed.

3 Base Year (2010) Natural Gas Use



This section provides a profile of Base Year (2010) natural gas use in B.C.'s Industrial sector. The discussion is organized into the following sub sections:

- Industrial sector segmentation
- Industrial end uses
- Base Year Industrial sector natural gas use

A brief description of each of the above sub sections is provided below, including a summary of the results. Additional information is provided in Appendix A.

3.1 Industrial Sector Segmentation

The first step in developing the Base Year profile required that the industrial account information be segmented by economic sub sectors. FortisBC information includes the North American Industrial Classification System (NAICS) data for each account. To facilitate the analysis of energy-efficiency options in later stages of this analysis, the account information was summarized by sub sector and service area. The applicable natural gas-using processes and technologies were assigned to each category (NAICS/service area). The conversion efficiencies multiplied by the category share of natural gas sales yielded the useful heat consumed by each category.

The Industrial sub sectors studied in this analysis are shown in Exhibit 2

Exhibit 2 Industrial Sub Sectors

- Agriculture
- Chemical
- Fabricated Metal
- Food & Beverage
- Mining
- Miscellaneous Manufacturing
- Non-Metal Manufacturing
- Pulp and Paper
- Wood Products
- Other

3.1.1 *Interruptible Customers*

Limited information about installed equipment and industrial processes was available prior to the beginning of the 2010 CPR. In order to learn about customers and their Industrial processes, an energy use survey was conducted targeting large consumers who purchase interruptible natural gas services. Nineteen customers, representing each of the dominant Industrial sectors, were contacted and offered a phone survey and/or a site visit. Eighteen customers completed the survey and 13 customer site visits were documented.

The site visits afforded the consultants the opportunity to identify savings opportunities through first hand observation and on-the-job interviews with customer personnel. Please see Appendix A for survey details.

3.2 Industrial End Uses

Industrial natural gas use provides heating for space conditioning (comfort) and industrial processes. The industrial end-use technologies are grouped by comfort heating and process heating, as summarized in Exhibit 3.

Exhibit 3 Industrial End Uses

Process	Comfort
▪ Boilers	▪ Boilers
▪ Water heaters	▪ Air / radiant heaters
▪ Ovens	
▪ Heat treating furnaces	
▪ Lumber kilns	
▪ Veneer dryers	
▪ Paper dryers	
▪ Pulp lime kilns	
▪ Cement kilns	
▪ Ore drying	
▪ Coal drying	
▪ Direct-fired end uses	
▪ Consumed in process	

3.2.1 *Distribution of Natural Gas Consumption by Sub Sector & End Use*

Exhibit 4 shows the distribution of industrial sector natural gas consumption between process and comfort heat, by sub sector and service area. As illustrated in Exhibit 4, process heat accounts for a large share of the natural gas consumption. It should also be noted that the share of natural gas consumption for process heat is larger in this study than in the 2006 CPR study. This is due to the inclusion of the interruptible accounts with large industrial processes in this study. It is worth noting that comfort heat makes up a large part of the Fabricated Metal sub sector since these sites consist mainly of a heated building with some metal working equipment that does not require significant amounts of gas. Also, some sub sectors have only a few smaller facilities in some regions, which can skew the data to indicate more comfort heat than would normally be expected.

Exhibit 4 Process/Comfort Heat Share (Percentage) by Sub Sector and Service Area

Industrial Sub Sector	Lower Mainland		Northern Interior		Northern Interior		Vancouver Island	
	Process Heat	Comfort Heat	Process Heat	Comfort Heat	Process Heat	Comfort Heat	Process Heat	Comfort Heat
Agriculture	80%	20%	68%	32%	82%	18%	96%	4%
Chemical	95%	5%	87%	13%	68%	32%	79%	21%
Fabricated Metal	74%	26%	77%	23%	40%	60%	53%	47%
Food & Beverage	92%	8%	77%	23%	78%	22%	95%	5%
Mining	46%	54%	82%	18%	94%	6%	n/a	n/a
Miscellaneous Manufacturing	42%	58%	20%	80%	28%	72%	94%	6%
Non-Metal Mineral	93%	7%	82%	18%	53%	47%	0%	100%
Pulp & Paper	95%	5%	93%	7%	93%	7%	93%	7%
Wood Products	98%	2%	95%	5%	95%	5%	100%	0%
Other[4]	45%	55%	36%	64%	29%	71%	96%	4%

[4] Other includes sub sector such as Transportation, Construction, Printing, Utility, and Laundry & Other Services.

3.2.2 *Natural Gas Fuel Share for Heating Applications*

Exhibit 5, Exhibit 6, Exhibit 7 and Exhibit 8 provide estimates of the current natural gas versus wood waste share by equipment size for, respectively, Lower Mainland, Northern Interior, Southern Interior and Vancouver Island. Equipment size is shown in the exhibits to provide an indication of fuel options. For example, it is difficult and often impractical to use wood waste in medium size boilers or furnaces, but it can be readily used in large kilns or large boilers in greenhouses. The exhibits also present potential opportunities for increasing or maintaining the natural gas share as well as the opportunities for increasing the wood waste share.

Exhibit 5 Natural Gas Fuel Share – Lower Mainland

Equipment	Estimate of Existing Share	Opportunities for Natural Gas	Opportunities for Wood Waste
Large (Process)	90%	1/No significant opportunity to expand share. 2/ Wood waste supply is not a transparent market and supplies remain uncertain. Natural gas flexibility and reliability can play a shaping role.	1/ Significant opportunity for wood waste, wood pellets and biofuels due to greenhouse gas management policies and regulation. 2/Replacement of gas consuming processes to meet greenhouse gas reduction /carbon content targets.
Medium (Process)	95%	1/No significant opportunity to expand share.	1/No significant opportunity for wood waste
Small (Comfort)	60%	1/ In new developments gas share could be increased over electricity. 2/ In backup systems for renewable energy supplies could be increased over electricity.	1/ No significant opportunity

Exhibit 6 Natural Gas Fuel Share – Northern Interior

Equipment	Estimate of Existing Share	Opportunities for Natural Gas	Opportunities for Wood Waste
Large (Process)	90%	1/ Could be some main extension opportunities in areas not served by natural gas. 2/ Wood waste supply is not a transparent market and supplies remain uncertain. Natural gas flexibility and reliability can play a shaping role. Also, the major price change in the gas market favours continued use of natural gas.	1/ Continued significant opportunity for wood waste particularly with lumber dry kilns. Possibility of further conversion from natural gas with wood waste. 2/Replacement of gas-consuming processes to meet greenhouse gas reduction /carbon content targets. 3/ Demand destruction due to global economic impacts on exporting entities.
Medium (Process)	95%	No significant opportunity to expand share.	No significant opportunity to expand wood waste share.
Small (Comfort)	70%	1/ In new developments gas share could be increased over electricity. 2/ In backup systems for renewable energy supplies could be increased over electricity.	No significant opportunity to expand wood waste share.

Exhibit 7 Natural Gas Fuel Share – Southern Interior

Equipment	Estimate of Existing Share	Opportunities for Natural Gas	Opportunities for Wood Waste
Large (Process)	90%	1/ Could be some main extension opportunities in areas not served by natural gas. 2/ Wood waste supply is not a transparent market and supplies remain uncertain. Natural gas flexibility and reliability can play a shaping role.	1/ Significant threat from wood waste particularly with lumber dry kilns. Possibility of further erosion of that market. 2/ Demand destruction due to global economic impacts on exporting entities. Overcapacity is being rationalized.
Medium (Process)	95%	No significant opportunity to expand share.	No significant opportunity to expand wood waste share.
Small (Comfort)	70%	1/ In new developments gas share could be increased over electricity. 2/ In backup systems for renewable energy supplies could be increased over electricity.	1/ Main threat is electric because of ease of installation and designation as a carbon neutral energy source in B.C.

Exhibit 8 Natural Gas Fuel Share – Vancouver Island

Equipment	Estimate of Existing Share	Opportunities for Natural Gas	Opportunity for Wood Waste
Large (Process)	80%	1/ A continual increase in lumber drying will provide opportunity to supply more dry kilns. 2/ Wood waste supply is not a transparent market and supplies remain uncertain. Natural gas flexibility and reliability can play a shaping role. 2/ Some large equipment now using propane or oil could be switched to natural gas with main extensions.	1/Wood waste is a serious alternative for lumber drying except change in gas pricing does not favour wood waste. 2/ Demand destruction due to global economic impacts on exporting entities. Overcapacity is being rationalized.
Medium (Process)	80%	1/ Main extensions to new industrial parks.	1/ Wood pellets are alternative to natural gas for medium size boilers
Small (Comfort)	70%	1/ In new developments gas share could be increased over electricity. 2/ In backup systems for renewable energy supplies could be increased over electricity.	1/ No significant opportunity with wood waste.

Additional details related to the fuel shares shown in the above exhibits are provided below.

- **Electricity and Large Process Heating Equipment:** In many situations, it is not practical to use electricity for large capacity equipment because the cost of the electrical equipment necessary to supply the peak heating equipment costs far more than gas connection costs. This electrical equipment at the customer facility generally involves, transformers, switch gear, cabling and protection equipment.

  Gas connections can usually handle a wider range of capacity requirements than electricity connections. For example, to convert a process unit requiring an energy input of 20 GJ/hr. of gas to electricity, a high-voltage transmission connection to the BC Hydro system would be required at the customer's cost. This cost would be in the millions of dollars, compared to a typical high-pressure gas connection that would cost hundreds of thousands of dollars. Furthermore, a gas connection with an average delivery rate of 20 GJ/hr. could accommodate a peak hour demand of 30 GJ/hr. for a cost that is insignificant compared to the cost of the equivalent peak capacity high-voltage transmission connection.

- **Electricity Lumber and Veneer Dryers:** Electric dehumidification kilns have been developed and applied in some sawmills, particularly for drying hardwood, or high-end planks. However, in typical B.C. wood products facilities (dimensional lumber or stud mills), electricity does not compete with natural gas as a fuel source for dryers, because the electric dehumidification process cannot supply sufficient heat capacity to dry the lumber as fast as gas-fired kilns. Wood waste is the principle heating fuel competitor to natural gas because it has been historically a waste byproduct of sawmills and, therefore, essentially free. Wood waste-fired kilns can also be designed to supply sufficient heating capacity to dry the lumber at the required speed.

- **Electricity and Comfort Heat:** The relatively small capacity equipment used in some comfort heating applications is the one end use that is suitable for electricity use. Electricity is attractive because of the low capital cost and simplicity of installation. This difference in capital cost is offset to a certain extent by the difference in electricity and natural gas rates. For example, the BC Hydro electricity rate for their general service customers is 6.7 cents/kWh (18.56 $/GJ) while the comparable rate 5 natural gas rate for the Lower Mainland is 2.1 cents/kWh (5.96 $/GJ).[5] Electricity on a unit heating basis is more than three times as expensive as natural gas.

3.3 Base Year Industrial Natural Gas Use

This section provides a summary of the 2010 Base Year natural gas consumption organized by sub sector, service area, end use and technology. The results are presented in the following exhibits.

- Exhibit 9, Exhibit 10, and Exhibit 11 show the distribution of Base Year natural gas use by major technology for all service areas.

- Exhibit 12 through Exhibit 16 show the distribution of Base Year natural gas use by major sub sector and end use for all service areas, and each of the four service areas.

- Exhibit 18 through Exhibit 19 show the distribution of Base Year natural gas and useful heat consumed by end use for three of the sub sectors (Food & Beverage, Agriculture and Wood Products). The remaining sub sectors are presented in Appendix A.

Selected highlights of the 2010 Base Year results are provided below.

- For the 2010 Base Year, the total natural gas consumption by the Industrial sector accounts considered in this CPR study is approximately 36,456,000 GJ, for both non-interruptible and interruptible accounts. Non-interruptible consumption in the Base Year is approximately 11,466,000 GJ. The pie charts in Exhibit 9 and Exhibit 10 present the non-interruptible consumption breakdown by major end use and Industrial sub sector, respectively.

- Standard efficiency boilers used to generate process heat account for approximately 23% of the total Base Year Industrial sector natural gas use, whereas efficient and condensing boilers account for 16%.

- Wood products drying technologies, including standard and efficient lumber dry kilns and veneer dryers, account for approximately 14% of Base Year natural gas use. The remaining Base Year natural gas use is split between comfort heat, 24%, other process heat, 17%, heat treating and annealing technologies in the metal fabrication industry, 7%.

[5] Electricity rate is the marginal portion of BC Hydro's LGS conservation rate, the natural gas rate is FortisBC's schedule 5 for the Lower Mainland.

- Three sub sectors, Food & Beverage, Agriculture and Wood Products, account for over 60% of total consumption by Industrial sector non-interruptible accounts. These figures incorporate the decline in the wood products industry in B.C. since 2006. The impact of this decline on natural gas loads is discussed in FortisBC's Utilities 2010 Long Term Resource Plan.[6]

- Overall, the results contained in the following exhibits show that natural gas use by FortisBC Industrial sector accounts is dominated by boilers within the food industry, while lumber dry kilns and veneer dryers dominate in the Interior and on Vancouver Island.

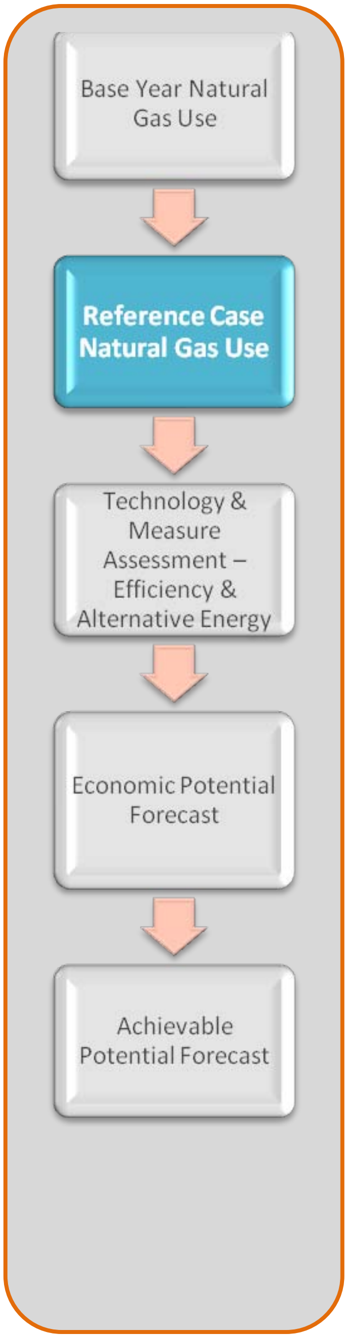
4 Reference Case Natural Gas Use

4.1 Introduction



This section presents the Industrial sector Reference Case for the study period (2010 to 2030) The Reference Case estimates the expected level of natural gas consumption that would occur over the study period in the absence of new energy-efficiency or fuel choice initiatives. The Reference Case, therefore, provides the point of comparison for the subsequent calculation of economically attractive energy-efficiency opportunities.

The discussion is presented within the following sub sections:

- Approach
- "Natural" efficiency improvements
- Expected growth in Industrial sector useful heat requirements
- Summary of model results.

4.2 Approach

The Industrial sector Reference Case was developed using a custom spreadsheet-based model. As noted previously, the three major input variables used within the model to determine the forecast levels of natural gas consumption over the study period are:

- Activity levels within each sub sector (useful heat requirements)
- Production processes employed
- The type and efficiency of specific major operating equipment.

The following steps were employed:

- The Base Year established the natural gas and useful heat consumption by each of the technologies for each of the sub sectors.
- The model recognizes and tracks efficiency improvements between milestone years for installed equipment and the process resulting from upgrades such as:
  - Controls and high-efficiency burners (bundled standard upgrades)
  - Heat recovery (off of boiler)
  - Insulation – equipment and distribution systems
  - Heat recovery (off of process)
  - Optimized heat balance and control
  - Steam trap maintenance.
- The natural gas consumption and useful heat for each technology for the milestone years were calculated using the model conversion efficiency changes due to efficiency upgrades occurring over the study period.

4.3 "Natural" Efficiency Improvements

4.3.1 Major Equipment Change Out

Growth in the amount of natural gas sold to the Industrial sector will be partially reduced due to "natural" increases in the use of more efficient technologies. Exhibit 17 presents the annual replacement rate based on the expected life of the equipment. Appendix B provides the assumptions for the efficiency upgrades, changes in conversion efficiency, and impact on market share for the conversion devices considered within each sub sector.

Exhibit 17 Expected Annual Turnover – Major Equipment

Equipment	Annual Replacement
Comfort heating	
Air heaters	5.0%
Process heating	
Boilers	4.0%
Water heaters	6.7%
Ovens	6.7%
Heat treating ovens	6.7%
Lumber kilns	6.7%
Veneer dryers	6.7%
Paper dryers	4.0%
Lime kilns	<2%
Cement kilns	<2%
Ore drying	4.0%
Coal drying	4.0%

The increasing share of more efficient boilers within the Industrial sector assumes an average boiler life of 25 years.[7] The natural increase in the market share of near condensing and condensing boilers is based on knowledge of the needs of the sub sectors, and an informal survey of suppliers to the commercial marketplace, which indicates that 70% of boilers sold today are standard type, 20% are near condensing and 10% are condensing. The food sector and greenhouses are the Industrial sub sectors best suited for condensing boiler uptake due to the amount of domestic water used and the low process temperatures needed. When boilers are up for replacement, it was assumed that 20% will be replaced with higher efficiency models as appropriate.

Water heaters for processing have a 15-year expected life. Instantaneous water heaters available today are relatively small with limited capacity and therefore are not expected to significantly penetrate the Industrial sector. Where applicable, standard water heaters were assumed to be replaced with more efficient instantaneous water heaters 20% of the time when they have reached end of life. Note that this end use is very small in the Industrial sector and typically limited to office space and small food processors.

[7] Boiler life depends on many factors including boiler water chemistry, materials used for the boiler tubes and headers, and the return water temperature relative to the materials in contact with the boiler water. Nominal range is 10-20 years for boilers with steel tubes and 15-30 years for cast iron tubes. Near condensing and condensing boilers may last longer than standard boilers because this type of boiler is more immune to cooler return water temperatures.

Baking ovens, heat treating ovens, lumber kilns veneer dryers and miscellaneous equipment all have an expected life of 15 years. It was assumed that 20% of these units are replaced with higher efficiency models when replacement is needed.

There has been recent interest in direct-fired paper drying technology expressed by some of the paper mills surveyed. However, no projects were scheduled for implementation at the time of the survey. It was assumed that there was no change over from steam drying to direct-fired drying during the Reference Case.

Based on discussions with pulp and paper mills about high-efficiency pulp kilns, there is unlikely to be any new installations or major upgrades during the study period. The Reference Case has no change in penetration of these kilns.

Upgrades to coal and ore dryers are dependent on remaining mine life. It is assumed that over the period of this study there would be no natural replacement of existing units with higher efficiency technology.

Cement kilns are assumed to undertake major rework every 25 years. It was assumed that 20% of these units are upgraded with higher efficiency technology during these rework periods.

4.3.2 Equipment or Process Upgrades

Switching out older, less efficient energy conversion devices with newer more efficient technology is a straightforward approach to energy conservation. Also, modifications to the existing equipment can also increase efficiency. Examples would be burner and control upgrades, heat recovery off of the exhaust or boiler blowdown, and insulation of the device.

There is also the potential for large efficiency gains by making improvements to the existing process or process equipment. For example, efficiency improvements can be gained through optimization of plant heat balance and control systems, heat recovery off of the process, and reduction in losses through methods like steam trap maintenance, insulation and greenhouse energy curtains.

Other conversion device upgrades include:

- Improved combustion controls and high-efficiency burner (bundled standard upgrades)
  - It is assumed that the penetration rate of this efficiency upgrade increases 5% every five years, with the exclusion of upgrades to pulp kilns, cement kilns, ore and coal dryers.
- Heat recovery
  - Heat recovery on the applicable conversion devices is assumed to occur on 25% of the equipment that is naturally being replaced, with the exclusion of upgrades to pulp kilns, cement kilns, ore and coal dryers. This means the penetration rate increases by 5% every five years.
- Insulation
  - It is assumed that the rate of deterioration of insulation matches the rate of replacement overall. Therefore, no natural increase in penetration rate occurs over the study period.
- Process heat system upgrades
- Insulation on distribution systems
  - It is assumed that the rate of deterioration of insulation matches the rate of replacement overall. Therefore, no natural increase in penetration rate occurs over the study period.
- Heat recovery (includes condensate upgrades)

    - Heat recovery on the applicable process and on building HVAC (exhaust air heat recovery) is assumed to naturally increase at a rate of 5% every five years.

- Optimized heat balance and controls
    - Optimized HVAC system control is considered to improve at a rate of 5% every five years.
    - Process heat balance and control optimization is considered to improve at a rate of 5% every five years, meaning that 13% of control systems are optimized if their expected life averages 12 years.

- Steam trap maintenance
    - It is assumed that the rate of deterioration of steam traps matches the rate of replacement/repair overall. Therefore, no natural increase in penetration rate occurs over the study period.

For the Reference Case, Exhibit 18 indicates the expected penetration rates over the equipment life for comfort and process heating upgrades.

Exhibit 18 Natural Efficiency Upgrades*

	Natural Penetration Rate Change
Conversion device equipment upgrades	
Bundled standard upgrades (controls and high-efficiency burners)	5%
Heat recovery	5%
Insulation	0%
Process and distribution system upgrades	
Insulation on distribution systems	0%
Heat recovery (includes condensate system upgrades)	5%
Optimized heat balance and control	5%
Steam trap maintenance	0%

**Excluding pulp and cement kilns and ore and coal dryers*

Exhibit 19 uses the Food & Beverage sub sector to illustrate the calculation method used in this CPR analysis. As illustrated in Exhibit 19, the conversion and process efficiency for the Base Year and milestone years are shown, along with the change in market share for each of the applicable end-use technologies for the periods between the milestone years.

4.4 Production Levels to 2030

The Reference Case relies on the FortisBC sub sector and rate forecasts to 2030. The decline in B.C. industrial output since 2005, with 2007 and 2008 possibly the trough years, has had an impact on the forecasts. For the purposes of this study, the Base Year reflects some of the upswing in B.C.'s economic activity seen in 2009 and early 2010 but the change in forecasted load between milestone years has been maintained, with an overall decline in natural gas sales to the Industrial sector of almost 20% to 2030.

The model takes an end-use approach to determining energy consumption by equipment and technologies employed in Industrial sub sectors. Combined with the forecasted decline in natural gas consumption, the study results will be focused on changing out currently installed equipment at end of life with high-efficiency equipment and, where economic, replacing equipment before end of life with high-efficiency equipment.

4.5 Summary of Model Results

This section presents the results of the model runs for the entire study period. The results are presented for the total FortisBC service territory. Additional details are provided in Appendix B.

- Exhibit 20 presents the total natural gas consumption (GJ) for the Base Year and milestones years for each service area.
- Exhibit 21 presents the Base Year and milestone years' natural gas and useful heat consumption by sub sector for all service areas. The remainder of the tables (by region and by technology) is in Appendix B.

Exhibit 20 Reference Case Natural Gas Consumption (GJ) – By Service Area

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Total
Base Year 2010	17,275,315	11,865,818	6,405,115	909,908	**36,456,156**
Milestone Year 2015	13,766,798	8,942,003	5,127,126	758,336	**28,594,262**

Milestone Year 2030	13,260,942	8,877,736	5,087,581	719,537	**27,945,797**

Exhibit 21 Reference Case Natural Gas Consumption (GJ) –
– By Sub Sector

Sub Sector	2010	2015	2020	2025	2030
Agriculture	4,522,525	3,176,184	3,159,952	3,144,517	3,129,837
Chemical	3,540,666	3,376,779	3,376,779	3,376,779	3,376,779
Fabricated Metal	2,297,858	1,340,346	1,274,656	1,212,185	1,152,776
Food & Beverage	4,300,611	3,896,877	3,896,877	3,896,877	3,896,877
Mining	3,071,601	2,533,909	2,533,909	2,533,909	2,533,909
Miscellaneous Manufacturing[8]	388,324	355,207	337,798	321,243	305,499
Non-Metal Manufacturing	2,093,340	1,769,216	1,682,507	1,600,047	1,521,629
Other	1,104,921	720,725	685,402	651,811	619,865
Pulp and Paper	11,696,893	8,219,713	8,213,971	8,208,511	8,203,319
Wood Products	3,439,418	3,205,306	3,205,306	3,205,306	3,205,306
Total	36,456,156	28,594,262	28,367,158	28,151,185	27,945,797

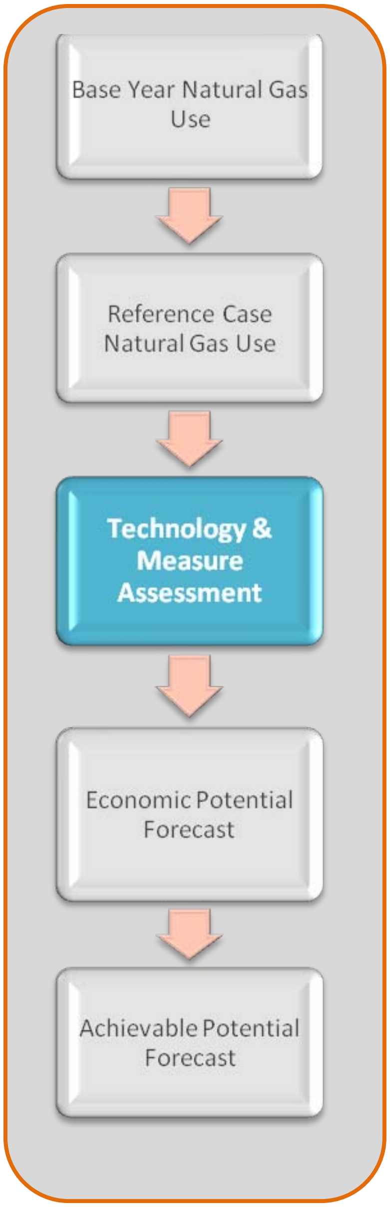
The results of the Reference Case analysis show that useful heat requirements will be reduced over the study period as more efficient equipment replaces existing equipment at end of life and/or system upgrades are completed.

Sub sectors relying on boilers for the majority of heating (process and comfort) may well see their useful heat requirements decline over the study period. In the Pulp and Paper sector, a change in technology (boiler steam replaced by direct heating for paper drying) will reduce useful heat needed for drying.

[8] Miscellaneous Manufacturing includes Machinery Manufacturing, Transportation Equipment Manufacturing, Ventilation, Heating, Air Conditioning and Commercial Refrigeration Equipment Manufacturing, and Electrical Equipment, Appliance and Component Manufacturing

5 Technology & Measure Assessment

5.1 Introduction



This section identifies and assesses the financial and economic attractiveness of the selected energy-efficiency and alternative energy measures for the Industrial sector. The discussion is organized and presented as follows:

- Methodology
- Energy-efficiency and alternative energy technologies
- Summary of results.

5.2 Methodology

The following steps were employed to assess the energy-efficiency and fuel choice technologies:

- Select candidate energy-efficiency and fuel choice technologies
- Establish technical performance for each technology within a range of applicable load sizes and/or service region conditions
- Establish the capital, installation and operating costs for each technology
- Calculate the simple payback from the customer's perspective
- Calculate the measure total resource cost (measure TRC)
- Calculate the benefit-cost ratio.

A brief discussion of each step is outlined below.

Step 1 Select Candidate Technologies

The candidate technologies were selected in close collaboration with FortisBC personnel based on a combination of a literature review and the previous experience of both the consultants and FortisBC personnel. The selected technologies are all considered to be technically proven and commercially available, even if only at an early stage of market entry. Technology costs, which will be addressed in this section, were not a factor in this initial selection of candidate technologies.

Step 2 Establish Technical Performance

Information on the performance improvements provided by each technology was compiled from available secondary sources, including the on-going research work of study team members. As applicable, the energy impacts of the technical technologies are reported for both natural gas and electricity.

Step 3 Establish Capital, Installation and Operating Costs for Each Technology

Information on the cost of implementing each technology was compiled from secondary sources, including the on-going research work of study team members. As applicable, both the incremental and full cost of each technology was estimated.

The incremental cost is applicable when a technology is installed in a new facility or at the end of the technology's useful life in an existing facility; in this case, incremental cost is defined as the difference between the efficient or fuel choice technology relative to the baseline technology. The full cost is applicable when an operating piece of equipment is replaced with the efficient or fuel choice technology prior to the end of the baseline technology's useful life.

In both cases, the costs and savings are annualized, based on the number of years of equipment life and the discount rate, and the costs incorporate applicable changes in annual operating and maintenance costs. All costs are expressed in constant (2010) dollars.

Step 4 Calculate Simple Payback

The simple payback is generated to show the customer's financial perspective. Simple payback is "*a measure of the length of time required for the cumulative savings from a project to recover its initial investment cost and other accrued costs, without taking into account the time value of money. The simple payback period is usually measured from the service date of the project*."[9] The cost of the measure (incremental or full, as appropriate) is divided by the expected annual savings. The answer is given in years**.**

The following equation illustrates how this calculation is applied to a situation where an upgrade has a higher upfront cost than the baseline technology, but lower ongoing operating costs:

$$\text{Payback}_{\text{(years)}} = (\text{CostUpgr} - \text{CostBase})/(\text{AnnBase} - \text{AnnUpgr})$$

Where:

CostUpgr	= initial capital cost of the upgrade ($)
CostBase	= initial capital cost of the baseline technology ($)
AnnBase	= ongoing operating cost of the baseline technology ($/yr.)
AnnUpgr	= ongoing operating cost of the upgrade ($/yr.)

Initial capital cost of the upgrade is the cost of equipment and installation of the energy-efficient technology while the initial capital cost of the baseline technology is the cost of equipment installation of the standard or baseline technology. The ongoing operating cost of the baseline technology is the cost to operate, including fuel cost, the baseline or standard technology while the ongoing operating cost of the upgrade is the cost to operate, including fuel cost, the energy-efficient technology.

Step 5 Calculate the Measure Total Resource Cost (TRC)

The measure TRC calculates the net present value of energy savings that result from an investment in an efficiency or fuel choice technology or measure. The measure cost is equal to its full or incremental capital cost (depending on application) plus any change (positive or negative) in annual operating and maintenance costs. The calculation of energy savings is based on the avoided natural gas and electricity supply costs, the life of the technology, and the selected discount rate, which in this analysis has been set at 7.4% for the Mainland and 6.9 % for Vancouver Island.

A technology or measure with a positive measure TRC value is included in subsequent phases of the analysis, which consists of the Economic and Achievable Potential scenarios. A measure with a negative measure TRC value is not economically attractive and is therefore not included in subsequent stages of the analysis.

[9] Sieglinde K. Fuller and Stephen R. Petersen. (1996). *Life Cycle Costing Manual for the Federal Energy Management Program.* National Institute of Standards and Technology Handbook 135, 1995 Edition, Washington, DC.

It should be noted that the measure TRC provides an initial screen of the technical technologies. Considerations such as program delivery costs, incentives etc., are incorporated in later stages of the program design process, which are beyond the scope of the study.

Step 6 Calculate Benefit-Cost Ratio

The measure benefit-cost ratio indicates the relative attractiveness of the measures. A measure that has a benefit-cost ratio in excess of "1" means that the measure's benefits outweigh its costs; it is, therefore, included in subsequent stages of the analysis. Similarly, a measure with a benefit-cost ratio that is well in excess of one (e.g., 3) means that it is very attractive. A measure with a benefit-cost ratio of less than one means that its costs outweigh its benefits and, hence, it is not included in subsequent stages of the analysis.

5.2.1 Energy Costs

The financial and economic results that are presented in this section are based on the following

- Avoided supply cost of natural gas
- Avoided supply cost of electricity
- Customer energy prices.

A brief discussion of each is provided below.

Avoided Supply Cost of Natural Gas

Natural gas avoided supply costs were provided by FortisBC[10] and are summarized in Exhibit 22. As illustrated, the avoided cost of gas on a per unit basis includes three components: an estimate of the commodity cost, an estimate of the distribution cost and the carbon tax.

- The commodity cost is based on the 10-year Alberta Energy Company (AECO) price forecast according to GLJ Petroleum Consultants (an independent energy consultant) based on their latest available forecast (updated by GLJ each quarter).

- The distribution costs are estimated by calculating an approximation of the pipeline transportation charges required by FortisBC to move the commodity supply to core markets as well as the storage costs associated with meeting winter load requirements.

- The carbon tax values shown are based on current estimates of $25/ton for 2011 and then remaining constant at $30/ton from 2012 and beyond.

The resulting avoided costs represent FortisBC's expected marginal cost to serve customers on a per unit basis. In this study, no distinction has been made between high load factor (flat) and low load factor (peaky) load shapes, or between different service areas within the province. Exhibit 22 provides a summary of the avoided natural gas supply costs on the basis of measure life.

[10] 1 kWh =3.6 MJ; 1GJ = 1000 MJ

Exhibit 22 Natural Gas – Avoided Supply Costs

	Marginal Cost of New Supply ($/GJ)			
Measure Life (Years)	**10**	**15**	**20**	**25**
Service Area				
Vancouver Island	12.97	14.25	15.64	15.64
Mainland	12.97	14.25	15.64	15.64

Avoided Supply Cost of Electricity

The avoided supply cost of electricity used in this analysis for was provided by FortisBC.[11] The $0.12 per kWh is consistent with BC Hydro's cost of new supply based on the successful bid responses to recent energy calls for new power. An adjustment reflecting the cost of demand was added to the cost of energy. The incremental demand cost of $170 for 1 kW for a year at 90% load factor adds approximately $0.02 per kWh to the energy cost, resulting in an avoided supply cost for industrial loads of approximately $0.14 per kWh. Exhibit 23 presents the avoided supply cost denominated in gigajoules (GJ).

A low load factor avoided cost of electricity was also calculated, based on a load factor of 65%. The result was an avoided electricity supply cost of approximately $0.15 per kWh for low load factor accounts.

The purpose of applying the low load factor avoided cost is to capture the additional benefits of reducing space heating and other loads that are highly coincidental with system peaks.

The same electricity avoided cost values apply to all service areas.

Exhibit 23 Electricity – Avoided Supply Costs

	Marginal Cost of New Supply ($/GJ)			
Measure Life (Years)	**10**	**15**	**20**	**25**
Service Area				
Vancouver Island	44.54	44.54	44.54	44.54
Mainland	44.54	44.54	44.54	44.54

Customer Energy Prices

The customer energy prices used in this analysis are presented in Exhibit 24. These values are used in the calculation of customer payback periods that are presented in later sections of this report. The electricity and natural gas prices were provided by FortisBC for the Residential and Commercial accounts. The prices shown are based on current rate schedules and, in the case of electricity, incorporate consideration of estimated demand charges. Where more than one rate schedule was applicable to a given sector, the rates were blended in approximately the same ratio as energy sales.

Industrial customer natural gas prices were prepared by the consultant and are based on FortisBC (Vancouver Island) rate sheet and FortisBC rate sheet as posted online at www.FortisBC.com. For Vancouver Island, an average rate, weighted by each rate class's energy sales in the 2010 Base Year

[11] $33.33/GJe.

resulted in an average rate of $0.0103 per MJ. For the Mainland, a weighted average of rates 2, 3, 5, 23, and 25 provided the non-interruptible rate. An interruptible rate of $0.006 per MJ was assumed, consistent with the July 1, 2010 FortisBC fixed price.

The industrial electricity cost is based on BC Hydro's Rate Schedule 1827, which is the blended rate for transmission-connected customers. Similar to the avoided cost of electricity, the annual demand charge of $67 per kW was the basis for an adjustment to the energy price at a load factor of 90%, bringing the cost of electricity for industrial customers to $0.041 per kWh.

Exhibit 24 Customer Energy Prices

	Industrial	
	Natural Gas $/GJ	Electricity $/GJ
Vancouver Island	$10.3	$11.4
Mainland Non-Interior	$7.1	$12.1
Mainland Interior	$6.0	$11.4

5.3 Technologies and Measure Assessment

Exhibit 25 lists the energy-efficiency technologies and measures that have been considered in this study. A description and detailed financial and economic assessment of each measure is provided in Appendix D.

Exhibit 25 Energy-efficiency Technologies and Measures Included in this Study

Conversion Device Upgrade Strategies

- Replace Unit Heater with Radiant Tube Heater
- Replace small standard efficiency boiler with condensing/near condensing boiler(Steady Load)
- Replace small standard efficiency boiler with condensing or near condensing boiler (Variable)
- Replace large standard efficiency steam boiler with near condensing boiler (Steady Load)
- Add Combustion Air Preheat to standard efficiency, steady load boiler
- Add Economizer to standard efficiency, steady load boiler
- Burner and Control Upgrades on Constant Load Standard Boiler
- Add Boiler Stack Condenser (Heat Recovery) to Large Steam Boiler
- Replace Standard Efficiency Baking Oven with High Efficiency Unit
- Replace Standard Efficiency Heat Treating Oven with High Efficiency Unit
- Add Ceramic Fiber Insulation for Constant Load Heat Treating Ovens
- Install Direct Fired Paper Drying Technology instead of Steam Heated Drums
- Burner and Control Upgrade to Pulp Lime Kilns
- Burner and Control Upgrade to Cement Kilns

Energy End Use Conservation Strategies

- Distribution System Insulation on Constant Process Load
- Optimized Heat Balance with Monitoring and Distribution System Control
- Steam Trap Maintenance Program
- Greenhouse Enclosure Upgrades (Energy Screens)

Unique Equipment Upgrades

- High Efficiency Lumber Dry Kilns
- High Efficiency Veneer Dryers
- Coal Centrifuge to reduce drying requirement
- Ore Dryer Upgrades (Copper Concentrate)
- Direct Fired Water Heating in Constant Process Load
- Direct Heat Upgrades – asphalt and gypsum
- Steam Cogeneration – Condensing Turbine

Cogeneration Options

- Install turbine generator on large steam system
- Install IC Engine Cogeneration device

5.3.1 Technology Screening Results

A partial summary of the results is provided in Exhibit 26. For each of the measures reviewed, the exhibit shows:

- End-use technology, applicable sub sectors and service areas
- The cost basis for the CCE that is shown, e.g., “full” versus “incremental”
- The simple payback in years and the total resource net benefits and the benefit-cost of the total resource cost.

Measures placed in Exhibit 26 have been ordered by customer payback period to provide a view of what customers could be expected to begin implementing. A measure that passes has positive TRC net benefits; on a full-cost basis it can be applied immediately, even if the piece of equipment that it replaces or improves is currently working properly. That means the rate at which the measure can be implemented as a utility DSM measure is limited by market and program constraints. A measure that passes only on an incremental basis, on the other hand, is limited by the rate of natural replacement (due to failure or obsolescence) or purchase of the piece of equipment it replaces.

Exhibit 26 Summary of TRC Measure Screening Results Industrial Sector Energy-efficiency Technologies

APPLICATION	MEASURE NAME	TECHNOLOGY	Full/ Incr	B/C Ratio	TRC Net Benefits ($,000)
Small Boilers	Efficient Boilers for Constant Annual Loads	2200 MBTU Output Near Condensing Boiler Standard Boiler Seasonal Efficiency = 68% New Boiler Seasonal Efficiency = 80%	I	16.1	247
Coal Dryers	Coal Drying	Conventional (Non-Vibrating) Fluid Bed Thermal Dryers with In-Bed Heat Exchangers	I	15.5	24,665
Boiler Related Upgrades	Add-on Condensing Heat Exchanger Large Boilers	Boiler Exhaust Stack Condensing Heat Exchanger add-on: 50,000 lbs/hour Standard Efficiency Boiler Baseline Efficiency = 68% Upgrade Efficiency = 83%	F	14.5	9,449

The TRC net benefits are calculated over the measure life of the technologies which ranges from 15 to 25 years. Selected highlights from Exhibit 26 are summarized below.

- Kiln upgrades are economically attractive at full cost for the pulp and paper and cement industries. Condensing boilers and stack condensers are all economic on a full cost basis. Direct-fired paper drying is economic on an incremental basis, i.e., it is economic to replace existing, standard efficiency equipment as soon as possible, and efficiency upgrades can be undertaken immediately.

- Efficient lumber dry kilns and veneer dryers are both economic on an incremental basis only.

- There are a number of other technologies that are economic but, due to their small market share, are not included in the results shown in Exhibit 26. These include economizers and air pre-heat for smaller boilers, efficient food processing ovens, and changes to direct-fired hot water heating.

5.4 Description of Energy-efficiency Technologies

Each of the technologies and measure shown in Exhibit 26 are briefly described below. In each case, the text provides the following:

- The current baseline technology
- A brief description of the upgrade technology
- The target sub sectors and process vintage(s) (new vs. existing) where the technology can be practically applied
- Information on the technology's energy performance and cost relative to the baseline technology
- A number of new technologies were added since the work plan list was developed because of the research that was done as a result of the interruptible customer survey
- If the technology has been dropped from further review since the list was developed for the work plan, a reason is given for doing so
- The expected useful life of the technology.

5.4.1 *Boilers*[12]

Boilers are used for steam or water heating in all sectors of manufacturing. Boilers make up 43% of the natural gas load in the Industrial sector, and a number of efficiency improvements are available.

Seasonal efficiency is used throughout the following discussion, as opposed to steady state boiler efficiency at full load. Seasonal boiler efficiencies for manufacturing range from 68% for a standard efficiency boiler to 92% for a condensing boiler. For Industrial sector retrofits, it is assumed that the installed cost is 2.5x the capital cost. Installed cost may be higher in the Industrial sector than for a comparable boiler size in the Commercial sector due to complexity of retrofits.

Energy-efficiency opportunities for boilers include:

- Near condensing boilers
- Condensing boilers
- Boiler economizers
- Boiler combustion pre-heating
- Advanced boiler controls

[12] Boiler technologies and economics based on personal communication with Kevin Woolley, Canadian Engineered Products, staff of Viessmann Manufacturing Company, Luc Mandeville of Sofame Technologies, and Greg Chapman of Chapman Burner.

- Low excess air burners
- Boiler heat recovery

Near Condensing Boilers

High-efficiency, near condensing boilers typically have a peak efficiency of 86%. A seasonal efficiency of 80% is assumed for this study. These boilers achieve high efficiency with advanced heat exchangers, modulating burner control, oxygen trim control systems, high quality insulation, and possibly a number of other features such as economizers, combustion air pre-heat, new combustion air fans and flue gas oxygen analyzers, low excess air burners and good insulation.

A simple payback period of four to five years is reported by vendors and in the literature for new installations of near condensing boilers over new installations of standard efficiency boilers. The useful life of these boilers is assumed to be 25 years. The average seasonal natural gas efficiency is assumed to increase from 68% for a standard boiler to 80% for a near condensing boiler.

Condensing Boilers

Condensing boilers have high-efficiency components such as modulating control and low excess air burners. They also have condensing heat exchangers that transfer heat from the exhaust flue gas to the return water. Condensing boilers need low return water temperatures (below 40°C) to operate at peak efficiency. If return water temperatures below 40°C cannot be provided, a condensing boiler will operate at efficiencies typical of a near condensing boiler. For this reason, although condensing boilers are economically attractive, they are not always feasible for the Industrial sector where technology growth is mostly in retrofit applications. The peak efficiency of condensing boilers can be as high as 97%. A seasonal efficiency of 92% is assumed for this study.

A simple payback period of between four and five years is reported by vendors and in the literature for new installations of condensing boilers over standard efficiency boilers. The useful life of a condensing boiler is 25 years. The average seasonal natural gas efficiency increase is assumed to be from 68% seasonal efficiency for a standard boiler to 92% seasonal efficiency for a condensing boiler.

Boiler Economizers

Economizers transfer waste heat from boiler exhaust gas to boiler feedwater or make-up water, thereby reducing the amount of heat that must be supplied by the fuel. High-efficiency, near condensing boilers usually have internal economizers and this technology is relatively common. Installing economizers on units that do not already have them is a practical and economical way of increasing energy efficiency and reducing the stack temperature only when installation costs are low. In retrofit applications, the cost of installing the economizer makes this technology economically unattractive for most applications. The useful life of economizers is 25 years. The average boiler efficiency increase by installing an economizer is approximated at 4% for either a standard boiler or a near condensing boiler.

Boiler Combustion Air Pre-heating

Boiler combustion air pre-heaters capture waste heat in the boiler flue gases, or from a hot building area to pre-heat the combustion air. This transfer reduces the amount of fuel needed to bring the air up to combustion temperature.

Note that since the combustion temperature will increase due to this practice, the NO_x emissions may increase if the burner design cannot accommodate the higher combustion air temperature. If this measure is to be promoted, acceptable NO_x levels must be maintained at all times.

A simple payback period of one year is reported by vendors and in the literature for installations of combustion air pre-heaters on standard efficiency boilers. The useful life of a pre-heat measure is 25 years. The average boiler efficiency increase by installing combustion air pre-heat is approximated at 4% for either a standard boiler or a near condensing boiler.

Controls and High-efficiency Burners (bundled standard upgrades)

Bundled standard boiler upgrades include advanced control and efficient burners. For this study, it is assumed that these upgrades are added as a bundle to a standard efficiency boiler, although it may be possible to add each technology individually.

Advanced boiler controls can lead to significant energy savings. Integrating the boiler control system with the process automation system allows for remote monitoring and changing of set points, and usually improves operation of the boiler system. Most advanced boiler controls include permitting higher turndown ratios than standard controllers. This contributes to energy efficiency by allowing the boiler to safely operate at a low firing rate.

Because perfect mixing between fuel and oxygen is never achieved, excess air is used to ensure complete combustion. Lowering the amount of excess air needed by the burner directly increases the fuel efficiency by reducing heat losses in the exhaust gas. A standard efficiency fire tube boiler usually operates at approximately 20% excess air. A low excess air natural gas burner may operate at as low as 10% excess air.

Oxides of nitrogen, collectively called NO_X, are formed during the high-temperature combustion conditions typical of low excess air burners. For that reason, high-efficiency burners are often also equipped with technology to reduce NO_X formation. The basic technology of low-NO_X burners usually involves carefully staged combustion and partial fuel premix, together with internal combustion gas recirculation. FortisBC will need to ensure that projects for burner upgrades or combustion air pre-heating do not adversely impact NO_x emission rates.

A simple payback period as low as 2.5 years is reported by vendors and in the literature for installations of condensation heat recovery on standard efficiency boilers. A payback this fast is likely only observed for processes with ideal conditions, such as a nearby heat sink with a heating load that is always higher than the amount of recovered heat. A more conservative value of three years is used in this study. The average natural gas efficiency increase is 6% over a standard efficiency boiler but only 2% for a near condensing boiler, because the boilers are typically designed with high-efficiency burners initially.

Large Boiler Replacement

There are a number of larger older wood waste steam boilers in pulp mills that could be replaced with more efficient fluidized bed units. There are also some large process boilers at food processors and other facilities that could be replaced with new more efficient units. In the 1980s and 1990s a number of these replacements occurred including units at Powell River, Port Alberni and Mackenzie. Over the last 10 years, due to low or no profit, these replacements have not been occurring. The capital cost is high and it is not practical to assume that a number of such boiler projects will occur. However, from an economic analysis perspective it is reasonable to assume that two large units in the Northern Interior could occur. An efficiency gain of about 10% would be likely for gas combustion, and 5% for wood combustion since the steam boilers would not be operating in the condensing regime.

Also it is likely that two older 50,000-lb/hr. gas-fired units in the Lower Mainland and one 50,000 lb/hr. gas-fired unit in the Southern Interior and another one on Vancouver Island could be replaced with more modern technology. An efficiency gain of about 10% would be likely since the steam boilers would not be operating in the condensing regime.

Addition of a Condensing Heat Exchanger to a Large Boiler

The addition of a condensation heat recovery unit to a boiler combustion stack recovers the latent heat of the flue gases for combustion air pre-heating and/or make-up water pre-heating. Essentially, this upgrade converts a standard boiler into a condensing boiler. The efficiency upgrade will be dependent on the temperature of the fluid that is circulated through the new condensing heat exchanger. This is an economic retrofit for processes that have a heat sink, such as significant boiler make-up water, or a significant domestic hot water load. Condensing heat recovery units require materials of construction that can withstand a corrosive environment, and newer heat exchangers have a useful life of more than 25 years. For this study, the addition of a condensing heat exchanger improves the efficiency of a standard boiler by 15%.

A simple payback period as low as 2.5 years is reported by vendors and in the literature for installations of condensation heat recovery on standard efficiency boilers. A payback this fast is likely only observed for processes with ideal conditions, such as a nearby low temperature heat requirement, and a large boiler with a high and consistent heating load.

5.4.2 *Direct-fired Water Heating*

Direct gas-fired water heaters have 95% or greater heat transfer efficiency. In one design, the combustion chamber is submersed in the water and the combustion gases are forced through the water, heating it by direct contact. This design is suitable for industrial applications with poor water quality, such as log or effluent ponds. In another design, cold water is sprayed downwards while combustion gases flow upwards. This design is appropriate for sanitary water applications such as laundries and food processing. This design is also used to heat boiler make-up water. No heat exchanger is needed with either design.

A simple payback period of three years is assumed for the installation of direct-fired water heaters over standard water heater heating using boilers. The useful life of direct-fired water heaters is assumed to be 15 years. The natural gas efficiency increase is assumed to be from a standard efficiency boiler of 68% to a direct-fired water heater seasonal efficiency of 95%.[13]

5.4.3 *Furnace Ceramic Fibre Insulation*

Direct gas-fired water heaters have 95% or greater heat transfer efficiency. In one design, the combustion chamber is submersed in the water and the combustion gases are forced through the water, heating it by direct contact. This design is suitable for industrial applications with poor water quality, such as log or effluent ponds. In another design, cold water is sprayed downwards while combustion gases flow upwards. This design is appropriate for sanitary water applications such as laundries and food processing. This design is also used to heat boiler make-up water. No heat exchanger is needed with either design.

A simple payback period of three years is assumed for the installation of direct-fired water heaters over standard water heater heating using boilers. The useful life of direct-fired water heaters is

[13] Direct-fired water heating economics and performance based on personal communication with Luc Mandeville, Sofame Technologies, and with Bill Carson, Direct Contact Inc.

assumed to be 15 years. The natural gas efficiency increase is assumed to be from a standard efficiency boiler of 68% to a direct-fired water heater seasonal efficiency of 95%.[14]

5.4.4 Direct-fired and Radiant Tube Heating

Direct-fired heating and radiant tube heating are both used in the Food & Beverage sector. Direct-fired heating is used in food processing and in poultry barns, and radiant tube heating is used in poultry barns. Direct-fired heating offers savings over boiler heat because it has higher natural gas efficiency; radiant tube heating offers savings over boiler heat because it allows poultry barns to operate at a lower overall temperature, while maintaining the same comfort levels for the animals.

A natural gas efficiency of 90% was assumed for direct-fired heating, and of 90% for radiant tube heating. A useful lifetime of 25 years is assumed for both of these technologies. A simple payback of three years is assumed for the installation of radiant tube heating or direct-fired heating over boiler heat.

Radiant tube heaters are a more efficient way to heat the large volume spaces typically found in the Industrial sector compared to air heating methods such as air handling units, unit heaters, and heat exchangers connected to the hot water or steam system.

Radiant tube heaters achieve the energy savings mainly because heat is radiated down to the floor space where the heat is needed, instead of trying to heat the large volume of air in an industrial building. An efficiency upgrade of 20% is used in this study when compared to an air handling unit, or make-up air unit. Industrial units are considered to have a life of 20 years.

5.4.5 Direct-fired Paper Drying

The Pulp and Paper sector that is the subject of this study primarily consists of board paper manufacturers and cellulose-based absorbent manufacturers. Traditionally, large industrial boilers provide steam to heat and dissolve the cellulose feedstock, and then to dry the final product after the cellulose is shaped into the form desired.

Drying board paper is usually accomplished by passing the sheet over steam-heated drums. However, the rate of drying is quite limited due to the low temperature of the steam. Therefore, the production rate of most paper machines is limited by slow rate of drying of the steam drums. As a result, the dryer section of a paper mill can be as large as a football field.

Various technologies have been developed to use natural gas to directly dry paper. Non-contacting infrared emitters have been developed to assist in moisture profiling of the sheet. The primary purpose of this technology is for moisture consistency, but it also allows the speed of the machine to be increased due to the additional drying capacity. Gas-heated dryer drums are the most common method of direct gas heating on paper machines. Overall thermal efficiencies can increase from 65% with steam to 90% with gas-heated dryer drum technology. The major benefit however is an increase in production of 15% due to the higher rate of drying. A board paper mill in Texas (Corrugated Services LP) recently installed both an infrared radiation dryer section and a gas-heated dryer drum on their corrugated board machine. They claim the fuel savings and increase in production due to these direct gas-heating technologies have provided significant economic benefits.

Total project costs of $1,500,000 were reported to add two gas-fired cylinders to a newsprint machine, with a resultant net revenue increase of $3,800,000 per year, much of it due to the

[14] Ibid.

increase in production rate. No change in maintenance costs is expected. For the smaller mills that are the subject of this study (about 10% the capacity of a newsprint machine), costing data was not available. It is assumed that a $1,000,000 investment will provide a 7.3% reduction in fuel usage per tonne of product, but will allow an increase in production of 16.7%, providing a simple payback of three years. The useful life of direct heated gas drying technologies is assumed to be 20 years.

Note that one of the pulp mills surveyed indicated that they are considering upgrading three existing paper dryers (with steam-heated drying drums) to direct-fired paper drying.

5.4.6 *Lime Kiln Upgrades*

The lime kiln operation in a Kraft pulp mill is one of the most challenging to control. First of all, it is a complicated mixed-phase chemical reaction process. Quickly moving combustion gases provide the heat input to chemically change the slowly moving solid-phase lime mud into lime.

Secondly, the many different types and degrees of process delays are very significant and difficult to manage manually. Adequate, but not optimum, manual control takes a well developed feel for the process and careful manual management of the individual control loop targets. In a process with such long time delays, it is common for operators to overreact to changes, resulting in long periods of instability and variable lime quality.[15]

It has been demonstrated in different facilities that the application of a sophisticated control system has resulted in significant savings. For the economic case analysis, a 4% savings on the natural gas used for lime kilns has been published. Paybacks for upgrading lime kilns are assumed to be nearly two years with gas at $6/GJ.

Adding insulation to a lime kiln also has a significant energy impact. A savings of 5% is achievable depending on the state of the existing kiln. Paybacks are assumed to be in the range of three years with gas at $6/GJ. BNZ Materials Ltd published a case history of two pulp lime kilns in Tennessee which achieved significant savings. A type of insulation called Marinite was installed between the refractory brick and shell when worn bricks were being replaced during regularly scheduled maintenance shutdowns.

5.4.7 *Distribution System Insulation*

This study considered insulating the boiler distribution system at partial and full levels. A standard pipe diameter of 2”, hot temperature of 82°C, and wind speed of five miles per hour were used for the calculations. A fully insulated distribution system was assumed to be insulated with mineral fibre to the economic thickness of one inch, and heat retaining efficiency of 92%, as per the North American Insulation Manufacturers Association (NAIMA) software 3E Plus. The baseline technology is a partially insulated distribution system, which is assumed to retain 50% of the heat lost in bare piping. The simple payback period for the installation of fully insulation was calculated to be 1.5 years, and a lifetime of 20 years, as per NAIMA.

A model typical facility was developed with a total pipe length of 815’ that could benefit from insulation. Standard heat loss values were used to calculate heat lost in the distribution system for partly and fully insulated pipe. It was assumed that in the Base Year, 75% of facilities would have partly insulated distribution systems, while the remaining 25% would have fully insulated distribution systems. Based on these assumptions, 4% of useful boiler heat was lost in the distribution system in the Base Year. Generally, any part of a heating distribution system above 50°C should be insulated.

[15] Heikki Imeläinen, Mauri Loukiala and Urpo Launonen. *Lime Kiln Optimization: Managing the Inputs to Stabilize The Outcome.*

5.4.8 *Large Process Steam Upgrades*

There are a number of facilities that involve large process steam networks, mainly at pulp mills, refineries and breweries. These systems involve distributing steam at a variety pressure levels: 200 kPa (29 psia[16]), 400 kPa (58 psia), and 750 kPa (109 psia) are examples. The steam is distributed to different end uses such as paper dryers, steam turbine drives, pulp chip digesters and space heating steam-heated fan coils.

All of these systems can be upgraded to a greater or lesser extent due mainly to equipment aging and due to the steam system network not being optimized with respect to process changes that have occurred. For example, some of the pulp mills are using steam turbines to drive fans or pumps and, due to deterioration, these drives are operating at a very low efficiency level. There are also situations where, due to process changes, higher pressures (750 kPa) are being used where lower pressures (200 kPa) would suffice.

Another common loss item is a deterioration of the condensate return system. At many of the end uses, after the energy in the steam is used, condensate (hot water in the order of 100°C) is available. The condensate return system captures this hot water and returns it to the boiler feedwater system. However, due to corrosion, in time these systems develop leaks and the hot water goes to the drain rather than being returned. The test to see how good the return system is the amount of make-up water required. In a theoretically perfect system no make-up water is required because all of the condensate is returned. Typically, if only 10% make-up water is required, the system is in excellent repair while a 30% make-up amount would indicate a system in poor shape.

Poor functioning steam traps are another loss item. A steam trap is a device used to discharge condensate and non-condensable gases with a negligible consumption or loss of live steam. Most steam traps are nothing more than automatic valves. They open, close or modulate automatically. Others are based on turbulent two-phase flows to obstruct the steam flow. In most large systems there are usually saving opportunities by repairing or replacing old poorly functioning traps.

Savings can be obtained in any large system at any time by conducting a detailed audit followed by repair and replacement of system components where required. However, the savings level will vary significantly from system to system depending on the existing state of repair and on the number of steam traps. FortisBC could facilitate capture of these savings by partially sponsoring detailed audit/upgrades of key systems. Savings from steam trap maintenance (and condensate return upgrades) are assumed to be in the order of 5%. Paybacks of two years are typical. On-going maintenance is required to maintain savings for this measure.

5.4.9 *Optimized Heat Balance with Monitoring and Distribution System Control*

Many industrial processes require heat to process materials into their final form. Examples include the conversion of wood into pulp and paper, hops into beer, and gas, oil and coal into plastics and pharmaceuticals. In each of these processes, different forms of heat and different temperatures may be required, such as high-temperature combustion gases, high- and low-pressure steam, and hot or warm water. In the late 1980s, with the rising cost of fuel and electricity, industries developed methods to decrease fuel requirements by capturing the waste heat from one process, and using that waste heat in another stage of the process. This was called “pinch” analysis and it provided the tools to analyze and optimize the recycling of heat within a plant to minimize the requirement for purchased energy. This process is also known as “process integration” and “heat of energy integration.” As analysis techniques developed, benefits went beyond energy conservation.

[16] The term “psia” means pounds per square inch absolute.

Pinch analysis considers an entire multi-step manufacturing process as one integrated process, permitting process optimization, resulting in improved product yield, decreased emissions, de-bottlenecking, improved flexibility and safety of the processes.

An example of the use of pinch analysis was presented in an article in *Innovation*, the monthly newsletter of the Professional Engineers and Geoscientists of BC, November 2002. A pinch analysis of a thermo-mechanical pulp mill operation in B.C. uncovered opportunities which resulted in the reduction in gas usage of 275,000 GJ/yr. of natural gas, with the potential for a further 155,000 GJ/yr. When completed, the mill may save $2.1 million per year in fuel costs, providing a seven-month payback on the expected $1.3 million capital cost. This example is not fully representative of a typical pinch case because the customer is much larger than the customer group which is the subject of this study, and because the savings resulted primarily from de-bottlenecking.

The Chemical, Pulp and Paper, and Food & Beverage processing sectors could potentially benefit from pinch technology. Pinch technology crosses over to all process streams within an operation, and the savings can be the result either low- or high-cost modifications to the mill. This study assumes that a plant-wide reduction in energy consumption of 10% is possible with an investment that would result in a four-year payback. This payback is an estimated average value. The application of pinch technology will increase maintenance requirements in some areas (e.g., additional heat exchangers may be required that will require maintenance), but will decrease maintenance in others (e.g., due to the increased efficiency, some heating units may actually be taken out of service). This study assumes no net change.

5.4.10 *Process Heat Recovery (Heat Exchangers and Storage)*

Further to the previous measure (Optimized Heat Balance), in most processes a great deal of waste heat is available that can be recovered and used. For example, breweries, sewage treatment plants, and pulp mills have warm effluent that can be used to pre-heat the incoming fluids through the use of a heat exchanger. This strategy is simple provided that the incoming flows are timed with the outgoing waste streams. If the timing is not concurrent, large storage tanks can be incorporated to store either the pre-heated incoming stream or the warm effluent until needed. This is a normal arrangement for pre-heating domestic water in many food industries from the refrigeration plant.

To further leverage heat recovery, a heat pump can be used to extract energy from the waste stream and heat the process stream to a greater degree. (Using a heat exchanger is called "passive heat recovery" and using a heat pump is called "active heat recovery.")

These strategies are most economic during new plant design, or major rework projects. Typical paybacks range from one to three years, depending on operating hours and the temperature difference between the waste stream and the process stream. Retrofit projects will have a longer payback, and higher capital cost because of the large amount of rework required. However some projects will exist with reasonable paybacks (two to four years) in energy-intensive industries that have long operating hours.

5.4.11 *Lumber Dry Kilns*[17]

- Advanced Dry Kiln Controls

Energy use in wood kiln drying is specific to operating conditions such as wood moisture content and species. Conventional heat and vent kilns are used in B.C. Larger sawmill operations use

[17] Dry kiln economics based on personal communication with Fred Spinola, General Manager, Coe Manufacturing, and Ken McClure, Sales and Marketing Manager, Wellons Canada.

natural gas, boiler-heated steam or thermal oil for kiln heating and significant amounts of electricity for fan power. Perhaps the most promising energy saving opportunity for conventional kilns is improved control. Most conventional kilns are operated on fixed time schedules. Computer controls with in-kiln moisture metering, fan speed control and vent control can offer significant energy savings. Replacing the old pneumatic controls with advanced control improves energy efficiency, drying time and final product quality.

The sawmill industry as a whole is moving away from natural gas and towards wood waste alternatives for heating dry kilns.

A simple payback period of two years is reported by vendors and in the literature for control upgrades to heat and vent kilns. The useful life of these control systems is 15 years. The average natural gas efficiency increase is assumed to be 30% for a standard kiln to 60% for a standard kiln with advanced controls. The average reduction in electricity consumption is assumed to be 15% following the installation of advanced controls.

- Efficient Dry Kilns

In addition to control systems, a number of upgrades are possible to turn an average kiln into an energy-efficient one. These upgrades include automatic venting, load balancing, insulation, baffling, variable speed drives and heat recovery.

An average simple payback period of four years is reported by vendors and in the literature for efficiency upgrades to heat and vent kilns. The useful life of the upgrades is 15 years. The average natural gas efficiency increase is assumed to increase from 57% for a standard kiln to 87% for an advanced kiln. The average reduction in electricity consumption is assumed to be 20% following the upgrades.

Based on the study team's knowledge, all the lumber kilns in operation are compartment or batch type kilns as opposed to progressive or continuous kilns. There has been considerable research conducted with respect to lumber drying, much of it involving continuous processes that utilize electric technologies such as microwave and radio frequency. However, to date these developments have not resulted in a commercially viable product.

Generally the improvements from the high-efficiency kilns are due to better airflow distribution, optimized airflow velocity and a reduction of energy losses due to better insulated and tighter kilns. The efficiency gain is then due to shorter drying times; the shorter the drying time the less energy that is used for thousand board feet of lumber dried. The temperature of the drying process does not change.

5.4.12 *High-efficiency Veneer Dryers*

Veneer dryers can also be heated with natural gas, steam or thermal oil at plywood plants.

Veneer dryers operate as a continuous process with multiple lines of veneer. Temperatures are between 350°C and 400°C and the chamber is pressurized. Veneer dryers are either direct natural gas-fired or indirectly heated with thermal oil or steam from a natural gas or wood waste-fired boiler. The largest efficiency and production improvement opportunity for veneer dryers is upgrading insulation and seals. As with lumber dry kilns, the plywood sector is moving away from natural gas as a heat source and towards wood waste.

A simple payback period of three years is reported by vendors and in the literature for upgrades to veneer dryers. The useful life of a veneer dryer upgrade is 15 years. A reduction in natural gas consumption of up to 40% is reported for some veneer dryer upgrades, but a more conservative value of 20% is used in this study. The natural gas efficiency is assumed to increase from 50% for a standard veneer dryer to 70% for an efficient veneer dryer.[18]

5.4.13 Greenhouse Enclosure Upgrades

Natural gas boilers are used to heat many greenhouses. Much of the heating is required due to heat loss from the greenhouse during the night hours. Energy screens (essentially retractable blankets that let a portion of the light through) are available that can reduce heat loss by up to 25%. Many newer greenhouses are installing these types of screens for heat and light control. For this analysis, a conservative estimate of savings was used at 17% for a new energy screen installation.

5.4.14 Ore Drying

- Coal Drying

It is assumed that the existing coal dryers being used are the conventional rotary flash dryer type. It was assumed that the efficiency of these units could be improved by 10% through improved combustion control and heat recovery. Also centrifuges that spin the coal at high speeds to drive off moisture prior to entering the dryer is an option for reducing the drying load on the coal dryers. For this analysis, a 10% energy savings was used with a payback of three years using $6/GJ gas.

- Copper Concentrate

At a number of copper mining operations wet copper concentrate is dried in large rotary kilns. The dryers use natural gas to produce hot combustion gases that are blown into the dryer. The gases should be as hot as possible to maximize thermal efficiency, but must not exceed the ignition temperature of the metal sulfide copper concentrates.

It was assumed that improved control measures could improve the efficiency by 5%. A Reference Case from the Kennecott Utah Copper mine demonstrated this savings level is feasible, with a payback of two years using $6/GJ gas.

5.4.15 Heat Treating and Annealing

Heat treating and annealing are used primarily in the Fabricated Metal sub sector. Fuel efficiency measures investigated are improved burner design, heat recovery and improved insulation.

Sequential Firing, High-velocity Burners

Sequential firing occurs when multiple burners are fired cyclically at full power. This creates a very agitated atmosphere within the furnace, increasing turbulence, and thereby increasing heat transfer by convection. An added benefit of pulse firing is that a consistent temperature can be achieved within the furnace with variations as low as 4°C.

High-velocity burners are a type of nozzle mix burner with burner velocity up to 150 m/sec. They provide deep penetration of heat into the stock, good rates of heat transfer and uniform temperature distribution in a furnace.

For the purpose of this study, it is assumed that sequential firing, high-velocity burners are added as a bundle to standard efficiency heat treating furnaces.

[18] Veneer dryer performance based on personal communication with Dave Chard, Westmill Industries.

A simple payback period of three years is reported by vendors and in the literature for new installations of sequential firing, high-velocity burners over standard burners. The useful life of these technologies is assumed to be 15 years. The average natural gas efficiency increase from a standard burner efficiency of 25% to an upgraded burner efficiency is 40%. For high-temperature applications such as heat treating, efficiency is typically low, and is defined as the heat that is transferred from the flame to the metal. Paybacks of three years are typical for the incremental cost when replacing the equipment.

5.4.16 High-efficiency Ovens

High-efficiency ovens are found in the Food & Beverage sub sector.

A simple payback period of three years is reported by vendors and in the literature for new installations of high-efficiency ovens over standard ovens. The useful life of high-efficiency ovens is 15 years. The average natural gas efficiency increase is from 65% for a standard oven to 80% for an efficient oven.[19]

5.4.17 Direct Heat – Asphalt and Gypsum

Natural gas is used in the asphalt to dry and heat aggregate and heat the asphalt in preparation for mixing. Plant design is varied, and both continuous or batch type processes are used. Literature indicates that in Canadian plants efficiency varies by 20% from plant to plant. Due to the varying nature of these plants, it is likely that most efficiency gains can be made by replacement of more modern plants, however, a modest efficiency gain of 10% is likely through burner upgrades, improved controls and insulation. For the economic case, a 10% improvement potential was assumed, using a payback of three years.

The process to manufacture drywall from gypsum requires direct-fired natural gas heat to dry the product. Based on information from the manufacturers, a 9% efficiency improvement is obtainable, bringing average efficiency up from 81% to 90%, which is in line with industry best practice. A payback of three years is used since the upgrades are deemed economical from the companies' perspective.

5.4.18 Cogeneration

Cogeneration, the simultaneous production of electricity and useful heat, is generally considered an efficiency technology because it is a much more efficient method for generating electricity than from a gas-fired electric utility plant. However, with respect to an application at a specific customer site, it does result in additional natural gas being used.

- Internal Combustion Engines

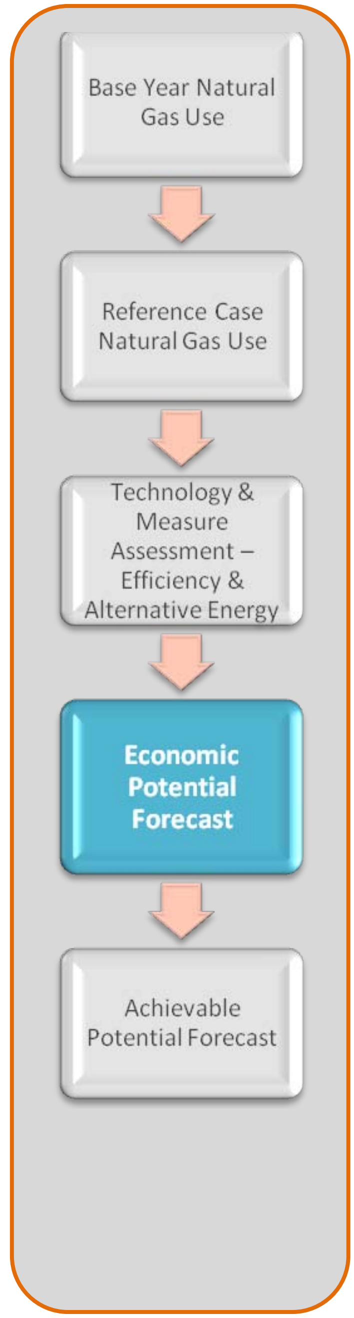
There is a significant opportunity for cogeneration in the greenhouse industry using natural gas-fired reciprocating engines. One greenhouse in B.C. already has a small operating internal combustion cogeneration engine that sells electricity back to BC Hydro, and recovers the waste heat to the greenhouse. The barriers to the more widespread application are the uncertainty as to the long-term cost of natural gas and, now, the carbon tax.

A method for overcoming these barriers is to use "green gas," as is the case with cogeneration unit at one greenhouse complex in the Lower Mainland. For this particular project, landfill gas is used. No value was assigned to this measure in the economic case analysis.

[19] Oven economics and heat savings based on personal communication with Revent Oven of New Jersey, USA.

6 Economic Potential Forecast

6.1 Introduction



This section presents the Industrial sector Economic Potential Forecast for the study period 2010 go 2030. The Economic Potential Forecast estimates the level of energy consumption that would occur if all equipment and processes were upgraded to the level that is cost effective. In this study, "cost effective" means that the technology upgrade passes the measure TRC test, as discussed previously in Section 5.

The discussion in this section is organized and presented in the following subsections:

- Major modeling tasks
- Technologies included in Economic Potential Forecast
- Presentation of results
- Interpretation of results.

6.2 Major Modelling Tasks

By comparing the results of the Industrial sector Economic Potential Forecast with the Reference Case, it is possible to determine the aggregate level of potential natural gas savings within the Industrial sector and to identify specific sub sectors and technologies that provide the most significant opportunities for savings. To develop the Industrial sector Economic Potential Forecast, the following tasks were undertaken:

- The results of the energy-efficiency measures screening, which were presented in the preceding Section 5, were reviewed. All the natural gas energy-efficiency upgrades that passed the measure TRC screening were included in this Economic Potential Forecast.

- New equipment measures meeting the screen on a full cost basis were "installed" at equipment annual turnover rates. Screened efficiency improvement bundles (e.g., optimization and controls) were installed in the first study year (2011). The conversion device efficiency and process efficiency for each technology/measure was updated for the sub sectors within each service area.

- The model calculated the change in market share for the screened technologies and measures based on the results of preceding task. The Reference Case energy consumption forecast was updated with the changes in technology/measure market share to produce the Economic Potential Forecast.

- The difference between the Economic Potential Forecast consumption and the Reference Case was calculated, to produce the Economic Potential savings.

6.3 Technologies Included in Economic Potential Forecast

The technologies presented in this energy-efficiency Economic Potential Forecast can be grouped into three main categories:

- Gas conversion devices (equipment) that are available in high(er) efficiency models as well as standard efficiency ones
- "Add-on" technologies, such as insulation or operating controls that reduce overall gas purchases but do not consume gas themselves
- Gas-consuming technologies where there is no practical upgrade.

A brief discussion of the approach to each of the above technology categories is outlined below.

6.3.1 *Conversion Devices with High-efficiency Models*

Most of the natural gas technologies in this analysis fall into this category. As briefly outlined in the preceding section, this analysis introduces the more efficient technologies into the Economic Potential Forecast model in one of two ways: on an incremental basis or on a full-cost basis.

The incremental basis was applied to those technologies where it is only economic to replace a standard unit with an efficient unit at the end of the standard unit's useful life. In this case, the market share of the efficient technology grows at the rate of stock replacement. The rate of stock replacement is calculated based on the technology's average useful life and the original installed stock of the technology being replaced. For the Economic Potential Forecast, it was assumed that replacement would be considered starting when the unit reached of the end of its useful life, and replacement would occur at the time if it were economic to do so.

The full-cost basis was applied to those technologies where it is economic to replace an existing standard model with an efficient model before the end of the standard unit's useful life. In this case, all standard models are replaced by the first milestone year. Unless otherwise noted, it is assumed that technologies are not interchangeable (e.g., an efficient boiler can replace a standard boiler but cannot replace a rooftop air handling unit).

6.3.2 *"Add-on" Technologies*

Some technologies, such as insulation or operating controls can reduce overall gas purchases. While these technologies do not consume gas themselves, not having them installed results in increased gas consumption. As with the higher efficiency models case, either the technology was applied immediately (full cost), or when the end of life is reached depending on if the measure was deemed economical

6.3.3 *"No Option" Technologies*

Some technologies that have market share have no practical efficiency upgrade. These technologies either have an efficient model that is not economically attractive, or are only available in one efficiency level. Although this analysis does not identify conservation potential for these technologies, they are included in the results because they have a market share of the heat sold.

Further discussion of the efficient equipment and process improvements selected for inclusion in the Economic Potential Forecast are presented in Exhibit 27. In each case, the exhibit shows:

- Energy end use
- Upgrade technology(s) selected
- Brief explanation of applicable sub sectors and the rate at which the technology is introduced into the Economic Potential Forecast.

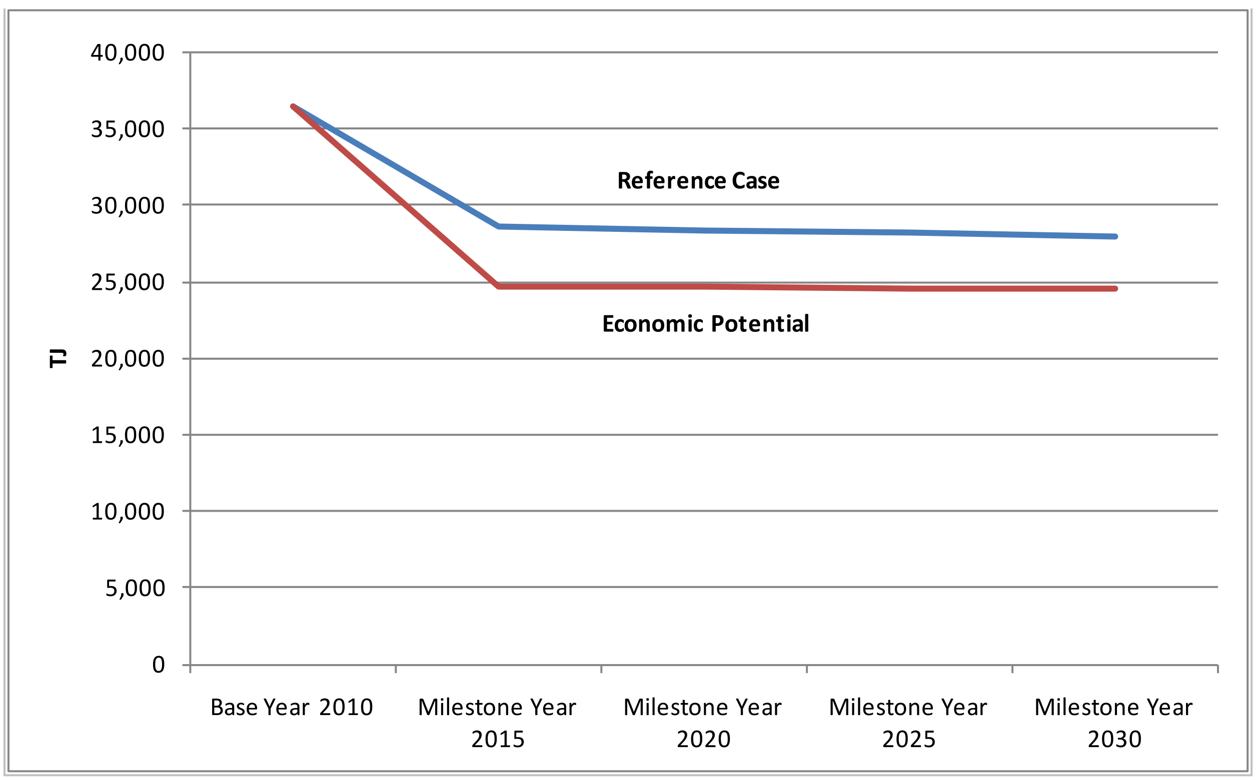
6.4 Presentation of Results

Exhibit 27 compares the Industrial sector consumption results from the Reference Case to those in the Economic Potential Forecast.

As illustrated, under the Reference Case, Industrial sector natural gas use would decrease from the Base Year level of about 36,500,000 GJ/yr. to approximately 28,000,000 GJ/yr. by 2030. This contrasts with the Economic Potential Forecast in which natural gas use would decrease to approximately 24,500,000 GJ/yr. by 2030 for an annual reduction of 3,400,000 GJ, or just over 14% of the Reference Case for 2030. This is in addition to the 22% load reduction for the study period (2010 to 2030) included in the Reference Case.

Exhibit 27 Reference Case versus Economic Potential Forecast

—Annual Industrial Natural Gas Consumption (TJ)



6.4.1 *Natural Gas Savings*

Further details on the potential energy savings provided by the Economic Potential Forecast are provided in the following exhibits:

- Exhibit 28 presents the results by service region and milestone year
- Exhibit 29 presents the results by sub sector and milestone year
- Exhibit 30 presents the results by major end use.

Exhibit 28 Total Economic Potential Natural Gas Annual Savings (GJ)

Milestone Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Total	Economic Savings over Reverence Case
2015	2,014,970	1,020,350	722,532	126,446	**3,884,297**	16%
2030	1,911,392	985,354	701,401	120,991	**3,719,138**	15%
2025	1,825,772	951,448	680,790	116,885	**3,574,896**	15%
2030	1,748,002	918,667	660,731	111,907	**3,439,307**	14%
2030 Percent Savings Over Reference Case	15%	12%	15%	18%	14%	

Exhibit 29 Total Economic Potential Natural Gas Annual Savings

- by Sub Sector and Milestone Year (GJ)

Sub Sector	2015	2020	2025	2030
Agriculture	419,252	374,778	336,858	303,481
Chemical	364,678	360,665	356,965	353,565
Fabricated Metal	195,323	180,337	165,385	151,767
Food & Beverage	807,873	791,578	776,124	761,523
Mining	357,879	350,639	343,400	336,175
Miscellaneous Manufacturing	17,051	18,741	20,116	21,215

Total	**3,884,297**	**3,719,138**	**3,574,896**	**3,439,307**

Exhibit 30 Total Economic Potential Natural Gas Annual Savings over Reference Case - by Major Technology and End Use (GJ)

Technology	2030 Savings	Technology Share
Boilers	1,938,475	56%
Air heating	474,596	14%
Lumber kilns	339,137	10%
Direct fired	219,840	6%
Coal drying	155,621	5%
Heat treating	94,455	3%
Pulp lime kilns	75,180	2%
Veneer dryers	51,326	1%
Cement kilns	48,129	1%
Ovens	27,773	1%
Ore drying	7,410	<0.1%
Water heaters	7,365	<0.1%
Total	**3,439,307**	100%

Detailed results are presented in Appendix D by sub sector, service area, end use and technology.

6.5 Interpretation of Results

Highlights of the results presented in the preceding exhibits are summarized below.

Savings by Industrial Sub Sector

- The Food & Beverage sub sector has the largest potential for efficiency upgrades at 22% of the total Economic Potential, closely followed by the Pulp and Paper sub sector at 21%, and the Wood Products sub sector at 15%. Chemical and Mining both make up 10% of the potential each, while the other sub sectors have more minor potentials.

Savings by Technology

- The dominant technologies throughout the Industrial sector are the boilers, showing the greatest savings potential at 56% of the total Economic Potential. As illustrated in Exhibit 30, improved efficiency boiler equipment in all applicable sub sectors offers approximately 1,938,000 GJ/yr. of process heat savings potential by 2030. These savings come from a range of boiler equipment upgrades including boiler replacement, add-on condensing units, and controls, as well as with heat recovery and controls for the process.

- Air heating (for comfort) makes up the second largest Economic Potential at 14%. This is due to the large number of smaller manufacturers who heat their industrial spaces with inefficient unit heaters or air handling units. Radiant tube heaters are an attractive option in high-bay buildings in the Industrial sector, especially near large doors that may be open for significant time periods during the day.

Savings by Service Area

- The Lower Mainland comprises 57% of the Economic Potential, while accounting for 48% of total Industrial sector Base Year sales. These results are explained by the large savings potential of boiler upgrades and replacement in the Food & Beverage sub sector located in the Lower Mainland.

- The Northern Interior's portion is approximately 25% of the Economic Potential, while the Southern Interior is at approximately 14%, reflecting the reduction of wood manufacturing capacity in the area.

- Vancouver Island makes up both a small part of Base Year sales, and a small part of the Economic Potential (approximately 2%).

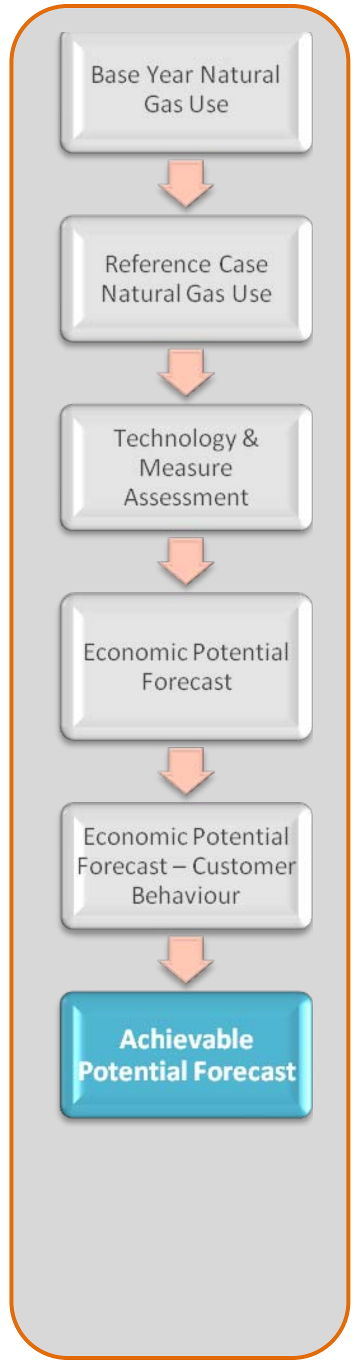
Savings by Milestone Year

- Exhibit 30 shows that in the Reference Case, annual gas consumption declines according to the forecast reduction in natural gas sales over the study period for the Industrial sector. The reduction is due to expected slowdown in manufacturing and industrial output in the first milestone period to 2015. After 2015, the rate of decline is approximately 1.5 % per milestone period.

- In the Economic Potential Forecast, gas consumption declines at a greater rate than the Reference Case up to the first milestone year (2015). Sales consumption continues to decline through each of the milestone years at approximately 7% per period. The captured savings rate reflects the increased market share of high-efficiency technologies and equipment upgrades.

7 Achievable Potential Forecast

7.1 Introduction



This section presents the Industrial sector Achievable Potential for the study period (2010 to 2030). The Achievable Potential is defined as the proportion of the energy-efficiency opportunities identified in the Economic Potential Forecast that could realistically be achieved within the study period.

The remainder of this discussion is organized into the following subsections:

- Description of Achievable Potential
- Approach to the estimation of Achievable Potential
- Results – energy-efficient technologies.

7.2 Description of Achievable Potential

Achievable Potential recognizes that, in many instances, it is difficult to induce all customers to purchase and install all the energy-efficiency technologies that meet the criteria defined by the Economic Potential Forecast. For example, customer decisions to implement energy-efficient measures can be constrained by a number of factors. The rate at which customers accept and purchase energy-efficiency products will be influenced by the level of financial incentives, information and other measures put in place by FortisBC, BC Hydro, governments and the private sector to remove barriers such as those noted above.

Exhibit 31 presents the levels of natural gas consumption that are estimated in the Achievable Potential scenario. As illustrated, the Achievable Potential scenarios are *banded* by the two forecasts presented in previous sections: the Economic Potential Forecast and the Reference Case.

As illustrated in Exhibit 31 energy savings under the Achievable Potential scenario are less than in the Economic Potential Forecast. In this CPR, the primary factor that contributes to the outcome shown in Exhibit 31 is the rate of market penetration. In the Economic Potential Forecast, efficient new technologies are assumed to fully penetrate the market as soon as it is economically attractive to do so. However, the Achievable Potential recognizes that under real world conditions, the rate at which customers are likely to implement new technologies will be influenced by additional practical considerations and will, therefore, occur at a rate less than that under the assumptions employed in the Economic Potential Forecast.

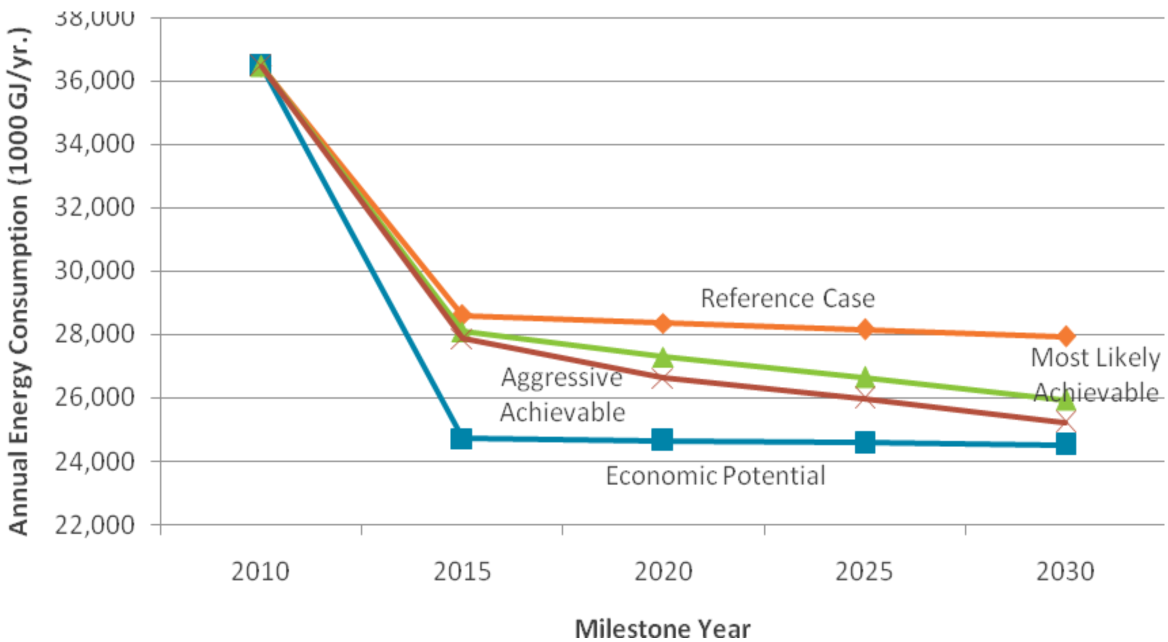
The following are examples of the additional considerations:

- Customers often do not have sufficient in-house technical staff to be able to perform the up-front site-specific engineering work that needs to be performed before an energy-efficiency project can be implemented.
- The particularly facility involved may have an uncertain future due to market conditions, which affects the demand for the product being produced. For example, over the last few years a number of pulp mills have shut down due to continually decreasing demand for

paper. If there is uncertainty as to the future of a particular mill, a new boiler cannot be financially justified.

- In some cases, the technical personnel are not familiar enough with a particular efficiency technology to risk replacing an existing reliable, but inefficient, piece of equipment with a more efficient unit.

Exhibit 31 Annual Natural Gas Consumption — Energy-efficiency Achievable Potential Relative to Reference Case and Economic Potential Forecast for the Industrial Sector, (GJ/yr.)



As also illustrated in Exhibit 31, the Achievable results are presented as a band of possibilities, rather than a single line. This is because any estimate of Achievable Potential over a 20-year period is necessarily subject to uncertainty. Consequently, two Achievable Potential scenarios are presented: most likely and aggressive.

The **most Likely Achievable Potential** assumes B.C. market conditions that are similar to those contained in the Reference Case. That is, the customers' awareness of energy-efficiency options and their motivation levels remain similar to those in the recent past, technology improvements continue at historical levels, and new energy performance standards continue as per current known schedules. It also assumes that FortisBC's ability to influence customers' decisions towards increased investments in energy-efficiency options remain roughly in line with previous company DSM experience.

The **aggressive Marketing Achievable Potential** assumes that B.C. market conditions become more supportive of investing in energy efficiency. For example, this scenario assumes that real energy prices increase over the study period. It also assumes that federal and provincial government actions to mitigate climate change result in increased levels of complementary energy-efficiency initiatives. Aggressive Achievable Potential typically does not reach Economic Potential levels; this recognizes that some portion of the market is typically constrained by barriers that cannot realistically be affected by DSM programs within the study period.

Typically, the barriers are as follows:

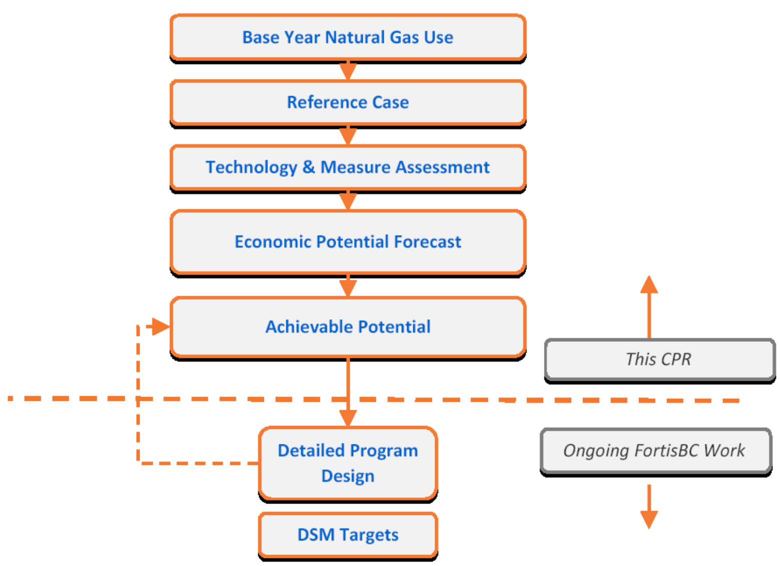
- Availability of technical assistance or resources to perform the site-specific engineering work
- Uncertain economic viability of a particular site
- Unwilling to take the risk of replacing equipment that is working reliably even though there is more efficient equipment available
- A particular efficiency technology may be available in other jurisdictions but is not readily available here in terms of suppliers who will look after installation and provide ongoing servicing and spare parts
- Customers are simply unaware that a more efficient technology is available.

7.2.1 Achievable Potential versus Detailed Program Design

It should also be emphasized that the estimation of Achievable Potential is not synonymous with either the setting of specific program targets or with program design. While both are closely linked to the discussion of Achievable Potential, they involve more detailed analysis that is beyond the scope of this study.

Exhibit 32 illustrates the relationship between Achievable Potential and the more detailed program design.

Exhibit 32 Achievable Potential versus Detailed Program Design



7.3 Approach to the Estimation of Achievable Potential

Achievable Potential was estimated in a five-step approach.

- Priority opportunities were selected
- Opportunity profiles were created
- Opportunity worksheets were created
- A full-day workshop was held to gain input from stakeholders
- Workshop results were aggregated and applied to the remaining opportunities.

Further discussion is provided below.

7.3.1 Step 1 Select Priority Opportunities

The first step in developing the Achievable Potential estimates required selection of the energy saving opportunities identified in the Economic Potential Forecasts to be discussed during the Achievable workshop. Several criteria determined selection, including:

- The priority measures should represent a substantial fraction of the overall Economic Potential
- The priority measures should represent sufficient energy end uses applicable across Industrial sub sectors
- The priority measures should have a variety of different likely patterns of market adoption, so the discussions will be widely varied.

A summary of the selected energy-efficiency actions, along with the approximate percentage that each represents in the Economic Potential, is provided in Exhibit 33.

Exhibit 33 Industrial Sector Actions – Energy Efficiency

Measure	End Use	2030 Economic Savings Share (%)
Efficient boiler systems	Boilers	57%
Radiant tube heating	Air heating	14%
High-efficiency kiln	Lumber kiln	10%
Advanced veneer dryer	Veneer dryers	1%
High-efficiency kiln	Pulp lime kiln	2%
High-efficiency coal and ore dryers	Coal and ore drying	5%
Direct-fired heating	Direct fired	6%
Grand Total		95%

7.3.2 Step 2 Create Opportunity Profiles

The next step involved the development of brief profiles for each of the opportunities noted above in Exhibit 33. The profiles are presented in Appendix E.

The purpose of the opportunity profiles was to provide a high-level logic framework that would serve as a guide for participant discussions in the Achievable workshop (see Section 7.3.4 below). The intent was to define a broad rationale and direction without getting into the much greater detail required of program design exercise, which, as noted previously, is beyond the scope of this project. As illustrated in Appendix E, each opportunity profile addresses the following areas:

Technology Description – provides a summary statement of the broad goal and rationale for the action.

Target Energy End Uses for Industrial Sub Sectors – highlights the technology improvements offering the most significant opportunities for each Industrial sector end use, and which provide a good starting point for discussion of the technology.

Financial and Economic Indicators – provides estimates of average simple payback, benefit-cost ratio (TRC analysis), and basis of assessment (full cost versus incremental).

Eligible Projects – provides an estimate of the number of equipment/system upgrades that could be affected during the study period if the entire Economic Potential were to be captured.

Economic Potential versus Time – shows the pattern of the changing size of the opportunity over the study period for each of the end-use technologies. Some opportunities grow steadily through the study period, as equipment reach replacement age. Other opportunities are economic to capture immediately, and after that the growth over time is limited to what would be new industrial loads coming onto the system. Still other opportunities decline with time as they are eroded by natural conservation activities.

Economic Potential versus Industrial Sub Sector and Region – shows how the opportunity is distributed through FortisBC's service territory.

7.3.3 Step 3 Prepare Opportunity Worksheets

A draft assessment worksheet was prepared for each opportunity profile in advance of the Achievable workshop. The assessment worksheets complemented the information contained in the Economic Potential model output by providing quantitative data on the potential energy savings for each opportunity as well as providing information on the size and distribution of potential equipment replacement/upgrade projects. Energy impacts and population data were taken from the detailed modelling results contained in the Economic Potential Forecast.

The worksheets, including the results recorded during the workshop discussions, are provided in Appendix E. As illustrated in Appendix E, each opportunity assessment worksheet addresses the following areas:

Approximate Benefit-Cost Ratio – shows the approximate ratio of economic benefits to costs. The benefit-cost ratio provides an indication of the relative economic attractiveness of the energy-efficiency measures from FortisBC's perspective. For the purposes of the workshop, this information provided participants with an indication of the scope for using financial incentives to influence customer participation rates.

Customer Payback – shows the simple payback from the customer's perspective for the package of energy-efficiency measures included in the opportunity. This information provided an indication of the level of attractiveness that the opportunity would present to customers. This provided an important reference point for the workshop participants when considering potential participation rates. When combined with the preceding benefit-cost information, participants were able to roughly estimate the level of financial incentives that could be employed to increase the opportunity's attractiveness to customers without making it economically unattractive to FortisBC.

Economic Potential in Terms of Applicable Upgrades/Replacement Projects (e.g., number of boilers replaced) — shows the total number of potential upgrades/projects in terms of either energy end use or technology (as appropriate) that could theoretically take part in the opportunity. Numbers shown are from the efficiency improvements in the Economic Potential Forecasts.

Participation Rates (%) – these fields were filled in during the workshops (described below in the following step), based on input from the participants. They show the percentage of economic savings that workshop participants concluded could be achievable in the last milestone period (usually 2030, but may be earlier for measures that peak earlier). As noted in the introduction to this section, two Achievable levels are shown: *most likely* and *aggressive*. For example, Exhibit 40 shows a savings capture rate of 29% (most likely) for high-efficiency lumber kilns in sawmills by the year 2030. This means that an estimated 29% of the upgrades/replacements for lumber kilns in that year would be to high-efficiency kilns under a most likely level of program activity. Under the comments column, participants indicated a likely shape for a curve to describe how quickly activity would rise to that level so that participation rates for the intervening milestone years could be estimated. The different curves are described below.

Achievable Potential in Terms of Economic Upgrades/Replacement to Equipment (e.g., number of boilers) **—** these fields were calculated by the spreadsheet based on the participation rates provided by the participants.

Participation Rates Relative to the Discussion Scenario – these fields were filled in during the workshop to provide guidance to the consulting team on how participation might differ in other regions.

Other Parameters – these fields were filled in during the workshop to capture other aspects of the discussion.

7.3.4 Step 4 Achievable Workshop

The most critical step in developing the estimates of Achievable Potential was a half-day Achievable Potential workshop that was held on January 27, 2011. Workshop participants consisted of core members of the consultant team, DSM program and technical personnel from FortisBC, and a Ministry of Energy Mines and Petroleum Resources representative. Together, the participating personnel brought years of experience to the workshop related to industrial energy use and practices, preferred technologies, and the needs of industry in B.C. to remain competitive.

The purpose of this workshop was to:

- Promote discussion regarding the technical and market constraints confronting the identified energy-efficiency opportunities
- Identify potential strategies for addressing the identified constraints, including potential partners and delivery channels
- Compile participant views related to how much of the identified economic savings could realistically be achieved over the study period.

The discussion of each opportunity profile began with a brief consultant presentation. The floor was then opened to participant discussion of the key factors affecting each of the market segments and technical opportunities contained in the opportunity profile and accompanying worksheet.

Following discussion of the broad market and intervention conditions affecting the opportunity, workshop participant views were recorded on the most likely and aggressive customer participation rates. General agreement was sought on participation levels to be carried forward into the analysis.

As noted earlier, the half-day workshop did not address all efficient technologies captured in the Economic Potential. Consequently, the workshop focused on opportunities selected based on the criteria described in Step 1. For the most part, it was possible to apply the Achievable savings rates to those remaining end uses not presented. The values shown in the attached appendices and in the following summary tables incorporate the results of all these inputs.

7.3.5 Step 5 Aggregate Opportunity Results

The final step involved aggregating the results of the individual opportunities to provide a view of the Achievable Potential savings for the total Industrial sector.

7.4 Results – Efficiency Technologies

A summary of the most likely and aggressive Achievable Potential results for the energy-efficiency opportunities is presented in this section. These results include the following:

- Natural gas consumption savings
- Peak day load impacts
- Greenhouse gas emission reductions.

7.4.1 *Natural Gas Consumption Savings – Aggressive Achievable Scenario*

The following exhibits present the potential natural gas savings under the aggressive Achievable Potential scenario. The results shown are relative to the Reference Case. The results are broken down as follows:

- Exhibit 34 presents the results for the total FortisBC service territory by service region and milestone year.
- Exhibit 35 presents the results for the total FortisBC service territory by sub sector and milestone year.
- Exhibit 36 presents the results for the total FortisBC service territory by end use and milestone year.
- Exhibit 37 presents the results for the total FortisBC service territory by technology and milestone year.

Exhibit 34 Aggressive Achievable Natural Gas Savings by Service Region and Milestone Year (GJ/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total	Savings Share of 2030 Reference Consumption
2015	350,187	180,859	158,902	24,141	714,089	2%
2020	868,886	435,480	386,735	55,512	1,746,613	6%
2025	1,077,803	572,251	445,296	70,812	2,166,162	8%
2030	1,351,586	736,599	554,314	82,694	2,725,193	10%

7.4.2 *Natural Gas Consumption Savings – Most Likely Achievable Scenario*

The following exhibits present the potential natural gas savings under the most likely Achievable Potential scenario. The results shown are relative to the Reference Case. The results are broken down as follows:

- Exhibit 38 presents the results for the total FortisBC service territory by service region and milestone year.
- Exhibit 39 presents the results for the total FortisBC service territory by sub sector and milestone year.
- Exhibit 40 presents the results for the total FortisBC service territory by end use and milestone year.
- Exhibit 41 presents the results for the total FortisBC service territory by technology and milestone year.

Exhibit 38 Most Likely Achievable Natural Gas Savings by Service Region and Milestone Year (GJ/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total	Savings Share of 2030 Reference Consumption
2015	236,686	121,019	125,568	16,317	499,589	2%
2020	499,166	253,895	278,172	33,695	1,064,929	4%
2025	727,212	385,275	343,947	48,817	1,505,251	5%
2030	975,680	525,685	447,794	60,828	2,009,988	7%
2030 Savings Share of 2030 Reference Consumption	7%	6%	9%	8%	7%	
2030 Savings share by Region	49%	26%	22%	3%	100%	

The energy saving percent calculations in Exhibit 38 are calculated on the Reference Case forecast. For example, the grand total savings of 7% in 2030 is 2,009,988 divided by the Reference Case forecast consumption of 27,946,000.

Exhibit 39 Most Likely Achievable Natural Gas Savings for the Total FortisBC Service Area by Industrial Sub sector and Milestone Year (GJ/yr.)

Sub sector	2015	2020	2025	2030	2030 Savings Share of Total 2030 Savings

7.4.3 *Peak Day Load Impacts – Energy-efficiency Scenarios*

This sub section estimates the peak day load impact that would occur as a result of the Achievable Potential scenarios presented in the preceding exhibits. Peak day load impact measures the relationship between a typical or average daily consumption rate and the consumption that occurs on a peak day when the demand for natural gas is at a maximum. The relationship is illustrated in the formula below.

$$\textit{Peak Day Consumption} = \frac{\textit{Average Daily Consumption}}{\textit{Load Factor}}$$

The following steps were employed to derive the estimated peak day load impacts:

- Annual natural gas decreases associated with each of the preceding Achievable Potential scenarios were identified (GJ/yr.).

FortisBC provided load factors that correlate the relationship between average and peak day consumption levels for each rate class and service region.

Finally, peak day load impacts were calculated by dividing the average daily consumption by the appropriate sector and service region load factors. The results for the aggressive Achievable Potential are presented in

- Exhibit 43 and the results for the most likely Achievable Potential are presented in Exhibit 44.

Exhibit 42 Peak Day Load Factors, by Sector and Service Region

CPR Sector	Sales Weighted Average/Peak Load Factor, by Sector & Service Region*		
	Lower Mainland	Vancouver Island	Interior
Residential	0.316	0.382	0.304
Commercial & Institutional	0.34	0.491	0.36
Industrial	0.369	0.509	0.443

*Above sector load factors are sales weighted values based on the rate class load factors shown below.

Rate Class	Average/Peak Load Factor, by Rate Class & Service Region#		
	Lower Mainland	Vancouver Island	Interior
1	*0.308*	*0.354*	*0.304*
2	*0.293*	*0.473*	*0.296*
3	*0.366*	*0.509*	*0.347*
5	*0.433*	*0.51*	*0.511*

#Source: FortisBC

Exhibit 43 and Exhibit 44 summarize the estimated peak day load impacts for each of the Achievable Potential scenarios. As illustrated, the natural gas savings contained in the two Achievable Potential scenarios would result in a total peak day load reduction of approximately 17,000 to 23,000 GJ by 2030, depending on scenario.

Exhibit 43 Peak Day Capacity Impacts – Aggressive Achievable Potential, by Scenario, Service Region and Milestone Year (GJ)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	3,250	1,398	1,228	162	6,039
2020	8,064	3,367	2,990	373	14,794
2025	10,003	4,424	3,442	476	18,346
2030	12,544	5,694	4,285	556	23,080

Exhibit 44 Peak Day Capacity Impacts – Most Likely Achievable Potential, by Scenario, Service Region and Milestone Year (GJ)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	2,197	936	971	110	4,213
2020	4,633	1,963	2,150	227	8,973
2025	6,749	2,978	2,659	328	12,715
2030	9,055	4,064	3,462	409	16,990

7.4.4 *Greenhouse Gas Emission Impact – Energy-efficiency Scenarios*

The natural gas savings associated with each of the Achievable Potential scenarios would also result in a reduction of greenhouse gas (GHG) emissions.[20] As illustrated in Exhibit 45 and Exhibit 46, by 2030 the GHG reductions are estimated to be in the range of 96,000 to 130,000 tonnes/yr., depending on the scenario.

Exhibit 45 Estimated GHG Emission Reductions – Aggressive Achievable Potential, By Scenario and Milestone Year (tonnes CO_2e/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	16,809	8,681	7,627	1,159	34,276
2020	41,707	20,903	18,563	2,665	83,837
2025	51,735	27,468	21,374	3,399	103,976
2030	64,876	35,357	26,607	3,969	130,809

Exhibit 46 Estimated GHG Emission Reductions – Most Likely Achievable Potential, By Scenario and Milestone Year (tonnes CO_2e/yr.)

Year	Lower Mainland	Northern Interior	Southern Interior	Vancouver Island	Grand Total
2015	11,361	5,809	6,027	783	23,980
2020	23,960	12,187	13,352	1,617	51,117
2025	34,906	18,493	16,509	2,343	72,252
2030	46,833	25,233	21,494	2,920	96,479

7.4.5 *Interpretation of Results*

Highlights of the potential natural gas savings presented in the preceding exhibits are summarized below:

[20] GHG impacts are estimated based on an emissions factor of 48 kg of CO_2e per GJ of natural gas. This is the B.C. natural gas emissions factor.

Savings by Service Region

The Lower Mainland service region represents approximately 50% of the identified savings in either of the two Achievable Potential scenarios. This is consistent with the large number of Industrial sector customers in this service region. The Northern Interior region represents approximately 25% of the identified savings, followed by Southern Interior at 22% and Vancouver Island at 3%.

Large industry is concentrated in the Lower Mainland and Northern Interior. The Vancouver Island Gas Joint Venture natural gas consumers' plants located on Vancouver Island were not included in the full CPR study. However, given their annual load (2010) of approximately 3,000,000 GJ, it could be assumed that if these customers were to participate in FortisBC's pulp and paper program, Achievable savings would increase about 10% respectively.

The Achievable Potential savings share of the Reference Case consumption in 2030 is fairly even across the regions, with the Southern Interior slighter higher than the other regions. The reason for this is due to the penetration rate of the lumber industry projects in the region, along with the identified coal facility for high-efficiency coal dryer project(s).

In the Southern Interior region, potential savings are 9%-11% of the Reference Case consumption in 2030, respective of the most likely or aggressive levels of Achievable Potential. This is the highest percentage of any of the regions. In the Lower Mainland region, potential savings are 7%-10% of the Reference Case consumption in 2030. In the Northern Interior, potential savings are 6%-8% of Reference Case consumption in 2030. In the Vancouver Island region, they are 8%-11% of Reference Case consumption in 2030.

Savings by Industrial Sub Sector

The Pulp and Paper sub sector accounts for almost 30% of potential energy savings by 2030. Improvement to lime kiln efficiency, boiler upgrades/replacements, process heat conservation, heat recovery projects, and moving to direct-fired paper drying are the savings measures available to this sub sector. The Agriculture and Food & Beverage sub sectors together account for about 25% of the 2030 total Achievable Potential savings. Boiler upgrades and heat recovery projects are responsible for the majority of the savings in these sub sectors. The Chemical sub sector could provide up 12% of potential savings, while the forecast portion of 2030 savings for the Wood Products and Mining sub sectors are 11% and 9% respectively. The remaining 12% of the potential savings in 2030 comprise the Fabricated Metal, Non-Metal Manufacturing, Miscellaneous Manufacturing and Other sub sectors.

Savings by End Use

Boiler replacement, upgrades, heat recovery, process heat conservation and controls, represent almost 55% of the total energy savings in the two Achievable Potential scenarios. Since these technologies are here today, the model for the economic savings assumed that all upgrades would occur during the first milestone period. The reason for this assumption is that the economic analysis indicates that the return on investment of replacing standard equipment is such that replacing all standard equipment could be justified over that period. The largest volume of savings was provided by replacing standard efficiency boilers with higher efficiency units. The Achievable case was more conservative, and assumed that the boilers would be replaced over time, typically prompted by the need replacement or major rework.

Radiant tube air heating technology offers significant savings over the standard natural gas space heating equipment in large high-bay type buildings typical in the Industrial sector because the air itself does not need to be heated, only energy radiated down to the working space. These types of heaters are particularly useful near large doors / shipping bays, which are frequently open. The saving potential for radiant heaters is large at 14%-17% of the total Achievable Potential savings. From a conservation potential, this is the second largest individual technology, due to the large number of high-bay buildings across the Industrial sector.

Lumber drying kilns show considerable potential for energy savings. The recent economy and wood market have historically been barriers to improving the efficiency or replacing kilns. Accordingly, there is a large inventory of older inefficient kilns that are in operation and there is a significant potential to either retrofit or replace them.

Savings potential for direct-fired drying and heating of gypsum and asphalt plants is about 5% by 2030. Coal dryers are limited in numbers, however one or two projects could provide upwards of 5% of the 2030 Achievable savings. These projects would be in the Southern Interior.

Peak Day Capacity Impacts

The natural gas savings contained in the two Achievable Potential scenarios would result in a total peak day load reduction of approximately 17,000 to 23,000 GJ by 2030, depending on the scenario.

Greenhouse Gas Emission Impacts

By 2030 the GHG reductions are estimated to be in the range of 96,000 to 130,000 tonnes per year, depending on scenario.

9 Glossary

achievable potential
The Achievable Potential is the proportion of the natural gas savings identified in the Economic Potential Forecast that could realistically be achieved within the study period. Achievable Potential recognizes that it is difficult to induce customers to purchase and install all of the efficiency technologies that meet the criteria defined by the Economic Potential Forecast.

avoided cost
The unit cost of acquiring the next resource to meet demand, which is used as a measure for evaluating individual demand side and supply side options. In the context of this study "avoided cost" is the capital expenditure offset by FortisBC's DSM activities (i.e., the cost of having to buy natural gas on the open market, contract for long-term supply, and the cost of associated transmission and storage.

Avoided supply cost of electricity
The avoided supply cost of electricity is a value that is used to determine economic value of reducing or increasing the amount of electricity used by a technology. The value of avoided cost of electricity used in this report was proved by BC Hydro and was $0.12 per kWh.

Avoided cost of natural gas
The avoided supply cost of natural gas is a value that is used to determine the economic value of reducing or increasing the amount of electricity used by a technology. The value of avoided cost of natural used in this report was provided by FortisBC and varies according to the life of the measure of technology. Specific values are provided in Exhibit 22.

base year
The Base Year is the year to which all potentials will be compared. It provides a detailed description of "where" and "how" natural gas is currently used in each sector. For this study, it is the calendar year 2010. The modeled base year energy use is calibrated against FortisBC's actual sales for 2009.

benefit-cost ratio
The measure benefit-cost ratio indicates the relative attractiveness of the measures. A measure that has a benefit-cost ratio in excess of 1.0 has benefits that outweigh its costs. Similarly, a measure with a benefit-cost ratio that is well in excess of one (e.g., 3.0) means that it is very attractive. A measure with a benefit-cost ratio of less than 1.0 has costs that outweigh its benefits.

building envelope
The material separation between the interior and exterior environments of a building. The building envelope serves as the outer shell to protect the indoor environment as well as to facilitate its climate control.

British thermal unit or Btu
The standard measure of heat energy. It takes one Btu to raise the temperature of one pound of water by one degree Fahrenheit at sea level.

cogeneration
The simultaneous production of electric or mechanical energy and useful heat energy from a single fuel source.

combustion efficiency
The ratio of energy released during combustion to the potential chemical energy available in the fuel.

demand side management (DSM)
Actions taken by a utility or other agency that are expected to influence the amount or timing of a customer's energy consumption.

discount rate
The interest rate used in calculating the present value of expected yearly benefits and costs.

economic efficiency
Allocation of human and natural resources in a way that results in the greatest net economic benefit, regardless of how benefits and costs are distributed within society.

economic potential forecast
The Economic Potential Forecast is an estimate of the level of natural gas consumption that would occur if all equipment and building envelopes were upgraded to the level that is cost effective from society's perspective. All of the energy-efficiency technologies and measures that have a positive measure TRC are incorporated into the Economic Potential Forecast. These technologies and measures are applied at either natural stock turnover rates or at designated years for immediate application.

energy audit
An on-site inspection and cataloguing of energy using equipment/buildings, energy consumption and related end uses. The purpose is to provide information to the customer and the utility. Audits are useful for load research, for DSM program design and for identification of specific energy savings measures.

energy conservation
Activities by energy users that result in a reduction of the energy used to provide services. Energy conservation can include a wide variety of behavioural or operational changes that result in energy savings.

energy efficiency
Using less energy to perform the same function.

energy intensity
The ratio of energy consumed per application or end use. For example, cubic metres per square metre of heated office space per day, or cubic metres per tonne of aluminum produced. All else being equal, energy intensity increases as energy efficiency decreases.

emerging technologies
New energy-conserving technologies that are not yet market ready, but may be market ready over next five to 10 years. This category includes technologies that could be accelerated into the market during that period through targeted financial or technical support.

end use
The final application or final use to which energy is applied. End use is often used interchangeably with energy service.

energy savings
The reduction in use of energy from the pre-retrofit baseline to the post-retrofit energy use that result from efficient technologies or activities. In this document, the term “energy” refers specifically to energy derived from natural gas unless otherwise noted.

energy service
An amenity or service supplied jointly by energy and other components/equipment such as buildings and heating equipment. Examples of energy services include residential space heating, commercial cooking, aluminum smelting and public transit. The same energy service can frequently be supplied with different mixes of equipment and energy.

energy use index (EUI)
End-use energy consumption divided by a specific parameter of production (e.g., m^3/unit).

environmental credit/environmental penalty
An increment or decrement to the cost of a resource or set of resources, to reflect the overall level of its/their environmental impact, relative to another resource or set of resources.

financial incentive
Certain financial features in the utility’s DSM programs designed to motivate customer participation. They may include features designed to reduce a customer’s net cash outlay, payback period or cost of finance to participate.

fuel share
The proportion of requirements for a specific service that is met using a certain fuel. In the Commercial sector, fuel shares are normalized on a floor area basis. For example, a natural gas fuel share of 90% for space heating in the Large Office sub sector implies that 90% of the sub sector floor space is heated using natural gas.

full capital cost
This is the capital cost of replacing a baseline technology with an energy-efficient technology and is applicable before equipment end of life. For example if a standard boiler is in good operating condition and has many years of life left, the full cost of replacement would apply.

free rider
A program participant who would have implemented the program measure or practice in the absence of the program.

Incremental capital cost
This is the capital cost difference between a baseline technology and an energy-efficient technology and is applicable at equipment end of life. For example, if a standard boiler had reached its end of life the incremental capital cost would be the cost difference between replacing the boiler with a standard boiler and a more efficient boiler.

interactive effects
In the context of natural gas use, interactive effects refer to the increase in gas consumed by heating equipment required to offset a decrease in “waste” heat generated by more efficient electrical fixtures or appliances after retrofit or replacement.

kilowatt (kW)
One thousand watts; the most common unit of measurement of electric power. (The amount of energy transferred at a rate of one kilowatt for one hour is equal to one kilowatt hour.)

kilowatt hour (kWh)
The most common unit of measurement of electric energy. One kilowatt hour represents the power of one thousand watts for a period of one hour.

load forecast
An estimate of expected natural gas requirements that have to be met by the utility in future years.

load research
Research to disaggregate and analyze patterns of natural gas consumption by various sub sectors and end uses. Load research supports the development of the load forecast and the design of DSM programs.

market transformation
A reduction in market barriers resulting from a market intervention, as evident by a set of market effects that lasts after the intervention has been withdrawn, reduced or changed.

measure total resource cost (TRC)
The measure TRC is the net present value of energy savings that result from an investment in an energy-efficiency measure. The measure TRC is equal to its full or incremental capital cost (depending on application) plus any change (positive or negative) in the combined annual energy and operating and maintenance (O&M) costs. This calculation includes among others, the following inputs: the avoided natural gas, electricity and water, the life of the measure, and the selected discount rate.

natural conservation
The future change in energy intensity or base usage that is expected to occur in the absence of utility DSM programs. Natural change represents the effects of energy related decisions that would have been made in the absence of the utility programs by both program participants and non-participants.

rate
Generically refers to a utility's rate structure.

rate structure
The formulae used by a regulated gas utility to calculate charges for the use of natural gas.

rebates
A type of incentive provided to encourage the adoption of energy-efficient practices, typically paid after the measure has been installed. There are typically two types of rebates: 1) a prescriptive rebate, which is a prescribed financial incentive/unit for a prescribed list of products, and 2) a customized rebate in which the financial incentive is determined using an analysis of the customer equipment and an agreement on the specific products to be installed.

reference case forecast
An estimate of the expected level of natural gas consumption that would occur over the study period in the absence of any new utility DSM market interventions after 2010. It is the baseline against which the scenarios of energy savings are calculated. The Reference Case forecast incorporates an estimation of "natural" conservation, namely, changes in end-use efficiency over

the study period that are projected to occur in the absence of new market interventions by the utility.

retrofit
Energy-efficiency activities undertaken in existing residential or non-residential buildings where existing inefficient equipment is replaced by efficient equipment.

saturation
The portion of floor area that receives a specific energy service. For example, a saturation of 86% for space cooling in the Large Office sub sector means that 86% of the sub sector floor space is cooled (regardless of fuel used to provide that cooling).

seasonal efficiency
The ratio of delivered useful energy relative to the input potential fuel energy determined over a full heating season (or year).

sector
A group of customers having a common type of economic activity.

service area
The portion of the Province of British Columbia that receives service from FortisBC Gas.

service region
For the purposes of this study, the total FortisBC Gas service area is divided into two service regions. They are the Southern region and the Eastern region.

simple payback
The simple payback is generated to show the customer's financial perspective. Simple payback is a measure of the length of time required for the cumulative savings from a project to recover its initial investment cost, without taking into account the time value of money.

sub sectors
A classification of customers within a sector by common features. Residential sub sectors are by type of home (single-family detached, duplex, apartment, etc.). Commercial sub sectors are generally by type of commercial service (Office, Retail, Warehouse, etc.). Industrial sub sectors are by product type (Pulp and Paper, Wood Products, Chemical, etc.).

supply curves
A curve illustrating the amount of energy (e.g., m^3) or societal benefit available at an appropriate screened price in ascending order of cost.

total resource cost (TRC) Test
A test that compares the total costs of energy-efficiency investments, including natural gas conservation programs, to the social cost of natural gas. Unpriced environmental and social costs may be accounted for by changing the cost of either the investment under consideration or the total cost of natural gas in such a way that relative unpriced impacts are reflected. It is used in designing and evaluating programs that are developed from the energy-efficiency potential study's results.

utility cost
The total financial cost incurred by the utility to acquire energy resources. For DSM, the costs include all utility program costs, including incentive costs.

watt
The basic unit of measurement of power, at a point in time as capacity or demand.

** *1KWh = 3.6 MJ*

Assumptions:

Standard boiler input of 3.3 MBTU (1MW)and 70% loaded annual operating hours of 4,000 per year based on average annual process heat purchase of accounts in manufacturing sector.

Installed cost of near condensing and condensing boilers is from Viessmann

Purchase cost of standard boilers is $7/kBTU Input as per FortisBC Efficient Boiler Program definition

Electricity use and savings are negligible for boilers

Incremental maintenance for condensing boilers is assumed to be 2 days annually.

Boiler efficiency as per FortisBC Efficient Boiler Program

1 MBTU	1.055	MJ

** *1KWh = 3.6 MJ*

Assumptions:

Standard boiler input of 3.3 MBTU (1MW)and 30% loaded annual operating hours of 4,000 per year
Installed cost of near condensing and condensing boilers is from Viessmann
Purchase cost of standard boilers is $7/kBTU Input as per FortisBC Efficient Boiler Program definition
Electricity use and savings are negligible for boilers
Incremental maintenance for condensing boilers is assumed to be 2 days annually.
Boiler efficiency as per FortisBC Efficient Boiler Program
For Space Heating, and intermittant load

Assumptions:

For process loads boilers will operate at full capacity 6,000 hours a year.
Installed cost is 2.5 times capital costs
A standard boiler input of 3.3 MMBtu/hr.
Choice of standard boiler size and operating hours based on average annual natural gas use of accounts in the manufacturing sub-sectors that use boilers.
Price and payback are from suppliers and literature as cited in the the Industrial Sector Report
Electricity use and savings are negligible for boilers
Incremental operating and maintenance costs are negligible for boilers

Financial & Economic Analysis - Energy-efficiency Measures

Measure Name: Steam Trap Maintenance and Pipe Insulation

	Measure Description	Baseline Energy Use (MJ/yr.)		Upgrade Energy Use (MJ/yr.)		Measure Capital & Installation Cost F = full I=Incremental		Incremental O & M ($/yr)	Measure Life (yrs.)	Annual Energy Svg (MJ/yr.)		Participant Impact			Measure Total Resource Cost	B/C Ratio
		Natural Gas	Electricity	Natural Gas	Electricity					Natural Gas	Electricity	Annual Energy Svgs (MJ)	Annual Cost Svgs ($)	Simple Payback (yrs.)		
1	Process Steam Upgrade Bundle, Steam Traps, Insulation	200,000,000	-	190,000,000	0	F	$60,000	$40,000	10	10,000,000	0	10,000,000	$23,539.90	2.5	$559,096	2.7

** *Measure TRC = Measure cost + chg in annual O&M +PV Electricity Avoided Cost/Supply + PV Natural Gas Avoided Cost/Supply*

** *Considerations such as incentives, program delivery costs occur in later stages of the analysis*

** *1KWh = 3.6 MJ*

Assumptions:

1 year payback based on $6/GJ gas - from sector report

Standard size based on average annual gas use 200,000 GJ.

Budget of 50,000 annually to maintain the steam traps

Appendix D Background-Chapter 6: Economic Potential Forecast

Economic Case - Output for 2015

1 Introduction

In addition to energy savings, DSM programs can have broad impacts on the provincial economy as measured through metrics such as employment, GDP, and industrial output. Impacts arise from short term investment activities, such as building retrofits, and longer term changes in household/business spending, which can be attributed to the persistence of energy savings.

This analysis uses the results from the FortisBC Conservation Potential Review (CPR) Update 2010 to provide an estimate of the net macroeconomic impacts expected from implementing the achievable potential scenarios outlined in the main sector reports. The impacts reported in this analysis are specific to British Columbia and include the following measures of economic activity:

- Changes in Output (total industry revenues). This measures the value or amount of a good or service produced by an industry. This includes all production costs, including intermediate goods. Put differently, one can interpret output as the *total economic impact within an industry*.

- Changes in GDP at factor cost (total value-added at producers' prices, or total output minus costs of production). This is a measure of the value added to the economy and does not include the cost of resources consumed during production. One can interpret GDP at factor cost as a *net economic impact within an industry*. Based on these definitions, changes in output always exceed changes in GDP at factor cost. Finally, note that the term "net" used here is not the same as our use of "net" when referring to program impacts in the following section; net impacts of the DSM programs reflect changes in all industries rather than a single industry.

- Changes in employment (number of jobs).

The above economic impacts are reported for three sectors (residential, commercial and industrial) under the most likely and aggressive achievable potential scenarios at two milestone years: 2021 and 2030.

2 Approach

The analysis is based on the application of B.C. specific economic multipliers, which are a set of proportionality constants that relate changes in domestic production in a particular sector to its impacts on the entire B.C. economy. BC Stats released a report[1] in March 2008 documenting the British Columbia provincial economic multipliers based on 2004 economic data.

The multipliers contained in the BC Stats report noted above were applied to activities across all sectors that would be affected by the achievable potential results contained in each of the CPR sector reports. The impacts (both positive and negative) were then totalled to determine the net impacts, which are relative to the baseline scenario where no new DSM program initiatives are implemented by FortisBC. Essentially, ratepayer money is being shifted from a general basket of goods and services and applied to DSM program activities, which is modeled as a zero-sum situation.[2]

It should be noted that the effects of energy performance standards and naturally occurring market transformation induced by FortisBC's DSM programs, which increase program savings over time, are not included in the reported impacts; consequently the results presented are a conservative estimate of the overall impacts of natural gas energy efficiency initiatives.

The analysis was conducted in three steps:

1. A DSM mapping framework was created.
2. The investment (capital and labour) required by the DSM activities contained in each of the achievable potential scenarios was calculated and allocated into each category using the DSM framework established in Step 1.
3. Economic multipliers were applied, by category, to the investment amounts developed in Step 2.

Further discussion of each step is provided below.

2.1 Step 1: Create DSM Mapping Framework

The first step was to develop a framework to translate the CPR energy results into economic inputs. Exhibit 1 shows how the energy-efficiency investment activities represented by the CPR's achievable potential scenarios and the results from those activities are mapped to the appropriate economic categories contained in the B.C. economic model.

---

[1] Garry Horne; *2004 British Columbia Provincial Economic Multipliers and How to Use Them;* BC Stats; March 2008.

[2] This is in contrast to "gross" impacts, which do not account for losses that occur as a result of activities modeled in the analysis. For example, the numbers reported in the BC Hydro analysis are gross and do not take into account the employment displaced due to potential supply-side projects avoided by DSM activities.

Exhibit 1 Map of DSM Activity to BC Stats Classification

BC Stats Classification	Description	CPR related DSM Activity
Induced impacts from wages and salaries (per CAN 2007$ saved)	General household spending in the economy is affected by the energy-efficiency strategy	▪ Increased disposable income from energy savings occurring in the year of analysis ▪ Increased ratepayer costs to fund DSM programs and incremental costs for the year of analysis
9 NATURAL GAS DISTRIBUTION, WATER, SEWAGE AND OTHER SYSTEMS	Lost utility revenue due to persistence of energy savings	Reduced final demand for gas distribution as a result of gas savings occurring in the year of analysis
10 CONSTRUCTION	Home weatherization and efficient whole building construction	Labour costs associated with construction and installation of measures in the year of analysis ▪ Building envelope ▪ Whole building measures ▪ Installation of equipment
22 NON-METALLIC MINERAL PRODUCT MANUFACTURING	Insulation materials	Production costs of ▪ Insulation measures (wall, roof, pipe, duct, DHW tank)
24 FABRICATED METAL PRODUCTS MANUFACTURING	Increased production of fabricated metal products	Production costs of ▪ Boilers, Condensing DHW boilers ▪ Heat recovery ▪ Faucet aerators ▪ Showerheads/Spray valves
25 MACHINERY MANUFACTURING	Increased production of machinery	Production costs of ▪ Rooftop units, Furnaces/Unit heaters ▪ Heat pumps ▪ CHP ▪ Pool heaters
27 ELECTRICAL EQUIPMENT, APPLIANCE AND COMPONENT MANUFACTURIN	Increased production of electrical equipment and appliances	Production costs of ▪ Ventilation /Fans ▪ Thermostat ▪ IR heaters ▪ Water heaters (all kinds)
31 WHOLESALE TRADE	Commercial/industrial equipment purchases go through wholesalers	Assume 15% wholesale margin
32 RETAIL TRADE	Residential equipment purchases go through retail store	Assume 15% retail margin
44 PROFESSIONAL, SCIENTIFIC AND TECHNICAL SERVICES	Program advertisement budget, consulting, implementation contractor	Assume 5% on top of equipment and labour annual investments
45 ADMINISTRATIVE AND SUPPORT SERVICES	Program admin budget	Assume 5% on top of equipment and labour annual investments

2.2 Step 2: Monetize Achievable Potential DSM Activities

Using the framework established in Step 1, inputs to the macroeconomic impact analysis were developed from the CPR results. The analysis first determined the monetary impact for each category in the preceding table for each scenario analyzed. The first category, wages and salaries, assumes that energy bill savings[3] from all sectors eventually result in changes to disposable spending. This can be approximated as an increase in wages/salaries. However, the increased disposable spending comes at a cost: lost utility revenue due to DSM activities.[4] This loss is captured in the second row of the table by the natural gas industry.

Note that we do not consider changes in utility rates over the study timeframe and assume that gas not consumed as a result of DSM programs is exported outside of the BC region. As FortisBC passes through commodity and midstream charges without mark-up, we gross down the expected lost revenue by the following percentages to get the gas distribution lost revenue portion of the total bill: 30% (residential), 27.5% (commercial), and 15% (industrial).[5]

All other categories represent investment activities that increase final demand for various goods and services. The level of investment was calculated based on the actual measures included in the achievable potential scenarios as reported in each of the sector reports. Incremental equipment and labour costs were reported separately for each measure. The model assumes that most residential equipment measures are purchased at retail stores while commercial and (most) industrial systems are purchased through wholesalers; the retail/wholesale margin of 15% is applied to the retail trade industry while the remaining 85% of consumer prices are allocated to the appropriate industries. For example, every $100 worth of showerheads purchased at the store, $15 was allocated to "retail trade" and $85 to "fabricated metal product manufacturing".

Investment activities related to the administration and implementation of the DSM programs are allocated to the following categories shown in Exhibit 1:

- 44 PROFESSIONAL, SCIENTIFIC AND TECHNICAL SERVICES and
- 45 ADMINISTRATIVE AND SUPPORT SERVICES.

The analysis assumes a combined overhead of 10% (5% Professional plus 5% Administrative) on the total installed costs described in the preceding Exhibit 1. This corresponds to 20% of program costs if Fortis' average conservation incentive is 50% of installed incremental cost. This level of administrative expense is consistent with other gas programs in North America.

Finally, the ratepayer experiences increased costs to cover the DSM programs and the incremental costs[6] of the efficiency activities.

---

[3] Estimated by using the following rates: $9.2/GJ (commercial) and $9.8/GJ (residential) and $6.5/GJ (industrial). It is difficult to predict how the commercial and industrial bill savings would be re-spent in the regional economy so it is assumed that cost savings either get passed down to customers or to employees in the region.

[5] Based on current natural gas commodity rates, if rates were to increase then the percentage of the total bill represented by the volumetric delivery change would decrease.

[6] Depending on the application and replacement conditions, incremental and full costs may be equal.

2.3 Step 3: Apply Economic Multipliers

The final step involves application of the appropriate model multipliers to the monetized direct activities from the previous step; the multipliers used for each category are shown in Exhibit 2.[7]

Exhibit 2 Economic Multipliers

BC Stats Classification	Output/Revenue [8]	GDP at Factor Cost [9]	Employment [10] Per $1 million CAN $2007 saved
Induced impacts from wages and salaries	0.809	0.458	6.860
9 NATURAL GAS DISTRIBUTION, WATER, SEWAGE AND OTHER SYSTEMS	1.250	0.860	4.190
10 CONSTRUCTION	1.540	0.590	10.000
22 NON-METALLIC MINERAL PRODUCT MANUFACTURING	1.580	0.670	7.480
24 FABRICATED METAL PRODUCTS MANUFACTURING	1.300	0.560	7.090
25 MACHINERY MANUFACTURING	1.320	0.570	6.130
27 ELECTRICAL EQUIPMENT, APPLIANCE AND COMPONENT MANUFACTURIN	1.650	0.620	6.990
31 WHOLESALE TRADE	1.460	0.810	12.050
32 RETAIL TRADE	1.470	0.820	20.000
44 PROFESSIONAL, SCIENTIFIC AND TECHNICAL SERVICES	1.510	0.800	14.530
45 ADMINISTRATIVE AND SUPPORT SERVICES	1.480	0.830	23.100

The multipliers for output and GDP represent impacts on the entire economy due to an increase or decrease in domestic production. Multipliers for employment impacts are per one million dollars in direct changes to a category. For example, assume that an activity increases

[7] A comprehensive discussion of the BC multipliers is included in the previously cited report by Garry Horne.

[8] Multipliers are broken down into specific components (direct, indirect, induced, etc.) in the 2008 report. Industry multipliers for output are calculated from the report by combining direct and indirect multipliers (1+total indirect). Direct changes in output brought on by DSM activities are by default "one" and indirect changes in the rest of the economy are represented by "total indirect," which is provided in a table in the referenced report

[9] Multipliers for GDP and Employment are produced by adding the direct and total indirect components.

[10] Multipliers are for the scenario *With Safety Net*. As explained in the BC Stats report, this scenario assumes that those who lose their jobs stay in the province and collect unemployment insurance or other social assistance; new jobs are filled by people formerly receiving assistance. Since costs in the CPR are in $2011, we use the CPI inflation calculator to translate $2011 into $2007 before applying employment multipliers. www.bankofcanada.ca/en/rates/inflation_calc.html

output in the construction industry by $1 million. The total impacts on the BC economy would be:

- Output = $1 million x 1.540 = $1.540 million
- GDP = $1 million x 0.590 = $0.590 million
- Employment = $1 million x 10.00 jobs/$1 million = 10 jobs

3 Results and Conclusions

The results of the analysis are presented in the following exhibits:

- Exhibit 3 shows the economic impacts that occur in 2021, by sub sector and economic indicator for the most likely achievable scenario.
- Exhibit 4 shows the economic impacts that occur in 2021, by sub sector and economic indicator for the aggressive achievable scenario.
- Exhibit 5 shows the economic impacts that occur in 2030, by sub sector and economic indicator for the most likely achievable scenario.
- Exhibit 6 shows the economic impacts that occur 2030, by sub sector and economic indicator for the aggressive achievable scenario.

Annual DSM Expenditures are included in each table and include all ratepayer investments required for that benchmark year, which includes program administration/implementation, labour, and equipment costs. Energy savings for each year are also annual, but include savings from measures installed from previous years up to the useful lifetime.

Exhibit 3 Economic Impacts, 2021, Most Likely Achievable Scenario

Sector	Assumed Annual DSM Expenditure	Output	GDP	Employment
Residential	$45,675,316	$35,134,637	$11,374,417	207
Commercial	$9,303,164	$15,801,465	$6,226,142	132
Industrial	$4,009,526	$7,289,923	$3,100,698	56
Total	$58,988,006	$58,226,025	$20,701,256	394
Impact per $1 million spent on DSM		$987,082	$350,940	6.7

Exhibit 4 Economic Impacts, 2021, Aggressive Achievable Scenario

Sector	Assumed Annual DSM Expenditure	Output	GDP	Employment
Residential	$105,800,196	$79,764,622	$25,635,718	462
Commercial	$13,552,259	$22,386,788	$8,807,267	185
Industrial	$6,530,929	$11,686,748	$4,949,398	89
Total	$125,883,383	$113,838,158	$39,392,383	736
Impact per $1 million spent on DSM		$904,314	$312,928	5.8

Exhibit 5 Economic Impacts, 2030, Most Likely Achievable Scenario

Sector	Assumed Annual DSM Expenditure	Output	GDP	Employment
Residential	$47,759,079	$42,655,567	$14,663,414	289
Commercial	$12,323,293	$28,916,837	$12,182,648	266
Industrial	$3,901,902	$10,681,592	$4,918,478	88
Total	$63,984,274	$82,253,997	$31,764,540	643
Impact per $1 million spent on DSM		$1,285,535	$496,443	10.0

Exhibit 6 Economic Impacts, 2030, Aggressive Achievable Scenario

Sector	Assumed Annual DSM Expenditure	Output	GDP	Employment
Residential	$78,408,933	$71,870,330	$24,889,914	493
Commercial	$17,604,257	$39,554,252	$16,630,752	361
Industrial	$5,290,263	$14,495,051	$6,671,977	119
Total	$101,303,454	$125,919,633	$48,192,643	973
Impact per $1 million spent on DSM		$1,242,994	$475,726	9.6

3.1 Conclusions

The analysis determined that the *net* impacts of DSM programs are overwhelmingly positive for the regional economy as measured by output, GDP, and employment. As illustrated in the preceding exhibits:

- The net impacts on output, GDP, and employment are all positive across all sectors for every scenario. This occurs because the DSM program shifts spending from low multiplier industries to industries with higher multipliers.
- Annual impacts increase over time and are larger for the aggressive achievable scenarios. This arises due to the accumulation of energy savings from measures installed in prior years.
- The residential sector, in every scenario, accounts for the greatest share of economic impacts. This is most likely due to the early replacement measures in this sector.
- By 2021, the net employment gains from CPR activities will range between 362 - 682 jobs, depending on scenario. This translates to between 5.8 – 6.7 jobs per $1 million invested in DSM that year.
- By 2031 the net employment gains from CPR activities would grow to between 580 - 881 jobs, depending on scenario. This translates to between 9.6 – 10.0 jobs per $1 million

invested in DSM that year. The increase in number of jobs per $1 million invested in 2031 includes the beneficial effects of DSM investments made in prior years.

- Benefits will continue to accrue after 2030, due to investments made in prior years, until the effective life of the installed program measures has been exceeded.

1 Introduction

1.1 Background

FortisBC[1] is conducting its Conservation Potential Review (CPR) – 2010 Update[2]. The completed CPR will provide FortisBC with a comprehensive planning document that the company can use on an ongoing basis to:

- Develop a long range energy efficiency (EE) strategy
- Design and implement energy efficiency programs
- Assess the impact of energy efficiency programs on both peak and annual load
- Assist the company to set its energy efficiency budgets
- Determine contribution EE programs can make towards meeting GHG reduction targets.

CPR studies, such as this one, provide a valuable basis for the identification of priority opportunities and for setting appropriate energy efficiency budgets and targets. Historically, the objective of utility operated energy efficiency programs was to capture short term, least-cost energy resources. However, more recently, a growing number of North American jurisdictions have expanded the objectives for these same energy efficiency programs to include carbon reduction targets intended to mitigate long term climate change impacts. The Province of British Columbia is a case in point. The Province has expanded energy efficiency objectives from "least cost" resource acquisition to carbon reduction and has set greenhouse gas (GHG) reduction targets of: a 33% reduction by 2020; and 80% reduction by 2050.

The Total Resource Cost (TRC) Test, which is one of the California Standard Tests (CSTs), has been widely used since the 1980s by North American utilities and regulatory bodies to determine cost-effective levels of EE investment. In that time EE initiatives have changed significantly in terms of both technologies and programs, and have expanded from a resource acquisition focus to market transformation. However the TRC test has not changed substantially in that time and, particularly as EE programs have become more aggressive, a growing number of EE practitioners have begun to identify challenges associated with reliance on the TRC test. These challenges become even more apparent as EE program objectives are expanded to address GHG reduction targets.

FortisBC is a case in point. The company has determined that the current British Columbia approach of using the TRC test as the screening mechanism for their energy efficiency and conservation (EEC) programs is limiting the scope of eligible programs that the company can provided to its customers in support of provincial energy efficiency and GHG reduction objectives.

The current British Columbia Government target for GHG reduction includes a 33% reduction from 2007 levels by 2020. If this objective is applied to the residential sector in B.C., a reduction in natural gas usage of about 28,000 TJ will be required. However, the recently completed Conservation Potential Review (CPR) has determined an economic potential of about 6,400 TJ,

---

[1] FortisBC (formerly Terasen Gas) includes FortisBC Energy Inc.(FEI), FortisBC Energy (Vancouver Island) Inc. (FEVI) and FortisBC Energy (Whistler) Inc. (FEW).

[2] It should be emphasized that the achievable potential results contained in the CPR are not synonymous with either the setting of specific program targets or with program design. While both are closely linked to the discussion of achievable potential, they involve more detailed analysis that is beyond the scope of a CPR study.

for the residential sector or less than 1/4 the amount necessary to meet the target. Achievable potential will be less than this.

1.2 Objective

Given the above conditions, FortisBC asked ICF Marbek to undertake a high level review and assessment of potential alternate approaches for program screening that could better enable the company to support provincial energy GHG reduction objectives. In setting out to undertake the review, it was recognized that:

- A single "silver bullet" approach to this issue is unlikely; rather, it may be useful to consider a combination of alternatives.
- The potential alternate approaches are likely to vary in their difficulty, and possibly in the timeframe, required to implement them. Therefore the change may be a series of steps over time rather than one major change.
- Any proposed modifications to the program screening framework employed by FortisBC will require agreement between FortisBC and the B.C. Utility Commission (BCUC) as well as the EEC stakeholders, the provincial government and possibly interveners.

1.3 Approach

The review and assessment of alternatives was undertaken in four steps:

- Step 1: Conduct literature review: As noted above, challenges with the use of the TRC as an economic benefit-cost (B/C) screen for DSM (energy efficiency programs) and for meeting GHG reduction targets have been surfacing in other areas in Canada (e.g., Ontario) and in the United States. This first step, therefore, provided a review of the major literature and summarized the range of suggested alternatives suggested.
- Step 2: Identify & group possible alternatives: Based on the results of the literature review and discussions with colleagues in other jurisdictions, the identified alternatives were grouped into three sets of options for further discussion.
- Step 3: Conduct an options workshop: The consultants convened a half-day Benefit-Cost (B/C) workshop with senior FortisBC personnel. The workshop was organized into three components. They were:
  - ✓ An overview of the carbon gap challenge posed by relying on the TRC test to determine the scope of cost-effective EEC programs.
  - ✓ An options assessment. Each option was subjected to a facilitated discussion that sought to establish both its potential effectiveness and whether it represented a short or longer term mechanism.
  - ✓ A high level Action Plan. At the conclusion of the discussions, workshop participants identified the most promising options.
- Step 4: Summarize Workshop & Literature Review Results. The results of the workshop were documented into a short paper, augmented by an overview of the results of the literature review.

1.4 This Paper

This paper represents Step 4, as noted above. It provides a summary of the information presented in the half-day B/C workshop, including a broad outline of the resulting Action Plan.

The remainder of this paper is organized and presented in the following sections:

- Section 2 presents a high level overview of the tests currently used to assess energy efficiency and DSM program cost effectiveness, together with selected examples of the types of challenges encountered.
- Section 3 identifies critical inputs used in the traditional TRC analysis and presents a short discussion of alternative approaches to the selection of those inputs.
- Section 4 identifies two alternative cost-effective tests that could be used to replace the TRC test and provides a summary of the pros and cons of each test, as discussed during the workshop.
- Section 5 outlines a potential carbon-specific assessment option that could be used instead of the TRC test to determine desirable levels of energy efficiency or DSM investment.
- Section 6 provides a summary of the conclusions reached by workshop participants, including the most promising options and a proposed timeline for next steps.

2 Current Practice – Program Cost Effectiveness

2.1 Introduction

The workshop began with a brief overview of the current framework for conducting energy efficiency program cost-effectiveness tests. The discussion was organized as follows:

- California Standard Tests
- Issues and Challenges
- Potential Options

2.2 California Standard Tests (CST)

The California Standard Tests (CSTs) consist of a suite of tests designed to assess the benefits and costs of energy efficiency programs. They are intended to support economically efficient investment in the growth of energy supply by balancing investment in energy efficiency with investment in new supply. The California Standard Practice Manual describes five main cost effectiveness tests; the reason for the different tests is that cost-effectiveness can be viewed and assessed from multiple perspectives.

The common tests are shown in Exhibit 1, including the costs, benefits and discount rates typically included in each. The tests are:

- Total Resource Cost Test (TRC)
- Ratepayer Impact Test (RIM), also referred to as the non-participant test
- Utility Cost Test (UCT)[3]
- Participant Cost Test (PCT)
- Societal Cost Test (SCT)

Exhibit 1: California Standard Tests

	Elements	TRC	RIM	UCT	PCT	SCT
Benefits	Avoided Supply Costs	√	√	√		√
	Avoided T&D Costs	√	√	√		√
	Bill Reductions (Primary Fuel)				√	
	Conservation "Adder" or Externalities (Environmental)					√
	Indirect Fuel Benefits	√				√
	Bill Reductions (Indirect Fuel)				√	
	Other Indirect Benefits					√
Costs	Direct Utility Costs	√	√	√		√
	Direct Customer Costs	√			√	√
	Utility Program Administration	√	√	√		√
	Lost Revenues		√			
	Discount Rate	WACC	WACC	WACC	IDR	SDR

[3] Sometimes referred to as the Program Administrator Cost test in the literature.

All benefit-cost tests for EE programs are essentially similar. In each case, forecast benefits are divided by estimated costs to generate a benefit cost ratio. Each of the tests noted in Exhibit 1 assesses economic cost effectiveness from a differing perspective; hence, the differences in which benefits and costs are included in each test.

Exhibit 2 shows the distribution of cost effectiveness tests used in a number of jurisdictions, as summarized in a recent report prepared for the Ontario Energy Board[4]. As illustrated:

- The Total Resource Cost (TRC) is most widely used among North American utilities as the primary cost effectiveness test.
- Four of the jurisdictions used the Societal Cost test (SCT) exclusively and two jurisdictions used it in conjunction with the TRC test.
- The remaining tests are often applied as a secondary step to ensure that distributional effects are recognized and, as applicable, addressed through program design considerations.

2.3 Issues & Challenges

The California Standard Tests and the TRC in particular has been the primary test for assessing energy efficiency program cost-effectiveness for over two decades. However, as noted previously the literature review found that DSM practitioners and regulators throughout North

[4] Concentric Energy Advisors; Review of Demand Side Management (DSM) Framework for Natural Gas Distributors; prepared for the Ontario Energy Board, March 2010. Pg 42.

America have noted a number of fundamental problems with the EE program benefit-cost tests as commonly applied today.

The core issue in each case is that energy efficiency programs are increasingly being called upon to achieve the public policy goal of reduced carbon emissions. However, the benefit-cost analysis methods (i.e., the CST) that are commonly used to assess the cost-effectiveness of energy efficiency programs are not well suited to assessing this larger goal of carbon reduction and mitigation of climate change impacts. The situation is summarized in a paper prepared by Hall et al. The authors contend that policy makers continue to review energy efficiency programs under the TRC test, which fails to capture non-energy related benefits to society such as carbon reduction and national security. Consequently, the current approach requires energy efficiency to be cheaper than carbon-based resources before they can be approved, thus moving energy efficiency to a minor position in the supply mix. [5]

In short, the TRC was intended to support economically efficient investment in the growth of energy supply by balancing investment in energy efficiency with investment in new supply, not to determine levels of carbon reduction investment. FortisBC does currently include the cost of the carbon tax in the TRC calculations. However, the inclusion of a carbon tax is inadequate as a screening value as it is intended to discourage the use of carbon fuels, not to represent a value for carbon damage or mitigation.

The literature also notes that in addition to not providing an adequate screen for GHG reduction:

- The CST has fallen short of its intention to balance investment in efficiency with investment in new supply. It is generally recognized that, especially in the residential sector, non-energy benefits are a significant contribution to program participation, but are often not captured adequately in the screening process.

- There are significant issues in areas such as handling free riders and spillover that have hampered the development and evaluation of programs, thus eliminating some potentially good program opportunities.

- While the Total Resource Cost Test uses discounting to capture the time value of money, it is inadequate in capturing the generational equity issues surrounding GHG emissions and policy, and saving scarce fossil fuel resources for future generations.

2.4 Options

Assuming the continued inclusion of the carbon reduction goal as part of energy efficiency programs, three groups of options were identified:

- **Option1**: Use the Total Resource Cost Test – the test used in B.C. and most commonly throughout North America – but rethink the input values employed to better reflect the GHG reduction policy goal.

- **Option 2:** Use a different cost-effectiveness test from the CST suite – use a test other than the Total Resource Cost Test.

[5] See: Nick Hall, et al; *Reaching Our Energy Efficiency Potential and our Greenhouse Gas Objectives – Are Changes to our Policies and Cost Effectiveness Tests Needed?* ACEEE Presentation, March 2009.

- **Option 3:** Move beyond the California Standard Tests (CSTs) and identify a carbon-specific screening approach to meet the GHG reduction objective, or expand the CST to allow inclusion of GHG impacts in addition to the energy reduction benefits.

The following sections provide a summary of the literature search and workshop discussions related to each of the above Options.

3 Option 1: Change Inputs to TRC

3.1 Introduction

This section of the workshop briefly examined each of the major inputs to the TRC test individually, namely:

- Avoided/marginal costs
- Discount rate
- Treatment of free riders and spill over
- Treatment of non-energy benefits
- Program and measure life

In each case, the workshop discussion was organized into 3 parts:

- **The Issue:** What is the inherent contradiction or unintended effect from the current approach?

- **Potential Options**: What are the options identified in the literature that address the above issue(s); are there challenges associated with the options?

- **Impacts:** How significantly is the TRC result affected by the optional approach? For illustration purposes, the discussion in this section provides an estimate of the individual and cumulative impacts of the potential options using tankless water heaters as an example, where applicable.

3.2 Avoided/Marginal Costs

Under the TRC test, the benefits of DSM programs are defined as "avoided costs", which represent the benefit to society of not having to provide an extra unit of natural gas supply to the customer. Typically, in the natural gas industry avoided cost consists of the costs related to obtaining, transporting, and storing the gas commodity. Associated electricity and water costs are also often included.

3.2.1 The Issue

In most North American jurisdictions avoided cost values used in the TRC analysis continue to be derived based on the costs of carbon based fuels. This means that carbon based fuels continue to be the supply of choice unless energy efficiency is less expensive[6]. However, If the policy objective is to reduce GHGs rather than optimize the energy supply system, then the logic of screening the investments against the cost of additional fossil fuel based energy supply appears questionable.

The question is not, are GHG reduction programs less expensive than the cost of additional fossil fuels? Rather, the question becomes....."is this initiative less expensive than the impacts associated with releasing additional GHGs?" The challenge with this latter question is that there is no consensus on the future cost of the GHG impacts.

[6] See: Nick Hall, et al; *Reaching Our Energy Efficiency Potential and our Greenhouse Gas Objectives – Are Changes to our Policies and Cost Effectiveness Tests Needed?* ACEEE Presentation, March 2009.

In most North American jurisdictions avoided cost values used in the TRC analysis continue to be derived based on the costs of additional carbon based fuels or new electricity generation technologies. However many jurisdictions world-wide have introduced initiatives that impose higher marginal costs on new energy supply. For example:

- Many jurisdictions world-wide have introduced renewable portfolio standards (RPS) that define a minimum required share of renewable or clean energy in the overall supply mix. British Columbia's requirement for 93% renewable/clean electricity supply is a good example, as it imposes higher marginal costs on new energy supply.

- Other jurisdictions such as Ontario, the EU, Australia, China, Iran, Israel, and South Africa have added higher "feed-in" tariffs for alternate energy such as photovoltaic or wind power.

The issue then arises of whether DSM should be screened against the marginal sources of "conventional" supply or against these higher cost alternate energy sources. As DSM is typically the most environmentally benign way to meet the energy service needs of an economy, it makes sense to screen DSM programs against these alternate energy options that share similar environmental characteristics.

It should be noted that the definition of the Societal Cost Test contained in the California Standard Practice Manual allows the use of higher marginal costs if its costs are lower than other utilities in the state or than its out-of-state suppliers[7]. Applying the same logic to marginal costs of alternate energy appears to be a reasonable extension of the principle.

3.2.2 Options & Challenges

Given the recognized challenges of determining the future costs of GHG impacts, the workshop discussions focussed on alternative options. The discussions noted that if the policy objective is to reduce GHG emissions, then GHG reduction programs need to be screened against a carbon free (or at least carbon constrained) future energy supply system. This effectively means that avoided costs should more appropriately be tied to the cost of carbon free renewable energy alternatives.

In the case of FortisBC, biogas was cited as a renewable alternative that could serve as a starting point in this process. The current range of avoided costs for biogas and natural gas are shown below.

- Biogas – 2011 $9.90 GJ - $15.28 GJ
- Natural gas – 2011 $$7.03 GJ - $13.52 GJ

The $9.90/GJ price for biogas was derived from a blended weighted average of the two biogas contracts that FortisBC has finalized to date and been approved by the BC Utilities Commission. This is the current approved price for biomethane. The $15.28/GJ price for biogas was derived from BC Hydro's Tier 2 Residential Inclining Block (RIB) rate. This is the rate that BC Hydro residential customers pay when they exceed a certain consumption level per month. To come up with the $15.28/GJ price point, the BC Hydro Tier 2 RIB rate was converted to gigajoules, using a 90% efficiency factor, and all other charges that a residential customer would pay were removed except for the commodity charge.

[7] P19, "California Standard Practice Manual: Economic Analysis of Demand-Side Programs and Projects", July 2002

3.2.3 Impacts

As illustrated above, using the lower range cost of biogas supply to derive the applicable marginal supply cost for the TRC analysis instead of the current forecast natural gas supply costs would increase the value from $7.03/GJ to $15.28/GJ, a more that twofold increase.[8]

Tankless Water Heater Example

The impact of a change to the avoided supply cost was tested using the tankless water heater as an example. An avoided supply cost of $9.90/GJ was applied instead of the current forecast natural gas supply costs.
As illustrated below, the impact of this one change, alone, is to increase the benefit-cost ratio from a base case of .37 to .53.

- Possible 40% increase in marginal cost (MC)
- Tankless water heater
  - ✓ Base B/C 0.37
  - ✓ MC + 40% 0.53

3.2.4 Additional Considerations

The discussions also noted that the "pricing" for biogas noted above may still be conservative as it does not place any value on the fact that if the biogas is not converted to biomethane, some of the biogas would likely escape as methane, a much more harmful greenhouse gas than carbon dioxide.[9]

3.3 Discount rate

Discount rates are used in the benefit-cost analyses to bring all costs and returns occurring over different timeframes to a common net present value that enables different investment choices to be more fairly compared.[10]

3.3.1 The Issue

The current practice in most jurisdictions (and the one specified in the TRC test) is to use the weighted-average-cost of capital (WACC) as the discount rate. In most Canadian jurisdictions this value tends to be in the range of 7 to 9%, which is considerably higher than current interest rates available to individuals and businesses.

When higher discount rates are used in benefit-cost tests the benefits of future energy efficiency measures are significantly reduced. For example, as shown in Exhibit 3 below, when a discount rate of 9% is applied to a measure such as insulation, which has a 50 year life, the analysis only recognizes 22% of the measure's lifetime benefits. However, 100% of the cost is

---

8 The second impact of moving to a biogas marginal cost is that these costs are based on engineering projects and will provide a much more stable price than natural gas whose commodity price moves with supply and demand pressures in the North American market.

9 Some facilities (landfills & WWTPs) are under obligations to flare the biogas product so the emissions are CO_2.

10 The TRC specifies using the weighted cost of capital as the discount rate but the SCT allows the use of a social discount rate (SDR).

included in the analysis. Situations such as this example, have raised concerns that the future value of benefits attributed to energy savings is being significantly undervalued, especially if energy efficiency and conservation are intended to reduce carbon emissions and slow climate change.

As a case in point, the workshop discussions noted that in B.C., we currently have a situation with new construction programs where measures may reduce the utilities bills to the homeowner, but do not pass a utility B/C test. This occurs because mortgage rates are lower than FortisBC's discount rate, which are based on the WACC.

Hall et al. provide a good summary of the issue. The authors state that "discounting is especially problematic when the discount rate is not being applied to the value of increasingly severe projected global impacts or applied to all costs and all future benefits. Every deferral of an energy efficiency measure means that the corresponding carbon emissions will linger in the atmosphere for years or until we spend additional money to remove it with technologies yet to be developed. The damage will affect the current population somewhat, but is projected to affect future generations even more."[11]

3.3.2 Options & Challenges

The option advanced in the workshop is to select a discount rate that better matches the current application. At least in the short term use of a social discount rate was identified as the most appropriate option. In Canada there is currently a discussion regarding the appropriate level for a social discount rate.[12,13] For projects with intergenerational impacts the discussion suggests that the appropriate rate is between 1.5% and 3.5%.

Use of the social discount rate would:

- Better align with the broader carbon reduction objectives, as noted above.
- Recognize the significant intergenerational issues associated with GHG impacts. Although detailed investigation is beyond the scope of this study, it should be noted that there is a substantial body of theory related to the use of social discount rates; some goes as far as noting that considerations of intergenerational equity and environmental externalities can <u>theoretically</u> reduce the SDR to near zero or cause it to be negative.[14]

Hall et al also note the potential case for negative discount rates. The authors note that if energy efficiency and conservation are intended to reduce carbon emissions and slow climate change it is possible to suggest that the discount rate for climate change purposes should be negative resulting in a higher value allocated to future energy savings. In other words, the decision to approve energy efficiency programs should be more than just an assessment of

[11] Hall et al. op cit

[12] "**Social Discount Rates for Canada",** Anthony E. Boardman (UBC), Mark A. Moore (SFU), Aidan R. Vining (SFU). September 28, 2008.

[13] The Canadian Cost Benefit Analysis Guide of the Treasury states that a social discount rate of 3% can be used in certain cases where there are no or minimal resources involving opportunity costs. This applies to certain projects that generate human health and environmental impacts. Treasury Board of Canada Secretariat (TBS) "*Canadian Cost-benefit Analysis Guide: Regulatory Proposals"* PRI Project, 2007.

[14] See: Partha Dasgupta*, Karl-Göran Mäler**, and Scott Barrett; **Intergenerational Equity, Social Discount Rates and Global Warming;** ** April 2000

alternative financial outcomes and should recognize that the financial benefits of energy savings and carbon reduction increase over time.[15]

3.3.3 Impacts

Exhibit 3 shows that the choice of discount rate has a significant impact on cost-effectiveness, especially for measures that have a long life.

As illustrated below in Exhibit 3, the benefit cost analysis of a measure with a 50 year life would include 100% of the costs but only 22% of the benefits when a 9% discount rate is used. At a discount rate of 3%, the analysis would still capture 100% of the costs but benefits would increase to 51%. Although a significant improvement, even the 3% discount rate results in a significant reduction in NPV benefits relative to a discount rate of zero.

Exhibit 3: Discount Rate and Value of Measured Benefits

Tankless Water	**Measure Life**	**Discount Rate**					
		9.0%	**7.0%**	**5.0%**	**3.0%**	**1.0%**	**0.0%**
NPV Measure Benefits @$100 annual benefit stream	**5**	$389	$410	$433	$458	$485	$500
	10	$642	$702	$772	$853	$947	$1,000
	15	$806	$911	$1,038	$1,194	$1,387	$1,500
	20	$913	$1,059	$1,246	$1,488	$1,805	$2,000
	50	$1,096	$1,380	$1,826	$2,573	$3,920	$5,000
Percentage NPV Measure Benefit relative to zero discount rate	**5**	78%	82%	87%	92%	97%	
	10	64%	70%	77%	85%	95%	
	15	54%	61%	69%	80%	92%	
	20	46%	53%	62%	74%	90%	
	50	22%	28%	37%	51%	78%	

Heater Example

The impact of a change to the discount rate was tested, again using the same tankless water heater as an example. A social discount rate of 3.5% was applied instead of the WACC rate of 7.38%.

As illustrated below, the impact of this one change, alone, is to increase the benefit-cost ratio from a base case result of .37 to .57. When combined with the biogas based avoided supply price the combined impact is to increase the benefit-cost ratio .81.

- Base B/C 0.37
- 3.5% Social Discount Rate (“SDR”) 0.57
- Combined (SDR & MC) 0.81

[15] See concentric paper

3.4 Free Riders/Spillover

A free rider is a program participant who would have installed a measure on his or her own initiative even without the program. Spillover works in the opposite direction, and provides credit for savings from people who were influenced by the program, but who did not receive an incentive.

3.4.1 Issues

Typically, free rider participants are excluded from the benefits attributed to an EE program, along with the equipment costs associated with these participants. However, all the utility program costs associated with free riders are typically included in the TRC analysis. The net effect is to increase overall program costs and reduce cost-effectiveness. For example, the evaluation (2007) of FortisBC's furnace program set the free rider rate at >50%.

Spillover includes credit for additional measures that were undertaken by program participants but for which they did not receive an incentive, and also for other people who were influenced by the program (perhaps by advertising) but who also did not receive an incentive. In both cases their actions are wholly or partially induced by the utility program.

A previous study conducted for the Nevada Power Company and Sierra Pacific Power Collaborative included an examination of the treatment of free ridership and spillover in 23 states and/or utilities serving those states. The study concluded:[16]

- Estimating free ridership and spillover is difficult, with no consensus on an approach for how best to estimate these values. There are inherent biases with both self-report and statistical approaches, and the selection of one approach over another can give significantly different results. Ultimately multiple approaches may be necessary to satisfy all parties that the research is done correctly.
- Over two-thirds (69%) of the 23 identified programs used a net-to-gross value (NTG)[17] of approximately 1.0. In most cases lower NTG values were only based on free ridership values; an even higher percentage of programs would have a NTG ratio of approximately 1.0 if spillover was examined.

Assuming a NTG ratio of 1.0 may provide a conservative estimate. Since most existing studies concentrate on self-reported free ridership while ignoring spillover, it is possible that better, more comprehensive research would yield NTG ratios over 1.0.

Free ridership has been topical in recent months due to a series of press reports about the new compact fluorescent lamp (CFL) standards, and the reduction in NTG from program CFL program evaluations. Several researchers have found that states that do not have programs have sales of CFLs that are similar to those states that do. The conclusion from this data was that the CFL programs were not nearly as cost-effective as originally thought.

[16] A Study of Methodologies for Evaluating Free Ridership and Spillover throughout the United States." Draft Report to the Nevada Power/Sierra Pacific Power Collaborative Sub-Committee on Free Ridership and Spillover. Prepared by Paragon Consulting Services, Inc. November 20, 2006.

[17] Gross benefits are calculated without consideration of free rider or spillover effects, while net benefits include them. Net to gross (NTG)refers to the ratio of the two sets of results.

However, another reading of the same market data reveals that these freeriders could actually be considered spillover! A decade ago – right after the west coast power crises in the United States – western states enacted comprehensive CFL programs that spread to the Upper Midwest, New England, Texas and other U.S. regions. The programs involved both downstream and upstream market transformation programs, including chains such as Costco and Home Depot.

As the programs spread two things occurred: wholesale and retail rivals jumped on board with their own CFL promotions to combat market share losses, and national chains began making national decisions in response to the bottom-up program push from the individual states. It is therefore no surprise that states like South Dakota and Kansas – which have not had widespread utility CFL programs – have bulb sales rivaling neighboring states that do. What is surprising is that the sales in program states are now branded as having significant free ridership rather than the non-program states being referred to as spillover areas.

In summary,

- Use of the net-to-gross (NTG) ratio often becomes an analysis of negative free ridership, while the positive spillover effects (e.g., free drivers) are ignored.
- Even when spillover is calculated, it is often done only for participants' "other measures" installed. The effects of program advertising and information and their influences on nonparticipants are usually not studied.
- The bias is one directional; it consistently lowers the NTG ratio and reduces the cost effectiveness of EE programs.

3.4.2 Options & Challenges

Two options were identified; however, both present a number of challenges. More specifically:

- **Require full estimation of free ridership and spillover.** While in theory this provide the optimum solution, in practice it is very difficult, with no consensus on the approach for how best to estimate these values. More specifically, there are inherent biases with both self-report and statistical approaches, and the selection of one approach over another can give significantly different results. Similarly, the costs associated with a symmetrical assessment of both free rider and spillover effects could significantly increase program evaluation costs, threatening program cost-effectiveness.
- **Assume free riders and spillover cancel out, and do not need to be estimated**. As demonstrated previously, this is the current practice in a number of U.S. jurisdictions.

  While a case can be made for assuming that the two effects cancel each other, the challenge remains of how to do this while ensuring that program designs don't lead to high free ridership with little spillover?

  Part of the answer may be through use of higher incentives, trade ally training and technical support, streamlined participation processes and focus on longer payback initiatives. Ultimately, the key is ongoing research designed to measure market share changes so it is known when market transformation effects are realized.

3.4.3 Impacts

At a program level, impacts can be high. For example, as noted previously the evaluation (2007) of FortisBC's furnace program set the free rider rate at >50%.

3.5 Treatment of Non-Energy Benefits

Efficiency is rarely the only attribute of a product that is of interest to either consumers or sellers. In some initiatives such as windows and building shell upgrades, energy savings may be overshadowed by benefits such as comfort and appearance.

3.5.1 The Issue

Measuring and quantifying "non-energy benefits" is difficult and often controversial for regulators to accept as a legitimate factor to consider in utility regulation. As a result, non-energy benefits are seldom included in cost-effectiveness screening under the TRC or even under the Societal Cost Test. In contrast, the full retail cost of an efficiency investment is easy to quantify, and is virtually always used in benefit-cost analyses.

Nemes and Kushler note that:

- Some benefits are a natural by-product of the measure. For example, reducing the leakiness of a home improves comfort at the same time it saves energy.
- Similarly, more comfortable work environments have been shown to improve worker productivity.
- Efficiency and other desirable attributes are sometimes intentionally merged by manufacturers', designers' or builders as part of their marketing or sales strategies.
- Market players sell an "entry-level" product that is as basic and inexpensive as possible – usually meaning it is also inefficient; they also often bundle efficiency upgrades with other attractive features and market this bundle as a "premium" product.

The end result is that cost-effectiveness screening becomes an inherently skewed comparison: all the costs are compared to just a portion – i.e. the energy portion – of the benefits[18].

3.5.2 Options & Challenges

One option is to include non-energy benefits within the cost-effectiveness screening. Concentric Energy Advisors note in their report to the Ontario Energy Board that for the past decade in Massachusetts, the regulators have explicitly allowed the utilities to conduct studies of non resource benefits and include the value of such benefits in their cost-effectiveness screening. However, the Concentric Energy Report also notes that with rare exceptions, the utilities have not factored such benefits into their analyses. In the past, regulators in Washington, D.C. have allowed a non-resource benefit adder to be applied to low income programs. However, such examples are very rare. [19]

[18] Nemes and Kushler; op cit; pg 5.

[19] Concentric Energy Advisors; Review of Demand Side Management (DSM) Framework for Natural Gas Distributors; prepared for the Ontario Energy Board, March 2010.

Non-energy benefit studies have been done locally in the commercial sector, but these are both lengthy and expensive. The primary weakness is that the results have not been readily transferable to other situations. Some consideration is being given to developing “standard” non-energy benefits for limited residential applications such as increased comfort and house price / saleability for advanced new construction and retrofits.

A second option, which is discussed in Section 4, is to move to the Utility Cost Test (UCT), thereby avoiding the whole issue. Implicit in the UTC approach is the idea that consumers will decide what is in their own best interests, and will not be swayed into “overinvesting” in DSM just because there are incentives[20].

3.5.3 Impact(s)

The impact of improved inclusion of non-energy benefits varies by measure. It is expected to be particularly important for building shell measures, which provide added comfort and aesthetics.

As noted previously in Exhibit 3, the benefit cost analysis of a measure with a 50 year life would include 100% of the costs but only 22% of the benefits, when a 9% discount rate is used.

Tankless Water Heater Example

As noted previously, tankless water heaters currently have about a 7% market share in new construction, and an unknown, but possibly similar market share in retrofit. This indicates that some developers and individuals find sufficient benefit in the product to pay the increased cost (2 to 3 times the cost of a conventional tank). Many cite the benefit of “unlimited hot water” and floor space saved, but program planners would have difficulty justifying a “non-energy benefit” large enough to provide a positive benefit / cost ratio.

3.6 Program and Measure Life

Measure life, or effective useful life (EUL) is the period of time that the measure is expected to perform in a typical installation. It is commonly defined as the period over which 50% of the installed measures have either failed or been removed.

3.6.1 The Issue

Many jurisdictions tend to cap measure life at between 18 and 22 years regardless of the period of time the measure is expected to perform. This approach is often linked to a perceived need to be “conservative” in estimating life. However, the effect of this “conservatism” is to bias the choice to increased levels of new supply.

The issue of measure life and discount rate are closely linked; as illustrated previously, the use of discount rates in the range of 7 to 9% minimize the benefits of longer life measures past 20 or 25 years anyway.

As in the discussion of discount rates this issue most significantly impacts long-life measures such as building insulation and air sealing.

[20] For example, tankless water heaters will not save enough energy to cover the additional cost. There could be a back lash if consumers interpret the existence of the incentive to mean that the utility thinks that the cost savings will cover the additional costs.

Concentric Energy Advisors provide a good summary of this issue. Their report notes that vast amounts of energy savings in the United States become essentially worthless under standard benefit cost tests when savings occurring beyond the policy-based effective useful life period are not valued as a future energy resource. The authors contend that the majority of the value from savings on energy efficiency measures such as replacement windows, attic insulation, and new building envelopes is not recognized in benefit cost calculations because policy makers have underestimated the value of the long-term savings provided by those measures.[21]

3.6.2 Options & Challenges

A three step approach was identified:

- Use the “best estimate” of measure life
- If there is concern about the “best estimate” of life, use sensitivity analysis to determine the shortest measure life that provides a positive B/C
- Focus on discount rates, as the longer measure life only provides increased benefit with lower discount rates.

3.6.3 Impact(s)

The impact of improved inclusion of non-energy benefits varies by measure. It is expected to be particularly significant for building shell measures, which provide added comfort and aesthetics.

As noted previously in Exhibit 3, the benefit cost analysis of a measure with a 50 year life would include 100% of the costs but only 22% of the benefits, when a 9% discount rate is used.

[21] Concentric Energy Advisors; Review of Demand Side Management (DSM) Framework for Natural Gas Distributors; prepared for the Ontario Energy Board, March 2010.

4 Option 2: Change Benefit Cost Test

4.1 Introduction

This section provides an overview of the second set of options that were identified, namely: use a different cost-effectiveness test from the CST suite – use a test other than the Total Resource Cost Test. Two alternates to the TRC are reviewed:

- The Societal Cost Test
- The Utility Cost Test

In each case the idea is to work incrementally within the CST paradigm in an attempt to bridge the gap between GHG reduction and Energy Efficiency policies.

4.2 Societal Cost Test

The Societal Test is a variant on the TRC. It is intended to represent a broader societal view of cost-effectiveness. As shown previously in Exhibit 1, the SCT is the same as the TRC except that it adds environmental and other non-energy benefits and costs to society into the calculation.

The other differences are that the SCT allows for the use of alternate marginal costs and uses a social discount rate, rather than a WACC. Selected references for discount rates from other jurisdictions are listed below:

- In the US, Moore et al. (2004) propose a SDR of 3.5%
- Iowa and some other US states use long-term Treasury rates
- Government of Canada benchmark bond yields are 2.5 to 3.5% depending on series used and the time horizon
- Researchers at UBC / Simon Fraser are calling for Canadian SDRs that vary "between 2.0 and 5.0% for intragenerational projects, and between 1.5% and 3.5% for projects with intergenerational impacts"
- US Center for Disease Control (CDC) "recommends that a 3% social discount rate be used in analyses that require adjusting future costs and benefits of public health interventions, programs, and policies"
- UK is now using a 3.5% SDR
- In his now famous report on the economics of climate change, Stern (2006) uses a SDR of 1.3%.

4.2.1 Pros

Use of the Societal Cost Test would acknowledge the trend toward expansion of regulatory and policy objectives beyond reducing gas consumption or load management to also include GHG reduction and other societal goals, such as support for low income customers. The inclusion of environmental and social externalities in the SCT would:

- Allow better treatment of environmental impacts
- Allow use of a societal discount rate (1.5 - 3.5%)
- Allow the use of higher avoided supply costs, which would be consistent with the possible use of renewable energy supply costs such as biogas that have similar environmental attributes as DSM.

4.2.2 Cons

Although it addresses some non-energy benefits such as environmental externalities, other non-energy benefits such as improved comfort, building durability, health and safety, worker productivity, public image and others are seldom addressed. These issues remain the same as for the TRC.

4.3 Program Administrator/Utility Cost Test

The Program Administrator Cost Test (also referred to as the Utility Cost Test) measures cost-effectiveness from a utility or program administrator perspective. It compares the value of the utility's avoided costs with the cost to the utility of acquiring the efficiency resources that produce those avoided costs. It differs from the TRC in several ways:

- It does not include any energy benefits for fuels the utility does not provide
- It does not include any other resource benefits such as water savings; and
- It does not include any customer contributions to the cost of an efficiency investment. [22]

4.3.1 Pros

Proponents of the PAC test note that energy efficiency opportunities are not assessed in the same manner as energy supply alternatives**.** For example, Nemes and Kushler note that "when a regulator approves a utility purchased-power contract with a customer with an on-site generator, there is no consideration given to what the customer costs or other benefits from that equipment might be. All that is considered germane is the purchase price to the utility for that resource. The authors ask, "why should regulators apply a more stringent standard to utility investment in energy efficiency resources?" [23]

Use of the PAC also avoids the difficulties associated with attempting to calculate the value of non-energy benefits and respects the consumers' ability to make choices that are in their own best interests. It therefore enables utilities to promote technologies that do not pass traditional cost-effectiveness tests, such as the tankless water heaters that discussed as an example in this report.

4.3.2 Cons

The energy savings of some technologies that may be promoted by a utility program may not fully cover their incremental cost. The utility will need to be careful not to imply that any product it promotes will provide sufficient cost savings to cover the incremental costs.

[22] See: Chris Nemes, Marty Kushler; Is it Time to Ditch the TRC? Examining Concerns with Current Practice in Benefit- Cost Analysis; published in 2010 ACEEE Summer Study on Energy Efficiency in Buildings. 5-303.

[23] See: Chris Nemes, Marty Kushler; Is it Time to Ditch the TRC? Examining Concerns with Current Practice in Benefit- Cost Analysis; published in 2010 ACEEE Summer Study on Energy Efficiency in Buildings. 5-303.

5 Option 3: Use Carbon Based Screening

5.1 Introduction

As noted previously, if one of the objectives of utility DSM programs is to meet government mandated GHG reduction targets, then the approach used to screen DSM programs needs to shift the focus from the marginal cost of additional energy supply to the value of GHG reductions.

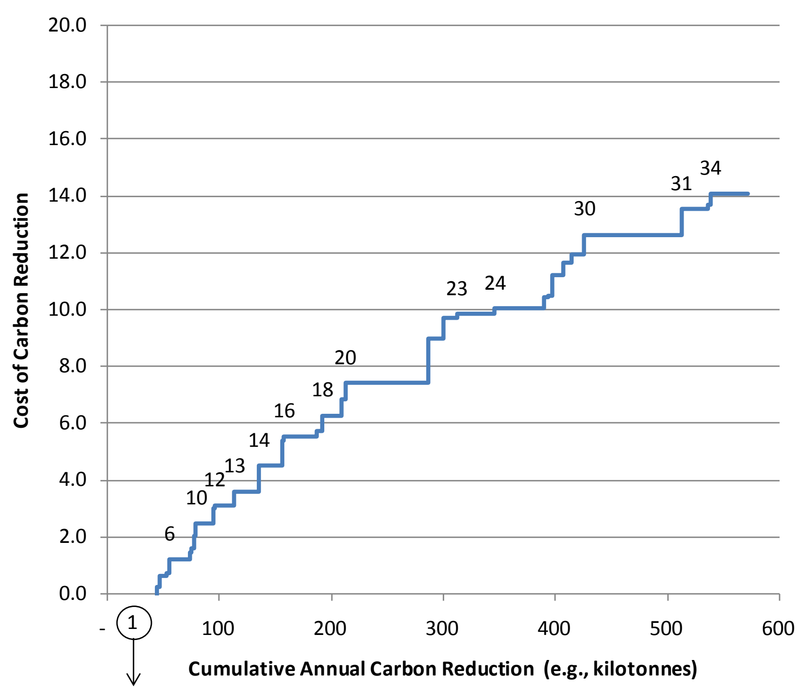
GHG reduction targets will require a reduction in the carbon intensity of our energy supply systems. On the one hand, as the amount of fuel required decreases, economics suggests that the marginal cost of that fuel will also decrease. On the other hand, the more "advanced" DSM measures needed to meet the GHG objectives will be progressively more expensive. If they are screened against a progressively lower MC of fuel, it is impossible to meet the GHG targets and move beyond the current level of DSM activity.

While studies have provided global estimates of the future costs of GHG impacts, there is a large range in potential values presented in these studies; moreover, there continues to be debate on the appropriate approach to be applied to these analyses. Consequently, it is evident that determining an agreed "value" for the cost of GHG emissions to be used in benefit cost analyses such those discussed in this paper is likely to be a lengthy and controversial process.

5.2 An Alternate Approach

Rather than attempting to determine a value for GHG reduction and then screen against it, an alternate approach is to build a "supply curve" of GHG reduction measures. This approach is an adaptation of "energy supply curves" that commonly included in energy efficiency market potential studies. Exhibit 4 provides an illustration.

Exhibit 4: Carbon Reduction Supply Curves – An Illustration



As illustrated in Exhibit 4, each step in the GHG reduction curve shows the cumulative amount of GHG reduction that could be achieved by each of the numbered measures and the associated cost. The measures in Exhibit 4 are organized from least cost to more expensive. Whereas conventional energy efficiency program screening would limit the inclusion of measures to those that met the marginal cost threshold, the approach shown in Exhibit 4 is to include all measures while noting their successively higher costs.

The detailed analysis of energy savings opportunities contained in the FortisBC Conservation Potential Review provides an opportune starting point for the construction of a carbon reduction supply curve. The detailed analysis of the FortisBC CPR identifies a wide range of measures together with the total amount of potential energy savings and associated costs for each. The amount of GHG reduction associated with each energy saving measure can also be readily calculated, which allows the construction of a GHG supply curve such as that shown in Exhibit 4.

Once the curve has been developed, it will identify the scope of GHG reduction potential at each cost point. This will provide the basis for discussions among the utility, the provincial government (who set the GHG reduction targets) and possibly the regulator to set the cost threshold and matching GHG reduction objectives.

One interesting aspect of this curve is that some part of the GHG reductions will be “free” in that they will be paid via the current DSM funding approach. That is, that portion of the curve or those measures that are cost effective from the TRC or SOC screening perspective can be obtained at no additional cost to society.

However for measures that are above this level, there is an additional cost that must be borne by society. This will likely lead to discussions of who should pay these costs, how programs are fund, approved, etc.

5.2.1 Additional Considerations

There may be an interim approach to approving programs that have GHG benefits but do not pass the TRC / SOC screening. The concept is to screen the program by DSM standards, and then determine the extent that the DSM costs exceed the DSM benefits, divide this by the GHG reduction and determine if the cost per ton of GHG reduction is less than the agreed threshold. If this test is met, then the program would be allowed to proceed.

5.3 Potential Benefits

This alternate approach outlined above has a number of potential benefits:

- It clearly accounts for the share of the program and incentive cost that is “paid for” by the DSM energy savings.
- It makes the cost of the GHG reduction explicit.
- It is an “add-on” to the CST tests, and as such may be easier to get agreement to than developing a completely new screening technology.
- It avoids having to develop a “definitive” value for GHGs which would be necessary if the value of GHG savings were to be included in an SOC type approach.

- It somewhat avoids the issue of “who should pay” in that the additional cost would be borne by the program participants (as opposed to general ratepayers or utility customers). The cost is carried by the program participant, who is free to join the program or not. This avoids any additional “non-participant” type issues. In some ways this is very similar to the “non-energy benefits”, and recognizes that people invest in measures or programs for a wide range of reasons, cost / benefit being only one, and perhaps a minor one.

- It protects the utilities financial ROI model for DSM. They still fund the programs and obtain ROI in the same manner as with current programs. However they will now be able to promote a wider range of programs.

6 High Level Action Plan

Exhibit 5 presents a summary of the Action Plan or next steps as developed through the workshop and in subsequent discussions within FortisBC

Exhibit 5: High Level Action Plan

Option	Workshop Conclusion/Recommendation
Change Inputs to TRC	
✓ Marginal Cost	✓ Internal agreement to use long term cost of biogas to set marginal supply cost, subject to regulator approval
✓ Discount Rate	✓ Internal agreement to move to social discount rate of 3.0% subject to regulator approval
✓ Free Riders//Spillover	✓ Apply to regulator for approval to treat as "net zero"
✓ Non-energy benefits	✓ Work towards stipulated NEB for some programs (esp. Building shell)
✓ Measure life	✓ Use full measure life
Change BC Test	
✓ Use SCT	✓ Apply to regulator to move to SCT including above inputs
✓ Use UCT	Not a priority; no further action
Use GHG Based Approach	Prepare Carbon Abatement Cost Curves – 3 sectors
	✓ Engage MEMPR / regulator to agree on maximum social value for GHG reduction from programs
	✓ Apply to regulator to include GHG reduction benefit as part of EEC program screening
Short Term Action Plan	✓ Apply to regulator to move to SCT as part of 2011 RRA
	✓ Develop Carbon Abatement Cost Curves - summer 2011
	✓ Discuss GHG approach with BC Gov't – fall 2011
	✓ Apply to regulator to include GHG in EEC program screening – date not determined

**ENERGY EFFICIENCY POLICY MANUAL
FOR POST-2005 PROGRAMS**

I. Introduction

This document presents the California Public Utilities Commission's (Commission) policy rules and related reference documents for the development and evaluation of energy efficiency programs funded by ratepayers in California. Referred to as the Energy Efficiency Policy Manual, Version 4.0, this document shall apply to all energy efficiency activities commencing in program year (PY) 2005 and beyond. The policy rules, terms and definitions contained herein apply to energy efficiency activities funded through the following mechanisms:

- The electric public goods charge (PGC), as authorized by Public Utilities (PU) Code Sections 381 and 399.
- The gas surcharge, as authorized by PU Code Sections 890-900.
- Procurement rates, as authorized by the Commission.

The rules in this manual do **not** currently apply to:

- Low-income energy efficiency programs (LIEE) funded by the electric PGC or gas surcharges
- California Alternative Rates for Energy (CARE) for low-income customers funded out of electric or gas PGC[1]
- Interruptible rate or load management programs[2]
- Self-generation and demand-responsiveness programs developed in response to AB970 (PU Code Section 399.15(b)).[3]

---

[1] A separate low-income rulemaking was initiated on January 25, 2007 (R.07-01-042).

[2] Interruptible and load management programs are addressed under Decision 05-11-009 (R.02-06-001).

[3] These programs were adopted in D.01-03-073, in R.98-07-037.

EE Policy Manual Version 4.0

This document supersedes all previous versions of the Energy Efficiency Policy Manual. Sections II-XI below articulate the Commission's policy rules ("Rules") governing energy efficiency activities, commencing in 2006.

The term "Program Administrators" refers to the following investor-owned utilities (IOUs): Pacific Gas and Electric Company (PG&E), Southern California Edison Company (SCE), San Diego Gas & Electric Company (SDG&E) and Southern California Gas Company (SoCalGas).

II. Energy Efficiency Policy Objectives and Program Funding Guidelines

1. Commission and state energy policy, as expressed in the Energy Action Plan and reaffirmed in Decision (D.) 04-12-048, make energy efficiency the utilities' highest priority procurement resource. In other words, cost-effective energy efficiency should be first in the "loading order" of resources used by the utilities to meet their customers' energy service needs. The Governor's and the state's policies also seek to reduce the environmental impact (including the greenhouse gas emissions) associated with the state's energy consumption, to protect the public's health and safety. Energy efficiency is a critical part of the state's strategy to achieve these goals.

1.a. For PY2009 and through 2020 and beyond, the utilities shall develop a single, comprehensive Strategic Plan updated annually for energy efficiency programs and program cycles. The plan shall incorporate collaboration with a wider range of stakeholders, integration with other demand-side management programs, and innovation of energy efficiency programs, as outlined under D.07-10-032. The utilities shall aggressively pursue energy efficiency as part of the Western Regional Climate Action Initiative, February 26, 2007 and the National Action Plan for Energy Efficiency (See http://www.epa.gov/solar/energy-programs/napee/index.html).

2. The Commission's overriding goal guiding its energy efficiency efforts is to pursue all cost-effective energy efficiency opportunities over both the short- and long-term. By D.04-09-060, the Commission translated this policy into specific annual and cumulative numerical goals for electricity and natural gas savings by utility service territory. These goals shall be updated periodically by the Commission as provided for in that decision. The Commission-adopted energy savings goals are expressed in terms of annual and cumulative gigawatt hours, million-therms and peak megawatt load reductions. By D.06-06-063, Ordering Paragraph 1, the definition of peak megawatt load reduction contained

in the 2005 Database for Energy Efficient Resources (DEER) shall be used for the purpose of verifying energy efficiency program and portfolio performance[4]. Program Administrators should develop their energy efficiency program portfolios so that they will meet or exceed these annual and cumulative savings goals, both over the short- and long-term.[5] As clarified in D.07-10-032, cumulative savings represent the savings in that year from all previous measure installations (and reflecting any persistence decay that has occurred since the measures were installed) plus the first-year savings of the measures installed in that program year.

3. In order to promote the resource procurement policies articulated in the Energy Action Plan and by this Commission, energy efficiency activities funded by ratepayers should focus on programs that serve as alternatives to more costly supply-side resource options ("resource programs"). Focusing energy efficiency efforts in this way is the most equitable way to distribute program benefits: By keeping energy resource procurement costs as low as possible through the deployment of cost-effective portfolio of resource programs, over time *all* customers will share in the resource savings from energy efficiency.

4. "Lost opportunities" are those energy efficiency options which offer long-lived, cost-effective savings and which, if not exploited promptly or simultaneously with other low cost energy efficiency measures or in tandem with other load-reduction technologies or distributed generation technologies being installed at the site (e.g., solar heating or photovoltaics), are lost irretrievably or rendered much more costly to achieve. "Cream skimming" results in the pursuit of only the lowest cost energy efficiency measures, leaving behind other cost-effective opportunities. Cream skimming becomes a problem when lost opportunities are created in the process.

5. Program Administrators should manage their portfolio of programs to meet or exceed the short- and long-term savings goals established by the

[4] D.06-06-063. As discussed in this decision, DEER defines peak demand as the average grid level impact for a measure between 2 p.m. and 5 p.m. during the three consecutive weekday periods containing the weekday temperature with the hottest temperature of the year.

[5] While the energy savings achieved by LIEE programs will count towards the Commission's savings goals, per D.04-09-050, the Commission considers factors other than cost-effectiveness in determining LIEE program design and funding levels.

Commission by pursuing the most cost-effective energy efficiency resource programs first, while minimizing lost opportunities. In addition, the Program Administrators should demonstrate in their program planning applications how their proposed portfolio will aggressively increase overall capacity utilization and lower peak loads through the deployment of low load factor/high critical peak saving measures. The aggressive annual and cumulative savings goals established by the Commission will serve to discourage cream- skimming program designs or implementation approaches that create lost opportunities. Nonetheless, Program Administrators should actively develop strategies to minimize lost opportunities, and should describe those strategies in the applications they submit for each program cycle.

6. Compliance with Rule II.5 will generally dictate the appropriate balance for portfolio funding of resource programs across market sectors (e.g., residential, industrial, commercial) and geography, as well as the most appropriate program designs. Program Administrators should also include a selection of statewide marketing and outreach programs, upstream market transformation programs, information and education programs, support for codes and standards and other activities in their proposed portfolios that support the Commission's short-term and long-term energy savings goals. Program administrators shall allocate a sufficient portion of portfolio funding to statewide marketing and outreach to continue and build upon the success of the existing program. Statewide marketing and outreach programs should convey a consistent statewide message to energy consumers in all sectors.

7. To further support the Governor's and State's goals to reduce greenhouse gas emissions, Program Administrators should explore with their advisory groups ways in which to co-brand with the California Climate Action Registry that will encourage the accurate reporting of emissions in California. This might include, for example, marketing and outreach efforts that provide information about the Registry to IOU customers and encourage larger commercial and industrial customers to participate in the Registry reporting protocols. In their program plan applications, Program Administrators shall describe the ways in which such co-branding will be supported through their proposed programs. Similarly, energy efficiency marketing efforts should strive to co-brand with water conservation messaging, recycling, toxic reductions (particularly mercury from fluorescent lamps), solar, distributed generation, green buildings, low income, and other related programs. (D07-10-043, mimeo p. 59)

EE Policy Manual Version 4.0

8. The deployment of new and improved energy efficiency products and applications can help sustain or increase current savings yields from program dollars, and serves to create a new generation of technologies available to tap the cost-effective potential of energy efficiency in ways we cannot predict today. In order to provide higher levels of bridging between available upstream innovations and the marketplace, annual funding for emerging technologies programs should increase. Program Administrators should work with the California Energy Commission (CEC) and other appropriate stakeholders to include appropriate levels of funding to demonstrate and commercialize emerging technologies funded through the California Public Interest Energy Research (PIER) program and other sources that otherwise would not receive funding for pre-commercialization demonstration. In their program planning applications, the Program Administrators shall jointly propose emerging technologies programs and increases to current funding levels for these programs. The main purpose of these programs should be to increase the probability that promising technologies will be commercialized within 6 years of program funding and thereby increase the chance of obtaining additional energy savings from these technologies in the long run. Program strategies should focus on reducing both the performance uncertainties associated with new products and applications and the institutional barriers to introducing them into the market.

9. Per D. 05-01-055, Program Administrators with input from the public and advisory groups will develop for Commission consideration their portfolios of energy efficiency programs utilizing selection criteria that are consistent with these Rules. Program Administrators will manage a portfolio of programs implemented by IOUs and non-IOUs that are selected and evaluated based on their ability to best meet the policy objectives articulated in these Rules.

10. Pursuant to PU Code sections 381, 381.1[6], 399 and 890-900, PGC and gas surcharge funds must be spent to deliver energy efficiency benefits to ratepayers in the service territory from which the funds were collected.

---

[6] Consistent with the provisions of AB117 (Chapter 838, Chaptered September 24, 2002), Section 381.1 was added to Public Utilities Code permitting community choice aggregators (CCAs) to apply to administer cost-effective energy efficiency and conservation programs. The Commission adopted certain procedures in Decision (D.) 03-07-034 (dated July 10, 2003) to implement portions of AB 117 affecting the allocation of energy efficiency program funds. [MOVED FROM FOOTNOTE 1]

Additionally, gas PGC collections must fund natural gas energy efficiency programs and electric PGC collections must fund electric energy efficiency programs. However, nothing in these Rules is intended to prohibit or limit the ability of the Commission to direct the IOUs to jointly fund with PGC, gas surcharges, or other collections (e.g., via procurement rates) selected measurement studies, statewide marketing and outreach programs, or other energy-efficiency activities that reach across service territory boundaries.

11. Fund Shifting Rules (D.05-09-043, Table 8) applicable to the 2006-2008 program cycle are added to these Policy Rules as an attachment to Appendix A. Appendix A is modified per D.07-10-032 for carry-back/carry-over funding to apply to the 2009-2011 funding cycle, and is repeated below.

12. Bridge Funding. Programs continuing from the 2006-2008 program cycle into the 2009-2011 cycle may use 2009-2011 funding, once the 2009-2011 portfolio has been approved and start-up costs for 2009-2011 programs may use 2009-2011 funding once the 2009-2011 portfolio has been approved. (D.07-10-032). Unspent or uncommitted funds from previous program years, or 2006-2008 funds that will not be needed should be used prior to using 2009-2011 funds. Both continuing program funding and start-up cost funding are limited to 15% of the current budget cycle without Commission approval. An Advice Letter is required for funding in excess of this percentage.

13. Funds may be committed for projects with lead times beyond three years under the following conditions:

- Long-term projects that require funding beyond the three-year program cycle shall be specifically identified in the utility portfolio plans and shall include an estimate of the total costs broken down by year and associated energy savings;
- Funds for long-term projects must be actually encumbered in the current program cycle;
- Contracts with all types of implementing agencies and businesses must explicitly allow completion of work beyond the end of a program cycle;
- Encumbered funds may not exceed 20% of the value of the current program cycle budget to come from the subsequent program cycle, except by approval in an advice letter process;

- Long-term obligations must be reported and tracked separately and include information regarding funds encumbered and estimated date of project completion; and
- Energy savings for projects with long lead times will be calculated by defining the baseline as the applicable codes and standards at the time of the issuance of the building permit.

14. For calculating the Performance Earnings Basis (PEB), funds encumbered for continuing programs or for programs with long lead times shall be counted when those funds are spent.
15. Mid-Cycle Funding Augmentations. See Rule IV.12 below.

III. Common Terms and Definitions

1. Common terms and definitions will facilitate the review, selection and evaluation of energy efficiency activities. In particular, program definitions should be designed to facilitate to the extent possible: (1) the identification of energy efficiency activities by end-use savings potential, (2) the evaluation, measurement and verification (EM&V) of those activities based on Commission-adopted EM&V protocols, and (3) the coordination of program development and evaluation with resource planning and procurement needs. To this end, Program Administrators and program implementers should use the definitions included in Appendix B to these Rules when characterizing any proposed program activity. The burden is on them to justify any departure from those terms and definitions.

IV. Cost-Effectiveness

1. The cost-effectiveness indicators referred to in these rules are described in the *California Standard Practices Manual: Economic Analysis of Demand-Side Management Programs* (SPM): Economic Analysis of Demand-Side Management Programs. Program Administrators and Implementers should perform cost-

effectiveness analyses consistent with the indicators and methodologies included in the SPM, unless otherwise indicated.[7]

2. This Commission relies on the Total Resource Cost Test (TRC) as the primary indicator of energy efficiency program cost effectiveness, consistent with our view that ratepayer-funded energy efficiency should focus on programs that serve as resource alternatives to supply-side options. The TRC measures the net resource benefits from the perspective of all ratepayers by combining the net benefits of the program to all ratepayers, both participants and non-participants. The benefits are the net present value of avoided costs of the supply-side resources avoided or deferred. The TRC costs encompass the net present value of the costs participants incur for the measures/equipment installed over the measure life and all non-rebate[8] costs incurred by the program administrator.[9] The TRC is calculated utilizing a discount rate that reflects each utility's weighted average cost of capital, as adopted by the Commission[10].

---

7 See Appendix A of this manual for information on how to obtain a copy of the SPM and its clarifications.

8 The SPM restricts rebates to include only dollar benefits such as rebates or rate incentives (monthly bill credits) paid from the Program Administrator to participating ratepayers.

9 The TRC test uses the "incremental" measure cost (not the full cost) and incremental energy savings benefit (not the full energy savings benefit) when an energy-efficient appliance or measure promoted through the program is installed in lieu of the standard (less efficient) appliance/measure that would have been installed, without the utility EE activity. The TRC test uses the full measure cost (at the time of installation) and the full energy savings benefit (of the new measure) for the <u>remaining useful life</u> of the pre-existing equipment (e.g., 3 or more years), where the utility EE activity causes measure/equipment to be replaced much earlier. The TRC test then uses the incremental savings for the balance of the effective useful life of the newly installed measure/equipment and deducts the full cost of that equipment discounted back to the date of the measure/equipment installation.

10 For the 2006-8 program cycle an average IOU weighted cost of capital may have been used for cost effectiveness calculations. The value used for *ex ante* calculations should also be used for *ex post* calculations.

3. The Program Administrator Cost (PAC) test of cost-effectiveness should also be considered in evaluating program and portfolio cost-effectiveness. Under the PAC test, the program benefits are the same as the TRC test, but costs are defined differently to include the net present value of costs incurred by the program administrator (including financial incentives and rebates paid to anyone), but not the costs incurred by the participating customer. Like the TRC test, the PAC test is calculated utilizing a discount rate that reflects each utility's weighted cost of capital, as adopted by the Commission.

4. Applying both the TRC and PAC cost-effectiveness test is called the "Dual-Test". In almost all instances, an energy efficiency program that passes the TRC test will also pass the PAC test. However, if deployment of the program requires rebates or financial incentives to participants that exceed the measure cost, then the program may pass the TRC test, but fail the PAC test. Considering the results of both tests when evaluating program proposals ensures that program administrators and implementers do not spend more on financial incentives or rebates to participating customers than is necessary to achieve TRC net benefits.

5. TRC and PAC benefits should be computed utilizing the avoided cost methodologies and input assumptions, including non-price factors (e.g., for avoiding greenhouse gas and non-greenhouse gas pollutants) that have been developed for the evaluation of energy efficiency programs in our avoided cost rulemaking, R.04-04-025[11]. The performance earnings basis (PEB) of energy efficiency resource programs shall be calculated from TRC and PAC benefits (being equal) minus TRC and PAC costs weighted two-thirds and one-third respectively. (D.05-04-051).

6. A prospective showing of cost-effectiveness using the Dual-Test for the entire portfolio of ratepayer-funded energy efficiency activities and programs (i.e., individual programs, plus all costs not assignable to individual programs, such as overhead, planning, evaluation, measurement verification and administrator compensation and performance, if applicable) is a threshold condition for eligibility for ratepayer funds. This prospective showing of cost-effectiveness shall include the costs for shareholder incentives that are projected

[11] See D.05-04-024 and D.06-06-063.

to be paid for portfolio performance under the energy efficiency risk/reward incentive mechanism in effect at that time.[12] This threshold requirement applies to each of the following: (1) the entire statewide portfolio of programs and (2) the service-territory wide program portfolios offered by each Program Administrator, excluding emerging technologies programs. Program administrators must demonstrate that this threshold requirement is met on a prospective basis in their program funding applications to the Commission. If a prospective showing of cost-effectiveness for the entire statewide portfolio *including emerging technologies programs* does not also pass the Dual-Test, Program Administrators shall describe the benefits associated with these programs that are not reflected in the TRC or PAC tests, and describe how these programs are expected to produce benefits in excess of costs for California ratepayers over the long-term. Program Administrators must also demonstrate that the proposed level of electric and natural gas energy efficiency program activities are expected to meet or exceed the Commission-adopted electric and natural gas savings goals, by service territory.[13]

7. As described in these Rules, fuel-substitution programs must also pass the Dual-Test to be considered for inclusion in the portfolio and eligible for funding. In addition, as a condition for the inclusion of solar water heating within the definition of energy efficiency measures, solar water heating installations must be cost-effective on a stand-alone basis, i.e., pass the Dual-Test of cost-effectiveness to be eligible for funding. Similarly, solar-powered water circulators must be cost-effective on a stand-alone basis (i.e., pass the Dual-Test) to be eligible for funding.[14] Other programs are not strictly required to pass the Dual test on a program level basis to be considered for funding, but their cost-effectiveness must be carefully considered in order to design an overall portfolio that passes the Dual-Test, per Rule IV.6. Accordingly, except where otherwise indicated in these Rules, Program Administrators must present estimates of TRC and PAC net benefits for each program on a prospective basis in their program funding applications, along with any other information that may be requested by the Commission, Assigned Commissioner, Administrative Law Judge or Energy

[12] D.07-09-043, Mimeo page 220.

[13] Per D.04-09-060, savings from LIEE programs will also count towards these goals.

[14] Per D.07-11-004, eligible for 2006-2008 funding and cumulative savings goals.

Division.[15] However, evaluation, measurement and verification costs should not be allocated to individual programs in the calculation of TRC and PAC net benefits. Rather, all costs associated with evaluation, measurement and verification should be allocated at the total portfolio level, rather than program by program.

8. To support comparisons of all resources in the utilities' procurement portfolio, the program administrators are required to also provide levelized unit cost estimates at the portfolio, end-use and measure level consistent with the methods described in the SPM. This information should be submitted with the program administrators' compliance filings on the competitive bid results, during each program cycle.

9. The usefulness of the TRC test as a primary indicator of cost-effectiveness is limited for certain programs which do not necessarily focus on the timing or type of resource needs of the utility, such as programs designed to demonstrate or commercialize promising emerging energy efficiency technologies or structurally change the marketplace. For statewide marketing and outreach programs and information-only programs, the link between programs and savings is also difficult to discern. Therefore, the Commission and program administrators will need to consider factors and performance metrics other than the TRC and PAC Tests of cost-effectiveness when evaluating such program proposals for funding and when evaluating their results.

10. Fuel substitution programs may offer resource value and environmental benefits. Fuel-substitution programs should reduce the need for supply without degrading environmental quality. Fuel-substitution programs, whether applied to retrofit or new construction applications, must pass the following three-prong test to be considered further for funding:

1. The program must not increase source-BTU consumption. Proponents of fuel substitution programs should calculate the source-BTU impacts using the current CEC-established heat rate.

2. The program must have TRC and PAC benefit-cost ratio of 1.0 or greater. The TRC and PAC tests used for this purpose

[15] See, for example, Ordering Paragraph 4, D.04-09-060.

should be developed in a manner consistent with these Rules.

3. The program must not adversely impact the environment. To quantify this impact, respondents should compare the environmental costs with and without the program using the most recently adopted values for residual emissions in the avoided cost rulemaking, R.04-04-025. The burden of proof lies with the sponsoring party to show that the material environmental impacts have been adequately considered in the analysis.

For purposes of applying these tests, fuel substitution proponents must compare the technologies offered by their program with the most efficient same-fuel substitute technologies available to prospective participants that would have TRC and PAC benefit-cost ratio of 1.0 or greater. The burden of proof falls on the party sponsoring the analysis to show that the baseline comparison adheres to this requirement. Fuel substitution programs with a predominantly load building or load retention character are not eligible for funding, and the proponent of a fuel-substitution program carries the burden of proof to demonstrate that the program focuses on energy efficiency and creates net resource value.

11. To the extent possible, the assumptions that are used to estimate load impacts (e.g., kWh, kW and therm savings per unit, program net-to-gross ratios, incremental measure costs and useful lives) in the calculation of the TRC and PAC tests shall be taken from the most up-to-date version of the Database for Energy Efficiency Resources (DEER). [16] If the required cost-effectiveness test inputs for a measure to be included into a portfolio are not available in DEER, documentation supporting the inclusion of new information from alternate sources must be provided to Energy Division for review and approval prior to the inclusion of that measure's use in a savings claim or to a portfolio filing's approval. Cost-effectiveness parameters for non-DEER measures should be developed using methods and data from DEER to the extent possible. The evaluation, measurement and verification protocols for post-2005 programs will include a schedule and process for updating DEER on a regular basis. (See Rule V.2 below) (D.08-01-042)

---

[16] See Appendix A of this manual for information on how to access DEER.

12. Costs and energy savings from mid-budget cycle funding additions for programs other than low income energy efficiency (LIEE) programs shall be counted when calculating portfolio cost-effectiveness and the performance earnings basis in applying the energy efficiency risk/return incentive mechanism. Energy savings from mid-budget cycle funding additions shall count towards the utilities' energy efficiency goals for resource planning purposes only. Such savings shall not be counted towards the energy efficiency goals for the purpose of 1) satisfying the minimum performance standard (MPS) associated with the energy efficiency risk/reward incentive mechanism, or 2) determining which "performance band" (e.g., deadband or applicable earnings tier level) should be used in calculating incentive payments or penalties. Each proposal to augment energy efficiency program funding must be carefully reviewed to ensure that such funding is not misclassified as LIEE, given the implications associated with LIEE classification that carry over to the adopted incentive mechanism. Savings associated with any mid-cycle funding augmentation to the LIEE program will not count towards the MPS. (OP 7, D.07-10-032)

V. Evaluation, Measurement and Verification (EM&V)

1. The development of energy efficiency programs that deliver reliable energy savings for California's ratepayers depends on well-designed methods of portfolio performance evaluation, measurement and verification (EM&V). Rigorous and strategically focused EM&V practices are required to gauge the performance of Program Administrators and Implementers, verify energy savings, improve the design and success of future energy efficiency programs and enhance the reliability of forecasted savings for resource planning purposes.

2. The performance basis and related EM&&V protocols for energy efficiency portfolios and programs for post-2005 energy efficiency activities were developed in the EM&&V phase of Rulemaking 01-08-028, and updated in Rulemaking 06-10-040, consistent with these Rules. The California Energy Efficiency Evaluation Protocols were initially adopted by ALJ Ruling dated April 25, 2006 (later updated in June 2006) to specify the current **minimum** acceptable approaches and procedures for the evaluation of utilities energy efficiency portfolios. Per D.05-01-055, Energy Division will have the lead role in the further development of EM&V protocols and procedures and the assigned ALJ may provide additional clarification and direction on EM&V administrative issues as needed.

3. In D.05-04-051 the Commission defined the current performance earnings basis, or PEB, as the net dollar benefits to ratepayers of the utilities portfolios calculated as specified in IV.5. above. In D. 07-09-043 the Commission defined the Minimum Performance Standard threshold, or MPS, for evaluation of the utility portfolios. Together the MPS and PEB form the "performance basis" focus for energy efficiency portfolio performance evaluation. Additionally, portfolio evaluation efforts are to be structured such that they can: 1) inform the program selection process, 2) provide early feedback to program implementers, 3) produce calculations of performance basis at the end of the funding period, and 4) feed back into the planning process for the next program cycle.

4. D.05-01-055 adopts an approach to EM&V administration whereby Energy Division has management and contracting responsibilities for all EM&V impact-related studies that will be used to 1) measure and verify energy and peak load savings; 2) generate data for savings estimates, cost-effectiveness inputs, and the Commission's adopted performance basis; and 3) evaluate whether portfolio goals are met.

5. As also directed in D.05-01-055, public participation in the development of impact-related evaluation studies will be provided in several stages including: 1) development of the EM&V protocols; 2) the overall EM&V plans, budget and the allocation of funding levels to studies will be addressed during each program planning cycle; 3) study results will be made available for public review and comment while in draft form; and 4) finalized studies will be made available for public review in an appropriate forum established by Assigned Commissioner's ruling.

6. D.05-01-055 adopts an approach to EM&V administration whereby Program Administrators and program implementers may directly contract for (and serve as technical lead in managing) program design evaluation and market assessment studies to assist them in selecting and managing a portfolio of programs to meet the Commission's objectives as well as provide them with access to information on a real-time basis to improve program delivery. While soliciting input from Energy Division, the Program Administrators should also take the lead in allocating Commission-authorized funding for this category of EM&V across individual studies, develop the scope of work for each study and prepare the RFPs. In their program plan applications, the Program Administrators should also describe each type of study (including general scope of work) they or their program implementers plan to manage and/or directly contract for in this category. All interested parties should have an opportunity to consider whether any of those proposed studies would create a conflict of

interest if the IOU Program Administrators or program implementers managed and directly contracted for them.

VI. Competitive Bidding and Partnership Programs

1. Competitive solicitations can help to identify innovative approaches or technologies for meeting savings goals with improved performance that might not otherwise be identified during the program planning process. However, not all program activities lend themselves to a competitive solicitation. It would be counterproductive to require open bids in instances where, for example, partnerships between IOUs and local governments ("local government partnership programs") can take advantage of the unique strengths that both partners bring to the table, or a combination of partnerships and bilateral contracting arrangements with private or public entities can deliver effective statewide initiatives, such as a statewide public awareness campaign or an upstream lighting program.

2. Competition in energy efficiency procurement should focus on soliciting good, new program ideas to achieve or exceed the Commission's savings goals, rather than allocating a specific percentage of program funding to particular implementers. Decisions on whether non-IOUs should be program implementers responsible for designing and delivering the program (rather than working to implement IOU-designed programs) should be made based on an evaluation of whether the program designs and delivery mechanisms proposed by non-IOUs are superior to those currently being implemented or planned for the future in achieving overall portfolio savings goals.

3. As directed in D.05-01-055, for each program planning cycle, the Program Administrators shall propose a portfolio of programs (with input from the Program Advisory Groups as described in that decision) that reflects the continuation of successful IOU and non-IOU implemented programs and new program initiatives designed to meet or exceed the Commission's savings goals with cost-effective energy efficiency. As part of that process, the Program Administrators will identify a minimum of 20% of funding for the entire portfolio of programs that will be put out to competitive bid to third-parties for the purpose of soliciting innovative ideas and proposals for improved portfolio performance. Per D.07-10-032, successful third-party programs from the 2006-2008 program cycle retained by the IOUs for successive budget cycles will count

towards the 20% and the extensions should be able to be structured as bilateral contracts. (D.07-10-032, OP 19) The portions to put out to bid could encompass programs currently designed and delivered by a combination of IOU and non-IOU program implementers. Any current program or group of programs (IOU or non-IOU designed and implemented) that can be improved upon in this way may be subject to open bids to replace, augment or otherwise enhance current efforts. However, open bids should not be required in instances where current or potential future partnerships between the Program Administrators and local governments can take advantage of the unique strengths that both partners bring to the table to deliver cost-effective energy efficiency services, or where combination of partnerships and bilateral contracting arrangements with private or public entities can deliver effective statewide initiatives that enhance portfolio performance. Such activities should be funded out of the 80% (maximum) core portfolio that is not put out to competitive bid.

4. As directed in D.05-01-055, the proposed portfolio of programs, portions to put out to bid and the bid evaluation criteria will be filed by the Program Administrators in their program plan applications for each funding cycle, and subject to Commission approval. Upon receiving Commission approval of the applications, the Program Administrators will complete the process of selecting programs and program implementers to design and deliver the programs in the next program cycle. During this process, the Program Administrators will develop and issue RFPs using criteria approved by the Commission and select a set of bids. For the 2007-2011 program cycle, third-party proposals will be included in the utility's portfolio application and the competitively bid RFP process and the PRG's review to ensure that the criteria are applied properly will occur prior to the utility's submittal of the application, as directed in D.07-10-032. The Peer Review Groups (including Energy Division's independent consultant(s)) will observe the Program Administrators' bid selection process to ensure that the criteria are applied properly. Before finalizing their selections, the Program Administrators will discuss the proposed results of their bid review process with the Peer Review Groups (and Energy Division's independent consultants). After incorporating feedback, the Program Administrators will make public all winning bids and submit compliance filings, as directed in D.05-01-055.

5. Future partnership programs need to be developed in a manner that places the Program Administrator and local government (or private) partner on more equal footing, in terms of involvement in program design and planning, information sharing and program implementation. We recognize that some program partners may prefer or be best suited to functioning as a subcontractor

to the Program Administrator and performing a supporting role for the program. However, this should not be the only option available for partnership programs. Other partnership arrangements, e.g., where the local government partner is fully involved in program planning and implementation, may take better advantage of the relative strengths of each partner. These arrangements must, in any event, be considered in light of other applicable Commission decisions, including the implementation of community choice aggregation , and should in no way diminish or dilute the responsibility and accountability of Program Administrators to meet the Commission-adopted savings goals.

6. Standard contract language should improve the effectiveness of future partnership programs. The standard language should establish the rights and responsibilities of the partners with sufficient flexibility to enable each partner to make improvements to program performance, as circumstances warrant. The standard language should also address information sharing, intellectual property ownership, reimbursement turn-around, dispute resolution, and other issues. Energy Division and Legal Division should work with the Program Administrators, interested local governments and other parties to develop a standard contract for future partnership programs, and submit that language with the program plans.

VII. Advisory Groups

Decision 07-10-032 eliminated the Public Advisory Groups (PAGs) for the purposes of planning for the 2009-11 program cycle and beyond. The following rules combine the functional descriptions of the PAGs with the Peer Review Groups (PRGs) for the 2006-2008 program cycle and the 2009-11 program cycle and beyond, and should be applied to the appropriate program cycle.

1. The Program Administrators should put together the advisory groups and implement the program design and selection process consistent with D.05-01-055 and D.07-10-032 and in the spirit of the collaborative approach they discuss in their filings. For 2009 and beyond, the Public Advisory Group (PAG) is eliminated while the Peer Review Group (PRG) is retained. Per Decision 07-10-032, the advisory function formerly performed by the PAG will be subsumed in the statewide strategic planning activity. These advisory groups should serve to: (1) promote transparency in the Program Administrator's decision-making process; (2) provide a forum to obtain valuable technical expertise from stakeholders and non-market participants; (3) encourage collaboration among stakeholders and (4) create an additional venue for public participation. The advisory groups will provide advice and feedback to the IOUs and provide

information to the Commission, but will not have any independent decision-making or contracting authority.

2. As discussed in D.05-01-055, members of the PAGs should be drawn from the energy efficiency expertise of both market and non-market participants across the full spectrum of program areas and strategies. One purpose of the PAGs is to provide guidance to the IOUs regarding region-specific customer and program needs, and provide a forum for input and collaboration with the local interests and stakeholders served by the programs. However, the PAGs must not focus exclusively on region-specific needs. The IOUs and their PAGs should also address statewide programs and consistency issues, bringing in national expertise as appropriate to consider these issues. For the purpose, the IOUs should form a subgroup of their PAG members who will closely collaborate and coordinate on statewide marketing and outreach, support for building codes and standards, education and training and other activities that secure both short- and long-term energy savings and peak demand reductions by providing a consistent and recognizable program presence throughout the state. In addition, the PAGs and IOUs should collaborate on statewide program designs and implementation strategies that increasingly integrate energy efficiency with demand response and distributed generation offerings to end-users. For 2009 and beyond, the Public Advisory Group (PAG) is eliminated while the Peer Review Group (PRG) is retained. Per Decision 07-10-032, the advisory function formerly performed by the PAG will be subsumed in the statewide strategic planning activity.

3. The IOUs and PAGs should ensure that statewide residential and nonresidential offerings take advantage of "best available practices" and avoid customer confusion by being as uniform and consistent as possible. While we recognize that differences in climate zones and other parameters may warrant some variations in program offerings to customers, these variations should be the exception and not the rule. If the need emerges to focus on a particular market segment, the IOUs and PAGs may also establish a separate working group of industry experts and stakeholders to address that need.

4. Energy Division and DRA staff will be *ex officio* members of each PAG and peer review subgroup described below, and CEC staff is invited to participate as *ex officio* members as well. The IOUs will select additional PAG members, but participation will be voluntary and there will be no formal voting rules or designation of voting or non-voting members. Within each PAG, the IOU will also identify and select a subgroup of non-financially interested members with extensive energy efficiency expertise that are willing to serve as

peer reviewers for the energy efficiency program evaluation and selection process, referred to as "Peer Review Groups" (PRGs.)

5. As described in D.05-01-055 and D.07-10-032, members of each PRG will be expected to: (1) oversee the development of criteria and selection of government partnership programs, (2) review the IOUs' submittals to the Commission and assess the IOUs' overall portfolio plans, their plans for bidding out pieces of the portfolio per the minimum bidding requirement and (3) review the bid evaluation utilized by the IOUs and their application of that criteria in selecting third-party programs. In addition, the three PRGs are expected to meet and assess the statewide portfolio in terms of its ability to meet or exceed short and long-term savings goals in compliance with these Rules.

6. The PAG meetings should be open to the public, and the IOUs should establish a clearinghouse website for noticing these meetings and posting documents to be discussed by the PAG at the meetings. In addition, the IOUs are expected to conduct public workshops, at least twice a year that are designed to solicit broad public input from non-PAG members concerning program design and implementation. For 2009 and beyond, the Public Advisory Group (PAG) is eliminated while the Peer Review Group (PRG) is retained. Per Decision 07-10-032, the advisory function formerly performed by the PAG will be subsumed in the statewide strategic planning activity.

VIII. Performance-Based Risk and Reward Incentive Mechanism

1. In accordance with Public Utilities Code Section 739.10, the Commission has established balancing accounts for each utility that remove significant regulatory disincentives for utility investments in energy efficiency and other demand-side management programs. With these balancing accounts, a large majority of the utilities' fixed-cost revenue requirements are no longer tied to the forecasted level of commodity electric and natural gas sales.

2. Per D.07-09-043 OP 2, as modified by D.08-01-042 OP 2, the risk/reward shareholder incentive mechanism applies to the energy efficiency programs funded for the 2006-2008 program cycle and for subsequent program cycles until further Commission notice. The risk/reward shareholder incentive mechanism is structured as follows:

a) To be eligible for earnings, SDG&E, PG&E and SCE shall meet the following minimum performance standard (MPS) for the energy efficiency portfolio as a whole, on an *ex ante* basis for load impacts, with verified installations and costs:

(1) Achieve a minimum of 85% of the Commission-adopted savings goals, based on a simple average of the percentage of each individual gigawatt-hour (GWh), megawatt (MW) and, as applicable, million therm (MTherm) goal they achieve, *and also*

(2) Meet a minimum of 80% of the goal for each individual savings metric.

b) SoCalGas shall meet the MPS and be eligible for earnings if it achieves a minimum of 80% of the MTherm savings goal on an *ex ante* basis for load impacts, with verified installations and costs.

c) Once the utility meets the MPS, earnings shall be calculated as a percentage (sharing rate) of the "performance earnings basis" (PEB) metric defined in Decision (D.) 94-10-059, as follows:

(1) Portfolio net benefits calculated using the Total Resource Cost test of cost-effectiveness are weighted by two-thirds, and

(2) Portfolio net benefits calculated using the Program Administrator Cost test of cost-effectiveness are weighted by one-third.

d) Program savings and costs shall be counted in determining whether the MPS is met and in calculating the PEB, as follows:

(1) Savings from low-income energy efficiency (LIEE) programs shall count towards determining whether the utilities have met their MPS, but neither LIEE program costs nor savings shall be included in the calculation of the PEB under the risk/reward shareholder incentive mechanism.

(2) With the exception of the Emerging Technologies Program and LIEE, all energy efficiency portfolio costs including associated evaluation, measurement and verification (EM&V) shall be included in the calculation of PEB.

(3) Verified savings from Codes and Standards Advocacy Programs[17] shall count as described in (a) and (b) below. Codes and Standards savings are to be *verified* (as opposed to *ex ante* estimates used for planning purposes).

(a) Fifty (50) percent of verified savings from pre-2006 Codes and Standards Advocacy Programs shall count towards the energy savings goals and minimum performance standards for the 2006-2008 (per D.07-09-043) and 2009-2011 (per D.07-10-032) program cycles.

(b One hundred (100) percent of verified savings from post-2005 Codes and Standards Advocacy Programs shall count towards the energy savings goals, minimum performance standards and performance earnings basis for the 2006-2008 and 2009-2011 program cycles.

Codes and Standards Advocacy costs are included as they are incurred in calculating the performance earnings basis and savings are included as they are realized.

e) If the utility has met the MPS, a first tier sharing rate of 9% shall apply. If the utility has met 100%

[17] D.05-09-043 and Attachment 10. ***Note*** – The 50% verified savings calculation for Codes and Standards Advocacy work applies only to savings leading to the adoption of the 2005 standards developed by the CEC. At the time, installed savings and committed savings had been counted during the same budget cycle. D. 05-04-051 had adopted a policy to count only verified savings. To avoid double counting of committed savings with verified savings, a methodology was developed and adopted to derive the amount of savings attributable to reducing energy over the future years concerned (post 2005) using a calculation considering economic potential, market potential and naturally-occurring savings associated with the codes adopted. The result was 50%.

of the savings goals, a second tier sharing rate of 12% shall apply, up to the earnings cap adopted for each utility.

(1) If the MPS is met, each individual savings metric must be no less than 5% below the second tier threshold to be considered within that tier based on the three-metric average.

(2) If the MPS is met utilizing *ex ante* assumptions for load impacts, with verified installations and costs, but the *ex post* EM&V results take an individual metric below the 80% threshold or take the overall portfolio results to between 65% and 85% of the Commission-adopted savings goals, the utility shall continue to earn at the first tier sharing rate of 9%, applied to the *ex post* PEB, and shall not return any interim claims payments. If, however, *ex post* results take a utility below 65% of Commission goals for any individual metric, the utility shall pay back any interim payments, in addition to any applicable penalty.

f) Penalties shall begin to accrue if portfolio performance for any single savings metric (GWh, MW or MTherm) falls to or below 65% of the savings goal for that metric. If this occurs, the larger of the following penalty provisions apply up to the penalty cap adopted for each utility:

(1) 5¢/kWh, 45¢/therm and $25/kW per unit penalties applied to each unit below the savings goal, or (if larger):

(2) Dollar-for-dollar payback of negative net benefits ("cost-effectiveness guarantee"), where negative net benefits are calculated based on the PEB formula adopted in D.04-10-059.

g) Total earnings and penalties are capped for the four utilities combined at $450 million over each three-year program cycle, beginning with the 2006-2008 program cycle. The $450 million combined cap is allocated to each utility as follows: PG&E--$180 million; SCE--$200 million; SDG&E-$50 million and SoCalGas--$20 million.

3. Earnings (or penalties) under the risk/reward shareholder incentive

mechanism shall be paid as follows:

a) There shall be two "progress payment" interim earnings claims and one final true-up claim for each three-year program cycle. They shall be linked to Energy Division's Verification and Performance Basis Reports as described in D.07-09-043 and in its Attachment 6.

b) Interim claims shall be evaluated on a "Cumulative-to-Date" basis, which counts the verified achievements from program year(s) in determining whether the MPS is met in each subsequent interim claim.

c) Thirty-five (35) percent of the earnings calculated for each interim claim shall be "held back" until the final true-up claim, in order to minimize the risk of overpaying earnings before the *ex post* true-up of load impacts in the final claim. (D.08-01-042)

d) The costs of shareholder incentives shall be included in calculations when (1) evaluating the cost-effectiveness of program plans submitted during the program planning cycle (on a projected basis), or (2) conducting a cost-effectiveness review of portfolio performance in hindsight. These costs shall not be included in the calculation of PEB.

See Appendix A for a graphic illustrating this mechanism.

4. Per D.08-01-042, for the 2006-2008 program cycle, the following *ex ante* assumptions of energy savings and demand reductions shall be used in conjunction with verified installations and verified costs to calculate the 1st and 2nd Claims:

(a) Except as otherwise provided for below, the *ex ante* measure savings parameters that are contained in the utilities' E3 calculators, as of the 4th quarter 2007 report for the 1st Claim and as of the 4th quarter 2008 report for the 2nd Claim.

(b) For measures contained in the Database for Energy Efficient Resources (DEER), the 2008 and 2009 DEER updates of *ex ante* measure savings parameters, including net-to-gross ratios and expected useful lives. The 2008 DEER update shall apply to the 1st Claim and the 2009 DEER update shall apply to the 2nd Claim.

(c) For customized measures or customized projects that represent aggregated measures in the E3 calculator, Energy Division shall identify the appropriate installed measure(s) based on its measure verification results and develop the associated *ex ante* load impact values. For this purpose, Energy Division may use the utilities' tracking system information, engineering workpapers, DEER values and methods, or other current measurement and verification results that are available.

5. Per D.08-01-042, direction on the *ex ante* assumptions used to calculate interim claims during the 2009-2011 program cycle shall be provided in the decision authorizing the 2009-2011 program plans.

6. Procedures for Review and Approval of Earnings/Penalties under the Energy Efficiency Risk/Reward Incentive Mechanism[18]. (D.07-09-043, OP 5, Attachment 7)

6a. <u>*Interim Claims*</u> - Payments under the interim claim(s) represent a "progress payment" towards total expected earnings:

(1.) Evaluation contractors use data requested from investor-owned utility (IOU) program tracking databases and reports to develop Contract Group[19] level reports that verify unit installations.

---

[18] These procedures augment and substitute for Attachment 4 to *Administrative Law Judge's Ruling Adopting Protocols for Process and Review of Post-2005 Evaluation, Measurement and Verification Activities,* dated January 11, 2006.

[19] These procedures augment and substitute for Attachment 4 to *Administrative*

Footnote continued on next page

(2.) California Public Utility Commission (CPUC) audit team develops financial audit reports that verify portfolio costs for each utility.

(3.) Energy Division aggregates evaluation contractor reports and *ex ante* measure parameters (updated as directed in VIII.4 and VIII.5 above) for each utility to quantify the portfolio resource benefits and uses that quantity in connection with the audit team reports to develop the draft Verification Report, which is posted on a publicly accessible website. Energy Division notifies the CPUC Energy Efficiency service lists and lists of other interested stakeholders [20] maintained by Energy Division of the availability of the draft Verification Report and the website posting location. Energy Division also notifies all of those stakeholders of the conference described in the next Step.

(4.) Energy Division holds a conference by telephone or in person. At this meeting, all stakeholders have an opportunity to discuss the draft Verification Report with those who prepared it (and supporting consultants). Stakeholders may raise questions about the draft report, receive responses from those who prepared it, and point out any errors they believe are contained in the report. The goal is to have a give and take between the stakeholders, report authors, and the supporting technical experts.

(5.) Stakeholders have an opportunity to provide written comments to Energy Division identifying any errors in the draft Verification Report. Stakeholders will be required to include in the written comments at least a brief description of every point in the draft report which they believe needs correction, even if discussed at the conference.

Law Judge's Ruling Adopting Protocols for Process and Review of Post-2005 Evaluation, Measurement and Verification Activities, dated January 11, 2006.

[20] "Stakeholders" refers to those listed on one of the CPUC's Energy Efficiency service list or who have notified Energy Division of their interest.

(6.) Energy Division makes any necessary changes to the Verification Report stimulated by the oral conference and written comments. All written comments, and Energy Division's treatment of them, will be reflected in an appendix to the Final Verification Report, which is posted on a publicly accessible website.

(7.) Final Verification Report is made publicly available.

(8.) Within 45 days of issuance of the Final Verification Report, the utility will file an advice letter for Energy Division disposition pursuant to section 7.6.1 of General Order 96-B, citing the Verification Report. The advice letter will address whether based on that report there are any earnings or penalties, and if so at what level, for the interim claim.

(9.) Energy Division will approve the advice letter as soon as practicable thereafter so long as it correctly incorporates the results of the Verification Report; if it does not, Energy Division will take other appropriate action under General Order 96-B.

6b. _Final Claim_ - The final claim and true-up of savings and performance basis estimates will be based on the Final Performance Basis Report:

(1.)Evaluation contractors complete draft final evaluation reports[21] and post them on a publicly accessible website. The evaluation contractors will notify the CPUC Energy Efficiency service lists and lists of other interested stakeholders maintained by Energy Division of the availability of the draft final evaluation reports and their website posting location(s). Energy Division will notify all of those stakeholders of the conference described in the next Step.

---

[21] Evaluation reports refer to either interim or final reports submitted to Energy Division by program evaluation contractors describing results of evaluations (e.g., impact evaluation studies) of the Contract Groups.

(2.) Evaluation contractors hold a conference, under Energy Division sponsorship, with stakeholders, by telephone or in-person, to discuss draft final evaluation reports.

(3.) Stakeholders have an opportunity to provide written comments identifying any errors in the draft final evaluation reports. Stakeholders will be required to include in the written comments at least a brief description of every point in the draft report which they believe needs correction, even if discussed at the conference.

(4.) Energy Division directs evaluation contractors to make any necessary changes to final evaluation reports stimulated by the comments. All written comments, and Energy Division's treatment of them, will be reflected in appendices to the final evaluation reports. The final evaluation reports are posted on a publicly accessible website.

(5.) Within 60 days of public release, program administrators will respond in writing to the final report findings and recommendations indicating what action, if any, will be taken as a result of study findings as they relate to potential changes to the programs. Energy Division can choose to extend the 60 day limit if the administrator presents a compelling case that more time is needed and the delay will not cause any problems in the implementation schedule, and may shorten the time on a case-by-case basis if necessary to avoid delays in the schedule.

(6.) Energy Division aggregates evaluation contractor reports for each utility to quantify the portfolio resource benefits and uses that quantity in connection with the audit team reports to develop the draft Final Performance Basis Report. Energy Division will notify the CPUC Energy Efficiency service lists and lists of other interested stakeholders maintained by Energy Division of the availability of the draft Final Performance Basis Report and the website posting location. Energy Division also notifies all of those stakeholders of the conference described in the next Step.

(7.) Energy Division, with the assistance of relevant contractors holds a conference with stakeholders, by telephone or in-person. At this meeting, all stakeholders have an opportunity to discuss the draft Final Performance Basis Report with those who prepared it (and supporting consultants). Stakeholders may raise questions about the draft report, receive responses from those who prepared it, and point out any errors they believe are contained in the report. The goal is to have a give and take between the stakeholders, report authors, and the supporting technical experts.

(8.) Stakeholders have an opportunity to provide written comments identifying any errors in the draft Final Performance Basis Report. Stakeholders will be required to include in the written comments at least a brief description of every point in the draft report or which they believe needs correction, even if discussed at the conference.

(9.) Energy Division makes any necessary changes to the Final Performance Basis Report stimulated by the oral conference and written comments. All written comments, and Energy Division's treatment of them, will be reflected in an appendix to the Final Performance Basis Report.

(10.) Final Performance Basis Report is made publicly available by posting on a publicly accessible website and sending it to the Energy Efficiency proceeding service list(s).

(11.) Within 60 days of issuance of the Final Performance Basis Report, the utility will file an advice letter for Energy Division disposition pursuant to section 7.6.1 of General Order 96b, citing the Final Performance Basis Report. The advice letter will address whether based on that report there are any earnings or penalties, and if so at what level, for the final claim.

(12.) Energy Division will approve the advice letter as practicable as possible thereafter so long as it correctly incorporates the results of the Final Performance Basis Report; if it does not, Energy Division will take other appropriate action under General Order 96-B.

IX. Affiliate and Disclosure Rules

1. To avoid anti-competitive behavior and cross-subsidies between IOUs and their affiliates, all transactions between the IOU administrator and any implementer that is an affiliate of PG&E, SCE, SDG&E or SoCalGas are banned, per D.05-01-055.

2. The Program Administrators will not provide preferential treatment to any provider of an energy efficiency service that uses energy efficiency program funds.

3. Bidders for EM&V contracts, including program design evaluation and market assessment studies, shall provide full disclosure of any potential conflicts of interest, including all current non-energy efficiency related contracts with Program Administrators and program implementers.

X. Reporting Requirements

1. The Program Administrators shall present information in their program planning applications in compliance with Ordering Paragraph 13 of D.04-12-048, and in compliance with any further direction by this Commission, the Assigned Commissioner or Administrative Law Judge regarding the content or format of these filings. Energy Division may develop reporting requirements through workshops or other means to ensure that the types of data and the format of the information presented in the Program Administrator filings and reports is as consistent as possible.

2. The Program Administrators shall file reports on portfolio and program activities on a regular basis during the program cycle using the standardized reporting formats, definitions, timelines and narratives established by the Energy Division, as updated from time to time. The design and oversight of program-specific, portfolio-level and financial reporting requirements for energy efficiency activities will remain the responsibility of the Energy Division, as discussed in D.05-01-055. Energy Division shall design the reporting requirements in consultation with the Assigned Commissioner and Administrative Law Judge.

3. In addition to other reports that may be required, the Program Administrators shall publish a summary of the achievements of the energy efficiency programs on an annual basis. This report will be available to the public on the web and will contain at least the following information for the entire portfolio as well as

each utility's portfolio: (1) energy savings (annual, cumulative, and lifecycle kWh and therms), peak demand savings[22], levelized costs, cost per kW saved, total cost to billpayers, total savings to billpayers, net benefits to billpayers and environmental benefits (tons of CO2 and other pollutants avoided). Following each program cycle, a summary of the *ex post* measured achievements from the entire portfolio will also be published.

4. The utilities shall incorporate the correction in the E3 calculator to the erroneous demand reduction estimated for lighting currently contained in DEER that is discussed in Section 8.3 of D.05-09-043. (D.05-09-043, OP 11.)

5. As discussed in D.05-09-043, the utilities are required to use the August 2005 updates to *ex ante* expected useful life (EUL) assumptions posted to DEER when reporting actual installations during program implementation, and when submitting calculations of savings, portfolio cost-effectiveness and performance basis during the 2006-2008 program cycle. Staff shall ensure that inputs to the E3 calculator are appropriately adjusted, so that these calculations will reflect the *ex ante* EUL values referenced above. (D.05-09-043, OP 12.)

XI. Process and Procedural Issues

1. The Commission, the assigned Commissioner, the assigned Administrative Law Judge, or the Energy Division may utilize both formal and informal procedural vehicles as needed to (1) revise the Rules and /or any of its referenced documents, in whole or in part, at any time, upon request by interested parties or on its own initiative, and (2) resolve disputes among or complaints from various market participants, as circumstances warrant. In addition, nothing in these Rules preclude the Commission from planning and developing future energy efficiency programs, or delegating that responsibility to the assigned Commissioner, the assigned Administrative Law Judge or to Energy Division in the future.

2. The Assigned Administrative Law Judge or Commission staff may hold workshops or other forums, as needed, for interested parties, customers and market actors to provide input and feedback on energy efficiency-related issues.

---

[22] By D.06-06-063, the definition of peak megawatt load reduction contained in the 2005 Database for Energy Efficient Resources (DEER) shall be used for the purpose of verifying energy efficiency program and portfolio performance.

3. Any program proposal for energy efficiency funding must describe a dispute resolution process to be used in dealing with complaints from end-use gas or electric consumers participating or attempting to participate in the program. In programs where the Program Administrators hold contracts with third parties, those contracts will also be required to include dispute resolution provisions.

Energy Efficiency Programs

Approved Savings Goals 2006 through 2013 (D.04-09-060)

SCE

Year	Energy Savings Annual Goal (GWH/Yr)	Cumulative Energy Savings (GWH)**	Demand Reductions (MW/Yr)	Cumulative Demand Reductions (MW)**
2006	922	2574.9	207	541
2007	1046	3621.3	219	760
2008	1167	4788.5	246	1006
2009	1189	5977.2	249	1255
2010	1176	7153.4	247	1502
2011	1164	8317.1	245	1747
2012	1151	9468.5	241	1988
2013	1139	10607.6	240	**2228**

(1) Total Savings = all savings from energy efficiency programs funded by public goods charge and procureme
funding. This total includes savings from EE programs already in the CEC forecast. For incremental savings a
the levels included in the CEC forecast, see D.04-09-060 Attachment 9.
(2) GWh savings converted to MW by multiplying by .21, average of utility GWh to peak savings for 2004/5 applications. This is an estimate of average peak savings not coincident peak = GWH savings in peak period /
hours in period.

PG&E

Year	Gas Savings Annual Goal (MMTh/Yr)	Cumulative Gas Savings (MMTh)**	Energy Savings Annual Goal (GWH/Yr)	Cumulative Energy Savings (GWH)**	Demand Reductions (MW/Yr)	Cumulative Demand Reductions (MW)**
2006	12.6	32.1	829	2316.5	180	503
2007	14.9	47.0	944	3260.5	205	708
2008	17.4	64.4	1053	4313.5	228	936
2009	20.3	84.8	1067	5380.8	232	1168
2010	21.1	105.9	1015	6396.3	220	1388
2011	22	127.8	1086	7482.8	236	1624
2012	23	150.9	1173	8656.2	254	1878
2013	25.1	176.0	1277	9933.2	278	**2156**

(1) Total Annual Energy Savings = all savings from energy efficiency programs funded by public goods charge and procurement funding. This total includes savings from baseline EE program funding of $100 MM/yr accounted for in the CEC sales forecast. For incremental savings above the levels included in the CEC forecast, see D.04-09-060 Attachment 9.
(2) GWh savings converted to MW by multiplying by .217, which is ratio of GWh to peak savings for 2004/5 applications. This is an estimate of average peak savings not coincident peak = GWh savings in peak period / 560 hours in period.

Energy Efficiency Programs
Approved Savings Goals 2004 through 2013 (D.04-09-060)

SoCalGas

Year	Gas Savings Annual Goal (MMTh/Yr)	Cumulative Gas Savings (MMTh)**
2004	9.6	9.6
2005	9.6	19.3
2006	14.7	34.0
2007	19.3	53.3
2008	23.3	76.5
2009	27.2	103.7
2010	28.3	132.0
2011	29.9	161.9
2012	32.3	194.2
2013	35.8	230.1

Total Savings = all savings from energy efficiency programs funded by public goods charges and procurement funding.
This total includes natural gas savings from energy efficiency programs already included in the CEC forecast.

SDG&E

Year	Gas Savings Annual Goal (MMTh/Yr)	Cumulative Gas Savings (MMTh)**	Energy Savings Annual Goal (GWH/Yr)	Cumulative Energy Savings (GWH)**	Demand Reductions (MW/Yr)	Cumulative Demand Reductions (MW)**
2004	1.8	1.8	268.4	268.4		50.4
2005	1.8	3.6	268.4	536.8		100.7
2006	2.7	6.3	280.5	817.3	54.6	155.3
2007	3.1	9.5	285.1	1102.4	54.2	209.5
2008	3.7	13.1	284.4	1386.8	54	263.5
2009	4.1	17.3	282.3	1669.1	53.6	317.1
2010	4.5	21.8	273.6	1942.7	52	369.1
2011	4.9	26.7	262.5	2205.2	49.9	419
2012	5.3	32.0	221.7	2426.9	42.1	461.1
2013	5.7	37.6	214.9	2641.8	40.8	**501.9**

Total Savings = all savings from EE programs funded by public goods charge and procurement funding. This total includes savings from EE programs already in the CEC forecast. For incremental savings above the levels included in the CEC forecast, see D.04-09-060, Attachment 9)
MW Savings derived by multiplying GWh Savings by 0.19, average value SDG&E GWh to peak savings for 2004/5 applications. This is an estimate of average peak savings during all the peak hours: = GWh savings in peak period/560 hours in period.

Total Electricity and Natural Gas Program Savings Goals (all IOUs) 2006-2013 (D.04-09-060)

		Total Annual Electricity Savings (GWh/yr)	Total Cumulative Savings (GWh/yr)	Total Peak Savings (MW)	Total Annual Natural Gas Savings (MMTh/yr)	Total Cumulative Natural Gas Savings (MMTh/yr)
2004		1,838	1,838	379	21	21
2005		1,838	3,677	757	21	42
2006		2,032	5,709	1,199	30	72
2007		2,275	7,984	1,677	37	110
2008		2,505	10,489	2,205	44	154
2009		2,538	13,027	2,740	52	206
2010		2,465	15,492	3,259	54	260
2011		2,513	18,005	3,789	57	316
2012		2,547	20,552	4,328	61	377
2013		2,631	23,183	4,885	67	444

Total annual energy savings = all savings from EE programs funded by public goods charges and Procurement funding. This total includes savings from baseline EE program funding of $100 MM/yr accounted for in the CEC sales forecast. For incremental program savings above the levels included in the CEC forecast, see Attachment 9 of D.04-09-060.

Average peak MW estimated by multiplying GWh from utility by the ratio they used in 2004/5 filings ranging from 0.19 to 0.21. This is an estimate of average peak savings, not coincident peak savings = GWh savings in peak period/560 hours in period.

EE Policy Manual Version 4.0
Appendices

D. 05-09-043

TABLE 8: ADOPTED FUND SHIFTING RULES, as modified by D.06-12-013 and D.07-10-032

Category	Shifts Among Budget Categories, Within Program	Shifts Among Programs, Within Category	Shifts Among Categories
Resource / Nonresource Programs (includes multiple program categories – see definitions below)	Yes, no formal Commission review/approval triggered.	• Yes, no formal Commission review/approval triggered. • However, 15 day PRG notification and comment required if shifts exceed 25% on an annual basis or 50% on a cumulative basis. • Adding a new program outside the competitive bid process triggers Advice letter process. • Advice letter required if allocation to third-party implementers is expected to fall below 20%.	• Yes, up to 25% on an annual basis or 50% on a cumulative basis. Advice letter required for larger shifts. • Adding a new program outside the competitive bid process triggers Advice letter process. • Advice letter required if allocation to third-party implementers is expected to fall below 20%.
C&S / ET / Statewide M&O	Yes, same as above	Advice letter required for shifts that would reduce any of these programs by more than 1% of budgeted levels.	Advice letter required to shift funds OUT of any program more than 1% of budgeted levels.
EM&V	Yes, within utility portion. Fund shifting between the utility and ED portions only with Assigned Commissioner or ALJ approval, in consultation with Joint Staff.	Not Applicable – Single Program	Assigned ALJ or Commissioner ruling required to shift funds OUT of EM&V by any amount.

For purpose of these fund-shifting rules, the Resource/Non-Resource program categories are as follows:

- Resource / Non-Resource Program categories for **SCE, SDG&E**, and **SoCalGas** are: (1) Residential; (2) Nonresidential; (3) Crosscutting (except C&S, ET, SW Marketing and Outreach, EM&V).
- Resource / Non-Resource Program categories for **PG&E** are: (1) Mass Market (residential/small commercial cross-cutting); (2) Residential targeted market sectors within Targeted Markets and (3) Non-Residential targeted market sectors within Targeted Markets.

Utility program administrators may carryover/carryback funding during the 2006-2008 program cycle without triggering a review/approval process. Authorization for utilizing 2006 funding in 2005 for specific purposes is described in D.05-09-043. Per D.06-12-013 (OP 2), utility program administrators may file an advice letter to seek authorization to shift existing, unspent uncommitted energy efficiency funds from previous program cycles to the 2006-2008 portfolio budgets to fund new energy efficiency programs or incremental energy efficiency activities as part of existing authorized programs. Utilities should consult with the PRG prior to submitting this type of advice letter. Per D.07-10-032, carryover/carryback funding is permitted during the 2006-2008 budget cycle so long as the 2009-2011 portfolio has been approved. CPUC approval is not necessary for up to 15% of the "current" program cycle. See Rules II.12 and II.13.

Changes to incentive levels or modifications to program design (such as changes to customer eligibility requirements) will not trigger Energy Division or formal Commission review, except as indicated below. We expect that the results of EM&V studies, statewide coordination efforts and ongoing consultation with advisory groups will enable utility program administrators to identify the best practices and program designs for portfolio implementation.

- If the proposed incentive level change impacts as statewide offering, e.g., is included in the deemed and calculated measure list presented in the statewide PAG meeting on August 2-3, 2005, and is less than 50% of the original incentive level on a cumulative basis over the three-year program cycle, the utility administrator will need to inform and solicit comment from the joint PRGs prior to the change taking place.
- If the proposed incentive level change impacts a statewide program offering and is more than 50% of the original incentive level on a cumulative basis, the utility administrator will follow the advice letter process described in these rules.
- The program administrator will notify the PRG of all incentive level changes that take place.

For all significant shifts in funding or modifications to program design, the utilities should seek informal review with their PRG members as part of the ongoing exchange of information during program implementation. Where an advice letter is required under these rules, absent a protest or written data request by Energy Division for additional information by the end of the 20-day protest period, the request will become effective on the twentieth day after filing. If Energy Division staff issues a data request before the end of the protest period, the response time requirements and other procedures applicable to our normal advice letter procedures, as updated by D.05-01-032, will take effect. All advice letters required for fund shifting shall be served on the service list in A.05-06-004 and R.01-08-028, or its successor rulemaking, unless otherwise specified by the assigned ALJ. The assigned ALJ, in consultation with the Assigned Commissioner, may provide further clarification on implementing these fundshifting rules, or consider modifications to these rules during the 2006-2008 program cycle, as appropriate.

APPENDIX B: GLOSSARY
COMMON ENERGY EFFICIENCY TERMS AND DEFINITIONS

Adopted Program Budget
The program budget as it is adopted by the Commission. Inclusive of costs (+/-) recovered from other sources.

Advanced Technologies
Measures or processes which exceed the efficiency or thermodynamic performance of standard energy using equipment or processes.

Affiliate
Any person, corporation, utility, partnership, or other entity 5% or more of whose outstanding securities are owned, controlled, or held with power to vote, directly or indirectly either by an administrator or any of its subsidiaries, or by that administrator's controlling corporation and/or any of its subsidiaries as well as any company in which the administrator, its controlling corporation, or any of the administrator's affiliates exert substantial control over the operation of the company and/or indirectly have substantial financial interests in the company exercised through means other than ownership. For purposes of these Rules, "substantial control" includes, but is not limited to, the possession, directly and indirectly and whether acting alone or in conjunction with others, of the authority to direct or cause the direction of the management of policies of a company. A direct or indirect voting interest of five percent (5%) or more by the administrator, its subsidiaries, or its affiliates in an entity's company creates a presumption of control.

Avoided Costs
Avoided costs refers to the incremental costs avoided by the investor-owned utility when it purchases power from qualifying facilities, implements demand-side management, such as energy efficiency or demand-response programs, or other wise defers or avoids generation from existing/new utility supply-side investments or energy purchases in the market. Avoided costs also encompass the deferral or avoidance of transmission and distribution-related costs. (D.08-01-006, Footnote 2)

Baseline Data
The initial base metric for comparing the net result of programmatic changes versus what would have happened in the absence of the program or activity.

Coincident Peak Demand
The metered or estimated demand of a device, circuit, or building that occurs at exactly the same time as the system peak for a given year and weather condition.

Community Choice Aggregators
Organizations created by local governments pursuant to Assembly Bill 117 for the purpose of procuring power and administering energy efficiency programs on behalf of local citizens.

Competitive solicitation
The process whereby parties are requested to submit bids offering innovative approaches to energy savings or improved program performance.

Conservation
Reduction of a customer's energy use achieved by relying on changes to the customer's behavior which may result in a lower level of end use service.

Conservation Measures
Activities and/or behaviors aimed at reducing energy consumption.

Conservation Programs
Programs which are intended to influence customer behavior as a means to reduce energy use.

Cost Effectiveness
An indicator of the relative performance or economic attractiveness of any energy efficiency investment or practice when compared to the costs of energy produced and delivered in the absence of such an investment.

Cream Skimming
Cream skimming results in the pursuit of a limited set of the most cost-effective measures, leaving behind other cost-effective opportunities. Cream skimming becomes a problem when lost opportunities are created in the process.

Cross Subsidization
Benefits enjoyed by one group, such as a customer class, which are funded by another group.

Customer
Any person or entity that pays an electric and/or gas bill to an IOU and that is the ultimate consumer of goods and services including energy efficiency products, services, or practices.

Cumulative Savings
As clarified in D.07-10-032, cumulative savings represent the savings in that year from all previous measure installations (and reflecting any persistence decay that has occurred since the measures were installed) plus the first-year savings of the measures installed in that program year.

Dual Test
The requirement that an energy efficiency activity pass both the TRC and the PAC cost-effectiveness test.

E3 Calculator
The E3 calculator is a model developed by Energy Environmental Economics (or "E3" for use by the utilities to map Commission-adopted avoided costs to energy efficiency programs for cost-effectiveness calculations.

Effective Useful Life (EUL)
An estimate of the median number of years that the measures installed under the program are still in place and operable.

Electricity Savings
Reduced electricity use (or savings) produced by either energy efficiency investments which maintain the same level of end use service or conservation actions which usually reduce energy use by reducing the quantity or quality of the baseline energy services demanded.

Emerging Technologies
New energy efficiency technologies, systems, or practices that have significant energy savings potential but have not yet achieved sufficient market share (for a variety of reasons) to be considered self sustaining or commercially viable. Emerging technologies include early prototypes of hardware, software, design tools or energy services that if implemented will result in energy savings.

Emissions Reductions
The Commission requires annual reporting of reduced emissions of carbon dioxide (CO2), sulfur oxides (SOx), nitrous oxides (NOx), and particulate matter (PM10) as a result of energy efficiency savings. The utilities use the E3 calculator to compute the

annual electric and natural gas emissions reductions, which are the units implemented in the year times the annual emission reduction for a particular measure. The E3 calculator calculates values of CO_2 in tons per kWh or therms; NOx and PM10 are in pounds per kWh or therms.

The following equations are from the "E3 Calculator Tech Memo" found at the following web link: http://www.ethree.com/CPUC/E3%20Calculator%20TechMemo%203c.doc

Emissions Reductions

Electric Reductions: CO2 tons per year *(Emission[E][CO2])*

$$Emission[E][CO2]_y = \sum_{Q=1+(y-1)*4}^{y*4} \left(IN_{M,Q} * kWh\_A_M * NTG_M * ER[CO2]_M \right)$$

Where

- y = year of consideration. 2006 = 1. "Total Annual" used for years 2008 through the end of the implementation period.
- Q = Quarter of the year. Jan-Mar 2006 = 1.
- $IN_{M,Q}$ = # of incremental of measures implemented in quarter *Q*.
- NTG_M = Net–to-Gross ratio for measure *M*.
- $ER[CO2]_M$ = Emission rate of CO2 in tons per kWh of measure *M*. (The emissions rate for each measure is calculated using the product of the hourly measure savings load shape and the hourly heat rate for the IOU.).
- kWh_A_M = Annual kWh reduction for measure *M*.

NOX and PM-10 equations are the same. Just replace [CO2] with the appropriate indicator. Note that CO2 emission rate is in tons per kWh. NOX and PM-10 are in pounds per kWh.

Gas Reductions: CO2 tons per year *(Emission[G][CO2])*

$$Emission[G][CO2]_y = \sum_{Q=1+(y-1)*4}^{y*4} \left(IN_{M,Q} * Th\_A_M * NTG_M * ER[CO2]_{GCT} \right)$$

Where

- y = year of consideration. 2006 = 1. "Total Annual" used for years 2008 through the end of the implementation period.
- Q = Quarter of the year. Jan-Mar 2006 = 1.
- $IN_{M,Q}$ = # of incremental of measures implemented in quarter *Q*.
- NTG_M = Net–to-Gross ratio for measure *M*.
- $ER[CO2]_{GCT}$ = Emission rate of CO2 in tons per therm, based on the gas combustion type (GCT) specified on the input sheet for the measure.

Th_A_M = Annual gas reduction (in therms) for measure *M*.

NOX and PM-10 equations are the same. Just replace [CO2] with the appropriate indicator. Note that CO2 emission rate is in tons per Therm. NOX and PM-10 are in pounds per Therm.

Energy Efficiency Groupware Application 2006 (EEGA2006)

The utilities post monthly and quarterly status reports to the EEGA2006 webpage, which is accessible to the public: **http://eega2006.cpuc.ca.gov.**

End Use

1) The purpose for which energy is used (e.g. heating, cooling, lighting).
2) A class of energy use that an energy efficiency program is concentrating efforts upon. Typically categorized by equipment purpose, equipment energy use intensity, and/or building type.

Energy Efficiency

Activities or programs that stimulate customers to reduce customer energy use by making investments in more efficient equipment or controls that reduce energy use while maintaining a comparable level of service as perceived by the customer.

Energy Efficiency Measure

An energy using appliance, equipment, control system, or practice whose installation or implementation results in reduced energy use (purchased from the distribution utility) while maintaining a comparable or higher level of energy service as perceived by the customer. In all cases energy efficiency measures decrease the amount of energy used to provide a specific service or to accomplish a specific amount of work (e.g., kWh per cubic foot of a refrigerator held at a specific temperature, therms per gallon of hot water at a specific temperature, etc). For the purpose of these Rules, solar water heating and stand-alone solar-powered water circulators are eligible energy efficiency measures. (Per D.07-11-004, OP 1.)

Energy Efficiency Programs

Programs that reduce customer energy use by promoting energy efficiency investments or the adoption of conservation practices or changes in operation which maintain or increase the level of energy services provided to the customer.

Energy Efficiency Savings

The level of reduced energy use (or savings) resulting from the installation of an energy efficiency measure or the adoption of an energy efficiency practice, subject to the condition that the level of service after the investment is made is comparable to the baseline level of service. The level of service may be expressed in such ways as the volume of a refrigerator, temperature levels, production output of a manufacturing facility, or lighting level per square foot.

Evaluation, Measurement and Verification (EM&V)
Activities which evaluate, monitor, measure and verify performance or other aspects of energy efficiency programs or their market environment.

Evaluation Project Budget
The project level evaluation budget as it is defined by the program administrators or Joint Staff for internal program budgeting and management purposes. Inclusive of direct and allocated overhead and costs (+/-) recovered from other sources.

Financial Incentive
Financial support (e.g., rebates, low interest loans, free technical advice) provided to customers as an attempt to motivate the customers to install energy efficient measures or undertake energy efficiency projects. (See Rebate)

Free Drivers
A free driver is a non-participant who adopted a particular efficiency measure or practice as a result of a utility program. (From April 2006 EM&V Protocols)

Free riders (Free Ridership)
Program participants who would have installed the program measure or equipment in the absence of the program.

Fuel Substitution
Programs which are intended to substitute energy using equipment of one energy source with a competing energy source (e.g. switch from electric resistance heating to gas furnaces).

Funding Cycle
Period of time for which funding of energy efficiency programs have been approved by the Commission.

Gas Savings
Reduced natural gas usage (or savings) produced by either energy efficiency investments which maintain the same level of end use service or conservation actions which can reduce energy use by reducing the quantity or quality of the baseline services provided.

Hard to Reach, Non Residential

Those customers who do not have easy access to program information or generally do not participate in energy efficiency programs due to a language, business size, geographic, or lease (split incentive) barrier. These barriers are defined as:

Language – Primary language spoken is other than English, and/or
Business Size – Less than ten employees and/or classified as Very Small, and/or
Geographic – Businesses in areas other than the San Francisco Bay Area, San Diego area, Los Angeles Basin or Sacramento, and/or
Lease – Investments in improvements to the building benefit the business only during the lease period; landlords benefit longer.

Hard to Reach, Residential

Those customers who do not have easy access to program information or generally do not participate in energy efficiency programs due to a language, income, housing type, geographic, or home ownership (split incentives) barrier. These barriers are defined as:

Language – Primary language spoken is other than English, and/or
Income – Those customers who fall into the moderate income level (income levels less than 400% of the federal poverty guidelines), and/or
Housing Type – Multi-family and Mobile Home Tenants, and/or
Geographic – Businesses in areas other than the San Francisco Bay Area, San Diego area, Los Angeles Basin or Sacramento, and/or
Home Ownership – Renters.

Incremental Measure Cost

The additional cost of purchasing and installing a more efficient measure. Calculated from the price differential between energy-efficient equipment and standard or baseline measures. The inclusion of the word "gross" in the definition reflects incremental measure costs, which have not been adjusted for free riders. Net incremental measure costs means that the term has been adjusted for free riders; i.e., the net-to-gross ratio has been applied.

Information & Education

Information and education programs can provide a wide range of activities designed to inform or educate a customer or customer group. Generally these range from in-depth, one-on-one, on-site or centrally located classroom style instruction in topics related to energy efficiency, to programs that target information to specific types of customers, to general information provided to a wide range of customers, to short inexpensive public service announcements on FCC approved communication frequencies. Programs intended to provide customers with information regarding generic (not customer-specific) conservation and energy efficiency opportunities. For these programs, the information may be unsolicited by the customer.

Innovation Incubator
A low-cost, stand-alone program designed to grow innovative energy saving programs and processes for the larger portfolio over the long term. The incubator funds new program ideas that meet reasonable scientific scrutiny for potentially cost-effective energy savings and peak reduction.

Institutional Barriers
A type of market barrier: In this case, the internal organizational hurdles that inhibit the evaluation and or choice to take energy efficiency actions.

Least Cost/Best Fit
The procurement of cost-effective supply and demand-side resources that, regardless of ownership, meet capacity and energy deliverability requirements. Energy efficiency resources are constructed from the bottoms up approach that aggregates the demand and energy savings from various energy-saving measures and activities into applicable end-use categories such as space cooling, space heating, lighting, and refrigeration, in order to provide near- and long-term peaking, intermediate, and baseload requirements.

Levelized Cost
An estimate of the annualized cost of installing an energy efficiency measures divided by the annual energy savings. Typically calculated by multiplying the incremental cost of the measure by capital recovery factor (function of discount rate and expected useful life of the measure) and then dividing by annual energy savings.

Load Management
Programs which reduce or shift electric peak demand away from periods of high cost electricity to non-peak or lower cost time periods, with a neutral effect on or negligible increase in electric use.

Load Serving Entities
Entities that provide electric and/or gas commodity to customers.

Lost Opportunities
Energy efficiency measures that offer long-lived, cost-effective savings that are fleeting in nature. A lost opportunity occurs when a customer does not install an energy

efficiency measure that is cost-effective at the time, but whose installation is unlikely to be cost-effective if the customer attempts to install the same measure later.

Market Effect
A market effect is a change in the structure or functioning of a market or the behavior of participants in a market that result from one or more program efforts. Typically these efforts are designed to increase in the adoption of energy-efficient products, services or practices and are causally related to market interventions. (From EM&V Protocols, April 2006).

Market Transformation
Decision (D.) 98-04-063, Appendix A, defines market transformation as "[l]ong-lasting, sustainable changes in the structure or functioning of a market achieved by reducing barriers to the adoption of energy efficiency measures to the point where further publicly-funded intervention is no longer appropriate in that specific market."

Marketing and Outreach
Communications activities designed to identify, reach and motivate potential customers to take actions to either learn more about or invest in energy efficiency opportunities.

Measures
1) Specific customer actions which reduce or otherwise modify energy end use patterns.
2) A product whose installation and operation at a customer's premises results in a reduction in the customer's on-site energy use, compared to what would have happened otherwise.

Minimum Performance Standard (MPS)
As part of the Shareholder Incentive Mechanism, the minimum performance standard is the minimum level of savings that utilities must achieve relative to their savings goal before accruing earnings and is expressed as a percentage of the Commission-adopted savings goals per utility. The utility MPS is based on the whole energy efficiency portfolio and the minimum goal of each individual savings metric. (See Rule VIII.)

Net to Gross Ratio
A ratio or percentage of net program impacts divided by gross or total impacts. Net to gross ratios are used to estimate and describe the free-ridership that may be occurring within energy efficiency programs.

Non-price Factors
Those factors included in cost effectiveness tests, other than commodity prices and transportation and distribution costs, e.g., environmental factors.

Operating Program Budget
The program budget as it is defined by the program administrators for internal program budgeting and management purposes. Inclusive of costs (+/-) recovered from other sources.

Participant Test
The Participant Test is the measure of the quantifiable benefits and costs to the customer due to participation in a program. Since many customers do not base their decision to participate in a program entirely on quantifiable variables, this test cannot be a complete measure of the benefits and costs of a program to a customer. (See SPM link under Attachment A.)

Partnership
Coordinated efforts of a utility and a local government or other entity to use the strengths of both parties to achieve energy savings goals.

Peak Demand (per OP 1 of D.06-06-063)
The average grid level impact for a measure between 2 p.m. and 5 p.m. during the three consecutive weekday period containing the weekday temperature with the hottest temperature of the year.

Peak Demand-General (kW)
1) The maximum level of metered demand during a specified period, such as a billing month, or during a specified peak demand period.
2) Extremely high energy use, usually with reference to a particular time period.

Peak Savings- Coincident (kW)
The estimated peak (e.g. highest) demand savings (MW or kW) from a program for a specific time, date, and location coincident with the forecasted system peak for a given area and a given set of weather conditions. This estimate must also include consideration of the likelihood that the equipment is actually on at the time of coincident peak. Usage of this definition: Resource planning- for making adjustments to forecasts of peak usage for understanding reserve margins and reliability purposes.

Peak Savings- Daily Average (kW)
The average peak demand savings (kWh impacts/ # of hours in the peak rate period) for a given utility during their peak season. Example for SCE-Peak period is for summer

weekdays from 12-6 PM. So - daily average savings would be the number of kWh saved/ # of kWhs saved for all weekday peak periods (= kWh/5 days/week * 12 weeks/ summer* 6 hours/day = kW average. Usage: Cost effectiveness analysis, primarily for valuing energy savings that occur during the peak period using "peak" average avoided costs.

Peak Savings –Non coincident (kW)

Estimated highest level of peak savings(kW or MW) for a given program during the peak time period for a given utility on the hottest day of a "normal" weather year. Thus if a group of measures saved 1MW at 2Pm, 1.7 MW at 3PM, 1.6 MW at 4PM, 1.0 MW at 5Pm and 1.2 MW at 6 pm, the peak non coincident savings would be 1.7 MW. This savings estimate does not take into account how many of the affected devices or equipment will be operating during the peak time period. Usage: Cost effectiveness analysis and procurement.

Peer Review Group (PRG)

A subset of the Program Advisory Group consisting of non-financially interested members who will review utility submittals to the Commission, assess overall portfolio plans, plans for bidding out pieces of the portfolio, and the bid evaluation criteria for selecting third-party programs.

Performance Basis

The metrics by which a program or a group of programs is measured and evaluated for the purpose of assessing the program(s) success at displacing or deferring more costly supply-side resources and or increasing more energy efficient design and practices.

Performance Earnings Basis (PEB)

A metric used in the shareholder incentive mechanism consisting of total portfolio net benefits (TRC) weighted 2/3rd and total Program Administrator Cost (PAC) portfolio net benefits weighted 1/3rd. (See Rule VIII.)

Performance Uncertainties

A market barrier: refers to new technologies or systems whose efficiency or system performance levels are uncertain due to lack of experience.

Portfolio

All IOU and non-IOU energy efficiency programs funded by ratepayers that are implemented during a program year or cycle. May also refer to a group of programs sponsored, managed, and contracted for by a particular IOU.

Portfolio Reporting
Regularly scheduled reporting by the portfolio administrators directly to the CPUC. Metrics reported are: portfolio budgets and expenditures, measures installed, services rendered, and other program activity deemed relevant to Energy Division's responsibility to support the Commission's responsibilities of quality assurance, policy oversight, and EM&V.

Pre-commercialization
A phase in the life of a product before it is readily available on the market.

Program
A collection of defined activities and measures that

- are carried out by the administrator and/or their subcontractors and implementers,
- target a specific market segment, customer class, a defined end use, or a defined set of market actors (e.g. designers, architects, homeowners),
- are designed to achieve specific efficiency related changes in behavior, investment practices or maintenance practice in the energy market,
- and are guided by a specific budget and implementation plan.

Program Activities
Any action taken by the program administrator or program implementer in the course of implementing the program.

Program Administrator
An entity tasked with the functions of portfolio management of energy efficiency programs and program choice.

Program Administrator Cost (PAC) Test
Under portfolio evaluation of cost effectiveness, the PAC test contains the program benefits of the TRC test, but costs are defined differently to include the costs incurred by the program administrator but not the costs incurred by the participating customer. (See the SPM link under Attachment A.)

Program Advisory Group (PAG)
Advisory groups for each utility service area composed of energy efficiency experts representing customer groups, academic organizations, environmental organizations, agency staff and trade allies in the energy market. For 2007 and beyond, the Public Advisory Group (PAG) is eliminated while the Peer Review Group (PRG) is retained. Per Decision 07-10-032, the advisory function formerly performed by the PAG will be subsumed in the statewide strategic planning activity.

Program Cycle
The period of time over which a program is funded and implemented.

Program Implementation Plan
A detailed description of a program that includes program theory, planned program processes, expected program activities, program budget, projected energy savings and demand reduction and other program plan details as required by the Commission, assigned ALJ, or Energy Division.

Program Implementers
An entity or person that puts a program or part of a program into practice based on contacts or agreements with the portfolio manager.

Program Strategy
The set of activities deployed by the program in order to achieve the program's objectives.

Program Year(s)
The calendar year(s) during which the program operates.

Ratepayer
Those customers who pay for gas or electric service under regulated rates and conditions of service.

Rebate
A financial incentive paid to the customer in order to obtain a specific act, typically the installation of energy efficiency equipment.

Report Month
The month for which a particular monthly report is providing data and information. For example, the report month for a report covering the month of July 2006, but prepared and delivered later than July 2006, would be July 2006.

Resource Value
An estimate of the net value of reliable energy (e.g., kWh, therms) and capacity (e.g., kW, Mcfd) reductions resulting from an energy efficiency program. This includes the

net present value of all of the costs associated with a program and all of the estimated benefits (both energy and capacity). The calculation of resource value and associated benefits should be consistent with the avoided costs adopted in the most recent Commission proceeding or otherwise provided for by the Commission.

Service Area
The geographical area served by a utility.

Short Term/Long Term
Planning terms referring to the timing or expected timing of program activities, program impacts, or program funding. Short term indicates program activities, program impacts, or program funding that occurs during the current program cycle. Long term indicates program activities, program impacts, or program funding that occurs beyond the current program cycle.

Source-BTU Consumption
Conversion of retail energy forms (kWh, therms) into the BTU required to generate and deliver the energy to the site. This conversion is used to compare the relative impacts of switching between fuel sources at the source or BTU level for the three-prong test required for fuel-substitution programs.

Spillover
Reductions in energy consumption and/or demand in a utility's service area caused by the presence of the DSM program, beyond program related gross or net savings of participants. These effects could result from: (a) additional energy efficiency actions that program participants take outside the program as a result of having participated; (b) changes in the array of energy-using equipment that manufacturers, dealers and contractors offer all customers as a result of program availability; and (c) changes in the energy use of non-participants as a result of utility programs, whether direct (*e.g.*, utility program advertising) or indirect (*e.g.*, stocking practices such as (b) above or changes in consumer buying habits)." **Participant spillover** is described by (a), and **non-participant spillover**, by (b) and (c). **Some parties refer to non-participant spillover as "free-drivers."** (From EM&V Protocols, April 2006)

Standard Practice Manual (SPM)
The California Standard Practice Manual: Economic Analysis of Demand-side Programs and Projects is jointly issued by the California Public Utilities Commission and the California Energy Commission. It defines the standard cost effectiveness tests and their components used for energy efficiency programs.

Statewide

Energy efficiency programs or activities that are essentially similar in design and available in all Commission regulated utility service areas in California.

Third Party/Non-IOU

Non-regulated implementers of ratepayer funded energy efficiency activities.

Total Resource Cost Test (TRC)

The TRC test measures the net resource benefits from the perspective of all ratepayers by combining the net benefits of the program to participants and non-participants. The benefits are the avoided costs of the supply-side resources avoided or deferred. The TRC costs encompass the cost of the measures/equipment installed and the costs incurred by the program administrator. (See SPM link under Attachment A.)

Zero Net Energy

Zero Net Energy is defined as the implementation of a combination of building energy efficiency design features and on-site clean distributed generation that result in no net purchases from the electricity or gas grid, at the level of a single "project" seeking development entitlements and building code permits. Definition of zero net energy at this scale enables a wider range of technologies to be considered and deployed, including district heating and cooling systems and/or small-scale renewable energy projects that serve more than one home or business. (D.07-10-032, Footnote 42.)

Attention: Ms. Alanna Gillis
Acting Commission Secretary

Dear Sirs/Mesdames:

Re: FortisBC Energy Inc. and Fortis Energy (Vancouver Island) Inc.
(the "FortisBC Energy Utilities")
Energy Efficiency and Conservation Program Natural Gas Vehicles Incentive

We enclose for filing in the above proceeding the electronic version of the Submissions on behalf of FortisBC Energy Utilities on Exhibit A-6.

Twelve hard copies of the Submissions on Exhibit A-6 will follow by courier.

Yours truly,

FASKEN MARTINEAU DuMOULIN LLP

BRITISH COLUMBIA UTILITIES COMMISSION

IN THE MATTER OF the *Utilities Commission Act,*

R.S.B.C. 1996, Chapter 473 (the "*Act*")

and

FortisBC Energy Inc. and

FortisBC Energy (Vancouver Island) Inc.

(the "FortisBC Energy Utilities")

ENERGY EFFICIENCY AND CONSERVATION PROGRAM

NATURAL GAS VEHICLE INCENTIVES

Submission of the FortisBC Energy Utilities on Exhibit A-6

June 10, 2011

Table of Contents

A. INTRODUCTION

1. This is the submission of FortisBC Energy Utilities (the "FEU") with respect to Exhibit A-6, in which the Commission requested submissions on the following:

> The ability and appropriateness of the utility moving EEC funds among programs that meet the definition of "demand-side measure" in the Utilities Commission Act and programs that do not.

2. In the context of this regulatory process regarding the use of incentive funding for Natural Gas Vehicles in the Commercial NGV Demonstration Program (the "NGV Program"), the implication of the statement above is that the NGV Program may not be a "demand-side measure". In this submission, FEU will first explain why the NGV Program is a demand-side measure within the meaning of the *Utilities Commission Act* ("UCA") and, second, will explain why the expenditures are recoverable as prudent expenditures regardless.

B. THE NGV INNOVATIVE TECHNOLOGIES PROGRAM IS A "DEMAND-SIDE MEASURE"

3. The FEU submit that the NGV Program meets the definition of "demand-side measure" in the UCA. The definition of "demand-side measure" in the UCA refers to the *Clean Energy Act* where the term is defined as follows:

> "Demand-side measure" means a rate, measure, action or program undertaken
>
> (a) to conserve energy or promote energy efficiency,
>
> (b) to reduce the energy demand a public utility must serve, or
>
> (c) to shift the use of energy to periods of lower demand,
>
> but does not include
>
> (d) a rate, measure, action or program the main purpose of which is to encourage a switch from the use of one kind of energy to another such that the switch would increase greenhouse gas emissions in British Columbia, or
>
> (e) any rate, measure, action or program prescribed;

4. The NGV Program is undertaken to promote energy efficiency and thus falls into paragraph (a) of the above definition. The fact that the FEU's innovative technology programs "promote energy efficiency" is reflected in the scope of the Innovative Technologies Program Area itself, as defined in the 2008 Energy Efficiency and Conservation ("EEC") Application, which states:[1]

> It should be noted that the initiatives listed in this Section do not include all the innovative technologies that the Companies may pursue, but rather provide an overview of the types of initiatives the Terasen Utilities intend to pursue, <u>all having the same underlying characteristics</u>:
>
> <u>1) Each promotes the efficient use of natural gas through sustainable design</u>
>
> 2) None are currently a mainstream technology
>
> 3) Each offers the potential for at least a 10% GHG benefit.
>
> <u>For all sectors, programs for fuel-substitution include plans that displace less efficient and dirtier fuels with natural gas or add cleaner renewable fuels to natural gas for further efficiency and GHG benefits</u>. [Emphasis added.]

5. Notably, paragraph (a) of the definition of "demand-side measure" includes programs that "conserve energy" or "promote energy efficiency." Meaning must be ascribed to the words in the legislation so that the words are not redundant or meaningless. "Promoting energy efficiency" must therefore be given a meaning that is different than "conserve energy". One important way of understanding energy efficiency beyond conserving energy is through the concept of the use of the right fuel for the right activity. Using the right fuel for the right activity can be a more efficient or effective use of energy from a variety of perspectives, such as in a system utilization sense, an economic sense, or an environmental sense such as promoting greenhouse gas ("GHG") reduction. The NGV Program promotes energy efficiency in all these ways.

6. The NGV Program is energy efficient from the perspective of the use of energy resources and delivery systems in the province. Without incentives for natural gas vehicles ("NGV"), customers would not purchase NGVs, and NGV load on the natural gas system would

[1] Exhibit B-3, CEC IR 1.1.3.

not occur; the transportation energy demands of these customers would have been met with diesel fuel. As the NGV demand is a relatively flat year-round load, it increases natural gas use in the lower demand summer period, resulting in an increased load factor and more efficient use of the natural gas delivery system overall.[2] The NGV Program thus accomplishes the objective identified in paragraph (c) of the definition of "demand-side measure": "to shift the use of energy to periods of lower demand." From the perspective of fleet owners, the use of natural gas is also more energy efficient in an economic sense.[3] In addition, the NGV Program promotes switching from high GHG-emitting forms of energy to natural gas as a transportation fuel.[4] This is more efficient as it results in the energy demand being met with less resulting GHG emissions. This objective is supported by British Columbia's energy objectives set out in section 2 of the *Clean Energy Act*.

7. The FEU's interpretation is supported by the Province's 2007 Energy Plan, which states on page 21:

> <u>Promote Energy Efficiency</u> and Alternative Energy
>
> <u>It is important for British Columbians to understand the appropriate uses of different forms of energy and utilize the right fuel, for the right activity at the right time. There is the potential to promote energy efficiency and alternative energy supplemented by natural gas.</u> Combinations of alternative energy sources with natural gas include solar thermal and geothermal. Working with municipalities, utilities and other stakeholders the provincial government <u>will promote energy efficiency</u> and alternative energy systems, such as solar thermal and geothermal throughout the province. [Emphasis added.]

8. Although not referring to NGV per se, the quote above demonstrates that promoting the switching to a lower GHG emitting source of energy is a way to promote energy efficiency. The users of energy in these situations may not be using *less* energy, but they are using energy more *efficiently* by using "the right fuel, for the right activity at the right time."

---

[2] Since NGV load has a flat year-round profile and FEU's core load is heavily weighted towards winter space heating use, adding NGV load will increase the summer throughput as a percentage of the annual throughput. When this is coupled with the fact that winter-weighted core throughput is declining due to the impacts of FEU's EEC programs and other drivers of declining gas use, the impact of adding NGV load on system efficiency and load factors is magnified. (Exhibit B-1, BCUC IR 1.7.3, 1.7.4 and 1.2.2.1.)

[3] Exhibit B-1, BCUC IR 1.7.4.

[4] Exhibit B-1, BCUC IR 1.7.4.

9. The FEU have been clear with respect to the scope of their EEC activities. In the Terasen Utilities May 2008 Energy Efficiency and Conservation Application, the introduction states:[5]

> EEC Activity is a term that describes what has been referred to in previous Regulatory filings as Demand Side Management ("DSM") activity. "EEC" and "DSM" are used interchangeably throughout this document; both terms refer to activities undertaken by the Companies that have the goal of affecting customers' use of natural gas, <u>either through conservation activity or through load-building/fuel switching activity</u>. [Emphasis added.]

10. Load building and fuel switching activities are a recognized form of demand-side management in the industry.[6]

11. Fuel switching programs may be "demand-side measures" within the meaning of the definition in the *Clean Energy Act*. Paragraph (d) of the definition of "demand-side measure" states that the definition excludes programs which encourage a switch from one kind of energy to another such that the switch would *increase* GHG emissions in B.C. The definition thus contemplates that programs that encourage a switch that would *decrease* GHG emissions in the Province may be demand-side measures. The NGV Program is just such a program, as it adds load by encouraging the switch from other forms of energy, such as diesel, to natural gas, which reduces GHG emissions.

12. Moreover, the Commission has previously accepted other EEC expenditures directed at fuel switching from fossil fuels with higher carbon content than that of natural gas.[7] The FEU currently provide incentives for customers to install Energy Star and EnerChoice equipment and appliances where customers wish to switch to natural gas as the fuel of choice. On Vancouver Island, for example, there is a program to encourage switching from the use of oil to natural gas for home heating.[8] Similar to the NGV Program, these programs add load to

[8] Ibid.

the system, reducing GHG emissions and resulting in a greater utilization of the distribution infrastructure.

13. The FEU therefore submit that the NGV Program is a “demand-side measure” within the meaning of the UCA and is similar to other EEC programs.

C. IMPLICATIONS IF NGV PROGRAM IS NOT A DEMAND-SIDE MEASURE

14. The FEU have made detailed submissions regarding the ability of the FEU to move EEC funds amongst program areas within the Commission-accepted EEC funding envelope.[9] The Commission’s acceptance of the EEC funding envelope was made pursuant to section 44.2(a) of the UCA which applies to “demand-side measures”. If the FEU were to expend funds in a program that was not a “demand-side measure,” as defined in the *Clean Energy Act,* this would mean that the FEU did not have a prior public interest approval pursuant to section 44.2 for the expenditure of those funds. However, this does not mean that it was inappropriate for the FEU to expend those funds.

15. The FEU have addressed the implications for FEU of a Commission determination that FEU does not yet have section 44.2 approval for the NGV Program expenditures.[10] Those submissions are equally applicable if the NGV Program was not a “demand-side measure.” As FEU have submitted, section 44.2 acceptance is optional and the UCA does not prohibit the FEU from engaging in EEC activities without prior approval from the Commission. In the absence of a section 44.2 public interest determination, the Commission must assess the forecast amortization expenses relating to past NGV Program expenditures when setting rates for the FEU. In fact, the NGV Program amortization expenses are currently included in the FEU’s Revenue Requirements Application before the Commission, and the FEU are seeking that these costs be recovered in rates.

---

[9] FEU Final Submissions, Part Two.

[10] FEU Final Submissions, Part Two (pp. 16-17).

16. The NGV Program has many benefits to customers, including keeping natural gas delivery rates low for the benefit of all users.[11] As explained in Part Three and Four of its Final Submissions, the FEU submit that the NGV Program expenditures are in the public interest, were prudently incurred, and should therefore be approved. These submissions apply whether or not the expenditures meet the definition of "demand-side measure."

D. CONCLUSION

17. The benefits of including NGV Program funding within the overall EEC portfolio are well-established, and the rationale for stakeholders - including customers and Government - supporting those initiatives is clear. The NGV Program initiatives pursued to date are among the strongest initiatives in the overall portfolio when assessed according to the Commission-approved Total Resource Cost ("TRC") test, and high-to-low carbon fuel switching has environmental and other benefits. The NGV Program promotes energy efficiency, adding relatively flat NGV load which results in a more efficient use of the natural gas delivery system and lower GHG emissions in the Province. The FEU respectfully submit the Commission should therefore conclude that the NGV Program is a demand-side measure within the meaning of the *UCA* and the *Clean Energy Act* and that the FEU are able to apply EEC funding to the NGV Program within the Commission-approved EEC expenditure schedule. In the alternative, the FEU submit that the Commission should nonetheless conclude the expenditures on the NGV Program were prudent and in the public interest and therefore eligible for recovery from ratepayers in rates to be set for the FEU.

ALL OF WHICH IS RESPECTFULLY SUBMITTED.

Maximizing Societal Uptake of Energy Efficiency in the New Millennium: Time for Net-to-Gross to Get Out of the Way?

Rafael Friedmann, Pacific Gas & Electric Co., San Francisco, CA[1]

ABSTRACT

Humans are running out of time to reduce global warming gas emissions to avoid horrendous socio-political and environmental consequences. Reducing global warming effects may require an 80% decrease in greenhouse-gas emissions by the year 2050. This will require a sharp reduction in the use of fossil-fuels our modern civilization is based on. Widespread uptake of energy efficiency and conservation are the best options available to mitigate global climate change and provide time for developing more sustainable and renewable energy supply sources.

California's thirty-year promotion of energy efficiency provides valuable experience and an institutional and market infrastructure to broaden and deepen customer uptake of energy conservation and efficiency. California policymakers, entrepreneurs, and public show a heightened interest in energy efficiency.

To accelerate uptake of energy efficiency will require California to update evaluation policies and protocols for overseeing the almost one billion dollar per year publicly funded energy efficiency endeavor. Current evaluation is more focused on regulators need of attributing energy savings to specific programs and less so on optimizing interventions. Programs and evaluations are focusing mostly on energy efficient measures (EEMs) that get incentives.

This paper calls both evaluators and policy-makers overseeing energy efficiency portfolios to acknowledge the need for, and move to develop alternate evaluation policies, protocols and methods that will ensure publicly funded energy efficiency efforts are cost-effective, while also being supportive of non-traditional, more economical and deep market transforming interventions. These new evaluation policies and protocols should still ensure continued public oversight. The paper draws upon the California context to show how the Net-to-Gross ratio as currently applied inhibits new, market transforming energy efficiency interventions. Paper ends providing some initial thoughts on how to improve this situation.

Background

Society has long understood the crucial nature of energy to transform the natural world to get goods and services. This initially led to social support for the creation of an increasingly larger and complex energy supply system. With time, this evolution has been accompanied with an understanding that there are social costs that are not fully internalized by private markets and thus, suboptimal investments and developments occur in the energy sector.

This awareness of the suboptimal investment has led to a willingness to collect and use public funds to foster more socially optimal development of the energy sector. Energy efficiency programs funded with public funds is a good example. This public energy efficiency expense comes from a generalized understanding that the free market will not adopt higher efficiency on its own, nor will it

---

internalize the socio-politic or economic benefits and costs of the variety of energy infrastructure it has developed.

Public good funds for energy efficiency seek to maximize public benefits at minimum cost. Figuring out how to best use these public funds is complicated by a myriad of factors including risks, uncertainty, investment in short versus longer term opportunities, and various intervention strategies that seek to overcome perceived barriers to energy efficiency adoption.

In California and elsewhere (NW, NE and mid-west USA), publicly funded energy efficiency has a long history. In California, it is over 30 years old and has encompassed a variety of intervention strategies and administrative structures. Since 1996, these interventions have been mostly administered and run by the four investor-owned-utilities (IOUs), using public funds collected in rates. Regulatory oversight by the California Public Utilities Commission (CPUC) has sought to ensure IOU expenses optimize the use of these public funds.

As part of the determination of optimal use of these public funds, evaluation protocols have been established and significant evaluation efforts have been done to measure savings from these program interventions (check www.calmac.org for evaluation studies, and TeckMarket Works 2004, 2006). To ensure that funds are used in the best fashion possible, evaluation has focused on determining both gross savings and net savings by energy-efficiency-measures (EEMs) and/or programs. Gross energy savings encompass the totality of energy saved by programs or portfolios. Net savings refer to the energy saved that can be attributed to the programs beyond what would have happened anyways or "baseline". Gross energy savings are adjusted using a "Net-to-Gross" (NTG) ratio which in principle should include both an upwards adjustment for savings obtained beyond the program (spillover) and a downward adjustment for savings which would have happened anyways absent the program (free-riders).

California's four main investor-owned-utilities are currently administering a three-year, 2.1 Billion dollar publicly funded energy efficiency effort, under oversight and policy guidance by the California Public Utilities Commission (CPUC). The goals for this three year effort are to save 5.1 TWh, 2.2 GW and 111 MM Therms of natural gas. These goals are part of a longer-term effort that sought to save during 2004-2012 about 23 TWh, 4.9 GW, and 444 MM Therms.

Given the most recent findings of the Intergovernmental Panel on Climate Change, there is an interest in trying to save even more energy. Indeed, California Assembly Bill 32 calls for California to return to 1990 greenhouse-gas emissions levels by the year 2020 and the Governor issued an executive order that seeks to cut emissions by 80% by 2050.

For California to reach these goals, will require doing more transformative energy efficiency by tapping and engaging markets both broader and deeper than those to date. Broader in the sense that everybody will need to engage in energy efficiency. Deeper in that everyone will need to do more than what they have done. We will need full adoption of energy efficient lighting, premium motors, systems focused energy efficiency rather than individual energy efficiency measures (EEMs), as well as capturing process engineering enhancements, integration with renewable energy technologies, etc.

The current energy efficiency evaluation protocols are too focused on attribution of savings; counting only direct program participants energy saving actions corrected for free ridership. This focus promotes portfolios based on EEMs that are easy to measure and verify; undervaluing resources spent on programs that have longer lead times and/or high spillover effects. Although the current evaluation focus addresses the CPUC's need to minimize crediting of free rider savings, it also affects and impacts addressing other important societal goals, such as maximizing net energy savings and GHG emissions reductions.

The remainder of this paper explores how California's evaluation protocols, especially with regards to NTG may be inadvertently constraining the variety of interventions and resulting in reduced energy savings yields. The paper begins by drawing on the diffusion of innovation concept (Rogers 1995) to describe barriers faced by customers seeking to adopt more energy efficient technology. The discussion focuses on how the NTG can vary at the various stages of technological market adoption. This provides insights that are then exemplified with three possible new interventions that could lead to large energy savings with minimal public goods funding but that are constrained by the current evaluation protocols from happening. The paper ends by discussing how these protocols make broader and deeper efforts riskier given the high savings targets/goals; reducing energy efficiency administrators and implementers shy away from broader and deeper, higher spillover, market transforming interventions.

Current context requires and allows for new, more cost-effective energy-efficiency adoption interventions

At least two major issues with past evolution of the energy sector have recently heightened interest in tapping all cost-effective energy efficiency options first: Global Warming and Resource Adequacy. Global warming requires a significant reduction of Greenhouse Gas (GHG) emissions (some say up to 80% by 2050) to avoid most of the expected socio-politico-environmental impacts identified in the most recent IPCC reports. The frailty of the current energy supply system has become especially obvious in the wake of the California electricity crisis of 2000-2001, the large northeastern blackout of 2005, and Hurricane Katrina. Energy efficiency showed its worth to society during and after the California crisis, saving up to 14% of peak demand and 7% of electricity use in 2001; saving California from experiencing ongoing blackouts that summer. Energy efficiency is also recognized as the most cost-effective option for reducing GHG emissions, with a variety of energy saving measures costing less than 3 ¢/kWh and 1.2 $/MMBtu (Prindle et al. 2007). Energy efficiency and conservation reduces pollution and also gives time to develop better supply alternatives, especially renewable energy technologies and services, where technical breakthroughs and more importantly, market maturity is needed for full cost-effective deployment.

The current context is very receptive to energy-efficiency. There is increased public and private interest in energy efficiency. Corporations are seeking to enhance profits and their image among consumers and shareholders. GE's Ecomagination division had revenues of 17 Billion dollars in 2006; Walmart has established a group focused on sustainability and advertised its intent to sell 100 million compact fluorescent lamps (CFLs) in 2007; Home Depot gave away 1 million of these CFLs this past Earth Day; IBM has announced a 1 Billion dollar program to help its client data centers become more energy efficiency; and among automakers, Toyota and Honda higher energy efficient cars have fueled these two companies profitability and increasing market share over there less energy-efficient-focused competitors. Venture and pension fund capital managers are also increasing its interest and "seeding" new renewable energy and energy efficient technologies. The media is not far behind, with stories about global warming, energy efficiency, and renewable energy technologies showing up regularly in both local and national print and video media, as well as long-term stalwarts of "free markets" like the Economist (Sep 2006). Customer interest in these topics and eagerness to "do what's right" is an at all time high. We've even seen customers banding together to stop TXU's Board's recent interest in building eight new coal-powered power plants.

Albeit the increased interest in energy efficiency, studies still show that not all cost-effective EE is being adopted by customers, nor is ongoing development of products and services fully obtainable from business-as-usual (D Goldstein 2007; Itron 2006). This is the reasoning behind the ongoing support of energy efficiency promotion with public funds.

The question that arises is whether these funds are being spent in the most cost-effective and energy saving manner. It is also important to examine how current evaluation protocols and policies may be impacting what energy efficiency interventions are undertaken. This paper only examines the impact of NTG's policies, leaving for another discussion other areas that require review and possible revamping.

Let us examine what precludes customers from adopting all cost-effective energy efficiency and how NTG and its determination are not straightforward. Current California protocols regarding application of NTG in essence, by only counting free-riders, ignore non-energy benefits, which typically are the key leverage points to get customers to adopt more efficient services or products. New evaluation protocols with a broader perspective on overall societal benefits could increase research on customers and market actors resource efficiency motivators; providing insights for the development of more cost-effective public interventions.

Barriers to Capturing Energy-Efficiency Opportunities

The objective of a publicly funded energy-efficiency portfolio is to accelerate adoption of efficient energy use practices and technologies across a variety of customers served. Theoretically, successful public interventions spur along the maturation of energy efficiency markets so that these reach a "tipping point" where public interventions are barely needed. To succeed, the portfolio offerings need to take into account this varied mix of customers and their needs, continuously adapting to the changing context in which they are implemented. This requires a thorough understanding of customers needs to enable program offerings to align and produce optimal results. In California, even with over a quarter century of publicly funded energy-efficiency promoting programs, the energy efficiency market is still immature. Yet a new, energy-efficiency enabling context is growing; providing new opportunities for public resources to leverage private efforts to hasten market maturity. The key therefore is to clarify where markets are, what are the key barriers to further development of the market, and how to best tap into public and private resources to hasten tipping points for energy efficiency adoptions when these are possible, while still supporting the needs of less mature market segments.

This section briefly discusses key barriers faced by customers seeking to adopt energy efficiency. It also discusses how the barriers and context customers face change as an innovative product disseminates into the marketplace. This sets the stage for understanding why the CPUC's focus on attribution and rules regarding application of NTG lead to suboptimal results.

Energy-efficiency proponents talk about at least four major barriers that preclude customers (and society) from adopting all the cost-effective energy efficiency options (see Friedmann & James 2005; Friedmann 2006). These barriers are:

- Awareness. Where customers lack information on the options available, and/or their benefits.
- Availability. Manufacturers do not make or market more efficient measures as they do not expect to have a market for these (usually invisible) enhancements to their products.
- Accessibility. Distributors and retailers may not stock or aggressively display the EEMs making it hard for customers to find the more efficient products and services they seek.
- Affordability. Usually, EEMs are more expensive than the widgets they seek to replace, partly because of better quality components, partly because of their less developed and less competitive markets, with higher transaction costs to get these to market.

In order to address the barriers mentioned above, a public energy efficiency portfolio will include research, development and demonstration (RD&D) efforts, information and education components, programs to persuade customers to adopt more energy efficiency widgets and practices, and codes and standards to enhance the efficiency of buildings and equipment. The resources devoted to each of these public interventions will be determined by the market maturity context in which the decisions are made. They will change over time, across customer segments, and draw upon appropriate programmatic and project-level interventions as needed.

The programmatic and project-level interventions used need to address in more efficient and cost appropriate methods the changing needs of the market they seek to influence. Thus, the energy efficiency portfolio will be ever changing, reaching into new areas for further energy-efficiency, and contracting in others, where savings have been tapped out, or where markets have evolved and do not require further public support to continue to evolve.

The evolution of the dissemination of an energy efficient technology can be theorized to follow an S-shaped curve with four major market stages (immature, maturing, mature, and new EE technology markets) as shown in Figure 1 (Rogers 1995). An effective portfolio will optimize the mix of offerings to best address the challenges being faced by each of these four stages of market evolution to align benefits with societal needs. The intent is to match portfolio offerings to market needs, and to do so at crucial leverage points. Some of these efforts will be upstream, midstream or downstream, and/or geographically defined.

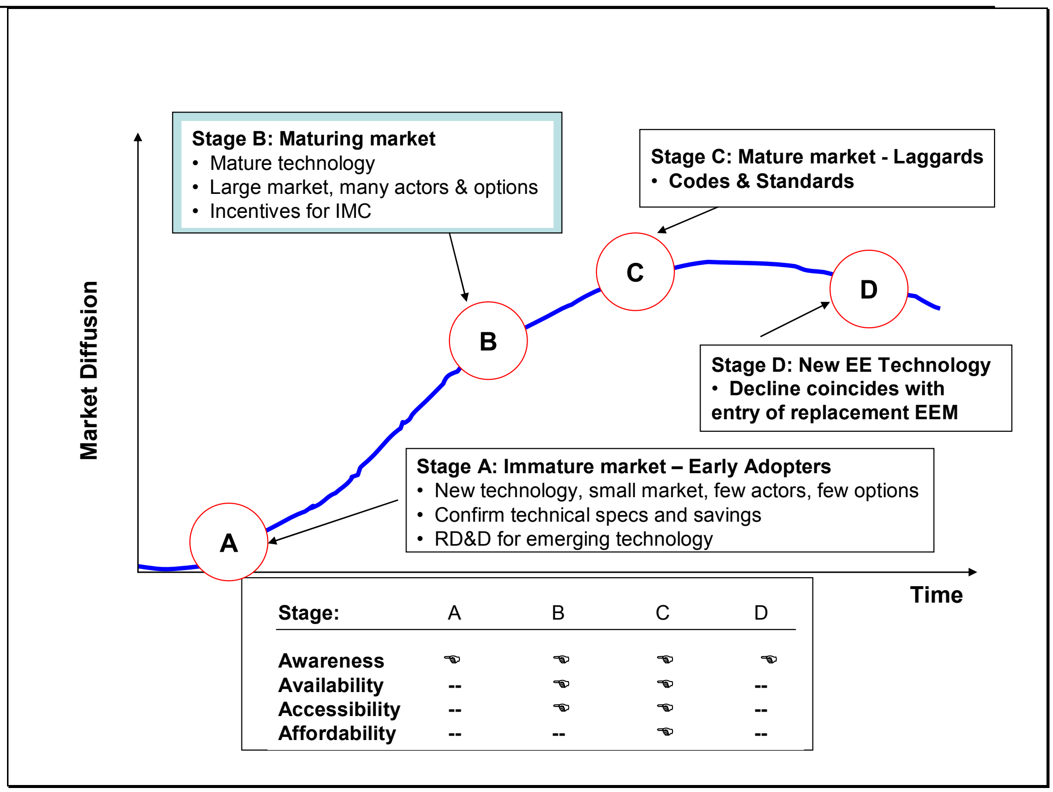

Figure 1. Market Evolution Curve for an EEM or EE Practice and Barriers Faced at Each Stage

There are important linkages among these four stages of market evolution. Stage A describes the early stages of a new technology or practice. Typical interventions for this stage focus on research, development and demonstration (RD&D). Decisions on what technologies or practices to include in the portfolio in Stage A depend on the remaining significant opportunities for energy savings. These depend in part on the previous maturation of other energy-efficiency measures addressing the more important customer energy end-uses. Indeed, Stage A and Stage D are interlinked, as the new technologies or practices being developed in Stage A begin to reduce the saturation in the market of the technology or practice that was previously being promoted by market interventions in Stages B, C and D. In Stage B, a technology or practice has become better known, is more available, accessible, yet still most likely, significantly more expensive than the less efficient technology or practice it seeks to supplant. Stage B is where most portfolio resources are typically spent currently, in the form of audits and incentive programs to help reduce the incremental costs of efficient measure's adoption. In Stage C, most of the customers have adopted the more efficient technology or practice, but some significant portion of the customers is unlikely to ever adopt it. In Stage C standards and codes are typically the intervention of choice to ensure that all customers adopt the more efficient technology given its significant societal benefits. By Stage C, the efficiency interventions administrator needs to be identifying and beginning to develop the next generation of technologies and/or practices to introduce (and start their own Stage A). This is reflected in Stage D, where the saturation of the current efficient technology is being impacted by the growing market presence of the next generation, even more efficient technology already in its own Stage A or perhaps even Stage B.

Eventually, as the private energy efficiency market grows and matures, one would hope that public support would center on Stages A and C, leaving private market actors to address most of Stage B. In this ideal theoretical construct, public funds would be used where most effective (namely where the private sector would not invest adequately due to the public good nature of that market), and be supplemented largely by private market actors positioning themselves to serve the maturing market customer in Stage B. Indeed, public resources would be used to guide and also provide credibility to private actors' best energy efficiency offerings in Stage B. This public-private market segmentation has only begun to occur in a few select situations, for example, with CFLs in homes and T-8 fluorescent bulbs in businesses. Even in these two cases, private market actors still look for various types of support from publicly funded programs. These public programs also are involved in coming up with the next generation of lighting products: LED and T-5 fluorescent lighting.

NTG and Maturing Markets for Energy Efficiency

Drawing from the diffusion of innovation for energy efficiency products and services curve, and the barriers inherent to each stage of market evolution, we examine here what factors affect the Net-to-Gross (NTG) ratio for any public interventions and the likely resulting value for NTG (see Table 1).

NTG at each stage of dissemination of innovation is different, as the key four barriers impact varies. NTG may be high in early adopter—because there is very low availability, accessibility for EEMs in Stage A. Although affordability and awareness also very low among the general population, they are actually high among the early adopter crowd. Thus, what the overall NTG—when defined as "what would have done without the program" depends on whether early adopters would have indeed been aware of the technology and been willing to spend more and seek it out to overcome the availability and accessibility barriers. Worse, should someone just focus on the early adopter participant customer's NTG it is likely the NTG would be quite low, and possibly lead to a decision to discontinue supporting the evolution of its' market. In this situation, spillover happens over time. Although the early adopters' NTG is low, through their actions and public support of market actors becoming engaged in the EEM, you are moving this technology to Stage B. Thus, just focusing on the early NTG, could lead to a decision to stop public support of the incipient EEM market, long before it is ready for uptake by the majority of customers and at least delaying capturing this technology's savings.

Table 1. NTG for Evolving Markets of EE Technologies

Market Stage	Participant Characteristics	Net-to-Gross Issues Of Participants
A. Immature	Early adopters. Embrace new technologies quickly	Awareness, affordability, accessibility, availability all low—imply high NTG; yet propensity to adopt is high among early adopters, possibly resulting in low NTG
B. Maturing	Majority of market. Require information, incentives, and other support to adopt efficient products	Relatively high NTG as these customers not "primed" to adopt new technologies and require information to be made aware, market support via upstream/midstream programs to enhance availability and accessibility, and incentives to improve affordability
C. Mature	Reticent/laggards. Lag at adopting new technologies or practices	Very high NTG as these customers very reticent to adopt EEMs. Indeed, C&S are used to force adoption, and even then, compliance with them can be very spotty
D. Decline	Back to early-adopters.	NTG indeterminate, depending on market barrier being faced for new, replacement EEM

In Stage B, all four barriers of awareness, availability, accessibility and affordability are being lowered. At this stage, the NTG for early adopters is low given the very high free-ridership; but for the mainstream customer, NTG is probably quite high initially and then, starts to decline as the market for the technology continues to mature.

In Stage C, all four barriers have been mostly overcome. The NTG is very low for both early adopters and mainstream customers, but very high for the late/never adopter. Adoption by the late adopters is obtained through mandatory energy efficient Codes and Standards. Yet compliance with the Codes or Standards remains a problem. NTG for these laggard customers is very high, but very low for all other customers.

We have seen that NTG is very dependent on the stage of market development for the energy efficient product being considered. Also, the rules on how NTG is applied can heavily influence the portfolio of energy saving strategies pursued. The market context within which we are seeking to enhance customer adoption of a particular energy efficiency product is also important. After 30 years of efforts and with the increased public and private interest in GHG, fossil fuel availability and socio-political implications of our dependence on them, it is becoming very hard to accurately estimate a NTG for a specific program intervention or EEM. Given the current context and energy savings goals under which California's energy efficiency programs are operating, it seems that a revision of the policies and their focus on NTG is needed. How these two aspects come together is discussed next.

NTG and Big, Bold Efficiency Interventions

In the search for new options to continue to garner energy savings and their accompanying socio-economic-environmental benefits to society, the question of how NTG (among other evaluation protocols) affects the possibility of carrying out effective new big and bold ventures comes up. We briefly describe three possible interventions being considered for the PG&E service territory and explore how current rules regarding NTG increase the risk of meeting savings goals making these interventions less interesting for the utility to pursue.

CFLs – Getting deeper and broader adoption by customers

About 31% of California homes have yet to install a single CFL. Of the remaining 69% of homes who have installed CFLs, only about 17% have installed 15 or more CFLs and can be assumed to have fully saturated their home lighting with CFLs (RLW 2005). Therefore, probably about half or more of the residential lighting is still using inefficient incandescent lights. According to the latest energy efficiency potential study (Itron et al. 2006), full saturation of CFLs would imply slightly over 100 million installed CFLs in PG&E serviced homes. The same study estimated at 53 million CFLs the maximum achievable saturation between 2004-2016. PG&E is seeking to accelerate adoption of CFLs via an upstream/midstream market program that offers about $2/CFL to manufacturers and distributors and retailers. This allows retailers to sell the CFLs for $1 each. Sales volumes have been increasing rapidly with up to 25 million expected in 2007, up from almost 7 million in 2006 and 4 million in 2005. Should this growth continue, PG&E homes will be close to CFL saturation in 2 to 3 years. The program has very low administrative costs by offering the incentives to manufacturers, distributors and retailers instead of customers. Yet this makes determining NTG very difficult, as participant contact information is unavailable. Instead success could be measured in terms of product availability, accessibility, affordability, and awareness. A survey of households (given that about 69% have CFLs) would still be hard pressed to get a reliable value for free-ridership given the multitude of energy efficiency messaging and promotions going on in the marketplace and that PG&E's incentive is almost invisible to the customer. Current evaluation protocols do not allow credit for any spillover, further reducing the per-protocols, official cost-effectiveness of the CFL upstream program. The program strategy is successful but can easily result in mistakenly high free ridership estimates. If the free ridership estimates come out too high, PG&E may decide to end this program (which also helps promote higher quality CFLs that have more of the characteristics customers want and that usually have led to rejection of CFLs in the past), before the CFL market is fully tapped out, leaving significant energy savings untapped.

Large Commercial Office Buildings

PG&E is currently offering a variety of products and services to large commercial office buildings. These include audits, retro-commissioning and commissioning, design-assistance, incentives for more efficient equipment, training on both, opportunities and enhanced operations and maintenance, etc. Customer outreach is mostly via PG&E Assigned Service Representatives (ASRs). The idea is that large office building managers can avail themselves of a variety of energy efficiency services to meet their needs through just one point-of-contact. Research is being conducted to allow for an even better focused program to meet this market segment needs. The idea is to characterize the large office buildings in PG&E territory by ownership and management set-up. PG&E will then reach out to these building owners and operators at the most appropriate levels of decision-making on energy-related investments, with appropriate messaging and utilizing the most appropriate PG&E staff level. This will imply establishing long-term relationships at various levels of both PG&E and the large office building manager or owner that will enhance uptake by the customers. Rather than focusing most of the effort on incentives, it is quite likely that efforts will be required at non-rebated aspects of the business decision. Tracking and determining the ultimate influence on energy savings of this variety of interventions among a variety of decision-makers (e.g., across the engineering or capital investments leadership within these organizations) over a long period of time, will be very difficult, and figuring out a free-ridership ratio even more difficult. How would one apportion such a free-ridership if say 8 of 9 decision makers were totally keen on adopting the technology (i.e., free riders) yet the 9th and final decision maker (or even the first one on the decision-tree) only agreed to the enhancement thanks to the intervention of PG&E? How will a NTG based only on participant free-ridership underestimate the energy savings from spillover, within the organization and variety of decision-makers involved and their impact on their peer groups and over time? How interested will PG&E be in pursuing this business model if there is a high level of risk on what savings will be ultimately apportioned to its efforts, partly because of current protocols governing NTG and the difficulty of estimating it?

Data Centers—Brave New World

PG&E estimates data center load growth at between 400 and 500 MW. A variety of hardware and software options are now available that can cost-effectively reduce the energy used by these data centers by one-half or more. This requires implementation of a variety of measures in a synergistic fashion, including the promotion of standards and metrics for data center equipment, and promotion of improved data center designs and operation schemes. Outreach and promotion from a credible source such as PG&E (who does not sell the equipment) is crucial. As PG&E only sells energy to these data centers, its efforts to promote a variety of products and services being offered by a variety of firms (including IBM, HP, Sun, Intel, VMWare, etc.) are providing critical credence to the claims of these various vendors as well as optimal integration of the services and products offered by them. PG&E also sponsored a data center design charrette in 2005 that helped develop ideas on how to improve energy efficiency in these facilities. Yet, how will the savings from these efforts be apportioned among the entities involved? Given that affordability is not a key issue for this market, whereas awareness and credibility are, how will free-ridership be measured? Given the quick uptake and high turnover of personnel typical of this marketplace, with the expectation that about half of it will have adopted for example virtualization (whereby they can get rid of about 70-80% of the servers and cooling needs of a data center by increasing the load from 10% to 70% in each server), will evaluations be able to gather reliable free ridership (or spillover) data before the market is basically transformed? Given the large savings being obtained with minimal public resources, this effort appears to be very cost-effective and something to try to emulate in other markets. Under current policies it is unclear what savings will be attributed to PG&E's efforts.

These three examples show issues around using NTG (especially based solely on free-ridership), and how focusing on attribution of savings is not only near impossible for these big and bold strategies, but worse, makes these very risky endeavors for PG&E to pursue.

California Needs New Evaluation Protocols for Energy Savings Attribution

Given the rapidly changing, increasingly embracing energy efficiency context we live in California, it is imperative to develop new evaluation methods, policies and protocols that will help guide and ensure optimal use of public energy efficiency resources. These new policies and protocols should foster leveraging much larger private resources with carefully crafted public interventions.

Current California protocols and CPUC rulings need to be updated to increase the focus on maximizing social benefits accruing from public resources, to balance these goals with the current one that focuses on attempting to attribute savings to specific public efforts; and take advantage of a societal context where there is a large opportunity for saving energy by leveraging market actors resources. There is an increasing level of activity from private market actors that is tapping into energy efficiency regardless of the presence of publicly funded, utility administered efforts. Customers are more interested in adopting energy efficiency than ever before as they try to do their part to solve a variety of issues they care about (Climate Change, USA's "addiction to oil", Iraq war, etc).

Utilities need to meet goals that are set at levels that are hard to achieve under current rules governing what counts or does not if they are to get shareholder incentives for their energy efficiency efforts. The CPUC requires evaluations to estimate NTG, but only considering free riders, with no credit for spillover savings. Given current market conditions, it is impossible to estimate a reliable free-rider-based NTG and/or spillover. Furthermore, the reticence to accept spillover leads to increased resources being assigned to programs where the savings not only are "counted" but also, "attributable" and help programs meet their large energy savings goals. Current policies lead implementers to avoid programs that may have large spillover effects; in essence spending the resources in less cost-effective efforts. And to add insult to injury, yesterday's spillover (that you never accounted) turns into today's baseline. In the long run this leads to underestimation of energy savings and cost-effectiveness.

The inordinate focus on attribution also takes away resources that could be used to better understand the markets we are trying to influence, thus detracting from the quality and depth of the information we use in designing and running publicly funded energy saving interventions. Evaluation activities are thus done in an institutional framework that determines the scope of the activities and analyses undertaken. The majority of energy efficiency programs are done with public monies overseen by a public entity. This institutional framework leads to evaluations that cater to the needs of ensuring public oversight, but not necessarily clearly identifying the needs of customers, or the programs that attempt to get customers to adopt energy efficiency. As these are the major evaluative efforts, they also affect the evaluation community framing the scope of enquiry and methods. In my view, the current framework may be giving us a distorted view-as it does not encompass other issues that may be crucial at really finding out what works, as efficiency markets evolve.

As the CPUC gets ready to define energy efficiency goals for 2009-2011, there is an increased awareness of the changing context, the increased difficulty for determining NTG, and the need to review the rules and evaluation protocols under which the IOUs administer the energy efficiency public endeavors.

Of late, there is a growing concern among evaluation practitioners about the capability of estimating accurately NTG and attribution of savings to specific programs given the current context, and/or using these to design program offerings (see recent conference proceedings of AESP 2007, IEPEC 2006, and Barnes 2007; Chappell et al. 2005; R Friedmann 2005, 2006; Saxonis 2007). Market effects indicators appear to be the preferred choice at this juncture (Chappell et al. 2005). Much more work is needed here to develop new indicators and then protocols aligned with them to foster the ongoing evolution of energy efficiency markets and energy savings by customers.

Conclusions

Paper has shown that the current context in California allows for new energy efficiency intervention strategies. Given the private market's interest in selling or adopting energy efficiency to increase profits and show good corporate citizenship and customer's increased interest to "do what's right", publicly funded efforts can change their "mainstream" efforts to interventions that optimize leveraging of private market actor efforts. Publicly funded efforts will still need to deal with creating new options for early adopters as well as addressing "laggard" customers via Codes and Standards. It is with the mainstream customer that publicly funded efforts can now let the relatively mature California energy efficiency market take a bigger role and even the lead, and intervene with public funds to "oil" this private markets' machinery.

Current evaluation policies and protocols make difficult such a change in public energy-efficiency interventions. They insist on calculating free-ridership and not allowing for savings from non-incented energy efficiency improvements. Changing current policies to allow for counting spillover from participants and non-participants needs to be addressed.

But both spillover and free-ridership are becoming much harder to determine as the context becomes one that embraces energy efficiency (for a variety of reasons that have little to do with saving energy). Therefore, new evaluation metrics, methods, policies and protocols need to be developed to better understand customer adoption decision-making, identification of key leverage points in the markets for energy efficient products and services, so that publicly funded interventions can continue to focus their efforts in the most cost-effective and socially beneficial manners.

Evaluation of Terasen's 2005-07 Heating System Upgrade Program

Executive Summary

This report summarizes the findings from the first phase of a two-phase evaluation of Terasen's 2005-07 Heating System Upgrade Program. The program offered a financial incentive of $250 towards the purchase of an Energy Star® qualified high efficiency natural gas furnace or boiler, and an additional $100 incentive if the customer chose a qualifying furnace / boiler equipped with a variable speed drive (VSM) motor. Incentives were in effect from September 2005 to March 2007. The primary objectives of the program were to reduce energy consumption and peak demand associated with the existing residential home heating applications, and to reduce greenhouse gas emissions by increasing the energy efficiency of home heating systems.

Evaluation objectives for the first phase of the two-phase evaluation included:

- Assessing the reasons for program participation, the effectiveness of program marketing / advertising, free ridership, reasons for non-participation, and overall customer and trade ally satisfaction with the program.
- Assessing program impact on sales of qualifying high-efficiency furnaces (HEF), and variable speed blower motors (VSM), for both participating and non-participating customers.
- Documenting and assessing program impact on furnace and secondary heating operating behaviours that affect energy use, with particular emphasis on hours of operation.
- Determining the status of market transformation for high efficiency furnaces, and furnaces with variable speed drive blower motors in the British Columbia market.
- Developing preliminary estimates of program impact on natural gas sales and carbon dioxide emissions.

The objectives of the first phase of the evaluation were addressed using data and information gathered from a combination of program records and primary research with customers and trade allies (furnace dealers and installers). Primary data collection efforts consisted of telephone surveys conducted with representative samples of:

- program participants (n=100);
- non-participants (n=100); and
- furnace dealers, contractors, and installers (n=50).

All surveys were conducted over the telephone during September 2007. Data on program participation, including the preparation of the survey sample frames, was the responsibility of Terasen. Implementation of the surveys was contracted by Sampson Research to Call Us Info Inc.

The second phase of the evaluation (scheduled for autumn 2008) will conduct a billing analysis of participating and non-participating customers to firm up estimates of program savings. This latter phase will commence after study participants have accumulated sufficient billing history (one full heating season) with their new furnace. Phase two will also use data gathered from the market research conducted under phase one of the evaluation.

The conclusions of the study are as follows:

***Objective 1: Assess the reasons for program participation, the effectiveness of program marketing / advertising, free ridership, reasons for non-participation, and overall customer and trade ally satisfaction with the program*.**

Understanding the importance of Terasen's Heating System Upgrade Program to the decision to install a high efficiency rather than a standard or mid-efficiency furnace is essential to the attribution of energy savings to Terasen's program. In this regard, 57% of participants in the Terasen program credited the program with influencing their decision to purchase a high efficiency furnace, meaning that 43% of participants were free-riders and would have selected a high efficiency furnace without the incentive. The free rider estimate is consistent with the fact that 38% of non-participants that were unaware of the Terasen program installed a high efficiency furnace. Based on information provided by participants, the proportion of free riders for the 2005-07 program is estimated at 43%. This is an increase from 28% estimated for the previous program. The increase is consistent with the continuing transformation of the furnace market to high efficiency units.

Thirty percent (30%) of participants credited the program and its incentives for their decision to replace their furnace, on average, 2.3 years earlier than planned. This is consistent with the significantly higher proportion of participants than non-participants reporting that their old furnace was still operational at the time of replacement (91% versus 71%).

Satisfaction scores assigned to various program attributes by program participants, based on a five-point satisfaction scale, were generally favourable, with the highest score given to application procedures (4.1) and the lowest score given to size of the rebate (3.7). Trade allies also rated the program positively using the same five-point scale with the highest satisfaction score given to the types and number of furnaces eligible for a rebate (4.2), and the lowest score given to the size of the rebate (3.6).

Participants in the program attributed their awareness of the program to an insert in their Terasen bill (29% of participants), heating or furnace contractor (26%), word of mouth (21%), and direct mail from Terasen (15%). Success in program marketing is often reflected in word of mouth traffic. The Terasen program appears to have successfully achieved this result.

More than half (52%) of Terasen's residential customers who replaced their furnaces during the past three years and did not participate in the Terasen program were simply unaware the program existed. The next most common reasons for not participating (mentioned by anywhere from 17% to 19% of non-participants) included the dollar amount of the rebate (i.e., too small), the hassle factor with applying for the rebate, and the fact that the furnace they chose did not qualify. Ten percent (10%) of non-participants indicated they had applied to the program but had their application rejected.

Participants in Terasen's Heating System Upgrade Program are generally very satisfied with their high efficiency furnace. Ten percent (10%) reported experiencing problems with their new furnace, but only 2% reported having major repairs. A large percentage (71%) of participants reported improvements in the comfort of the home after installing their high efficiency furnace. In contrast, 42% of non-participants reported improvements in home comfort after installing their furnace. Customers installing VSM-equipped furnaces were significantly more likely than those installing PSC-equipped furnaces to experience an increase in home comfort (68% versus 43% respectively).

***Objective 2: Assess program impact on sales of qualifying high-efficiency furnaces (HEF), and variable speed blower motors (VSM), for both participating and non-participating customers*.**

Information provided by customers and trade allies during the 2004 and 2007 furnace evaluations confirms that the replacement furnace market in British Columbia is moving towards high efficiency furnaces. Trade allies reported that high efficiency furnaces represented 48% of all replacement furnace sales prior to the launch of the most recent program. This share rose to 65% during the program and then declined to 56% after rebates ended in March 2007. VSM-equipped furnaces (either mid- or high efficiency) accounted for 34% of all furnace sales prior to program launch, and 44% following the program conclusion. Trade allies reported the share rising to 56% while the program was in operation.

Forty-three percent (43%) of non-participants reported installing high efficiency furnaces, while 39% installed standard or mid-efficiency furnaces. The remaining 13% of non-participants were not sure of their furnaces' efficiency. The decision not to install a high efficiency model was influenced by first cost, length of payback period, and a general lack of awareness of the relative costs and benefits of high efficiency furnaces. Non-participants were more likely than participants to have annual household incomes of less than $40,000, meaning that the relatively higher cost of a high efficiency furnace (approximately $700 more than a mid-efficiency furnace) was more of a financial hurtle for these households.

The top three reasons for installing a furnace equipped with a variable speed motor were the desire to save electricity (mentioned by 42% of participants), the contractor's recommendation (35%), and the $100 incentive offered by Terasen and its partners (11%). Trade allies were somewhat less likely than customers to attribute the decision to purchase a VSM-equipped furnace to the influence of the rebate (53% versus 57%). The customer-based estimate of free riders was used in the analysis of program impact.

Objective 3: Document and assess program impact on furnace and secondary heating operating behaviours that affect energy use, with particular emphasis on hours of operation.

Four factors influencing furnace operating costs (and savings) were explored in this evaluation – changes in furnace fan operating behaviours, changes in thermostat setting, changes in operating settings, and changes in supplementary heating.

How homeowners use their furnace to heat or cool the house, or to provide ventilation either occasionally or continuously before and after the installation of a VSM-equipped furnace affects the amount of electricity savings realized from the VSM blower motor. The economics of VSM furnace fans depend on operating hours – low operating hours significantly increases the payback period for VSM-equipped furnaces.

This evaluation found that, regardless of the furnace blower type, the number of households using their furnaces to intermittently heat or cool their homes during the heating/cooling seasons declined after installing their new furnace, and a proportion increased their use of the fans to provide continuous heat or cooling during the heating / cooling seasons. The data is inconclusive as to the influence of blower motor choice on behaviours as a significant proportion of households installing furnaces equipped with PSC motors also changed their usage to one of providing more continuous heat or cooling, or to provide ventilation for part of the year . Households that installed VSM-equipped furnaces, however, were more likely to use their fans continuously.

Executive Summary

The evaluation found that households who replaced their old PSC-equipped furnaces with a VSM-equipped furnace are comprised of several user types – with no conclusive evidence to suggest that households that used their old furnaces either continuously for heating/ cooling, continuously, or to provide ventilation were predisposed to purchase a VSM-equipped furnace. Instead, energy efficiency, the recommendation of the contractor, and non-energy benefits (e.g., improved comfort, improved air quality via air circulation, pollen filters, etc.) appear to have been more important considerations. Interestingly enough, some households purchasing VSM-equipped furnaces appear to have had unrealistic expectations regarding the electricity savings potential of VSM blowers, as they rated their satisfaction with electricity bill savings from their VSM-equipped furnaces significantly lower than households who purchased PSC-equipped furnaces (3.8 versus 4.2 using a five-point satisfaction scale). Data on furnace fan operating behaviours prior to furnace change out suggest that a significant number of households installing VSM-equipped furnaces tended to use their old furnace fans only intermittently, implying their electricity bill savings would be less significant that those who operated the fans more frequently or continuously.

Changes to Furnace Thermostat Setting

Only 4% of participants and 11% of non-participants increased their thermostat setting to keep their house warmer since installing their new furnace. A significantly greater proportion of participants than non-participants reported turning down the thermostat since replacing their furnace (22% versus 9%). When increases or decreases in temperature (in degrees Celsius) are added to those who reported no change, the net change in indoor temperature for participants was minus 0.6 degrees Celsius compared to plus 0.4 degrees for non-participants. This suggests that participants are maintaining their home temperatures a full degree lower than non-participants, effectively adding to the energy savings attributable to participation in the Terasen program.

Changes to Furnace Operating Settings

Only 5% of participants and 1% of non-participants reported changing one or more operating settings. Participants mentioned changing the furnace to run less frequently, resetting the blower, installing a digital readout, and installing air conditioning. The non-participant reported adjusting the timing of the second stage burner so that it engaged sooner.

Changes to Supplementary Heating

The evaluation found that participants were significantly more likely than non-participants to reduce their use of supplemental heating after replacing their furnace (-16% versus -2%). This suggests that participants' new furnaces are picking up some of the heating load previously met through supplemental sources, most notably the natural gas fireplaces, and to a lesser degree, electric heaters. The transfer of the heating load to the new furnace may result in additional savings as the furnace will be more efficient than the natural gas fireplace. However this may be partially offset if supplementary heating in the pre-furnace change-out period was being used to improve the comfort in the home or parts of the home (e.g., temperature variations between rooms, temperature fluctuations between furnace cycles, etc.). The forthcoming refinement of program savings using a billing analysis will, by its nature, capture these changes in supplementary heating use and the net impact of other changes in heating/cooling use.

Objective 4: Determine the status of market transformation for high efficiency furnaces, and furnaces with variable speed drive blower motors in the British Columbia market.

Market transformation is measured, in part, by changes in market shares of high efficiency products, and declines in the relative price differential of high efficiency units relative to standard efficiency units.

High efficiency furnaces' share of the replacement furnace market rose from 48% prior to program launch to 65% during the program phase, before retreating to 56% after the conclusion of the program. A review of market share data from the past and present evaluations suggests a moderate pullback in the market when no program is in place.

Trade allies reported that 54% of all furnaces replaced between September 2005 and March 2007 were eligible for a rebate from Terasen Gas or its partners.

Trade allies reported that the share of the replacement furnace market represented by VSM-equipped furnaces increased from 34% in the pre-program period to 56% during the program, and then falling to 44% in the post-program period. Terasen's program records indicate that 65% of participants in the heating upgrade program installed a high efficiency furnace equipped with a VSM blower motor. A review of historical market share data suggests that like high efficiency furnaces, VSM market shares seesaw when programs are in effect versus when they are not, although the general trend is upward.

A comparison of equipment and installation costs provided by trade allies surveyed in 2003 and 2007 suggests that equipment prices for all furnace models regardless of efficiency increased over the four-year period, while installation costs either stayed the same or declined somewhat. High efficiency furnaces still cost more on an installed basis than mid- or standard efficiency units. The incremental cost of installing a 75,000 BTU/hour high efficiency furnace compared to a 90,000 BTU/hour mid-efficiency furnace (comparable in output based on efficiency) is $696, down from $877 in 2002, but up somewhat from $608 in 2003.

Objective 5: Develop preliminary estimates of program impact on natural gas sales and carbon dioxide emissions.

Energy savings attributable to Terasen's 2005-07 residential Heating System Upgrade Program, using a net to gross ratio 0.57, include 66.1 terajoules (TJ) in annual savings, plus an additional 22.6 TJ of savings for the first 2.3 years (spillover). Estimated peak day savings are 0.48430 TJ for the first 2.3 years, and then 0.36091 TJ for the remaining years. Assuming an emissions factor of 50 tonnes carbon dioxide per terajoule of energy saved, Terasen is credited with reducing CO^2 emissions from residential furnaces by 4.435 kilotonnes in the first 2.3 years, and 3.305 kilotonnes for subsequent years.

1 Introduction & Objectives

This report presents the results of the first phase of a two-phase evaluation of Terasen's 2005-07 Heating System Upgrade Program. The program offered a financial incentive of $250 towards the purchase of an Energy Star® qualified high efficiency natural gas furnace or boiler, and an additional $100 incentive if the customer chose a qualifying furnace / boiler equipped with a variable speed drive (VSM) motor. Incentives were in effect from September 2005 to March 2007. The primary objectives of the program were to reduce energy consumption and peak demand associated with the existing residential home heating applications, and to reduce greenhouse gas emissions by increasing the energy efficiency of home heating systems.

Evaluation objectives for the first phase of the two-phase evaluation included:

- Assessing the reasons for program participation, the effectiveness of program marketing / advertising, free ridership, reasons for non-participation, and overall customer and trade ally satisfaction with the program.
- Assessing program impact on sales of qualifying high-efficiency furnaces (HEF), and variable speed blower motors (VSM), for both participating and non-participating customers.
- Documenting and assessing program impact on furnace and secondary heating operating behaviours that affect energy use, with particular emphasis on hours of operation.
- Determining the status of market transformation for high efficiency furnaces, and furnaces with variable speed drive blower motors in the British Columbia market.
- Developing preliminary estimates of program impact on natural gas sales and carbon dioxide emissions.

The second phase of the evaluation (scheduled for autumn 2008) is to conduct a billing analysis of participating and non-participating customers to firm up estimates of program savings. This latter phase will commence once study participants have accumulated sufficient billing history (one full heating season) with their new furnace. Phase two will also use data gathered from the market research conducted under phase one of the evaluation.

The objectives of the first phase of the evaluation were addressed using data and information gathered from a combination of program records and primary research with customers and trade allies (furnace dealers and installers). Primary data collection efforts consisted of telephone surveys conducted with representative samples of:

- program participants (n=100);
- non-participants (n=100); and
- furnace dealers, contractors, and installers (n=50).

All surveys were conducted over the telephone during September 2007. Data on program participation, including the preparation of the survey sample frames, was the responsibility of Terasen. Implementation of the surveys was contracted by Sampson Research to Call Us Info Inc.

Introduction & Objectives

1.1 Report Organization

The main body of this report is organized into six sections. Following the introduction, Section 2 provides an overview of high efficiency furnace design and characteristics, an overview of the Terasen Heating System Upgrade Program, and a discussion of issues, data sources, and methodologies used in the evaluation. Section 3 summarizes the findings from the telephone survey of participating and non-participating customers. The results from the survey of furnace dealers and contractors (trade ally survey) are summarized in Section 4. The analysis of the program's impact on customer behaviours, the replacement furnace market in Britsh Columbia, and energy and carbon dioxide emissions is presented in Section 5. Summary and conclusions are presented in Section 6. A bibliography of publications referenced in the report is found immediately after Section 6.

This report is accompanied by three appendices. Appendix A includes the participant and non-participant survey questionnaires. Appendix B includes the trade ally survey questionnaire, the steps and analysis undertaken by Terasen staff to prepare the samples of participants, non-participants, and trade allies for use in the surveys are documented in Appendix C. Appendix D presents expanded tabulations for select questions from the customer and trade ally surveys.

2 Background & Methodology

2.1 Furnace Efficiency

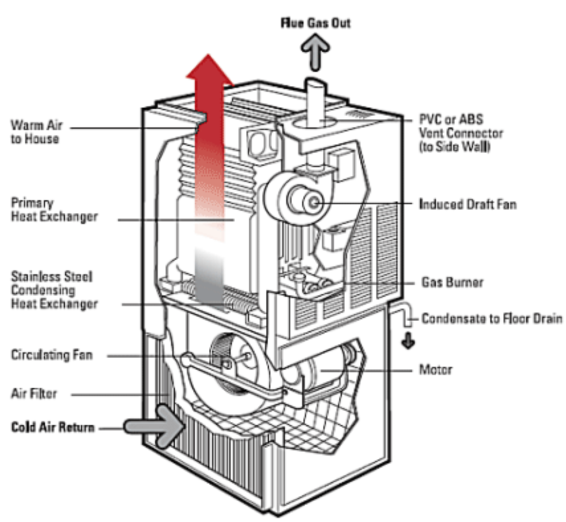
The efficiency of home heating systems is measured by the annual fuel utilization efficiency (AFUE) rating. The AFUE rating is the ratio of the heat output to the total energy consumed by the furnace. An AFUE rating of 90%, for example, tells homeowners that every dollar spent on energy will deliver 90 cents of heat output. Based on their efficiency rating, furnaces are typically grouped into one of three possible efficiency classes: standard efficiency, mid-efficiency, or high efficiency. High efficiency furnaces are also known as condensing furnaces.

Standard efficiency furnaces have a seasonal AFUE of 60% to 70% and typically use a standing pilot light, a single stage heat exchanger (captures heat from the combustion of the natural gas), and draw air for combustion from inside the house. These furnaces require a chimney to expelled combustion gases to the outside of the house.

Mid-efficiency furnaces have a seasonal AFUE of 78% to 84%, use electronic ignition, a draft hood, and incorporate a power controlled vent fan to reduce indoor air lost up the chimney. This is the base level of efficiency available for sale in Canada.

High efficiency or condensing furnaces represent the most efficient furnaces available with an AFUE of 90% to 97%. They are characterized by electronic ignition and a secondary heat exchanger that recovers 10 to 17% more of the heat given off by combustion. Some draw air for combustion from a pipe to the outside of the house. The heat extracted from the combustion gases causes the gases to cool to the point that they condense (turn to water). The remaining gases are cool enough to be vented to the outside by way of a PVC or ABS pipe. The condensate (water) empties to a floor drain. A cutaway schematic of a high efficiency furnace is presented in Exhibit 1.

Exhibit 1: Cutaway Schematic of a Typical High Efficiency Condensing Furnace



Source: "Choose the Right Condensing Gas Furnace" fact sheet published by Natural Resources Canada, http://oee.nrcan.gc.ca/publications/infosource/pub/gas-furnace-2007/index.cfm

2.2 Energy Star®

Terasen's Heating System Upgrade Program required that all furnaces eligible for a rebate be Energy Star® qualified. Energy Star gas furnaces and boilers represent the most fuel efficient units in their class, having met the efficiency and quality criteria set by the Energy Star program. Energy Star qualified furnaces display the Energy Star symbol (Exhibit 2) on the furnace, on the packaging, or in promotional or educational literature. Currently, Energy Star qualified gas furnaces have an annual fuel utilization efficiency (AFUE) rating of 90% or more. Most leading manufacturers of home heating and cooling equipment are producing high-efficiency systems that qualify for Energy Star certification.

Exhibit 2: Energy Star Label

2.3 Furnace Fans

Furnace blowers (fans) are operated by either a Permanent Split Capacity (PSC) motor or the more energy-efficient Electronically Commutated Permanent Magnet (ECPM or ECM), also commonly referred to as a Variable Speed Motor (VSM). PSC motors can be set up to operate at any one of up to four speeds to match the needs of the installation, with maximum efficiency achieved at their highest speed. When operated at lower speeds, the efficiency of a PSC motor quickly drops off. VSMs, by comparison, operate through a range of speeds, with their efficiency maintained by electronics. They use less energy than PSC motors throughout their operating range – with estimates ranging from 20% to 50% less depending upon how the homeowers use their furnace fans. In addition to their higher efficiency, VSMs typically last longer and run quieter.

Some furnace blowers are run continuously at a low speed during the heating season to improve home comfort. Some homeowners install central air-conditioning systems that utilize the same furnace blower. Both practices dramatically increase annual electrical consumption by the furnace, compared with the traditional demand-only mode of operation during the heating season. The electricity savings achieved from switching from a PSC-equipped furnace to a VSM- equipped furnace are maximized if the furnace fan is typically operated in either continuous mode or to provide ventilation in addition to intermittent heating.

Some of the gas savings from a furnace equipped with a VSM motor will be offset by the need for the furnace to supply heat traditionally given off by the lesser efficient PSC motor. However, when central air conditioning is used, VSM blower motors will provide additional savings since they give off less heat than a PSC motor.

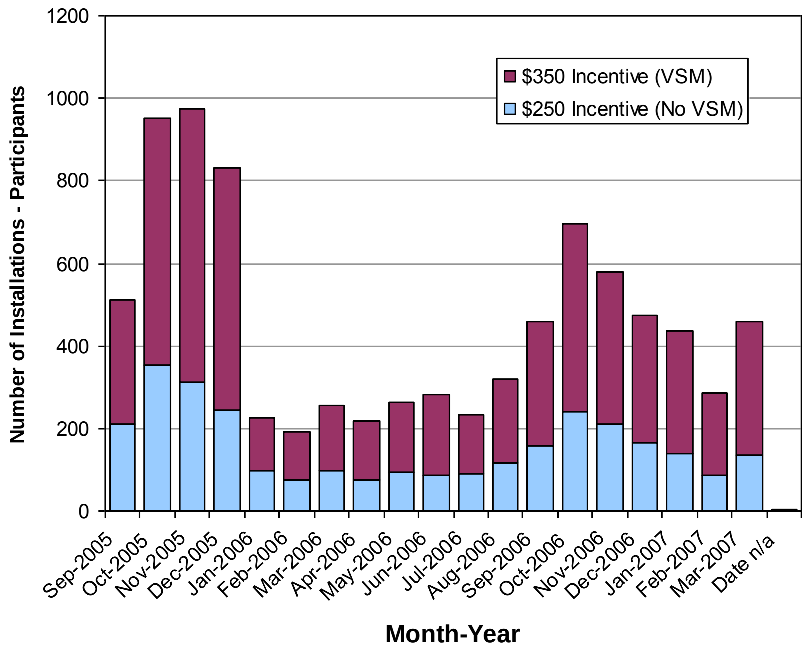
2.4 Program Description and Statistics

Terasen's 2005-07 Heating System Upgrade Program offered a financial incentive of $250 towards the purchase of an Energy Star® qualified high efficiency natural gas furnace or boiler, and an additional $100 incentive if the qualifying furnace / boiler was equipped with a variable speed drive motor

(VSM). Incentives were offered from September 2005 to March 2007. The $250 incentive was funded by Terasen and the British Columbia Ministry of Energy Mines and Petroleum Resources. The VSM incentive was funded by Terasen, Natural Resources Canada (co-funding ceased March 2006), BC Hydro (BC Hydro customers only), and Fortis BC (Fortis BC customers only). The primary objectives of the Heating System Upgrade Program were to reduce the energy consumption and peak demand associated with the existing residential home heating applications, and to reduce harmful greenhouse gas emissions by increasing the energy efficiency of home heating systems. The economic effectiveness of the program depends upon the marginal cost of energy conserved being less than the marginal cost of new supply.

In total, 8,652 households participated in the initiative, with 65% or 5,667 households opting to install a high efficiency furnace equipped with a VSM blower motor. Figure 1 illustrates the monthly program activity in terms of the number of installations per month.

Figure 1: Terasen Heating System Upgrade Program – Installations by Month-Year



2.5 Evaluation Issues, Data Sources, and Methods

The evaluation of the 2005-07 Heating System Upgrade program is being conducted in two phases. The first phase addressed factors influencing program participation, free riders, program-induced changes to furnace and furnace blower operating behaviours, customer and trade ally satisfaction, and preliminary estimates of program savings and reductions in carbon dioxide emissions. The second phase of the evaluation will undertake a billing analysis of participating and non-participating customers to firm up estimates of program savings. This latter phase will commence after study participants have accumulated sufficient billing history (one full heating season) with their new furnace. The phase two evaluation will also use data gathered from the market research conducted under the first phase of the evaluation plan.

Exhibit 3 lists the evaluation objectives for the first and second phases of the evaluation, and identifies the data sources and methods used to satisfy each. Primary data and information for phase one came from telephone surveys conducted with representative samples of program participants (n=100), non-participants (i.e., customer who replaced a furnace but did not participate in Terasen's furnace program) (n=100), and trade allies (i.e., furnace dealers and contractors) (n=50). The surveys were used to estimate a wide range of variables pertaining to program awareness; satisfaction; characteristics of customers, trade allies, furnaces, housing, and the market; furnace prices; and free rider and spillover effects. Each of these estimates have a different level of confidence due to variations in the size of their respective standard errors.

Exhibit 3: Evaluation Issues, Data Sources and Methods

Evaluation Issue	Data Sources	Methods
Phase 1.		
Assess the reasons for program participation, the effectiveness of program marketing / advertising, barriers to participation, and overall customer and trade ally satisfaction with the program.	Participant survey Trade ally survey	Cross tabulations
Assess program impact on sales of qualifying high-efficiency furnaces, and variable speed blower motors (VSM), for both participating and non-participating customers.	Participant survey Non-participant survey Trade ally survey	Cross tabulations
Document and assess program impact on furnace and secondary heating operating behaviours that affect energy use, with particular emphasis on hours of operation.	Participant survey Non-participant survey	Cross tabulations
Determine the status of market transformation for HEFs, and VSMs, in the British Columbia market.	Participant survey Non-participant survey Trade ally survey	Cross tabulations
Develop preliminary estimates of program impact on natural gas sales and carbon dioxide emissions.	Program records Previous research Participant survey	Engineering algorithm Previous billing analysis
Phase 2.		
Determine program impact on natural gas consumption using weather-adjusted billing data	Customer survey Billing records Weather files	Weather-adjusted billing analysis
Calculate estimates of program impact	Billing analysis Customer survey	Engineering algorithm
Determine program impact on carbon dioxide reductions	Billing analysis Terasen assumptions	Engineering algorithm

The participant survey sample was developed using program records. Non-participants were drawn from Terasen's general billing database. Non-participants were eligible to complete a survey if they had replaced their furnace during 2005, 2006, or the first three months of 2007. The survey of trade allies used information on registered contractors that participated in the program. Appendix C provides details on the steps undertaken to prepare the survey samples for each of the three surveys.

2.5.1 Survey Results

The participant (n=100) and non-participant surveys (n=100) were conducted between September 6 to 23, 2007. Results for proportion-based questions are accurate to plus or minus 9.8%, 19 times out of 20.

The trade ally survey (n=50) was conducted between September 10 to 15, 2007. Applying a finite population correction factor, questions yielding sample proportions are accurate within plus or minus 13.3%, 19 times out of 20.

2.6 Phase One Impact Formulae

Analysis of Terasen's impact on high-efficiency furnace sales is based on the following equation (1), where the number of units rebated was obtained from program information and the free rider rate was derived using participant survey information.

(1) Net furnace sales due to program = Units rebated $*$ (1 – free rider rate)

Analysis of program impact on sales of variable speed blower motors (VSM) was calculated using equation (2), where units rebated came from program information and free rider rate is derived from the participant survey.

(2) Net VSM sales due to program = Units rebated $*$ (1 – free rider rate)

Determination of annual energy savings due to the program considered two actions that were taken in response to the incentive: installation of a high-efficiency furnace rather than a standard efficiency furnace, and early replacement of a furnace (spillover).

Determination of program savings, exclusive of any spillover, is determined by equation (3), where units rebated comes from program information and the free rider rate was based on consumer survey information.

(3) Direct Energy Savings = $C_{RF} * (AFUE_{rep} / AFUE_{leg} - AFUE_{rep} / AFUE_{prgm}) * (1 - FR) * \text{Units}$

C_{RF}	- Annual consumption of replaced furnace
$AFUE_{rep}$	- AFUE of replaced furnaces
$AFUE_{leg}$	- Current legislated minimum AFUE for furnaces sold in British Columbia
$AFUE_{prgm}$	- Average AFUE of furnaces rebated by Terasen
FR	- Free riders (proportion of gross participants)
Units	- Number of units rebated

Equation (3) explicitly accounts for the fact that the least efficient furnace available on the market today, has, by law, an AFUE (78%) that is higher than the AFUE of the typical furnace being replaced (~70% to 71%). This means that even without Terasen's program, the vast majority of households replacing their old furnaces would have no choice but to purchase a unit with an AFUE higher than their old furnace. Without this adjustment, energy savings from this incremental improvement in furnace efficiency would be incorrectly attributed to Terasen's Heating System Upgrade Program.

Equation (4) details the determination of spillover (SO) savings based upon information regarding attribution and years of advancement provided from the customer survey.

(4) Spillover Energy Savings = $C_{RF} * (1 - AFUE_{rep} / AFUE_{leg}) * \text{Units} * \text{Years Advanced}$

C_{RF}	- Annual consumption of replaced furnace
$AFUE_{rep}$	- AFUE of replaced furnaces
$AFUE_{leg}$	- Current legislated minimum AFUE for furnaces sold in British Columbia
Years	- Number of years early replacement
Units	- Number of units rebated

Spillover savings are calculated to estimate the additional natural gas that would have been consumed had the conventional furnace been used for the "years advanced" period. They are based on the difference in consumption between the conventional furnace and the legislated level, as the reduction between the legislated level and the high efficiency furnace is captured in Equation (3) above.

Calculating the reduction in carbon dioxide (CO^2) emissions from the energy saved by the program is achieved using equation (5), with the emissions factor supplied by Terasen.

(5) ΔCO_2 = (Direct Energy Savings + Spillover Energy Savings) x EF

ΔCO_2 - Change in CO^2 emissions in tonnes
EF - Emissions factor (tonnes CO^2 per GJ energy)

2.7 Phase Two Billing Analysis

Estimated monthly consumption by calendar month for participants and non-participants will be provided by Terasen. Post-program consumption information will be weather normalized using information on heating degree-days from a suitable regional weather station. This weather normalized data will be augmented with pre-installation weather normalized data. An initial estimate of the difference in pre/post consumption due to the program will be estimated as follows in equation (6).

(6) Change in consumption in gigajoules = change in participant consumption – change in non-participant consumption

Analysis of carbon dioxide emissions is based on the following equation (7) where the emissions factor is provided by Terasen.

(7) Change in carbon dioxide emissions in tonnes = number of participants x b $*$ emissions factor/1000 tonnes

3 Customer Survey Results

The participant (n=100) and non-participant surveys (n=100) were conducted between September 6 to 23, 2007. Results for a typical proportion-style question are accurate within plus or minus 9.8%, 19 times out of 20.

3.1 Customer Characteristics

A series of questions were asked of all survey respondents to understand the demographic make-up of participants and non-participants, and to identify any characteristics that distinguished the two groups of customers from one another other than participation or non-participation in Terasen's Heating System Upgrade Program.

Exhibit 4 summarizes the age profile of participants and non-participants. Compared to participants, non-participants tended to have proportionately fewer homeowners who were in the middle age group (35 to 55 years) and relatively more homeowners aged 55 years of age and older (63%). Indeed, 41% of non-participants were 65 years of age or older, compared to 28% of participants.

Exhibit 4: Age of Respondents

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Less than 19 years	-	-	-
19 to 24 years	1%	1%	1%
25 to 34 years	4%	2%	5%

35 to 54 years	*34%*	*39%*	*28%*
55 years and older	*59%*	*54%*	*63%*

Totals may not sum due to rounding
DK/NR = Don't know / no response

The participants were more likely than non-participants to be married or in common-law relationships (81% versus 71% respectively) (Exhibit 5). Non-participants were more likely to be single or widowed, an outcome consistent with the higher proportion of young adults and seniors in this group.

Exhibit 5: Marital Status of Respondents

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Single	10%	6%	13%

*** The number of household members by each age category were queried individually. Consequently, the number of DK/NR responses sometimes differed by age group. This, in turn, affected the base (n) counts after removing DK/NR responses.*

The education profile of survey respondents is presented in Exhibit 7. It shows that participants in Terasen's 2005-07 Heating System Upgrade Program are more likely than non-participants to have taken some form of post-secondary education (73% versus 66%).

Exhibit 7: Educational Status of Survey Respondents – Highest Level of Schooling Attained

Totals may not sum due to rounding
** excluding DK/NR*

Exhibit 8 presents the income profiles of participant households versus non-participant households rebased to exclude respondents who did not know or declined to answer the question. Consistent with differences observed in the education profile of participants versus non-participants, more than half of all participants (52%) earned more than $80,000 in 2006 compared to less than one third (30%) of all non-participants. On the other end of the income spectrum, non-participants were more likely to earn less than $40,000 a year than participants (30% versus 16%). These results are also consistent with the age profiles of the two respondent groups, with seniors more likely to be living on fixed incomes.

3.2 Furnace Characteristics

3.2.1 New Furnace

All survey respondents were read descriptions of high efficiency and standard efficiency furnaces, and then were asked to describe the efficiency level of their new furnace. If participants indicated something other than high efficiency, the descriptions were repeated and the question asked again.[1,2] Exhibit 9 shows that despite the effort to clearly communicate the differences between standard and high efficiency furnaces, a small proportion of program participants (6%) still believed they installed a standard efficiency furnace.

Exhibit 9: Efficiency Level of the New Furnace

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Standard Efficiency	23%	6%	39%
High Efficiency	71%	93%	48%
DK/NR	7%	1%	13%

Forty-eight percent (48%) of non-participants indicated their new furnace was a high efficiency model, and 39% indicated their furnace was a standard efficiency model. The higher proportion of non-participants versus participants who were unsure of the efficiency of their new furnace (13% versus 1%) suggests that participation in Terasen's program helped educate the consumer on furnace efficiency. The difficulty some respondents, particularly non-participants, had in identifying the efficiency level of their new furnace, was identified during the previous evaluation (Habart 2004). A review of the data on the efficiency level and age of the replaced furnace (discussed in the upcoming Section 3.2.2) suggests that a small proportion of participants and non-participants also incorrectly identified the efficiency level of their old furnace. Given this, readers should use caution when interpreting analyses using self-reported furnace efficiency data.

Depending upon the treatment of non-participants who were unsure of their new furnace's efficiency, the estimate of baseline market share for high efficiency furnaces can range from 48% to 61%. For example, if "unsure" respondents are assumed to have installed standard efficiency furnaces, the market share of high efficiency furnaces remains at 48%. Conversely, if they are assumed to have installed high efficiency furnaces, then the high efficiency share rises to 61% (48% plus 13%). This assumption, however, is likely optimistic. A conservative approach is to proportion the unknown respondents according to the current breakdown between high and standard efficiency provided by non-participants who knew their furnaces' efficiency (48% + 48%/(39%+48%) * 13%). This approach yields an estimate of high efficiency furnace share among participants of 55%.

Participants and non-participants were asked to identify the size of their new furnace in Btu/hour. As the results presented in Exhibit 10.clearly show, the majority of respondents, regardless of participation, were unable to answer this question. Of the small number that did, participants reported an average furnace size of 64,250 Btu/hour and non-participants reported an average of 72,400 Btu/hour. The small number of responses for each group makes these estimates subject to a large standard error, requiring caution in their interpretation and use.

[1] Only high efficiency furnaces were eligible for a rebate from Terasen.

[2] To avoid adding unnecessary complexity to the customer survey, respondents were not required to differentiate between a standard versus a mid-efficiency furnace. Rather, a standard efficiency furnace was defined in the survey as having an AFUE rating of between 55% to 85%, which, by industry-accepted definitions, includes both standard and mid efficiency furnaces. References to standard efficiency furnaces throughout the customer survey and the analysis of the customer survey results, by default, include both standard and mid efficiency furnaces. The traditional definitions of standard, mid, and high efficiency furnaces were used in the trade ally survey.

Exhibit 10: Capacity of New Furnace (Btu/hour)

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
*Valid (n) ** *	*22**	*12**	*10**
Average	67,955	64,250	72,400
Standard Error	5,361	7,174	8,246
DK/NR	89%	88%	90%

** Caution is advised when comparing responses based on small samples*
*** sample excluding DK/NR responses*

The inability of a large number of respondents to identify the capacity of their new furnace was noted in the evaluation of Terasen's 2003 heating upgrade program (Habart 2004).

All non-participants, and participants that did not receive the $100 VSM incentive were read a description of a variable speed motor and then asked whether their new furnace was equipped with a furnace fan that used a VSM. Exhibit 11 summarizes the findings for participants and non-participants, organized by efficiency level of the furnace. Participants with VSM blowers include all who received the VSM rebate plus those who did not but indicated, through questioning, that they had installed a VSM-equipped furnace.

Exhibit 11: Blower Motor Type by Efficiency of New Furnace
Participants versus Non-Participants

	Participants				Non-Participants			
	Standard Efficiency	High Efficiency	Unknown Efficiency	All Efficiency Levels	Standard Efficiency	High Efficiency	Unknown Efficiency	All Efficiency Levels
Base (n)	*6**	*93*	*1**	*100*	*39*	*48*	*13**	*100*
PSC	17%	9%	-	9%	26%	35%	31%	31%
VSM	83%	82%	-	81%	46%	40%	15%	39%
DK/NR	-	10%	100%	10%	28%	25%	54%	30%
Total	100%	100%	100%	100%	100%	100%	100%	100%

** Caution is advised when comparing responses based on small samples*

In total, 81% of participants surveyed indicated their new furnace is equipped with a VSM. This percentage includes participants who received a $100 VSM incentive (69%) and participants who indicated their new furnace was equipped with a VSM despite not receiving a VSM incentive from Terasen (12%). VSM-equipped furnaces were installed by an estimated 39% of non-participants. Despite providing a description of the two types of furnace blower motors to survey respondents, 10% of participants and 30% of non-participants did not know whether their furnaces were equipped with a PSC or VSM blower motor.

3.2.2 Replaced Furnace

Eighty-eight percent (88%) of participants indicated their old furnace was a standard efficiency unit, 3% said it was a high efficiency unit, and 9% were unsure of the old furnace's efficiency (Exhibit 12). Non-participants reported similar proportions of standard to high efficiency. A significant percentage (17%) of non-participants could not / did not answer the question.

Exhibit 12: Efficiency Level of Old (Replaced) Furnace

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Standard Efficiency	83%	88%	78%
High Efficiency	4%	3%	5%
DK/NR	13%	9%	17%

Survey respondents were asked about the age of the furnace replaced, and whether the furnace was working at the time it was replaced. If households that participated in the Terasen rebate program replaced their furnaces at a younger age, and/or prior to the furnace failing, this would be viewed as an indicator of potential spillover. If so, Terasen could be credited with additional savings arising from the early replacement of less efficient furnaces. Exhibit 13 summarizes the findings from the participant and non-participant surveys.

Exhibit 13: Age and Operational Status of Old Furnace at Time of Replacement

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Age of furnace at time of replacement	24.4	24.1	24.7
Percent of respondents' furnaces that were working at time of replacement	84%	91%	77%

Ninety-one percent (91%) of participants versus 77% of non-participants indicated their furnaces were working prior to replacing them. Participants and non-participants estimated the average age of their replaced furnace at 24.1 years and 24.7 years on average. These two estimates are not statistically different at the 95% confidence interval.

An analysis of the furnace age data and self-reported efficiency level of replaced furnaces suggests that some households have mistakenly identified their old furnace as high efficiency. For example, three participants reported that their new furnace replaced an existing high efficiency furnace. Two of these furnaces were at least 15 years old when replaced (i.e., one was 15 years old and the other was 27 years old). While it is possible that these participants are correct, high efficiency furnaces represented a very small proportion of the market 15 years ago, and they were just entering the market 27 years ago. The third participant did not know the age of the replaced furnace so an assessment of the correctness of their answer on furnace efficiency was not possible. For non-participants, five reported that their old furnace was a high efficiency unit. However, all but two of these furnaces predated the introduction of high efficiency models.

3.3 Customer Awareness

Forty-eight percent (48%) of Terasen customers who installed a new furnace between January 2005 and March 2007, but did not participate in the furnace rebate program (non-participants), were aware of the rebate program (Exhibit 14). The evaluation of the 2003 program found that only 31% of non-participants were aware of the Terasen Heating System Upgrade Program in effect at that time. There was no statistically significant difference between the age groups of non-participants who were aware versus unaware of the program.

Exhibit 14: Awareness of Furnace Rebate Program among Non-Participants by Age

	Aware	Unaware
*Base (n)**	*48*	*46*
34 years and younger	2%	10%
35 to 54 years	33%	24%
55 years and older	65%	65%
Average	48%	52%

** excludes DK/NR*

Those who participated in the Terasen program (participants) identified four primary sources of their awareness of the program: Terasen bill inserts (mentioned by 29% of participants), furnace contractor (26%), word of mouth (21%), and direct mail from Terasen (15%). Exhibit 15 lists all sources of awareness, ranked by most frequently mentioned to least mentioned.

Exhibit 15: Source of Program Awareness – Participants
Percent of Respondents (Multiple Responses Allowed)

	Percent of all Participants
Base (n)	*100*
Insert in Terasen Gas bill	29%
Through heating or furnace contractor	26%
Word of mouth	21%
Direct mail from Terasen Gas	15%
Terasen Gas website	4%
Newspaper or magazine advertisement	3%
Radio advertisement	3%
TV advertisement	3%
Trade shows and consumer events	2%
Other websites	1%

3.4 Customer Satisfaction

Satisfaction with a series of program and furnace attributes was queried.

3.4.1 Satisfaction with Program Attributes

Exhibit 16 summarizes participants' satisfaction with five different attributes of the rebate program using the average ratings based on a five-point scale, where five represented "very satisfied" and one represented "not at all satisfied". The highest mean score (4.1 out of 5.0) was given to the application procedures to obtain the rebate, while the lowest satisfaction rating (3.7) was given for the amount of the rebate. The standard error of the estimate was 0.1, meaning that differences larger than plus or minus 0.2 in the means are significant at the 95% confidence interval. Satisfaction ratings are generally very favourable, with no apparent program miscues on program information, equipment coverage, or participation procedures.

Exhibit 16: Customer Satisfaction with Various Program Components - Participants
Mean scores using a 5-point satisfaction scale

	Mean Score
Base (n)	*100*
Application procedures to obtain the rebate	4.1
Information on the rebate	4.0
Number or type of furnaces eligible for the rebate	3.9
Information about efficient furnaces	3.9
Amount of the rebate	3.7

See Appendix D for additional detail on this table.

The frequency and nature of calls to a customer call centre about a program can be a useful indicator of potential gaps or confusion in program eligibility, application procedures, or processing times. Slightly more than two of every ten program participants (22%) contacted the Terasen Gas Customer Call Centre about the furnace rebate program. Exhibit 17 lists the reasons for the call based on the frequency of mention. Clarifying their eligibility for receiving the rebate was, by a considerable margin, the reason mentioned by 73% of respondents who called the centre. Determining whether their furnace was eligible for the rebate, and understanding the rebate, were mentioned by 18% of all respondents. The proportion of participants calling Terasen's call centre is not considered excessive.

Exhibit 17: Purpose of Participant's Call to Terasen Gas' Customer Call Centre
Percent of Callers (Multiple Responses Allowed)

	Percent of all Callers
Base (n)	*22**
To clarify my eligibility for the incentive	73%
To determine if the furnace was eligible for the rebate(s)	18%
To understand the rebate	18%
DK/NR	5%

** Caution is advised when comparing responses based on small samples*

3.4.2 Satisfaction with Furnace Attributes

Satisfaction with an energy efficiency program can be strongly influenced by customers' satisfaction with the technology or service for which they received an incentive. In the case of Terasen's furnace rebate program, participants were asked to rate their satisfaction with their choice of furnace. Non-participants were also asked the same question to test for differences related to program participation and furnace efficiency levels.

Exhibit 18 summarizes customers' satisfaction with the choice of furnace, delineated by participants versus non-participants, and those who purchased furnaces with PSC motors versus those who purchased furnaces with variable speed motors (VSMs). Note, both participants and non-participants installed VSM-equipped furnaces.

Overall satisfaction with furnace choice among participants is high, with 86% saying they were either extremely or very satisfied with their choice of furnace. Only 3% said they were not very satisfied or not at all satisfied. Expressed as a mean score using a five point scale (where 5 equals "extremely satisfied" and 1 equals "not at all satisfied"), participants gave their furnaces an average satisfaction score of 4.2 out of 5. By comparison, non-participants gave their furnaces a somewhat lower average score of 4.0 out of 5.0, with fewer non-participants assigning the top score (i.e., extremely satisfied) to their furnace choice.

The proportion of homeowners who were very or extremely satisfied with VSM-equipped furnaces (89%) was significantly higher than those who chose PSC-equipped furnaces (75%), with VSM owners giving an average score of 4.2 out of 5.0 versus 3.9 for PSC owners. The higher satisfaction scores given by households with VSM equipped furnaces appears largely attributable to improvements in home comfort (Section 3.4.3).

Exhibit 18: Customer Satisfaction with Their Choice of Furnace

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*200*	*100*	*100*	*40*	*120*	*40*
Extremely Satisfied (5)	29%	38%	20%	15%	36%	23%
Very Satisfied (4)	54%	48%	60%	60%	53%	53%
Somewhat Satisfied (3)	14%	11%	16%	20%	8%	25%
Not Very Satisfied (2)	2%	2%	1%	5%	1%	-
Not at all Satisfied (1)	1%	1%	1%	-	2%	-
DK/NR	1%	0%	2%	-	2%	-
Total	**100%**	**100%**	**100%**	**100%**	**100%**	**100%**
Extremely or Very Satisfied	83%	86%	80%	75%	89%	76%
Not Very or Not at all Satisfied	3%	3%	2%	5%	3%	0%
Mean	**4.1**	**4.2**	**4.0**	**3.9**	**4.2**	**4.0**

Totals may not sum due to rounding

Exhibit 19 summarizes the mean satisfaction scores assigned to seven different attributes of the new furnace by participants, non-participants, and participants and non-participants combined. Attributes that received the highest rating from participants included reliability (4.7 out of 5.0), ease of installation (4.4), and after sales service (4.2). Non-participants also rated these the highest, with comparable scores, albeit with slight variations. Participants rated their satisfaction somewhat lower than non-participants for natural gas bill savings, the price of the furnace, and electricity bill savings after installing the furnace. These somewhat lower scores for participants may reflect the higher expectation of energy savings associated with the high efficiency furnaces promoted by Terasen and the trade allies.

Of note, respondents with VSM-equipped furnaces (participants and non-participants) gave significantly lower satisfaction scores to the amount of electricity bill savings compared to those who installed PSC-equipped furnaces. The lower score may be indicative of unmet expectations of electricity savings promised in program literature or through contact with trade allies.

Exhibit 19: Customer Satisfaction with Their New Furnace
Mean Scores using a 5-point Satisfaction Scale

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type

See Appendix D for additional detail on this table.

The incidence of problems with new furnaces is relatively low with only 8% of survey respondents indicating they have experienced problems (Exhibit 20). The difference in the proportion of participants experiencing problems versus non-participants is not statistically significant.

Exhibit 20: Incidence of Problems with New Furnace

Totals may not sum due to rounding

Those who had experienced problems with their new furnace were asked to elaborate on the nature of the problems. Responses are listed in Exhibit 21. Caution is advised in the interpretation of these results because of relatively few responses.

Exhibit 21: Types of Problems Experienced with New Furnace
Percent of Respondents Experiencing Problems (Multiple Responses Allowed)

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*14**	*10**	*4**	*4**	*9**	*2**

Furnace is too noisy	29%	20%	50%	25%	22%	100%
Other	14%	20%	-	50%	-	-
DK/NR	1%	0%	2%	0%	1%	3%

** Caution is advised when comparing responses based on small samples*

The relatively small number of issues reported by respondents who installed VSM equipped furnaces suggests that reliability of VSMs has improved over that observed in the previous evaluation (Habart 2004).

3.4.3 House Comfort

Energy-efficient natural gas furnaces are often promoted as improving the comfort of the home. Participants and non-participants were asked whether comfort in the home has increased, decreased or remained the same since the installation of their new furnace. The results are shown in Exhibit 22. Seventy-one percent (71%) of program participants reported that comfort in the home improved after installing their high efficiency furnace, compared to only 42% of non-participants. Non-participants were twice as likely to say their home's comfort remained the same as before the furnace change-out. Homes with VSM-equipped furnaces were significantly more likely than those with PSC-equipped furnaces to experience an increase in home comfort (68% versus 43% respectively). The proportion of survey respondents indicating that comfort had increased after installing their new furnace did not vary significantly by furnace efficiency.

Exhibit 22: Comfort in House after Furnace Replacement

Total	100%	100%	100%	100%	100%	100%

Totals may not sum due to rounding

Homeowners who reported an increase in comfort were asked to elaborate on how comfort had improved. Exhibit 23 provides the responses, ranked by frequency of mention. The most commonly mentioned benefit was that temperatures between rooms in the house were now more even (59% of all respondents whose comfort has increased). Participants were more likely than non-participants to have mentioned this benefit (69% versus 43%), although there was no difference between those with PSC- versus VSM-equipped furnaces. The next two most frequently mentioned benefits included a warmer house (22%), and increased comfort (non-specific answer) (21%).

Exhibit 23: How Comfort Level in the House Increased
Percent of Respondents who Indicated Comfort has Improved (Multiple Responses Allowed)

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type

More even temperatures between the rooms	59%	69%	43%	65%	65%	20%
House warmer now	22%	27%	14%	24%	22%	20%
House more comfortable	21%	15%	31%	12%	22%	27%
Indoor air quality has improved	13%	17%	7%	6%	16%	7%
Rooms that were previously cold are warmer	13%	14%	12%	6%	16%	7%
Quiet operation of fan / less noise	12%	17%	5%	6%	15%	7%
DK/NR	3%	1%	5%	0%	1%	13%

** Caution is advised when comparing responses based on small samples*

Those reporting that their homes were less comfortable than before the furnace change complained of cool drafts and increased noise level (Exhibit 24). The one complaint about noise level with VSMs may be related to small duct sizing and the VSM attempting to push more air through the duct that it was designed for.

Exhibit 24: How Comfort Level in the House Decreased

** Caution is advised when comparing responses based on small samples*

3.5 Furnace Operation

Program participants and non-participants were queried as to the use of their furnace fan before and after the installation of their new furnace. How the furnace fan is used affects the cost-effectiveness of furnace model choice, namely the choice of PSC or VSM-equipped high efficiency furnace. A 2004 Energy Centre of Wisconsin study found that VSM-equipped furnaces used about half the electricity of comparable (PSC-equipped) high efficiency furnaces (Pigg 2004). The study also found that electricity savings for VSM-equipped furnaces increased dramatically for households that run their furnace fan all the time, either to improve air circulation or to eliminate room-to-room variations in temperature.

The participant and non-participant surveys queried four primary modes of furnace fan operation:

- **Intermittent Use**– the blower operates only when the furnace or air conditioning is operating for either:
  - Heating
  - Heating and cooling

- **Continuous Use**– the blower operates at low speed through the year, and at higher speeds when delivering heat or cooling.

- **Seasonal Continuous Use** – the blower operates continuously during the heating and/or cooling seasons. Heating period is assumed to be five months. Cooling period is three months.
  - Heating
  - Heating and cooling

- **Intermittent Use Plus Ventilation** – refers to intermittent use for circulation for part of the year.

Survey respondents were read the six behaviours and asked to indicate which best described their use of the furnace fan prior to replacing the furnace. Exhibit 25 summarizes the results for this question.

Exhibit 25: Furnace Fan Behaviour before Furnace Change

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*200*	*100*	*100*	40	120	40
Intermittently when providing heat	42%	41%	42%	43%	43%	38%
Continuously during the heating season	18%	17%	18%	28%	16%	13%
Intermittently when providing heat or air conditioning	6%	10%	7%	3%	7%	5%
Continuously during the heating / cooling seasons	8%	5%	6%	3%	9%	8%
Intermittently to also provide ventilation for part of the year	3%	4%	5%	3%	3%	0%
Continuously	4%	3%	3%	5%	4%	0%
No furnace fan (boiler)	5%	2%	2%	13%	3%	3%
DK/NR	18%	18%	17%	5%	16%	35%
Total	100%	100%	100%	100%	100%	100%

Totals may not sum due to rounding

Participants and non-participants were remarkably similar in their furnace fan behaviours prior to replacing their old furnace. The largest use of furnace fans for both groups was to provide heat intermittently (41% and 42% respectively), followed by continuous use during the heating season (17% and 18%). Of note, 18% of participants and 17% of non-participants could not, or chose not to, answer this question (DK/NR).

Respondents were next asked to indicate how they operate their furnace fans since installing their new furnace. The results for this question are summarized in Exhibit 26. Providing heat intermittently remains the most common fan behaviour for both participants and non-participants (36% and 31% respectively), followed by continuously during the heating season (12% and 16%). The proportion of participants who were unable or chose not to answer this question increased to 21% from 18% in the earlier question. The proportion of non-participants who were unable or chose not to answer this question was 21%, up from 17% in the earlier question.

Exhibit 26: Furnace Fan Behaviour after Furnace Change

Totals may not sum due to rounding

Differences in the number of respondents who were unable or chose not to answer questions regarding furnace fan usage before and/or after the furnace change meant that any before and after comparisons are potentially distorted by the lack of an unequal and/or unmatched base of respondents.[3] The datasets were subsequently rebased to include only those respondents who responded to both the before or after questions. Respondents with boilers were also removed from the analysis. Exhibit 27 summarizes the change in percentage shares between the before and after datasets (net change).

Exhibit 27: Net Change in Furnace Fan Behaviour Shares (Percentage Points) Excluding Non-Responses and Respondents with Boilers

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*143*	*74*	*69*	*29**	*91*	*23**

Intermittently to also provide ventilation for part of the year	3	0	6	0	3	4
Continuously	1	3	-1	0	1	0

** Caution is advised when comparing responses based on small samples*

The proportion of participants and non-participants reporting intermittent use of their new furnace to provide heat declined (down by 9 percentage points and 13 percentage points for the two groups respectively). The proportion of participants using their fans intermittently to provide heat or air conditioning increased 9 percentage points suggesting that some chose to add air conditioning when they replaced their furnace.[4] Proportionately more non-participants than participants reported an

[3] Some respondents answered the "before" questions but not the "after" questions, or vice versa.

[4] An increase in the proportion of participants using their fans intermittently when providing heat or air conditioning was noted during the evaluation of Terasen's 2003 heating upgrade program (Habart 2004).

increase in continuous operation during the heating and cooling seasons (+12 percentage points versus +3 percentage points). As well, the proportion of non-participants using their furnace to provide ventilation for part of the year increased. The latter result is consistent with the proportion of non-participants who reported purchasing a furnace with a variable speed motor (39%).

Use of Furnace Fans to Provide Ventilation

Respondents who indicated they operated their fan intermittently to provide ventilation for part of the year were asked to indicate how many months in a given year they operated their fan this way. Unfortunately, there were an insufficient number of responses by both participants (n=2) and non-participants (n=4) in the pre-installation scenario to report results. In the post-installation case, eight non-participants were able to estimate the number of months (4.3 months per year on average). The two participants who ran their furnaces in this manner could not, or chose not to, provide an estimate of the number of months.

Changes to Thermostat Setting

Participants were queried about their thermostat settings pre- and post-installation of their new furnace to understand whether they offset part of their energy savings by keeping the house warmer. If this hypothesis is correct, estimates of energy savings attributable to participants of the Terasen program would be lower than expected.

Exhibit 28 shows that only 4% of participants and 11% of non-participants have adjusted their thermostat to keep their house warmer in the winter months compared to before the furnace change-out. Interestingly, a significantly greater proportion of participants than non-participants reported turning down the thermostat in the winter months since replacing their furnace (22% versus 9%).

Exhibit 28: Change in Thermostat Setting since Furnace Change - Winter Months Only

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*200*	*100*	*100*	*40*	*120*	*40*
Warmer	8%	4%	11%	5%	8%	10%

DK/NR	6%	4%	8%	15%	1%	13%
Total	100%	100%	100%	100%	100%	100%

Totals may not sum due to rounding

Respondents who changed their thermostat setting (either direction) were asked how many degrees warmer or cooler they were keeping their house since the furnace change. The average increase in temperature (in degrees Celsius) and the average decrease in temperature, and those reporting no change (i.e., an average change of 0 degrees Celsius) were first calculated and then weighted to derive a net change in the temperature for participants and non-participants. The relative proportion of respondents that responded to the three response categories, rebased to exclude “too soon to know” and DK/NR responses, were used as the weights. The results are summarized in Exhibit 29.

Exhibit 29: Average Degree (Celsius) Change in Thermostat Setting since Furnace Change Winter Months Only

	Participants			Non-Participants		
	Average Degree Change	Weight	Weighted Degree Change	Average Degree Change	Weight	Weighted Degree Change
Base (n)	*93*	*93*	*93*	*90*	*90*	*90*
Degrees Warmer	4.7	0.04	0.2	5.0	0.12	0.6
Degrees Cooler	-3.3	0.24	-0.8	2.5	0.10	-0.2
No Change	0.0	0.72	0.0	0	0.78	0.0
Net Change	-	-	-0.6	-	-	0.4

Totals and multiplicative results may differ due to rounding

The net change in indoor temperature for participants was minus 0.6 degrees Celsius compared to plus 0.4 degrees for non-participants. In effect, participants are keeping their homes a full degree cooler than their non-participant counterparts.

Other Changes to Furnace Settings

Other than changes to the thermostat setting, survey respondents were asked whether they had changed any of the furnace operating settings since installing the furnace. Only 5% of participants and 1% of non-participants reported changing one or more operating settings (Exhibit 30).

Exhibit 30: Change Any Other Furnace Operating Setting since Furnace Replacement

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type

Total	100%	100%	100%	100%	100%	100%

Totals may not sum due to rounding

When asked to elaborate on what settings were changed, participants mentioned changing the furnace to run less frequently, resetting the blower, installing a digital readout, and installing air conditioning. The sole non-participant that answered yes to this question, reported adjusting the timing of the second stage burner so that it engaged sooner.

3.5.1 Factors Influencing Decision to Purchase a VSM Equipped Furnace

Respondents identified as having a VSM-equipped furnace were asked why they chose a model with a VSM blower. Their answers are summarized in Exhibit 31.

Energy efficiency and the contractor’s recommendation were mentioned by significantly more respondents than any of the other possible factors (44% and 38% of respondents with VSM-equipped furnaces). Eleven percent (11%) of participants mentioned the $100 rebate as a motivating factor in their decision.

Exhibit 31: Reasons for Choosing a VSM-Equipped Furnace
Percent of Respondents with VSMs – Multiple Responses Allowed

	Total	Participants	Non-Participants
Base (n)	*99*	*71*	*28**
It is more energy-efficient	44%	42%	50%

Part of the better furnace I wanted	3%	4%	0%
It keeps my house warmer	2%	1%	4%
I wanted better indoor air quality	1%	1%	0%
DK/NR	23%	20%	32%

** Caution is advised when comparing responses based on small samples*

Twenty-one percent (21%) of participants in Terasen's furnace rebate program who knew their furnace blower type were aware of variable speed blower motors prior to purchasing their VSM-equipped furnace, and another 12% were considering purchasing a VSM-equipped furnace (Exhibit 32). The 10% of participants and 30% of non-participants who were unsure whether their furnace had a VSM were excluded from this question.

Exhibit 32: Aware of or Considering the Purchase of a Furnace with a VSM Prior to Installing Furnace?

3.6 Program Design

Survey respondents were asked to rate the relative importance of various home heating attributes in their choice of furnace using a five point scale where five meant “very important” and one meant “not at all important”. Exhibit 35 summarizes the mean scores for six different attributes. Participants rated energy efficiency as the most important attribute, scoring an average of 4.5 out of 5. Next most important was home comfort (4.3) and operating cost (4.2). Non-participants gave equal scores to energy efficiency, home comfort, and indoor air quality (4.3 for all three). The lower average score assigned to the initial cost of the system by participants (3.8) versus non-participants (4.1) is consistent with the larger proportion of lower income households that make up the non-participant group. First cost (i.e., purchase and installation costs) is a common barrier for lower income households targeted by energy efficiency programming.

Exhibit 35: Attributes that Influenced Choice of Home Heating System (Mean of the 5-point scale)

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Energy efficiency	4.4	4.5	4.3
Comfort in your home	4.3	4.3	4.3
Indoor air quality	4.2	4.1	4.3
Operating cost of the system (ie: fuel cost)	4.2	4.2	4.2
Both initial cost and operating costs	4.1	4.0	4.1
Initial cost of the system	4.0	3.8	4.1

See Appendix D for additional detail on this table.

The proportion of participants in Terasen's rebate program who said they were familiar with the Energy Star label for natural gas furnaces was significantly higher than non-participants (82% versus 54%) (Exhibit 36).

Exhibit 36: Familiar with Energy Star Label for Natural Gas Furnaces?

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Yes	68%	82%	54%
No	28%	17%	38%
DK/NR	5%	1%	8%
Total	100%	100%	100%

Totals may not sum due to rounding

Of those who said they were familiar with Energy Star, significantly more participants than non-participants recalled seeing the Energy Star label on their furnace or furnace brochure (83% versus 44%) (Exhibit 37). This is consistent with the current 90% AFUE threshold for Energy Star qualified furnaces.

Exhibit 37: Recall Energy Star Label on Furnace or Furnace Brochure?

	Total	Participants	Non-Participants
Base (n)	*136*	*82*	*54*
Yes	68%	83%	44%
No	10%	2%	20%

Total	100%	100%	100%

Totals may not sum due to rounding

When asked to rate the importance of Terasen's incentive program including Energy Star qualified furnaces on a five point scale, where five represented "very important" and one represented "not important at all", 89% of program participants aware of the Energy Star label felt it was important (4 or 5 on the five point scale). Alternatively stated, respondents gave a mean importance rating of 4.5 out of 5.0 (Exhibit 38).

DK/NR	2%
Mean	4.5

3.7 Furnace Prices

Exhibit 39 summarizes the information provided by survey respondents on the installed cost of their new furnace. These figures represent the sum of the cost of the furnace, contractor mark-up, installation charges, and any applicable taxes and permits. The mean installed cost of the new furnace reported by participants was $3,666, 43% higher than the average $2,567 reported by non-participants. The most commonly reported cost among participants was $3,500 (20% of all participant responses excluding DK/NR) versus $3,000 for non-participants (37% of all non-participant responses excluding DK/NR). PSC-equipped furnaces were less expensive than VSM-equipped furnaces ($2,620 versus $3,493 respectively). The average cost of VSM equipped furnaces installed by participants was $3,740 (not shown), significantly higher than the $2,786 average (not shown) paid by non-participants who installed VSM equipped furnaces. This difference may be due to the incidence of mid-efficiency furnaces sold to non-participants, and possible confusion among non-participants regarding the furnace motor type (i.e., confusing a PSC with a VSM). The price premium for VSM-equipped furnaces may also reflect the presence of other features including two stage burners and better heat exchangers.

** Excludes DK/NR*
*** Caution is advised when comparing responses based on small samples*
Totals may not sum due to rounding

The mean installed cost of furnaces reported by respondents unaware of their furnace blower motor type ($2,738) suggests that the majority of these were likely standard efficiency furnaces. Twenty-six percent (26%) of participants and 35% of non-participants were unable to recall the cost, or chose not to answer the question.

The evaluation of Terasen's 2003 heating upgrade program found that participants paid an average of \$3,727. This average cost is not statistically different than the \$3,666 recorded in 2007.[5]

Additional detail about installed furnace costs are provided in Exhibit 40. Non-participant costs were delineated by their self-reported furnace efficiency (standard or high efficiency). The average installed cost for high efficiency furnaces purchased by non-participants was \$2,665, higher than the average for standard efficiency furnaces (\$2,370), but less than the participant average (\$3,666). The higher average costs for participant versus non-participant high efficiency furnaces reflects the larger percentage of participant furnaces that were equipped with VSMs (81% versus 40%). The lower average cost for non-participant high efficiency furnaces may also be due to some non-participant households confusing a mid-or standard efficiency furnace for a high efficiency furnace, despite being provided with verbal descriptions of each during the survey. Trade allies reported that the installed cost of high efficiency furnace was approximately \$700 more than a standard or mid-efficiency furnace (Section 4.10).

3.8 Housing Characteristics

The housing characteristics of participants and non-participants are summarized in the next three exhibits. Exhibit 41 provides a breakdown of survey respondents by dwelling type. The data show that the two groups were similar in their dwelling types.

[5] Based on a 95% confidence level and standard errors of \$125 for the 2003 estimate (Habart 2004) and \$122 for the 2007 estimate.

Exhibit 41: Dwelling Type

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
Single detached	93%	96%	89%
Semi-detached	2%	1%	2%

Row/townhouse	2%	1%	2%
Mobile home or other	2%	-	4%
DK/NR	2%	2%	2%
Total	100%	100%	100%

Totals may not sum due to rounding

Exhibit 42 summarizes participant and non-participant dwellings by age. Of note, non-participants were significantly more likely than participants to live in structures built between 26 and 50 years ago. A relatively larger proportion of participants tended to live in homes aged 16 to 25 years.

Exhibit 42: Dwelling Age

	Total	Participants	Non-Participants
Base (n)	*200*	*100*	*100*
15 years or younger	12%	14%	10%
16 to 25 years	19%	24%	14%
26 to 50 years	64%	57%	70%

Patio heater	2%	2%	1%
Indoor pool heating	1%	1%	1%
Outdoor pool heating	1%	1%	-
DK/NR	2%	3%	-

Water heating and main space heating represent the two most common natural gas end-uses in the home. The incidence of natural gas used in main and secondary heating is surprisingly low. It may be that some households, despite having a natural gas fired furnace, use other source of heating as their main source (e.g., wood stove, heat pump, etc.). Some respondents may also have assumed that the interviewer already knew they had a natural gas fired furnace or boiler and, therefore, was asking about end uses other than the furnace or boiler.

3.9 Supplementary Heating

Exploring changes in supplementary heating in participant homes and non-participant homes is important for understanding its possible influence on energy savings attributable to the program. First, households were asked to identify whether they had a source of supplementary heating in the home. If they answered in the affirmative, they were asked to identify the fuel(s) used for the supplementary heating (e.g., electricity, natural gas, etc.), and the method of supplemental heating (e.g., portable electric heater, wood stove, etc.).

Forty-four percent (44%) of respondents affirmed that they had supplementary heating in the home (Exhibit 45). Participants were somewhat more likely than non-participants to have a supplementary heat source (48% versus 40%).

Exhibit 45: Presence of Supplementary Heating

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*200*	*100*	*100*	*40*	*120*	*40*

No	55%	50%	59%	50%	57%	53%
DK/NR	2%	2%	1%	-	2%	3%
Total	100%	100%	100%	100%	100%	100%

Totals may not sum due to rounding

The next two exhibits summarize the fuel used for supplementary heating and the types of supplemental heating used. An initial review of the datasets revealed some inconsistencies. For example, some respondents indicated they had a wood stove but did not mention wood as a fuel source in the earlier question. A similar issue was identified for electricity (e.g., had an electric space heater or electric baseboard heat but did not identify electricity as a fuel source). In light of this, data for electricity and wood supplemental fuels were recoded. If a respondent indicated they had an electric appliance of any sort (e.g., electric space heater, electric baseboard heaters, etc.) they were assumed to have electricity as a fuel source. A similar procedure was taken for wood stoves. In the end, natural gas was the most frequently mentioned fuel used for supplementary heating (42% of all respondents with supplemental heat), followed by electricity (38%) and wood (27%) (Exhibit 46).

Exhibit 46: Fuel Used for Supplementary Heating
Percent of Respondents with Supplementary Heating - Multiple Responses Allowed

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*88*	*48*	*40*	*20**	*50*	*18**
Natural Gas	42%	44%	40%	40%	40%	50%
Electricity	38%	38%	38%	35%	42%	28%

Other	1%	2%	-
DK/NR	3%	4%	3%

3.10 Free Riders

Free riders are defined as those households that participated in the Terasen Heating System Rebate program, but would have purchased a high efficiency furnace or boiler even if the incentive had not been available. The energy savings attributable to free riders are excluded from the final determination of program effect.

To assess the degree of free riders, participants were asked to rate the importance of the Terasen financial incentive in their decision to purchase a high efficiency furnace or boiler using a scale of one to five where one meant “not at all important” and five meant “very important”. The results are summarized in Exhibit 48. To determine the importance of the program, a weighted average of the importance scores was calculated. The weights were selected to give the most weight to those indicating the incentive was very important (weight of 1.0) and the least weight to those who indicated it was not at all important (weight of 0). The weighted average of the importance scores was 0.57, meaning the free rider rate is 43% (calculated as 1 - Weighted Average Score).

Exhibit 48: Calculation of Free Riders – Influence of Overall Incentive on Participants

	Very Important (5)	(4)	(3)	(2)	Not at all Important (1)	DK/NR	Total	Free Rider Rate
Distribution of Responses (n=100)	26%	27%	17%	10%	13%	7%	100%	-

Product	0.26	0.20	0.08	0.03	0.00	0.00	0.57	**0.43**

3.11 Spillover

Exhibit 50 summarizes the spillover analysis conducted using participant survey data. Spillover refers to the early replacement of a standard or conventional furnace with an energy-efficient model due the influence of the Terasen heating upgrade program. Thirty percent (30%) of participants credited the Terasen program with advancing their decision to replace their furnace. The average advancement was estimated at 2.3 years.

Exhibit 50: Spillover Analysis - Participants (Multiple Responses Allowed)

	Participants	Average Early Replacement (Years)
Base (n)	*100*	*23**
Yes	30%	2.3
No	67%	-
DK/NR	3%	-
Total (All Participants)	100%	-

** Excludes DK/NR*
Totals may not sum due to rounding

3.12 Barriers to Participation

Non-participants were asked why they did not participate in the Terasen program. Their responses are summarized in Exhibit 51. By far, the single most common reason was a simple lack of awareness of the program (52% of all non-participants). The next most commonly mentioned reasons included not worth the effort / didn't want to bother (19%), rebate was too small (19%), and furnace did not qualify (17%). Ten percent (10%) said they had submitted a rebate application but were rejected.

Exhibit 51: Reasons for Not Participating in Terasen's Heating Upgrade Program Percent of Non-Participants - Multiple Responses Allowed

	Percent of Non-Participants
Base (n)	*100*
Unaware of program	52%
Not worth the effort / Didn't want to bother	19%
Rebate too small	19%
Furnace did not qualify for rebate	17%
Tried to - rebate application was rejected	10%
Didn't know how to apply	8%
Had planned to / didn't get around to it	6%
Contractor was not registered with program	6%

4 Trade Ally Survey Results

A sample of 50 furnace dealers, contractors, and gas fitters (trade allies) were surveyed between September 10th and 15th, 2007. Trade allies were selected at random from Terasen's list of qualifying furnace contractors. Including a finite population correction factor, questions yielding sample proportions are accurate within plus or minus 13.3%, 19 times out of 20.

4.1 Trade Ally Characteristics

Exhibit 52 presents the distribution of trade ally respondents by the number of employees in their firm. This measure is used as a proxy for firm size. The vast majority (82%) of respondents worked for firms of ten employees or less, with 16% (not shown) of respondents being owner/operators (single person firms).

Exhibit 52: Distribution of Trade Ally Respondents by Firm Size (Number of Employees)

	Percent of Trade Allies
Base (n)	*50*
1 to 2	30%
3 to 5	28%
6 to 10	24%
11 to 15	10%
16 to 20	4%
Over 20	4%
Total	100%
Mean	*6.9*

Totals may not sum due to rounding

Consistent with the significant proportion of single person firms participating in the survey, 26% of respondents categorized themselves as independent heating contractors. Another 18% of trade allies described themselves as furnace dealers and heating contractors. Only 4% of respondents described themselves as gas fitters. Almost half of trade allies (46%) indicated their business was best described by all three categories – dealer, heating contractor, and gas fitter.

Exhibit 53: How Trade Allies Described Their Business

	Percent of Trade Allies
Base (n)	*50*
Furnace Dealer and Heating Contractor	18%
Independent Heating Contractor	26%
Gas fitter	4%
All of the Above	46%
Other	6%
Total	100%

Totals may not sum due to rounding

An analysis of Terasen's program records revealed that 25% of the 665 contractors participating in the program installed 85% of all the rebated furnaces (Exhibit 54). One contractor was responsible for more than 400 installations.

Exhibit 54: Distribution of Trade Allies by the Number of Rebated Furnaces Installed

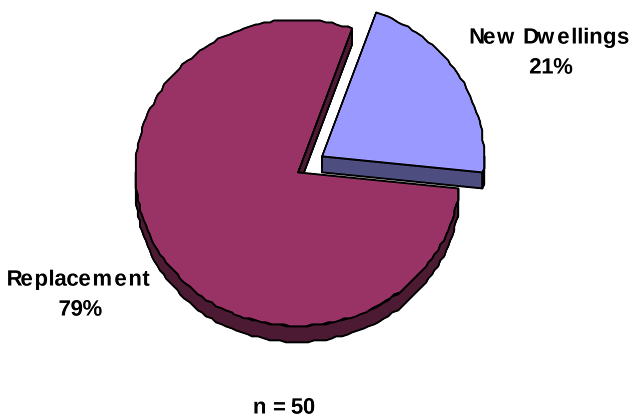
Number of Installations	Percent of All Participating Trade Allies	Percent of All Furnaces Rebated
Base	*665*	*8,652*
1 to 10	15%	75%
11 to 50	31%	18%
51 to 100	28%	5%
101 to 200	21%	2%
> 200	5%	0.2%
Total	100%	100%

Source: Terasen program records

4.2 Market Characteristics

Trade allies estimated that, on average, 79% of their furnace sales / installations were to replace existing furnaces (Figure 2). However this data does not mean that new construction has 21% of the new furnace market. In BC there are a number of firms that only install in new construction, and they are not included in the trade ally survey.

Figure 2: Share of Residential Furnace Sales / Installations: Replacement versus New Dwellings



Trade allies were asked to estimate the percentage of all furnaces sold or installed before, during, and after the Teresan rebate program that were high efficiency. The results, summarized in Exhibit 55, show that the proportion increased from 48% to 65% during the program period before declining to 56% after the end of the program (as indicated in the September 2007 survey).

Exhibit 55: Composition of Replacement Furnace Sales / Installations by Furnace Type Mean Percentages

	Percent High Efficiency	Percent VSM
Base (n)	*50*	*50*
Before Program	48%	34%
During Program	65%	56%
After Program	56%	44%
DK/NR	8%	8%

Trade allies reported that the proportion of furnace sales/installations equipped with variable speed blower motors also increased during the program period, rising from 34% to 56% before declining to 44% as of September 2007.

4.3 Trade Ally Satisfaction

Trade allies were asked to rate their satisfaction with four aspects of Terasen's furnace rebate program using a five point scale, where one represented "not at all satisfied" and five represented "very satisfied". Exhibit 56 summarizes the mean scores. Responses were generally very favourable. The highest satisfaction score was given to the types or numbers of furnaces eligible for the rebate (mean satisfaction score of 4.2). The amount of the rebate received the lowest mean score (3.6).

Exhibit 56: Trade Ally Satisfaction with Various Aspects of the Terasen Rebate Program Mean of the 5-point Satisfaction Scale

	Mean Score
*Base (n)**	*46 - 49*
Types or numbers of furnaces eligible for the rebate	4.2
Application procedures to obtain the rebate	4.1
Information on the rebate	3.8
Amount of the rebate	3.6

** base varies by aspect due to varying numbers of DK/NR responses*
See Appendix D for additional detail on this table.

Fifty-eight percent (58%) of trade allies felt the Terasen rebate was either very or somewhat important in the choice of a high efficiency furnace when asked to rate the importance using a five point scale, where five represented "very important" and one represented "not at all important" (Exhibit 57). Averaged across all valid responses, trade allies gave the rebate a mean score of 3.7 out of 5.0.

Exhibit 57: Importance of the Rebate in Furnace Choice

	Percent of Trade Allies
Base (n)	*50*
Important (4 or 5)	58%
Not Important (1 or 2)	18%
DK/NR	4%
Mean	3.7

Trade allies assigned somewhat less importance to the role of the $100 VSM rebate in their customers' choice of furnace blower motor efficiency (Exhibit 58). Forty-six percent (46%) felt the rebate was either very or somewhat important in the decision to acquire a VSM-equipped furnace. Averaged across all valid responses, trade allies gave the VSM rebate a mean score of 3.2 out of 5.0.

Exhibit 58: Importance of the VSM Rebate in the Choice of a VSM-equipped Furnace

	Percent of Trade Allies
Base (n)	*50*
Important (4 or 5)	46%
Not Important (1 or 2)	34%
DK/NR	2%
Mean	3.2

Sixty-four percent (64%) of trade allies unequivocally felt that high efficiency furnaces were the best choice for their customer (Exhibit 59). Another 22% qualified their responses by saying that it depended upon the customer.

Exhibit 59: Are High Efficiency Furnaces the Best Choice for Customers?

	Percent of Trade Allies
Base (n)	*50*
Yes	64%
No	14%
Sometimes / Depends upon the customer	22%

Exhibit 60 summarizes the reasons, by frequency of mention, why trade allies believe high efficiency furnaces are the best choice for their customers. The most frequently mentioned reason was they save money / are more cost effective (mentioned by 56% of trade allies answering in the affirmative). The next most frequently mentioned reason was that they are more environmentally friendly (26%). Trade allies that said they only sometimes believe a high efficiency furnace is the best choice for the customer or that it depends on the customer were most likely to mention structural constraints present (or not present) in the home as a factor and/or that homeowners found high efficiency furnaces too expensive (data subset not shown)

Exhibit 60: Why Trade Allies Believe High Efficiency Furnaces Are the Best Choice for Customers
Percent of Respondents (Multiple Responses Allowed)

	Percent of Respondents
Base (n)	*43*
Saves money / more cost effective	56%
More environmentally friendly	26%
Structural constraints in home (flue location, electrical panel access)	16%
More energy-efficient	14%
Too expensive for some households	7%
Runs quieter	5%
Provides more even heat	5%
More reliable	2%
Recommend heat pumps / heat pumps more efficient	2%
Other	14%

Totals may not sum due to rounding

Reasons why 14% of trade allies do not believe high efficiency furnaces are the best choice for customers are summarized, by frequency of mention, in Exhibit 61. The most frequently mentioned reason was the preference given to heat pumps (mentioned by 57% of all trade allies who do not recommend high efficiency furnaces). Less frequently mentioned reasons were the expense (14%) and structural issues (14%).

Exhibit 61: Reasons Why Trade Allies Do Not Recommend High Efficiency Furnaces

Base (n)	*50*
1 Year or less	16%
2 to 5 years	58%
More than 5 years	20%
DK/NR	6%
Total	100%
Mean	*4.7*

4.5 Frequency and Impact of Heat Loss Calculations

The correct sizing of a furnace is important for maximizing the cost effectiveness of a new furnace and is determined by conducting a heat loss calculation. A heat loss calculation determines the amount of heating in GJ (i.e., the size of furnace) needed to replace the heat lost from a home during the cold winter months. Heat loss calculations consider several variables including the square footage of the home, the number, type, and orientation of windows, outside wall construction, insulation thickness, and size of exterior doors. While the particular method used to determine heat loss were not queried, contractors have access to heat loss/furnace sizing methodologies provided by the Canadian Standards Association (CAN/CSA F280) and the Heating, Refrigeration, and Air Conditioning Institute of Canada (HRAI).[6]

Of the trade allies surveyed, 78% said they routinely conduct a heat loss calculation prior to installing the furnace, significantly higher than 48% of trade allies surveyed in 2004. Although the proportion of trade allies conducting a heat loss calculation has improved, the percentage of the calculations that lead to the installation of small capacity furnace varies depending upon the trade ally (Exhibit 71).

Exhibit 71: Share of Heat Loss Calculations that Lead to Smaller Capacity Furnace
Percent of Trade Allies That Routinely Conduct a Heat Loss Calculation

	Percent of Trade Allies
Base (n)	*39*
0%	8%
1% to 10%	15%
11% to 50%	21%
51% to 80%	18%
81% to 100%	28%
DK/NR	10%
Total	100%
Mean	*55%*

Totals may not sum due to rounding

On average, contractors estimated that the heat loss calculation leads to a recommendation to install a smaller capacity furnace in more than half (55%) of the cases.

6 Source: Canada Housing and Mortgage Corporation, www.cmhc-schl.gc.ca/en/co/renoho/refash/refash_018.cfm

4.6 Furnace Fan Usage

Trade allies were asked questions regarding the operating behaviours of furnace fans before and after the furnace change-out. Fan operation after the change-out was differentiated by furnaces equipped with PSC versus VSM blower motors. The results from these questions are summarized in Exhibit 72.

Exhibit 72: Trade Ally Perspective on Pre- and Post-Replacement Furnace Fan Behaviours

	All Replaced Furnaces	New Furnaces with PSC Motors	New Furnaces with VSM Motors
Base (n)	*50*	*50*	*50*
Intermittently when providing heat	30%	30%	26%
Continuously during the heating season	17%	16%	13%
Intermittently when providing heat or air conditioning	29%	23%	21%
Continuously during the heating / cooling seasons	6%	5%	9%
Intermittently to also provide ventilation for part of the year	6%	6%	6%
Continuously	15%	16%	28%
DK/NR	22%	20%	21%

Totals may not sum due to rounding

Trade allies installing VSM-equipped furnaces reported a significant increase in the continuous use of the furnace fan (increase from 15% of pre-retrofit furnaces to 28% of post-retrofit furnaces equipped with VSM blower motors) and a decline in the percentage of furnace fans operating intermittently to provide heat or air conditioning (29% to 21%).

4.7 Program Design Issues

All but one of the 50 trade allies surveyed (98%) were familiar with Energy Star label for natural gas furnaces. Of these, 90% recommended Energy Star natural gas furnaces to their customers, and another 4% said they sometimes recommended them depending upon the customer’s requirements. Six percent of trade allies do not recommended Energy Star natural gas furnaces (Exhibit 73).

Exhibit 73: Energy Star Furnaces Recommended to Customers?

	Percent of Trade Allies
Base (n)	*50*
Yes	90%
No	6%
Sometimes / Depends on the customer	4%
Total	100%

Totals may not sum due to rounding

Eighty-two percent (82%) of trade allies felt customers had enough information to make an informed decision about the choice of furnace (Exhibit 74). Another four percent qualified their response by saying that customers sometimes had sufficient information or that it depended upon the customer.

Exhibit 74: Do Customers Have Enough Information to Make an Informed Decision on Choice of Furnace?

	Percent of Trade Allies
Base (n)	*50*
Yes	82%
No	14%
Sometimes / Depends on the customer	4%
Total	100%

Totals may not sum due to rounding

The comments from the handful of trade allies who answered no to this question are listed verbatim in Exhibit 75. Trade allies suggested that households rely upon contractors to educate them on mid-to high efficiency furnaces. This education process includes both the mechanics of upgrading to a high efficiency furnace, and placing the furnace prices in the context of expected savings.

Exhibit 75: Information Missing Regarding the Choice of Furnace Efficiency Percent of Respondents

Base (n)	*9**
Some don't understand about the mid-efficiency furnace.	2%
Some understand the mechanics, and some have no idea at all.	2%
Terasen doesn't explain it.	2%
The efficiency for high efficiency is so much higher. This is what they want, but they get a price regarding that and basically walk away.	2%
They are missing everything without us to explain it to the customers.	2%
They are not informed of the actual savings they will receive by installing the high efficiency furnace.	2%
They are not well informed about furnaces until they speak with us.	2%
They don't know how they [furnaces] work	2%
DK/NR	2%

** Caution is advised when comparing responses based on small samples*

Seventy-eight percent (78%) of trade allies felt customers had sufficient information to choose between a PSC or VSM-equipped furnace (Exhibit 76). Another 6% said they sometimes had sufficient information or that it depends upon the customer.

Exhibit 76: Do Customers Have Enough Information Regarding the Choice of a PSC or Variable Speed Furnace Motor?

	Percent of Trade Allies
Base (n)	*50*
Yes	78%
No	16%
Sometimes / Depends on the customer	6%
Total	100%

Feedback from trade allies who felt households did not have enough information regarding the choice of furnace motor blower type is listed in Exhibit 77. Several alluded to the tendency for customers to use contractors to explain the differences and/or benefits of the different blower motor technologies. Others referred to barriers associated with building codes, customer lack of interest, uniformed salespeople, or because the trade ally does not recommend furnaces with VSMs.

Exhibit 77: What Information is Missing Regarding the Choice of Furnace Blower Motor? Trade Allies Who Felt Customers Did Not Have Enough Information Regarding the Choice of a PSC or Variable Speed Furnace Motor

I explain the differences between the two motors.	2%
I tell them about the efficiency of the motor.	2%
It is hard, especially with the codes, so it depends due to the fact of the codes.	2%
Some people care, and some don't have an interest in it.	2%
Terasen doesn't provide it.	2%
The only way they know is if we tell them, or if they have gone on the internet to find information.	2%
They don't know about how efficient they are. They know the cost may be higher, but that they do pay for themselves.	2%
You can't even teach salespeople because the technicians have all the technical information.	2%
DK/NR	2%

** Caution is advised when comparing responses based on small samples*

4.8 Trade Ally Suggestions – High Efficiency Furnaces

Trade allies were asked how customers could be encouraged to install high efficiency rather than mid-efficiency furnaces. Trade ally suggestions could be grouped by three primary themes: (1) improve education and awareness of high efficiency furnaces, (2) lower the cost of high efficiency furnaces, and (3) improve program delivery. Exhibit 78 summarizes the responses by these three themes.

Exhibit 78: Suggestions on How to Encourage Customers to Choose High-Efficiency Furnaces over Mid-Efficiency Furnaces
Percent of Trade Allies - Multiple Responses Allowed

	Percent of All Trade Allies *
Base (n)	*50*
Improve education and awareness	
Increase emphasis on the benefits of high efficiency furnaces ($ savings, environment, resale value of home)	38%
Increase awareness of rebates (Terasen, federal government, manufacturer, etc.)	4%
Increase the amount of promotion (generic)	2%
Educate customers on construction of their home	2%
Lower the cost of high-efficiency furnaces	
Reinstate rebate	2%
Increase the rebate	10%
Pressure wholesalers to reduce cost	4%
Make dealers offer rebates	2%
Improve size of federal government rebate	2%
Improve program delivery	
Run program year round	4%
Improve access (generic)	2%
More promotion prior to start of heating season	2%
No Suggestions	36%

** Suggestions are not additive as multiple responses were allowed.*

The majority of suggestions made on ways to encourage the adoption of high efficiency furnaces focused on raising the awareness and educating customers about high efficiency furnaces. The majority of suggestions in this sub-group focused on emphasizing the benefits of high efficiency furnaces (mentioned by 38% of all trade allies), including the cost savings, environmental benefits, and improved resale value of the home. The next most common group of suggestions revolved around lowering the cost of high efficiency furnaces through the use of rebates or pressuring dealers and wholesalers to lower their prices. While increasing the amount of the rebate was the most frequently made suggestion in this sub-group, it was mentioned by only 10% of trade allies. A small number of trade allies (2% to 4%) suggested changes to program delivery, including extending the program year round, and increasing the amount of program promotion prior to the start of the heating season. Thirty-six percent (36%) of trade allies did not offer suggestions.

4.9 Trade Ally Suggestions – Blower Motors

Suggestions on how to encourage customers to install variable speed furnace motors rather than the less efficient PSC motors could be arranged by three major subject groups: provide education / raise awareness of VSMs, lower the cost of VSM-equipped furnaces, and/or miscellaneous (other). Exhibit 79 summarizes the suggestions by these three subject areas.

Suggestions related to providing education on the costs, benefits, and operating characteristics of installing furnaces with VSMs were offered by trade allies surveyed. Within this general category, trade allies most frequently mentioned raising the awareness of the cost savings (mentioned by 26% of trade allies). Other benefits cited included air quality, quieter operation, improved comfort, and durability. Consistent with the themes heard throughout the survey, several trade allies suggested that

Terasen emphasize the environmental benefits of VSM-equipped furnaces in their education and awareness programming. As well, several trade allies felt customers needed to be educated on how VSMs work, and how their operating characteristics differ from PSC-equipped furnaces. One trade ally alluded to legislating a ban on the sale of PSC-equipped furnaces, while another felt manufacturers should bear more of the responsibility of increasing VSM sales. Twenty-six percent (26%) of trade allies did not offer any suggestions.

Exhibit 79: Suggested Ways to Encourage Customers to Choose Variable Speed Blower Motors over PSC Motors

4.10 Prices

Trade allies provided typical equipment and installed prices for a 90,000 Btu/hour mid-efficiency furnace, a 90,000 Btu/hour high efficiency furnace, and a 75,000 Btu/hour high efficiency furnace. The means of the responses for each furnace type are provided in Exhibit 80. The difference between the mean equipment and installed price effectively represents an approximation of the installation cost.

Exhibit 80: Mean Equipment and Installed Furnace Prices

	90,000 BTU/Hr Mid-efficiency	90,000 BTU/Hr High Efficiency	75,000 BTU/Hr High Efficiency
*Base (n)**	*37-39*	*39-41*	*37-40*
Equipment Price (a)	$1,569	$2,246	$1,925
Installed Price (b)	$2,487	$3,452	$3,183
Installation (b-a)	$918	$1,206	$1,258

** base varies because of differing proportions of DK/NR*

The average equipment price for a 75,000 Btu/hour high efficiency furnace was 23% more than a 90,000 Btu/hour mid-efficiency furnace. Because of its higher efficiency, a 75,000 BTU/hour high efficiency furnace is comparable in its output to a 90,000 BTU/hour mid-efficiency furnace. Installation costs were also higher for the higher efficiency model (37% more), likely reflecting the need to vent the furnace through the side of the house and higher set up costs. Including equipment and installation costs, a 75,000 BTU/hour high efficiency furnace costs 28% more than a 90,000 BTU/hour mid-efficiency furnace.

Equipment costs for a 90,000 Btu/hour high efficiency furnace were significantly higher than a 75,000 Btu/hour high efficiency furnace, commensurate with its size. Installation costs, however, did not statistically differ between the two models.

4.11 Free Riders

Trade allies were asked to rate the importance of the Terasen rebate in their customers' choice of furnace efficiency on a five point scale, where five represented "very important" and one was "not at all important". Trade allies gave an average importance rating of 3.7 out of 5.0. Exhibit 81 uses weights to derive the trade ally based estimate of free riders. A weight of 1 is given to the highest score, 0.75 to the next, 0.5 to the next, and so on. Weights of zero were assigned to an importance score of 1 or DK/NR. Using this method, 66% of trade allies felt the rebate influenced their customers' choice of furnace efficiency, implying a free rider rate of 33%.

Exhibit 81: Trade Ally Estimate of Free Riders – Influence of Overall Incentive

	Very Important (5)	(4)	(3)	(2)	Not at all Important (1)	DK/NR	Total	Free Rider Rate
Distribution of Responses (n=50)	34%	24%	20%	14%	4%	4%	100%	-
Weight	1	.75	.50	.25	0	0	-	-
Product	0.34	0.18	0.10	0.04	0.00	0.00	0.66	**0.33**

Trade allies were next asked to rate the importance of the $100 rebate that was offered to customers who purchased a VSM-equipped furnace. Trade allies gave an average importance score of 3.2 out of 5.0. Using weights identical to those used with the previous question, it is estimated that 53% of customers receiving the VSM rebate would not have purchased the VSM-equipped furnace if the rebate had not been available (Exhibit 82). This suggests a free rider rate for the VSM incentive of 47%.

Exhibit 82: Trade Ally Estimate of Free Riders – Influence of VSM Incentive on Blower Motor Choice

	Very Important (5)	(4)	(3)	(2)	Not at all Important (1)	DK/NR	Total	Free Rider Rate
Distribution of Responses (n=50)	20%	26%	18%	18%	16%	2%	100%	-
Weight	1	.75	.5	.25	0	0	-	-
Product	0.20	0.20	0.09	0.05	0.00	0.00	0.53	**0.47**

The next section compares and discusses the relative merits of the free rider estimates derived from trade ally data versus those derived from the customer survey. Based on that discussion, the decision was made to use the customer survey based free rider estimates in the calculation of program impact.

5 Impact Analysis

This section summarizes the analysis and calculations used to derive a preliminary estimate of energy savings associated with Terasen's 2005-07 Heating System Upgrade Program. Key factors influencing net program savings include attribution (free riders), spillover (advancement of the furnace replacement decision), and operational/behavioural changes. Estimates of program savings are preliminary at this point and will be revised using a comparison of billing histories for participants and non-participants (billing analysis). The billing analysis will occur after participants have used their new furnaces for one full heating and cooling season (12 months). This will allow a comparison of their energy use patterns pre- and post-furnace change-out and will factor in behavioural changes using a comparable group of non-participants. Behavioural changes at this stage of the program's evaluation are limited to description and discussion only.

5.1 Operational/Behavioural Changes

Following the decision of which furnace model to purchase, homeowners can influence the amount of savings realized from the operation of their new furnace in three primary ways:

- pre-post changes in the furnace fan use;
- pre-post changes in furnace settings, most importantly the thermostat or fan operating settings; and
- pre-post changes in the use of supplementary heating.

5.2 Furnace Fan Use

How homeowners use their furnace to heat or cool the house, or to provide ventilation either occasionally or continuously, ultimately affects the amount of energy savings realized from installing a VSM-equipped furnace (assuming their old furnace used a PSC motor). These behaviours also influence the program's economics that justify incentives encouraging the adoption of VSM-equipped furnaces. The economics of VSM blowers are such that households that tended to use their old PSC-equipped furnaces to provide heating/cooling on a continuous basis, and/or to run their fans intermittently to provide ventilation or air circulation, will realize the greatest electricity savings from switching to a furnace with a VSM blower motor. Households that use their fans only intermittently to provide heating or cooling realize considerably less savings. In short, insufficient operating hours significantly increases the payback period for VSM-equipped furnaces. Data from the customer and trade ally surveys on furnace fan behaviours before and after replacing the furnace were analyzed to better understand the cost effectiveness, and targeting, of the VSM incentive.

Information on fan usage from the customer survey was recombined to create four primary groups of fan use – intermittent (heat / cool season), continuous (heat / cool season), to provide ventilation, and continuous. These results were then cross-tabulated by the type of furnace blower motor on the new furnace (PSC versus VSM). Participants and non-participants were combined by furnace blower motor choice to facilitate interpretation. The distribution of fan use for the two motor types was rebased to exclude DK/NR and households without furnace fans (boilers). The results of this analysis are presented in Exhibit 83.

Exhibit 83: Pre-Post Furnace Fan Behaviours by Blower Motor Type (Customer Survey) Participants and Non-Participants Combined

	Before		After		Net Change	
Post Furnace Change Motor Type >	**PSC**	**VSM**	**PSC**	**VSM**	**PSC**	**VSM**
Base (n)	33	98	32	96	-	-
Intermittently (heat / cool season)	55%	60%	47%	52%	-8%	-8%
Continuously (heat / cool season)	36%	31%	41%	32%	+5%	+1%
To also provide ventilation	3%	4%	6%	7%	+3%	+3%
Continuously	6%	5%	6%	8%	0%	+3%

The data suggest that relatively fewer households from both groups – those who installed PSC-equipped furnaces and those who installed VSM-equipped furnaces – are using their new furnace to intermittently heat or cool their homes during the heating/cooling seasons (8% of households for each group). The proportion of households using their furnace fan to provide continuous heat or cooling during the heating / cooling seasons also increased although a larger proportion of PSC households (+5%) did versus VSM-equipped households (+1%). The proportion of households that use their fan to provide ventilation for part of the year increased equally for both groups (+3%); however the proportion of VSM-equipped households that use their fans continuously increased by 3%.

Based on the data presented in Sections 3 and 4 of this report, and this analysis, there are several observations that can be made. One, households that replaced their old PSC-equipped furnace with a VSM-equipped furnace are comprised of several user types. Two, some households have changed how they use their furnace fan after installing their new furnace. Some have gone from using their furnace fan intermittently to continuous use or to provide ventilation, while others have not changed their behaviours – using their furnace fan only on an intermittent basis (yielding the least electricity savings), or running their fan continuously or to provide ventilation in the pre-post periods (highest electricity savings from switching to VSMs). The amount of electricity savings is directly related to pre-post operating hours of the furnace fan, thus the economics of the VSM incentive will depend upon the relative proportion of those who tended to use their fan the most in the pre-change out period and continue to do so afterwards. Finally, there is also evidence that, regardless of motor type, some households have used the furnace replacement decision as an opportunity to add air conditioning. A similar observation was made in the 2004 evaluation (Habart 2004). Finally, while electricity use for both PSC and VSM users will increase due to the addition of air conditioning, those with VSMs should realize some savings relative to PSC-equipped furnaces as VSMs give off less heat than PSC motors.

The finding that some households that installed PSC-equipped furnaces have increased their use of the furnace fan to provide continuous heat/cooling or to provide ventilation for part of the year may be due to improvements in the operating characteristics of the new furnace (e.g., two-stage burner, multi-speed PSC fan motor).

Data from the customer survey suggests that households that had higher operating hours for their old furnace fan (i.e., operated their fans continuously or for air circulation / ventilation) were no more likely to purchase a furnace equipped with VSM than those who had lower operating hours. Instead, energy efficiency and the recommendation of the contractor appear to be relatively more important than the desire for improved circulation / ventilation for many households that purchased a furnace equipped with a VSM blower (Exhibit 31, p. 25). It may be that some of these households were expecting significant electricity savings, but because they used their fan only intermittently prior to the furnace change-out they have been disappointed. Indeed, households with VSM-equipped furnaces rated their satisfaction with the electricity bill savings as 3.8 out of 5.0, significantly lower than the 4.2 satisfaction rating assigned by households who installed PSC-equipped furnaces (Exhibit 19, p. 18). There is also sufficient evidence to suggest that the non-energy benefits of purchasing a high efficiency furnace equipped with a VSM motor (e.g., improved comfort, improved air quality via air circulation, pollen filters, etc.) influenced the decision to purchase the furnace, and is influencing how that furnace is now operated. Non-energy benefits are common selling features for VSM-equipped furnaces.

Information on the before and after use of the furnace fan provided by trade allies was reviewed to provide alternative insight into furnace fan operating behaviours. Trade allies were questioned about fan usage for furnaces they replaced (the majority of these are assumed to be PSC equipped furnaces), newly installed PSC equipped furnaces, and newly installed furnaces with VSMs. Trade allies were not asked about operating behaviours for replaced VSM equipped furnaces as very few VSM models were available prior to 2000 and thus very few households would be replacing a VSM equipped furnace.

Exhibit 84 summarizes the trade ally data organized into the four operating behaviour groupings, rebased to eliminate non-responses (DK/NR). Compared to the old furnace, newly installed VSM-equipped furnaces were more likely to have their fans operate continuously (up from 15% to 27%) and less likely to operate intermittently during the heating / cooling seasons (down from 57% to 46%).

Exhibit 84: Pre-Post Furnace Fan Behaviours by Blower Motor Type (Trade Ally Survey) Percent of Households

	PSC Furnaces		VSM-Equipped Furnaces	Net Change	
	Before	After	After	PSC Equipped Furnaces	VSM-Equipped Furnaces **
Base (n) *	38-40	38-39	37-38	-	-
Intermittently (heat / cool season)	57%	56%	46%	-1%	-11%
Continuously (heat / cool season)	22%	21%	21%	-1%	-1%
To also provide ventilation	6%	6%	6%	0%	0%
Continuously	15%	17%	27%	+2%	+12%

* *Excludes DK/NR*
** *VSM equipped furnaces compared to PSC furnaces*

Compared to the customer surveys, the trade ally data suggest a significantly larger increase in the proportion of households that shift from intermittent to continuous use. It also suggests no change in the relative proportion of households using their furnaces either continuously to provide heat or cooling, or to provide ventilation.

5.3 Changes to Furnace Operating & Control Settings

Exhibit 85 shows that 22% of participants and 9% of non-participants are setting the thermostat lower during the winter months compared to before they replaced their furnace. Only 4% of participants and 11% of non-participants have adjusted their thermostat to keep their house warmer compared to before the furnace change out.

When participants who turned up their thermostat are added to those who turned down their thermostat and those who made no change, the net change in indoor temperature for participants as a group is negative (-0.6^{o} Celsius). It may well be that the increase in home comfort associated with the high efficiency furnaces (e.g., less temperature variation between rooms, better temperature maintenance between furnace cycles, etc.) led participants to lower their thermostat. This, everything else held constant, should increase energy savings somewhat.[7]

Exhibit 85: Average Degree (Celsius) Change in Thermostat Setting since Furnace Change Winter Months

	Change in Indoor Temperature Post-Installation		Amount Warmer / Cooler (Degrees Celsius)		
	Participants	Non-Participants	Participants	Non-Participants	All Respondents
Base (n)	100	100	*100*	*100*	*200*
Warmer	4%	11%	4.7	5.0	4.9
Cooler	22%	9%	3.3	2.5	2.9
No Change	67%	70%	0.0	0.0	0.0
DK/NR/Too soon to tell	7%	10%	-	-	-
Net Change	-	-	-0.6	0.4	-0.2

** Weighted average change including no change (0^o)*

In contrast to participants, non-participants, overall, increased their thermostat setting by 0.4 degrees Celsius. When combined with the 0.6 degree Celsius decline in temperature reported by participants, this suggests that participation in the Terasen furnace program results in a one degree reduction in average temperature setting, and should, everything else held constant, add to participant savings. The forthcoming billing analysis will implicitly capture any relative differences in temperature setting.

5.4 Other Changes to Furnace Settings

Only 5% of participants and 1% of non-participants reported changing one or more operating settings on their furnace (other than the thermostat setting). The relatively small number of households changing their furnace settings, and the nature of the changes identified (e.g., changing the furnace to run less frequently, resetting the blower, installing a digital readout, and installing air conditioning, etc.) suggest these changes are too small to be isolated in determining program savings – using either an engineering estimate or billing analysis approach.

5.5 Changes in Supplemental Heating

Changes in the use of supplementary heating following the installation of the new furnace has the potential to increase or decrease the savings from the furnace upgrade. Reduced use of a supplemental heat source following the furnace change-out means that, everything else held constant, the heating load carried by the natural gas furnace should increase. If the displaced secondary fuel is electricity, then pre-post bill savings for natural gas will be reduced.[8] However, if the secondary fuel is natural gas, then savings are likely increased as the high efficiency furnace will be more efficient that the secondary heat source, such as a fireplace.

Data from the customer survey regarding supplementary heat sources, and the fuel type for supplementary heat, revealed that natural gas fireplaces are the most common source of supplementary

[7] Natural Resources Canada's website suggests that a 1 degree reduction in thermostat setting translates into a 2% reduction in heating costs (www.nrcan.oee.nrcan.gc.ca).

[8] The program should receive credit for the electricity savings in the Total Resource Cost test. However, there is insufficient data in the evaluation methodology to estimate this impact accurately.

heating; present in 41% of participant homes.[9] This suggests that natural gas savings should increase somewhat in these homes if the new high efficiency furnace picks up some or all of the heating load previously carried by the lesser efficient natural gas fireplace.

Exhibit 86 shows that the majority of participants and non-participants (52% and 53% respectively) indicated their use of supplementary heating had not changed since installing their furnace.

Exhibit 86: Change in Supplementary Heating Use since Furnace Replacement Among Those with Supplementary Heating

	Total	Participants	Non-Participants	PSC	VSM	Unknown Blower Motor Type
Base (n)	*88*	*48*	*40*	*20**	*50*	*18**
Increase	8%	6%	10%	5%	12%	0%
Decrease	30%	33%	25%	35%	32%	17%
Stay the Same	52%	52%	53%	45%	48%	72%
DK/NR	10%	8%	13%	15%	8%	11%
Total	100%	100%	100%	100%	100%	100%

** Caution is advised when comparing responses based on small samples*

If the data are rebased to exclude the differing number of non-responses for the two groups (data not presented in tabular format), the proportion of participants reporting a decrease in their use of supplemental heat increases to 36% (rebased) from 33% (non-rebased). Using the same rebasing technique, the proportion of non-participants reporting a decrease in supplemental heating increased to 29% from 25%. The proportion of participants and non-participants reporting increased use of supplemental heating represented 7% and 11% of the two groups, respectively, up from 6% and 10% respectively in the non-rebased series.

The amount of the decrease in supplementary heating, reported in one-quarter increments, is summarized in Exhibit 87. The estimated mean change was calculated by taking the mid-point value of each range (e.g., 0% to 24% was set to 12%, 25% to 49% was set to 37%, and so on) and weighting them by the proportion of responses for each range. This approach provides an approximate indication of relative differences in the reduction in supplementary heating use for participants compared to non-participants.[10] In this case, participants who decreased their use of supplementary heating, cut their use of supplementary heating by almost half (average reduction of 45%). In contrast, non-participants who reduced their use of supplementary heating, did so by 22% on average. A similar calculation was conducted for those who increased their supplementary heating (Exhibit 88).

[9] Determined by cross tabulating supplementary heat sources against fuel types used for supplementary heating. Table not shown.

[10] This procedure allows a comparison of the relative change and direction of change in supplementary heating use by a number of criteria such as program participation and type of blower motor. The comparisons are largely illustrative as the relative amount of energy used for supplementary heating prior to the furnace change is not known, only the relative change since installing the new furnace.

Exhibit 87: Amount of Decrease in Supplementary Heating since Furnace Replacement

Weighted by the relative proportion that reported an increase, decrease, or no change to their supplementary heating, participants with supplementary heating reported a decrease of 16%, and non-participants recorded a 2% decrease (Exhibit 89). Weighted across all households – with or without supplementary heating – the average decrease in supplementary heating for participants and non-participants is 7% and 1%, respectively.

Totals may not sum due to rounding

The results appear to suggest that participants were more likely than non-participants to reduce their use of supplemental heating after replacing their furnace. This suggests that participants' new furnaces are picking up some of the heating load previously met through supplemental sources, most notably the natural gas fireplaces, and to a lesser degree, electric heaters (see Exhibit 47, p. 32).

Estimating the impact on program savings due to the change in supplementary heating, at this point, is problematic due to the considerable number of assumptions required to correctly proportion the heating load borne by the supplementary heating pre- and post-furnace change-out, and to adjust for differing AFUEs of supplementary end use equipment and appliances. Additionally, the heating load transfer may be less than it appears if supplementary heating in the pre-furnace change-out period was needed because of temperature variations between rooms, temperature fluctuations between furnace cycles, and so on – in effect, supplementary heating was being used to improve the comfort in the home or parts of the home. The forthcoming refinement of program savings using a billing analysis will implicitly capture these changes in supplementary heating use and the net impact of other changes in heating/cooling use.

5.6 Market Transformation – Replacement Market

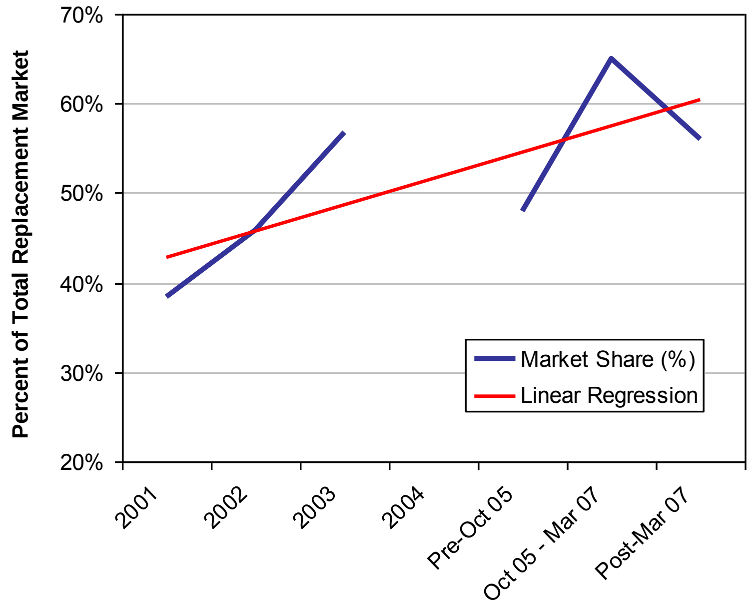
When first introduced to the market, high efficiency technologies are typically priced at a premium compared to standard efficiency units. This "first cost" premium can pose a barrier to the adoption of the technology – one which rebates and other incentives, combined with education and awareness programming, are designed to overcome. The incentives and related programming send signals to manufacturers and suppliers – both in terms of the intent to promote the high efficiency market, and through the eventual increase in demand for the high efficiency product. The mark of successful market transformation programs has been an increase in the awareness and availability of the high efficiency product, and a decline in the price differential between it and lesser efficient models. Understandably, the ability to transform a market depends on the scale and scope of the program, the ability for manufacturers to realize economies of scale, and a host of other factors that influence supply and demand for the technology in the market place.

5.7 Market Shares – High Efficiency Furnaces

Based on results from the survey of trade allies, the proportion of the replacement market captured by high efficiency furnaces saw an increase during the program period. High efficiency furnaces captured 65% of the market while the program was operating, up from 48% prior to launch, and then declining to 56% afterwards. The results from the customer survey suggested that the share of the replacement furnace market captured by high efficiency furnaces was 55% during the program period.

Figure 3 summarizes the replacement market share data from this evaluation and the 2004 evaluation. The data series is imperfect and caution in over-interpreting the results is advised. The time periods are inconsistent and data are missing for 2004, although pre-September 2005 does, by default, infer some overlap. Inserting a simple linear regression trend line suggests an upward trend in the proportion of the replacement furnace market captured by high efficiency furnaces. This was expected. The data does suggest that the market shares fall off after incentives cease. This, too, is expected and is commonly observed with incentive based demand-side management programs.

Figure 3: Shares of High Efficiency Furnaces in the Replacement Furnace Market
Source: Trade Ally Surveys – 2003, 2007



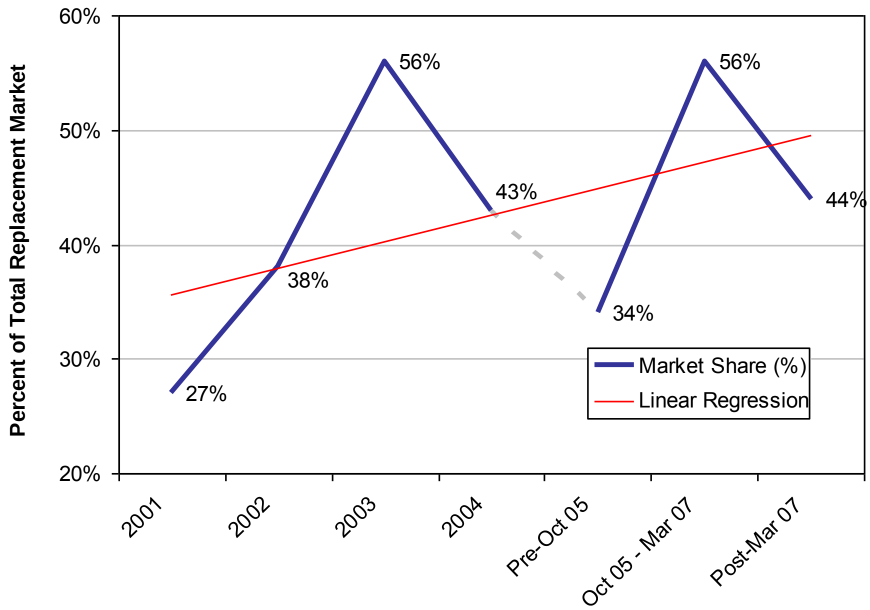
Trade allies reported that, on average, 54% of all furnaces they replaced between September 2005 and March 2007 were eligible for a rebate from Terasen Gas or its partners.

5.8 Market Shares – Variable Speed Motors

According to trade allies, the share of the replacement furnace market represented by furnaces with VSM blower motors increased from 34% in the pre-program period to 56% during the program, and falling to 44% in the post-program period. Data from the customer survey put the share of VSM-equipped furnaces (high or mid-efficiency) at 60%. Focusing just on high efficiency furnaces, Terasen's program records indicate that 65% of participants in the heating upgrade program opted for a high efficiency furnace equipped with a VSM blower motor.

Figure 4 pulls together VSM market share data from the 2004 evaluation and the trade ally estimates for the 2005-2007 period. The data, while imperfect for reasons discussed under furnace efficiency market shares, suggest a seesaw pattern, where VSM shares increase significantly during periods where Terasen's rebate program is in effect.

Figure 4: Share of VSM-equipped Furnaces in the Replacement Furnace Market
Source: Trade Ally Surveys – 2003, 2007



Despite the pullback in the periods following termination of incentives, the general trend in VSM market share for furnaces equipped with VSMs appears to be increasing.

5.9 Prices

For many homeowners, the cost of replacing a furnace (first cost) can be the predominate factor influencing the choice of furnace model efficiency. The relatively greater equipment and installation cost of a high efficiency furnace can become a barrier for households for several reasons: not excluding insufficient funds or access to funds (financing), plans to sell the home in near future (e.g., will not realize the long-term cost savings associated with a high efficiency unit), or a lack of understanding of the lifecycle cost savings from adopting a high efficiency unit.

The trend in prices of high versus mid-efficiency furnaces (i.e., lowest cost option now allowed by legislation) were explored using data from the 2007 trade ally survey and data gathered for the 2004 evaluation (survey conducted in 2003). The results in Exhibit 90 suggest that equipment prices have increased for both mid and high efficiency models over the four-year period. However, on an installed cost basis, a decline in installation costs has offset more than half (57% to 58%) of the increase.

Exhibit 90: Furnace Equipment and Costs for 90,000 BTU/Hr Units - 2007 Versus 2003

	90,000 BTU/Hr Mid-efficiency Furnace			90,000 BTU/Hr High Efficiency Furnace		
	2003	2007	Difference	2003	2007	Difference
Base (n)	*40*	*50*	-	*40*	*50*	-
Equipment Price (a)	$1,104	$1,569	$465	$1,806	$2,246	$440
Installation Charges (b-a)	$1,185	$918	-$267	$1,391	$1,206	-$185
Final Installed Price (b)	$2,289	$2,487	$198	$3,197	$3,452	$255

Exhibit 91 compares installed furnace prices for a 90,000 BTU/hour mid-efficiency furnace and a 75,000 BTU/hour high efficiency furnace for the years 2002, 2003 and 2007. Because of its higher efficiency, a 75,000 BTU/hour high efficiency furnace is comparable in its output to a 90,000 BTU/hour mid-efficiency furnace. The incremental installed cost declined from 2002 to 2003 from $877 to $608 before increasing to $696 in 2007.

Exhibit 91: Installed Furnace Costs – 2002, 2003, 2007

	90,000 BTU/Hr Mid-efficiency Furnace	75,000 BTU/Hr High Efficiency Furnace	Incremental Cost
2002	$2,194	$3,071	$877
2003	$2,289	$2,897	$608
2007	$2,487	$3,183	$696

Exhibit 92 compares the equipment and installation costs for the same two furnaces for the survey years 2003 and 2007. Of note, equipment costs for both furnaces are higher in 2007. In the case of the 90,000 BTU mid-efficiency furnace, a decline in the average installation cost has partially offset the $465 dollar increase in equipment cost. For the 75,000 BTU high efficiency model, equipment costs rose by $277 but installation costs were effectively unchanged.

Exhibit 92: Equipment and Installation Cost Comparisons - 2007 Versus 2003

	90,000 BTU/Hr Mid-efficiency Furnace			75,000 BTU/Hr High Efficiency Furnace		
	2003	2007	Difference	2003	2007	Difference
Base (n)	*40*	*50*	*-*	*40*	*50*	*-*
Equipment (a)	$1,104	$1,569	$465	$1,648	$1,925	$277
Installation Charges (b-a)	$1,185	$918	-$267	$1,249	$1,258	$9
Final Installed Cost (b)	$2,289	$2,487	$198	$2,897	$3,183	$286

The comparison of equipment and installation costs for the past two survey periods fails to provide an indication that the differential between a comparable mid-efficiency and high efficiency furnace has narrowed. Equipment prices for all models appear to have increased over the four year period. Installation costs for high efficiency models still remain higher than a mid- or standard efficiency unit.

5.10 Free Riders

5.10.1 Free Riders – High Efficiency Furnaces

The results from the participant and trade ally surveys provided two estimates of the free rider rate for high efficiency furnaces rebated under the Terasen program, with the participant survey suggesting 43% and the trade ally survey suggesting 33%. The relatively high proportion (58%) of non-participants who installed a high efficiency furnace but were unaware of Terasen's heating upgrade program (Exhibit 93) suggests that the free rider rate is probably closer to that estimated using participant survey data. The non-participant data should be interpreted with caution, as there is evidence that some have difficulty in accurately identifying the efficiency level of their furnace.

Exhibit 93: Non-Participant Furnace Efficiency Choice by Awareness of Terasen's Program

	Total	Aware	Unaware & DK/NR
Base (n)	*100*	*48*	*52*
Standard Efficiency	39%	48%	31%
High Efficiency	48%	38%	58%
DK/NR	13%	15%	12%
Total	100%	100%	100%

Totals may not sum due to rounding

5.10.2 Free Riders – Variable Speed Drives

The free rider rate for variable speed drives represents the proportion of participants who received the $100 incentive for purchasing a VSM-equipped furnace but would have purchased a VSM-equipped furnace without the incentive. Again, the participant and trade ally surveys provided two estimates of the free rider rate for VSMs. The participant survey suggested a free rider rate of 43% while the trade ally survey suggested a slightly higher rate of 47%. Which estimate is closer to the true rate is subject to interpretation.

The relatively high estimates are consistent with evidence that suggests the incentive was less instrumental in the decision to purchase than, for example, the potential to save energy or the recommendation of the furnace dealer/contractor (Exhibit 31, p. 25). The customer survey indicates that 34% of participants and 36% of non-participants who purchased a VSM-equipped furnace indicated they were aware of VSMs or considering the purchase of VSMs prior to purchasing their furnace. These households are most likely to be classed as potential free riders. However, awareness, while fundamental to the consideration of a VSM in the first place, doesn't necessarily ensure the choice of VSM-equipped furnace in the final decision by the consumer.

Exhibit 94 looks at the issue from the non-participant's perspective. The data suggest that 53% of non-participants who were unaware of Terasen's Heating System Upgrade Program purchased a furnace with a VSM. While this lends support to the use of the trade ally estimate, the free rider estimate of 43% derived from the participant survey will be used for determination of net impact because it was derived in a manner consistent with the free rider rate for high efficiency furnaces in general.

Exhibit 94: Non-Participant Blower Motor Choice by Awareness of Terasen's Program

	Total	Aware	Unaware & DK/NR
Base (n)	*70*	*32*	*38*
PSC	44%	41%	47%
VSM	56%	59%	53%
Total	100%	100%	100%

Totals may not sum due to rounding

5.11 Spillover

There are several reasons why households replace their old furnaces. Some furnaces cease working and require expensive repairs, while others are diagnosed as needing expensive repairs in the not-so-distant future. Some households will choose to replace their older, inefficient furnaces to realize energy savings or to improve the comfort in the home. However, change-outs such as these typically occur only when the furnace is nearing the end of its useful life.[11] Finally, some households made the decision to replace their furnace earlier than planned because of the availability of incentives, such as those offered through the Terasen Heating System Upgrade Program. The energy savings realized from advancing the decision to replace the furnace that can be attributed to Terasen's program are termed spillover savings. They are calculated by taking the difference in the efficiency levels of the replaced furnace and the new furnace, and multiplying the savings by the average number of years of advancement.

Spillover savings for Terasen's 2005-07 Heating System Upgrade Program were determined by querying participants about the operational status of their old furnace at the time of replacement, and then asking them whether the program caused them to advance their decision to replace the furnace. Finally, those participants who answered in the affirmative to both questions were asked to indicate by how many years they advanced their decision.

The customer survey found that 91% of participants' furnaces and 77% of non-participants' furnaces were still working and producing heat when replaced. The average age of the furnace at the time of replacement for participants was 24.1 years versus 24.7 years. These statistics confirm that participants were more likely to replace their furnaces prior to failure, and at an earlier age. Thirty percent (30%) of participants confirmed that they replaced their furnaces earlier than planned because of the availability of the rebate. They indicated an average advancement of 2.3 years.

5.12 Calculation of Program Savings

5.12.1 Key Inputs and Assumptions

Average AFUE for Rebated Furnaces

Program records listed brand names and corresponding model numbers, but not AFUE ratings for the rebated furnaces. To determine the average AFUE rating of the new high efficiency furnace for use in the impact calculations, a random sample of 400 participant furnaces were manually cross-referenced with the Energy Star database of qualifying natural gas furnaces.[12] Matching was based on the furnace brand name and model number. Where matches were not possible, the records were excluded from calculation of the AFUE average.[13] In cases where the Energy Star database listed a range of AFUE for a particular furnace model (e.g., 90.1% – 92.0%) , the lower AFUE rating was selected. In the end, 362 of the 400 participant records were matched successfully to an AFUE rating yielding an average AFUE rating of 93.0%. The previous evaluation had used an assumption of 92% AFUE.

AFUE and Average Consumption of Replaced Furnace Stock

Current legislation in British Columbia prohibits the sale of natural gas furnaces with an AFUE of less than 78%, defining the minimum efficiency base for calculating program savings. A billing analysis conducted for the 2002 Residential Heating System Upgrade program determined that the efficiency of the average furnace replaced during that year's program was 70.6%. As an update to this value is not available, it will be used for this analysis. The same study estimated the annual consumption of the average replaced furnace was 91.5 GJ. As an update to this value is not available, it will be used in the phase one impact analysis as well.

[11] Only 14% of households surveyed indicated their replaced furnace was younger than 15 years.

[12] The database is available for download from *http://www.energystar.gov/index.cfm?c=furnaces.pr_furnaces*

[13] Model numbers for gas furnaces can vary significantly between manufacturers, with most using lengthy alphanumeric combinations. Some of the model numbers recorded in the program database were either incomplete or had typographical errors making it impossible to accurately match the furnace model to the Energy Star database.

Number of Participants

Based on program records, 8,652 customers participated in the Terasen program during the September 2005 to March 2007 period. Of these, 5,667 applicants received an incentive for a VSM-equipped furnace.

Free Riders

Free riders in the overall program were estimated at 43%. Free riders among those participants receiving an incentive for a VSM-equipped furnace were calculated as 43%.

Spillover

Thirty percent (30%) or 2,596 participants indicated that they replaced their furnace earlier than planned because of the Terasen program. The average number of years of advancement for these customers was 2.3 years.

5.13 Energy Savings

The estimated energy savings attributable to Terasen's 2005-07 residential Heating System Upgrade Program is summarized in Exhibit 95. Based on a net-to-gross ratio of 0.57, the program generates 66.1 terajoules (TJ) in annual savings, plus an additional 22.6 TJ of savings for the first 2.3 years (spillover).

Exhibit 95: Energy Savings Estimates – September 2005-March 2007

	Unit Savings (GJ)	Gross Participants	Gross Savings (TJ)	Net to Gross Ratio	Net Savings (TJ)
Direct	13.4	8,652	115.9	0.57	66.1
Spillover	8.7	2,596	22.6	--	22.6
Annual – first 2.3 years	-	-	-	-	88.7
Annual – subsequent years	-	-	-	-	66.1

5.14 Peak Day Reductions

To estimate peak savings, the heating load on any day is assumed proportional to the heating degree days for that day. In the coldest month (January) the average daily heating load is equal to:

Annual Heating Load (GJ) * Monthly Share of Annual Heating Degree Days (January) * 1/31 days

The change in peak day load is then calculated as the change in average daily load for January. Exhibit 96 calculates the weighted peak day heating load share for January using a representative weather station for each of Terasen's five zones and the thirty year typical meteorological year heating degree-day shares for the month. Estimated peak day savings are then calculated as the weighted peak day heating load share for January multiplied by net savings. Estimated peak day savings are 0.48430 TJ for the first 2.3 years, and then 0.36091 TJ for the remaining years.

Exhibit 96: Peak Day Savings

	Representative Weather Station	Zone Customer Share	Peak Day Heating Load Share	Weighted Peak Day Heating Load Share	Peak Day Savings (TJ) – First 2.3 years (Including Spillover)	Peak Day Savings (TJ) – Remaining Years
Zone 1	Vancouver	0.244	0.00501	0.00122	-	-
Zone 2	Burnaby	0.173	0.00511	0.00084	-	-
Zone 3	Surrey	0.280	0.00510	0.00143	-	-
Zone 4	Kamloops	0.117	0.00625	0.00073	-	-
Zone 5	Cranbrook	0.186	0.00667	0.00124	-	-
Total	-	1.000	-	0.00546	0.48430	0.36091

5.15 Carbon Dioxide Reductions

Terasen assumes an emissions factor of 50 tonnes carbon dioxide (CO_2) per terajoule of energy saved. Using this factor allows the saving estimates to be translated into the equivalent reduction in CO_2 emissions (Exhibit 97). In total, the program reduced the amount of annual CO_2 emitted by residential furnaces by 4.435 kilotonnes in the first 2.3 years, and 3.305 kilotonnes for subsequent years.

Exhibit 97: Reduction in Carbon Dioxide Emissions

	Net Savings (TJ)	Emissions Factor	$C0_2$ Reduction (Kilotonnes)
Direct	66.1	0.050	3.305
Spillover	22.6	0.050	1.130
Total – first 2.3 years	88.7	0.050	4.435
Total – Remaining Years	66.1	0.050	3.305

6 Summary & Conclusions

Summary comments and conclusions for the evaluation of Terasen's 2005-07 Heating System Upgrade Program are organized by the five main evaluation objectives.

Objective 1: Assess the reasons for program participation, the effectiveness of program marketing / advertising, free ridership, reasons for non-participation, and overall customer and trade ally satisfaction with the program.

Understanding the importance of Terasen's Heating System Upgrade Program to the decision to install a high efficiency rather than a standard or mid-efficiency furnace is essential to the attribution of energy savings to Terasen's program. In this regard, 57% of participants in the Terasen program credited the program with influencing their decision to purchase a high efficiency furnace, meaning that 43% of participants were free-riders and would have selected a high efficiency furnace without the incentive. The free rider estimate is consistent with the fact that 38% of non-participants that were unaware of the Terasen program installed a high efficiency furnace. Based on information provided by participants, the proportion of free riders for the 2005-07 program is estimated at 43%. This is an increase from 28% estimated for the previous program. The increase is consistent with the continuing transformation of the furnace market to high efficiency units.

Thirty percent (30%) of participants credited the program and its incentives for their decision to replace their furnace, on average, 2.3 years earlier than planned. This is consistent with the significantly higher proportion of participants than non-participants reporting that their old furnace was still operational at the time of replacement (91% versus 71%).

Satisfaction scores assigned to various program attributes by program participants, based on a five-point satisfaction scale, were generally favourable, with the highest score given to application procedures (4.1) and the lowest score given to size of the rebate (3.7). Trade allies also rated the program positively using the same five-point scale with the highest satisfaction score given to the types and number of furnaces eligible for a rebate (4.2), and the lowest score given to the size of the rebate (3.6).

Participants in the program attributed their awareness of the program to an insert in their Terasen bill (29% of participants), heating or furnace contractor (26%), word of mouth (21%), and direct mail from Terasen (15%). Success in program marketing is often reflected in word of mouth traffic. The Terasen program appears to have successfully achieved this result.

More than half (52%) of Terasen's residential customers who replaced their furnaces during the past three years and did not participate in the Terasen program were simply unaware the program existed. The next most common reasons for not participating (mentioned by anywhere from 17% to 19% of non-participants) included the dollar amount of the rebate (i.e., too small), the hassle factor with applying for the rebate, and the fact that the furnace they chose did not qualify. Ten percent (10%) of non-participants indicated they had applied to the program but had their application rejected.

Participants in Terasen's Heating System Upgrade Program are generally very satisfied with their high efficiency furnace. Ten percent (10%) reported experiencing problems with their new furnace, but only 2% reported having major repairs. A large percentage (71%) of participants reported improvements in the comfort of the home after installing their high efficiency furnace. In contrast, 42% of non-participants reported improvements in home comfort after installing their furnace.

Customers installing VSM-equipped furnaces were significantly more likely than those installing PSC-equipped furnaces to experience an increase in home comfort (68% versus 43% respectively).

***Objective 2: Assess program impact on sales of qualifying high-efficiency furnaces (HEF), and variable speed blower motors (VSM), for both participating and non-participating customers*.**

Information provided by customers and trade allies during the 2004 and 2007 furnace evaluations confirms that the replacement furnace market in British Columbia is moving towards high efficiency furnaces. Trade allies reported that high efficiency furnaces represented 48% of all replacement furnace sales prior to the launch of the most recent program. This share rose to 65% during the program and then declined to 56% after rebates ended in March 2007. VSM-equipped furnaces (either mid- or high efficiency) accounted for 34% of all furnace sales prior to program launch, and 44% following the program conclusion. Trade allies reported the share rising to 56% while the program was in operation.

Forty-three percent (43%) of non-participants reported installing high efficiency furnaces, while 39% installed standard or mid-efficiency furnaces. The remaining 13% of non-participants were not sure of their furnaces' efficiency. The decision not to install a high efficiency model was influenced by first cost, length of payback period, and a general lack of awareness of the relative costs and benefits of high efficiency furnaces. Non-participants were more likely than participants to have annual household incomes of less than $40,000, meaning that the relatively higher cost of a high efficiency furnace (approximately $700 more than a mid-efficiency furnace) was more of a financial hurtle for these households.

The top three reasons for installing a furnace equipped with a variable speed motor were the desire to save electricity (mentioned by 42% of participants), the contractor's recommendation (35%), and the $100 incentive offered by Terasen and its partners (11%). Trade allies were somewhat less likely than customers to attribute the decision to purchase a VSM-equipped furnace to the influence of the rebate (53% versus 57%). The customer-based estimate of free riders was used in the analysis of program impact.

Objective 3: Document and assess program impact on furnace and secondary heating operating behaviours that affect energy use, with particular emphasis on hours of operation.

Four factors influencing furnace operating costs (and savings) were explored in this evaluation – changes in furnace fan operating behaviours, changes in thermostat setting, changes in operating settings, and changes in supplementary heating.

How homeowners use their furnace to heat or cool the house, or to provide ventilation either occasionally or continuously before and after the installation of a VSM-equipped furnace affects the amount of electricity savings realized from the VSM blower motor. The economics of VSM furnace fans depend on operating hours – low operating hours significantly increases the payback period for VSM-equipped furnaces.

This evaluation found that, regardless of the furnace blower type, the number of households using their furnaces to intermittently heat or cool their homes during the heating/cooling seasons declined after installing their new furnace, and a proportion increased their use of the fans to provide continuous heat or cooling during the heating / cooling seasons. The data is inconclusive as to the influence of blower motor choice on behaviours as a significant proportion of households installing furnaces equipped with PSC motors also changed their usage to one of providing more continuous heat or cooling, or to provide ventilation for part of the year . Households that installed VSM-equipped furnaces, however, were more likely to use their fans continuously.

The evaluation found that households who replaced their old PSC-equipped furnaces with a VSM-equipped furnace are comprised of several user types – with no conclusive evidence to suggest that households that used their old furnaces either continuously for heating/ cooling, continuously, or to provide ventilation were predisposed to purchase a VSM-equipped furnace. Instead, energy efficiency, the recommendation of the contractor, and non-energy benefits (e.g., improved comfort, improved air quality via air circulation, pollen filters, etc.) appear to have been more important considerations. Interestingly enough, some households purchasing VSM-equipped furnaces appear to have had unrealistic expectations regarding the electricity savings potential of VSM blowers, as they rated their satisfaction with electricity bill savings from their VSM-equipped furnaces significantly lower than households who purchased PSC-equipped furnaces (3.8 versus 4.2 using a five-point satisfaction scale). Data on furnace fan operating behaviours prior to furnace change out suggest that a significant number of households installing VSM-equipped furnaces tended to use their old furnace fans only intermittently, implying their electricity bill savings would be less significant that those who operated the fans more frequently or continuously.

Changes to Furnace Thermostat Setting

Only 4% of participants and 11% of non-participants increased their thermostat setting to keep their house warmer since installing their new furnace. A significantly greater proportion of participants than non-participants reported turning down the thermostat since replacing their furnace (22% versus 9%). When increases or decreases in temperature (in degrees Celsius) are added to those who reported no change, the net change in indoor temperature for participants was minus 0.6 degrees Celsius compared to plus 0.4 degrees for non-participants. This suggests that participants are maintaining their home temperatures a full degree lower than non-participants, effectively adding to the energy savings attributable to participation in the Terasen program.

Changes to Furnace Operating Settings

Only 5% of participants and 1% of non-participants reported changing one or more operating settings. Participants mentioned changing the furnace to run less frequently, resetting the blower, installing a digital readout, and installing air conditioning. The non-participant reported adjusting the timing of the second stage burner so that it engaged sooner.

Changes to Supplementary Heating

The evaluation found that participants were significantly more likely than non-participants to reduce their use of supplemental heating after replacing their furnace (-16% versus -2%). This suggests that participants' new furnaces are picking up some of the heating load previously met through supplemental sources, most notably the natural gas fireplaces, and to a lesser degree, electric heaters. The transfer of the heating load to the new furnace may result in additional savings as the furnace will be more efficient than the natural gas fireplace. However this may be partially offset if supplementary heating in the pre-furnace change-out period was being used to improve the comfort in the home or parts of the home (e.g., temperature variations between rooms, temperature fluctuations between furnace cycles, etc.). The forthcoming refinement of program savings using a billing analysis will, by its nature, capture these changes in supplementary heating use and the net impact of other changes in heating/cooling use.

Objective 4: Determine the status of market transformation for high efficiency furnaces, and furnaces with variable speed drive blower motors in the British Columbia market.

Market transformation is measured, in part, by changes in market shares of high efficiency products, and declines in the relative price differential of high efficiency units relative to standard efficiency units.

High efficiency furnaces' share of the replacement furnace market rose from 48% prior to program launch to 65% during the program phase, before retreating to 56% after the conclusion of the program. A review of market share data from the past and present evaluations suggests a moderate pullback in the market when no program is in place.

Trade allies reported that 54% of all furnaces replaced between September 2005 and March 2007 were eligible for a rebate from Terasen Gas or its partners.

Trade allies reported that the share of the replacement furnace market represented by VSM-equipped furnaces increased from 34% in the pre-program period to 56% during the program, and then falling to 44% in the post-program period. Terasen's program records indicate that 65% of participants in the heating upgrade program installed a high efficiency furnace equipped with a VSM blower motor. A review of historical market share data suggests that like high efficiency furnaces, VSM market shares seesaw when programs are in effect versus when they are not, although the general trend is upward.

A comparison of equipment and installation costs provided by trade allies surveyed in 2003 and 2007 suggests that equipment prices for all furnace models regardless of efficiency increased over the four-year period, while installation costs either stayed the same or declined somewhat. High efficiency furnaces still cost more on an installed basis than mid- or standard efficiency units. The incremental cost of installing a 75,000 BTU/hour high efficiency furnace compared to a 90,000 BTU/hour mid-efficiency furnace (comparable in output based on efficiency) is $696, down from $877 in 2002, but up somewhat from $608 in 2003.

Objective 5: Develop preliminary estimates of program impact on natural gas sales and carbon dioxide emissions.

Energy savings attributable to Terasen's 2005-07 residential Heating System Upgrade Program, using a net to gross ratio 0.57, include 66.1 terajoules (TJ) in annual savings, plus an additional 22.6 TJ of savings for the first 2.3 years (spillover). Estimated peak day savings are 0.48430 TJ for the first 2.3 years, and then 0.36091 TJ for the remaining years. Assuming an emissions factor of 50 tonnes carbon dioxide per terajoule of energy saved, Terasen is credited with reducing CO^2 emissions from residential furnaces by 4.435 kilotonnes in the first 2.3 years, and 3.305 kilotonnes for subsequent years.

INTRODUCTION

Hello, my name is __________ from Call Us Info, a marketing research firm. Today I am calling on behalf of Terasen Gas.

The purpose of my call is to collect information that will help Terasen Gas evaluate its efforts to improve the efficiency of home heating systems in BC. I would like to speak to the person responsible for decisions related to your natural gas furnace. Would that person be you?

Yes: CONTINUE
No: ASK TO SPEAK TO THE PERSON RESPONSIBLE FOR DECISIONS RELATED TO THE NATURAL GAS FURNACE. IF NOT AVAILABLE, ASK WHEN IS A BETTER TIME TO CALL BACK. RECORD TIME

Would you be willing to participate in a survey that should take less than 15 minutes of your time?

Yes: CONTINUE
No: ASK IF THERE IS A BETTER TIME TO CALL BACK. RECORD TIME
THANK AND TERMINATE

IF NECESSARY: If respondent would like to verify the legitimacy of this study, they can contact Terasen Gas at 604-576-7000 and advise that they would like to verify a market research study.

PARTICIPANTS:
Did you purchase and install a new natural gas furnace in your home in 2006 or during the first three months of 2007?

IF PARTICIPANT INDICATES NO, THEN RECORD CLIENT ID, THANK AND TERMINATE.

NON PARTICIPANTS:
Did you purchase and install a new natural gas furnace in your home in 2005, 2006, or the first three months of 2007?

Yes: CONTINUE
No: THANK AND TERMINATE

Do you rent or own your home?

Own: CONTINUE

Rent: THANK AND TERMINATE

Q1: Just to confirm, in which month and year did you have the new natural gas furnace installed?

Month _____ Year _____
DK _____

Q2: How old was the old furnace when it was replaced?

Years _____
DK _____

Q2a: Did you receive an incentive from Terasen Gas on the purchase of the new furnace?

Yes _____
No _____
DK _____

IF PARTICIPANT INDICATES NO, THEN RECORD CLIENT ID, THANK AND TERMINATE.

YES: NON PARTICIPANTS FORCE TO PARTICIPANTS

Q3: Was the old furnace still working and producing heat at the time it was replaced?

Yes _____
No _____
DK _____

Now I would like to ask about the efficiency of your new furnace.

- A high efficiency furnace has a minimum efficiency of 90% or more. It is characterized by venting the exhaust through the side of the house rather than through the roof. High efficiency furnaces are usually designated as ENERGY STAR qualified.
- A standard efficiency furnace has an efficiency rating of between 55% and 85%. It is characterized by venting the exhaust through the roof in a flue or chimney.

Q4: Is the new furnace a standard efficiency or a high efficiency unit?

(Note to interviewer, some respondents may refer to a standard efficiency furnace as a mid-efficiency unit). (IF RESPONDENT IS PROGRAM PARTICIPANT THE ANSWER SHOULD AUTOMATICALLY BE HIGH EFFICIENCY. IF NOT PROBE by reviewing the definitions of standard and high efficiency furnace.)

Standard efficiency _____
High efficiency _____
DK _____

Q5: Was the old furnace that was replaced a standard efficiency furnace or a high efficiency furnace?

Standard efficiency _____
High efficiency _____

DK ______

Q6: How satisfied are you with your choice of new furnace? (READ)

Extremely satisfied ____
Very satisfied ____
Somewhat satisfied ____
Not very satisfied ____
Not at all satisfied ____
DK ____

If Extremely / very / somewhat: SKIP TO Q8

Q7: Why are you not satisfied with your choice of furnace?

(SPECIFY) _______

PARTICIPANTS WITH Variable Speed Motors (VSM=1) SKIP TO Q9

Q8: Does your new furnace have a variable speed fan motor? Furnaces equipped with these motors use less electricity but typically cost more than furnaces with standard motors. They can operate over a range of speeds when providing heat or circulating air. (NOTE: standard furnace motors (called PSC motors) typically operate at only one or two fixed speeds).

Yes: _____
No: _____
DK: _____

Yes: CONTINUE WITH Q10a
No: SKIP TO Q11a
DK: SKIP TO Q13

Q9: Unused

IF PARTICIPANT with VSM=1, READ: Our records show that you selected a furnace with a variable speed drive motor.

Q10a: Why did you select a model with a variable speed furnace motor? (DO NOT READ – CHECK ALL THAT APPLY)

It is more energy-efficient ____
It is quieter ____
It can operate through a range of speeds ____
It provides more comfortable ventilation ____
I wanted better indoor air quality ____
It keeps my house warmer ____
It provides even heat ____
I wanted to have continuous ventilation ____
The contractor recommended it ____
I was motivated by the $100 rebate ____
Part of the better furnace I wanted ____

Other (RECORD) ____

Q11a: Prior to installing this furnace, were you aware of, or were you considering, the purchase of, a variable speed furnace motor?

Aware of: _____
Considering purchase: _____
No: _____
DK: _____

NO/NOT AWARE/DK: SKIP TO Q13a

Q11b: How did you become aware of a variable speed furnace motor? (DO NOT READ – CHECK ALL THAT APPLY)

Contractor ____
Terasen Gas ____
BC Hydro ____
Power Smart ____
Other (RECORD) ____

IF Q8=YES/DK/BLANK SKIP TO Q13a

Q12: Why did you not select a furnace model with a variable speed motor (DO NOT READ)?

Was unaware of the variable speed motor ____
Was unaware of the rebate for the variable speed motor ____
Furnace with variable speed motor was too expensive ____
Variable speed motor not available on furnace I chose ____
Contractor did not recommend it ____
Other (RECORD) ____

Q13a: Now we would like to understand how you use your furnace fan.
How did your furnace fan, if any, operate before the furnace change? (READ CHOICES BEFORE GETTING ANSWER)

Intermittently when providing heat ____
Continuously during the heating season ____
Intermittently when providing heat or air conditioning ____
Continuously during the heating / cooling seasons ____
Intermittently to also provide ventilation for part of the year ____
Continuously ____
No furnace fan (boiler) ____
DK ____

IF "Intermittently to also provide ventilation for part of the year"
Q13b: Approximately how many months per year did you operate the fan in this way? RECORD _____

Q13c: How does your furnace fan, if any, operate after the furnace change? (READ CHOICES BEFORE GETTING ANSWER)

Intermittently when providing heat ____
Continuously during the heating season ____
Intermittently when providing heat and air conditioning ____
Continuously during the heating / cooling seasons ____
Intermittently to also provide ventilation for part of the year ____
Continuously ____
No furnace fan (boiler) ____
DK ____

IF "Intermittently to also provide ventilation for part of the year"
Q13d: Approximately how many months per year do you plan to operate the fan in this way?
RECORD ____

Q13e: Thinking of the winter months only, have you set the thermostat to keep your house warmer, cooler, or the same than before the furnace change?

Warmer ____
Cooler ____
Neither (The Same) ____
Too soon to know ____
DK ____

IF "THE SAME" SKIP TO Q13f

Q13e – 1: If warmer/cooler – On average, how many degrees warmer/cooler do you keep your house during the winter compared to before you changed your furnace.(NOTE: CONFIRM UNITS – CELCIUS OR FARHENHEIT)
____° Celsius
____° Fahrenheit

Q13f: Other than adjusting the thermostat, have you changed any operating settings on your furnace since it was installed? (PROMPT: For example: changed when or how long the blower fan operates…)

Yes: _____
No: _____
DK: _____

Q13g: If Yes: What operating settings did you change? ___________________________

Q13h: Why did you make this change? ___________________________

Q14a: Are you familiar with the ENERGY STAR label for natural gas furnaces? Only furnaces that meet a high level of energy efficiency can qualify for ENERGY STAR.

Yes: _____
No: _____
DK: _____

Yes: CONTINUE WITH Q14
No/DK: SKIP TO Q16

Q14b: Was your furnace identified with an ENERGY STAR symbol on the furnace or the furnace brochure?

Yes: _____
No: _____
DK: _____

NON-PARTICIPANTS: SKIP TO Q16

Q15: On a scale of 1 to 5 where 1 is not at all important and 5 is very important, how important is it to you that the Terasen Gas incentive program included products that met the Energy Star high efficiency levels?

1 2 3 4 5 DK

Q16: What was the installed price of the new furnace, including any applicable taxes? (PROMPT IF NECESSARY: AN ESTIMATE IS OK)

Price: $ _____
DK: _____

Q17a: NON-PARTICIPANTS: Were you aware of the Terasen Gas program which offered an incentive for the purchase of a high efficiency ENERGY STAR qualified natural gas furnace?

Yes ____
No ____
DK ____

Yes: CONTINUE WITH Q17a-1
No/DK: SKIP TO Q29

Q17a-1: NON-PARTICIPANTS: Why did you not participate in the Terasen program? (DO NOT READ – CHECK ALL THAT APPLY)

Furnace did not qualify for rebate ____
Had planned to / didn’t get around to it ____
Not worth the effort / Didn’t want to bother ____
Rebate too small ____
Didn’t know how to apply ____
Tried to – rebate application was rejected ____
Contractor was not registered with program ____
Other (SPECIFY) _____________ ____

SKIP ALL REMAINING NON-PARTICIPANTS TO Q29

Now I would like to obtain your opinion on the Terasen Gas incentive program.

Q17b: How did you become aware of the incentive program? (DO NOT READ - CHECK ALL THAT APPLY)

INTRODUCTION

Hello, my name is __________ from Call Us Info, a market research firm. Today I am calling on behalf of Terasen Gas. I would like to speak to the person responsible for residential furnace sales and installation with your firm.

Available: CONTINUE
Not available: ASK WHEN IS A BETTER TIME TO CALL BACK. RECORD TIME.

The purpose of my call is to collect information that will help Terasen Gas improve the efficiency of home heating systems in BC. We will use this information to better understand the impact of more efficient furnaces on natural gas consumption in B.C. and the effectiveness of our promotion programs. Would you be willing to participate in a survey that will take less than 15 minutes of your time?

Yes: CONTINUE
No: ASK IF THERE IS A BETTER TIME TO CALL BACK. RECORD TIME.

IF NECESSARY: If respondent would like to verify the legitimacy of this study, they can contact Terasen Gas at 604-576-7000 and advise that they would like to verify a market research study.

I understand that your firm provides contracting and installation services for replacement natural gas furnaces in BC. Is that correct?

Yes: CONTINUE
No: SEEK CLARIFICATION AND CONTINUE IF FIRM PROVIDES EITHER CONTRACTING OR INSTALLATION SERVICES FOR NATURAL GAS FURNACES. IF NOT, THANK AND TERMINATE

Q1: About what percentage of your furnace sales and installations involve new residential dwellings and what percentage involves replacement furnaces?

New dwellings _____%
Replacements _____%
DK _____

Q2: We are interested in understanding the role of high efficiency furnaces in the market in BC and the impact of Terasen Gas' High Efficiency Furnace program. High efficiency furnaces have a AFUE rating of 90% or better. Terasen's furnace program ran from October 2005 to the end of March 2007.

About what percentage of your replacement furnace sales and installations were high efficiency before, during and since the program terminated at the end of March 2007? (PROBE: IF THE RESPONDENT SAYS "DON'T KNOW" INDICATE THAT AN ESTIMATE IS ALL WE ARE LOOKING FOR)

Before Program _____%
During Program_____%
After Program _____%
DK _____

Q3: We are also interested in the impact of the program on the sale of furnaces with variable speed blower motors. These motors may also be referred to as “ECM” motors. About what percentage of your furnace replacement sales and installations before, during and after the Terasen program included variable speed blower motors? (PROBE: IF THE RESPONDENT SAYS “DON’T KNOW” INDICATE THAT AN ESTIMATE IS ALL WE ARE LOOKING FOR)

Before Program _____%
During Program_____%
After Program _____%
DK _____

Q4: Unused

Now we would like to understand if the Terasen Gas incentive program encouraged customers to replace furnaces earlier than they would otherwise do so.

Q5a: About what percentage of the furnaces you replaced between October 2005 and March 2007 were eligible for a rebate from Terasen Gas or its partners?

Percentage ____ %
DK ____

Q6: What was the average remaining length of life of those furnaces that were replaced while still operational?

Years _____
DK _____

Q7: Do you routinely do a heat loss calculation when installing a replacement furnace?

Yes _____
No _____

No: SKIP TO Q9

Q8: What percentage of the time does doing the heating loss calculation lead to the choice of a smaller capacity furnace than you would have recommended if the heat loss calculation had not been done?

Percentage _____
DK _____

Q9: What would be a typical equipment price excluding taxes for a 90,000 BTU/hr input mid-efficiency natural gas replacement furnace?

Price ______

DK/NR ______
(NOTE TO INTERVIEWER, IF RESPONDENT DOES NOT HAVE A 90,000 BTU/HR INPUT PRODUCT, PLEASE ASK FOR THE INFORMATION REGARDING THE NEAREST SIZED FURNACE.)

Q10: What would be a typical installed price excluding taxes for a 90,000 BTU/hr input mid-efficiency natural gas replacement furnace?

Price ______
DK ______

Q11: What would be a typical equipment price excluding taxes for a 90,000 BTU/hr input high efficiency natural gas replacement furnace?

Price ______
DK/NR ______

Q12: What would be a typical installed price excluding taxes for a 90,000 BTU/hr input high efficiency natural gas replacement furnace?

Price ______
DK ______

Q13: What would be a typical equipment price excluding taxes for a 75,000 BTU/hr input high efficiency natural gas replacement furnace?

Price ______
DK/NR ______

Q14: What would be a typical installed price excluding taxes for a 75,000 BTU/hr input high efficiency natural gas replacement furnace?

Price ______
DK ______

Now I would like to obtain your opinion on the Terasen Gas incentive program which supported the installation of high efficiency furnaces and high efficiency variable speed fan motors. The program offered rebates for high efficiency furnaces from October 2005 to March 2007.

Q15: On a scale of one to five, where one is not at all satisfied, and five is very satisfied, how satisfied were you with the following aspects of the rebate program? (ROTATE)

Information on the rebate	1 2 3 4 5 DK
Types or numbers of furnaces eligible for the rebate	1 2 3 4 5 DK
Application procedures to obtain the rebate	1 2 3 4 5 DK
Amount of the rebate	1 2 3 4 5 DK

Q16: On a scale of one to five, where one is not at all important and five is very important, how important was the rebate in your customers' choice of furnace efficiency?

1 2 3 4 5 DK

Q17: Unused
Q18: Unused
Q19: Unused

Q20: The program included an additional incentive for the purchase of a furnace with an energy-efficient variable speed blower motor. On a scale of one to five, where one is not at all important and five is very important, how important was the $ 100 incentive in your customers' choice of furnace blower motor efficiency?

1 2 3 4 5 DK

Q21: Unused

Q22: Unused

Q23: Of the furnace models you sold while the program was in operation, what percentage had:
Single speed PSC blower motors ____%
Multi-speed PSC blower motors ____%
Variable speed blower motors ____%
DK ____

PROMPT IF NECESSARY: A PSC OR PERMANENT SPLIT CAPACITOR MOTOR REFERS TO A BLOWER MOTOR THAT TYPICALLY OPERATES AT ONE OR TWO SPEEDS BUT IS LESS EFFICIENT THAN VARIABLE SPEED MOTORS THAT CAN OPERATE THROUGH A BROAD RANGE OF SPEEDS. FURNACES EQUIPPED WITH PSC MOTORS ARE LESS EXPENSIVE THAN THOSE EQUIPPED WITH VARIABLE SPEED MOTORS.

PROMPT IF NECESSARY: THE TERASEN FURNACE PROGRAM WAS IN EFFECT FROM OCTOBER 2005 TO MARCH 2007.

Q24a: What percentage of the standard (mid) efficiency furnaces you sold during the program period had a variable speed motor?
____%

Q24b: What percentage of the high efficiency furnaces you sold during the program period had a variable speed motor?
____%

Q24d: What were the reasons why customers purchased a furnace with a variable speed blower motor? (DO NOT READ - SPECIFY ALL THAT APPLY)

It uses less electricity ____
It is quieter ____
It provides more comfortable ventilation ____
It can operate through a range of speeds ____
The $ 100 rebate ____
Customer wanted continuous ventilation___ ____
Customer wanted the "best" furnace ____
Contractor / sales person sold the feature ____
Came with the furnace that was ordered _______
Other (RECORD) ______________________

Q25: Are you familiar with the ENERGY STAR label for natural gas furnaces:

Yes: _____
No: _____
DK: _____

NO / DK: GO TO Q29.

Q26: Do you recommend ENERGY STAR natural gas furnaces to your customers?

Yes _____
No _____
Sometimes/depends on the customer _____
DK _____

Q27: Unused

Q28: Unused

Next we would like to understand your views of high efficiency furnaces.

Q29: Do you believe that high efficiency furnaces are the best choice for your customers?

Yes _____
No _____
Sometimes/depends on the customer _____
DK _____

Yes, no, sometimes/depends on the customer: CONTINUE WITH Q30
DK: SKIP TO Q31

Q30: Why do you say this?

Record response _____

Q31: Do you recommend variable speed blower motors to your customers?

Yes _____
No _____
Sometimes/depends on customer _____
DK _____

Yes, no, sometimes/depends on the customer: CONTINUE WITH Q32
DK: SKIP TO Q33

Q32: Why do you say this?

Record response _____

Q33: Do you recommend two-stage mid-efficiency furnaces to your customers as a preferred option to a high efficiency furnace?

Yes ______
No ______
Sometimes/depends on customer ______
DK ______

Yes, no, sometimes/depends on the customer: CONTINUE WITH Q34
DK: SKIP TO Q35

Q34: Why do you say this?

Record response ______

The next few questions are to help Terasen understand how their rebate program may have influenced how households operate their furnaces.

Q35: In what percentage of the furnaces that you replaced did the ventilation fans run:
(READ THE CATEGORIES BEFORE OBTAINING RESPONSES. ANSWERS SHOULD SUM TO 100%. IF NOT, REVIEW THE RESPONSES WITH THE RESPONDENT AND ADJUST ACCORDINGINGLY)

Intermittently when providing heat ____%
Continuously during the heating season ____%
Intermittently when providing heat and air conditioning ____%
Continuously during the heating and cooling seasons ____%
Intermittently to also provide ventilation for part of the year ____%
Continuously ____%
DK ______

Q36: In what percentage of all your installations of furnaces with PSC motors do the ventilation fans run: (READ THE CATEGORIES BEFORE OBTAINING RESPONSES. ANSWERS SHOULD SUM TO 100%. IF NOT, REVIEW THE RESPONSES WITH THE RESPONDENT AND ADJUST ACCORDINGINGLY)

Intermittently when providing heat ____%
Continuously during the heating season ____%
Intermittently when providing heat and air conditioning ____%
Continuously during the heating and cooling seasons ____%
Intermittently to also provide ventilation for part of the year ____%
Continuously ____%
DK ______

Q38: Thinking now of only those furnaces with variable speed motors, in what percentage of all your installations of furnaces with variable speed motors do the ventilation fans run: (READ THE CATEGORIES BEFORE OBTAINING RESPONSES. ANSWERS SHOULD SUM TO 100%. IF NOT, REVIEW THE RESPONSES WITH THE RESPONDENT AND ADJUST ACCORDINGINGLY)

Intermittently when providing heat ____%
Continuously during the heating season ____%
Intermittently when providing heat and air conditioning ____%
Continuously during the heating and cooling seasons ____%
Intermittently to also provide ventilation for part of the year ____%
Continuously ____%
DK _____

Q39: Do you believe that your customers have enough information to make an informed decision on their choice of furnace efficiency?

Yes _____
No _____
Sometimes/depends on customer _____
DK _____

No, sometimes/depends on the customer: CONTINUE WITH Q40
Yes / DK: SKIP TO Q41

Q40: What information are they missing when making a decision on the choice of furnace efficiency?
Record answer: __________

Q41: Do you believe that your customers have enough information to make an informed decision on whether to purchase a furnace with a PSC or variable speed furnace motor?

Yes _____
No _____
Sometimes/depends on customer _____
DK _____

No, sometimes/depends on the customer: CONTINUE WITH Q42
Yes / DK: SKIP TO Q43

Q42: What information are they missing when making a decision on the choice of furnace blower motor?
Record answer: __________

Q43 – Q47: Unused

Finally we have a few questions to help us classify the data.

Q48: How many employees are there in your firm?

Number _____
DK/NR _____

Q49: Which of the following categorization best describes your business?

Furnace Dealer and Heating Contractor ____

Independent Heating Contractor ____
Gas fitter ____
Other (RECORD) ____

Q50. Do you have any suggestions on how consumers could be encouraged to install higher efficiency rather than mid-efficiency furnaces?

Record answer _____

Q51: Do you have any suggestions on how consumers could be encouraged to install variable speed furnace blower motors rather than the less efficient PSC motors?

Record answer _____

Terasen Gas and Call Us would like to thank you for your help and for your assistance.

Appendix C

Preparation of Survey Samples

Appendix C
Preparation of Survey Samples

C.1 Survey Groups

Survey samples were developed for four different survey groups:

- Program participants
- Program non-participants
- Program declined non-participants (alternative source of non-participating customers)
- Trade allies (furnace dealers, contractors, installers)

C.1.1 Participants, Non-Participants, & Declined

Participant and declined lists were assembled from program records for the 2006-07. The list of non-participants was created by sampling the Energy Extracts provided by ABSU. The non-participant list was screened for customers showing up the 2005-2007 participant or declined lists, or on the 2002-2004 participant lists provided by ABSU. The regional breakdown of the non-participants matches that of the participants. Customers in the declined lists represented customers that submitted a rebate application but were denied due to furnace ineligibility, self-installation, or other reason. This list was prepared as an alternative list of non-participants if the non-participant sample was exhausted prior to achieving quota.

C.1.1.1 Pre-Weather Normalization Filters

For the participants and declined list, consumption information was collected based on the most recent 12 month period prior to the installation. For the non-participants, 36 months of consumption up to March 31, 2007 was obtained.

To improve the likelihood of a non-participant having replaced their furnace in the past three years, it was decided to remove any accounts where the premise was younger than 15 years (i.e., the average life of a furnace is approximately 15 years). This step was possible for the LML region but due to issues with the SupplyReqDate field in the Energy Extracts, only premises less than eight years old could be excluded in the other regions.

C.1.1.2 Weather Normalization & Other Billing History Filters

Using the bi-monthly meter reads (and associated consumption) and weather data, the average daily consumption per meter read, and the average daily HDD13 and HDD18 for that same period, are determined. The following regression model (1) was then run:

(1) Average Daily Consumption = $\beta_0 + (\beta_1 \text{ X } HDD_{13}) + (\beta_2 \text{ X } HDD_{18})$

The total HDD_{13}'s and HDD_{18}'s during a "normal" year (basically the average of the past ten years) were determined. Normalized annual consumption was then calculated using equation (2):

(2) Normal Consumption = $(365 \text{ X } \beta_0) + (\text{Total } HDD_{13}\text{'s X } \beta_1) + (\text{Total } HDD_{18}\text{'s X } \beta_2)$

Finally, the following elimination criteria (i.e., screens) were applied to generate finalized lists:

1. Remove all customers not in the same premise for at least one year prior to and after the installation date.
2. Remove all customers where the regressions give an R-Square value below 0.75. This ensures the remaining customers results reflect a good fit with the data, and their consumption is predictable.
3. Remove those customers where the heat slope coefficients (HDD_{13}, HDD_{18}) are negative. It is reasonable to expect that customers will consume more gas when the heating degree days increase. Negative heat slope coefficients suggests that consumption declines as heating degree days increase.
4. Remove all customers with annual consumption less than 30GJ. Customers with annual consumption less than 30GJ are unlikely to be using natural gas for space heating.
5. Remove customers where the EDF (Error Degrees of Freedom) is less than three. In effect, this removes customers with less than five meter reads.
6. Remove all customers with suspect meter reads. These include meter reads where the transaction period refers back to a date prior to the last read date output (i.e., the read date less the corresponding read days is before the last read date).
7. Remove all customers where consumption for one read date or more is zero. There should be at least six meter reads per a year's worth of consumption. One year of consumptions is the minimum acceptable time.
8. Remove all customers where the weather effect is more than two standard deviations away from the average weather effect. The weather effect is defined as:

   Weather Effect = (Normal Consumption – Actual Consumption) / Actual Consumption

   Since 96% of all data is within two standard deviations of the mean, this eliminates those with abnormally large weather effects (i.e., outliers).

C.2 Trade Allies

A list of 640 contractors who participated in the Heating System Upgrade Program was generated by matching contractor registration numbers from the application with the list of contractors registered with the British Columbia Safety Authority (BCSA). Access to this list was allowed under the Safety Standards Act Sec 21.

C.3 Summary

Exhibit 98 summarizes the starting sample sizes for the customer and trade ally surveys.

Commercial Energy Assessments

Program Evaluation

Friuch Consulting

This report outlines and reports the outcome of work done between May and August, 2008 by Friuch Consulting for Terasen Gas, Demand Side Management and Marketing Department under the direction of Michelle Petrusevich.

Friuch Consulting

#3 13936 72 Ave., Surrey, BC, V3W 0J8

CONTENTS

EXECUTIVE SUMMARY

Friuch Consulting's services were retained in May, 2008 by Terasen Gas to complete an evaluation of the Commercial Energy Assessment Program between the periods of mid- 2005 and June, 2007. The program was created to help Terasen's commercial and small industrial customers identify inefficiencies in their energy consumption, and provide them with an action plan to reduce their natural gas consumption.

This program offers energy assessments at no cost to qualifying participants. Similar versions of this program have been offered to Terasen's commercial and small industrial customers since 2001. The current version of the program was launched in mid-2005 and provides free energy audits, conducted by third-party energy consultants to qualified program participants. The program is open to commercial and small industrial customers in the Lower Mainland, Squamish and BC Interior customers who spend more than $20,000 per year on natural gas.

There is a formal application process to qualify for the program but in practice, customers have liaised with their Account Manager who determines if an audit is warranted. Once an application is approved, a third-party energy efficiency consultant visits the customer's site and performs an evaluation. Site visits are typically completed within two hours and the third-party consultant produces a report summarizing the audit as well as any recommendations to increase energy efficiency.

Two third-party energy consultants carried out this work on behalf of Terasen Gas between mid-2005 and June, 2007. The primary consultants during this time period were Bill Hennessy and Peter Hill. Between them, they completed over 150 audits. Customers were to receive a written assessment and recommendations within two weeks of the visit and then a follow-up letter at a later date to verify what, if any, recommendations were implemented. Due to time constraints and staff limitations, this follow-up was done inconsistently amongst program participants during this period.

However, since July, 2007 Terasen has contracted this work Environ to provide a more "turnkey" service.

Note that this study was tasked with reviewing the effectiveness of the program prior to the date that Environ took the delivery of the commercial energy assessments.

The specified deliverables for this study are:

1. *Confirm the number of completed audits*
2. *Determine whether customers acted on recommendations provided in the energy audits*
3. *Estimate of energy savings (planned and achieved)*
4. *Determine top 2-5 recommended measures that were put forward by consultants and explain each in detail*
5. *Determine the percentage of measures that were implemented by the customers and estimate energy savings based on findings*
6. *Determine other factors that might have affected a customer's energy usage after recommendations were put forward*
7. *Provide feedback on overall effectiveness of program*

8. *Perform a free-rider analysis on the assessments,* i.e. what percentage of customers would have undertaken an energy audit in the absence of the free assessment program

9. *Provide recommendations on further improvements of the program*

10. *Determine other factors that might have affected a customer's energy usage after recommendations were put forward (increase or decrease in production/output, change of ownership, equipment upgrade, etc.)*

11. *Provide feedback on the overall effectives of the program*

All of the above deliverables were achieved and are covered in detail in the following sections. At a high-level, the findings are:

- **All of the audits conducted by Bill Hennessey and Peter Hill appear to have been successfully completed on 189 properties**

- **Research shows only 35% of customers audited actually implemented any of the recommended changes**

- **It is estimated that nearly 129,000 GJs of natural gas was saved as a direct result of Energy Assessments conducted during the study period as calculated by the sum of actual consumption decreases against expected usage for customers who implemented recommended changes**

- **The best recommended measures were ones that either had short return on investment for the customer and low up-front costs OR ones that replaced equipment at the end of its operational life-span with high efficiency boilers.**

- **The program was most effective with manufacturing customers in the rate classes that were eligible to apply for this program**

- **29% of respondents who did not make recommended changes also saw a decrease in their consumption after the audit – no attributable factor is known**

- **Overall, the program was effective in getting commercial customers to use less gas but the program was most cost-effective amongst customers in the manufacturing sectors which saw a nearly 300% return on investment**

- **The study determined that about 10% of program participants are "free riders" – defined as customers who would have paid for a Commercial Energy Assessment if it was not free.**

- **Detailed recommendations for improvements to the program are in the body of this report but at a high level: significantly reduce the number of free audits conducted for office buildings, apartments/strata corporations, hotels, restaurants and care homes and increase the intensity of the program for manufacturing sector customers**

<u>Note that data tables from this study were provided to Terasen in a digital format (Microsoft Excel) and will not be appended to this report.</u>

There are a number of benefits and dynamics to consider beyond what this study required that will be discussed in the body of this report. For example, the Commercial Energy Assessment Program has created a lot of good will for Terasen Gas that may have non-direct monetary gains for the company in this increasingly competitive market.

Terasen could also consider some lower-cost per customer demand side management activities in the future that would achieve results with a positive return on investment.

Friuch Consulting believes that Terasen Gas can improve upon the success of the Commercial Energy Assessment Program by screening the types of customers who receive free audits, offering new program options such as public workshops on demand-side management (DSM) and review some of the policies and procedures of the program overall.

Specific recommendations for improving the program include:

1. Spend more time nurturing and providing free Commercial Energy Assessments to manufacturing (light industrial) customers.

2. Do not conduct Commercial Energy Assessments with non-manufacturing customers unless there is a compelling reason to do so.

3. Develop public workshops aimed at non-manufacturing commercial customers that teach basic DSM techniques. Use these workshops to pre-qualify customers who are not manufacturers for free Commercial Energy Assessments.

4. Re-evaluate policies and procedures to ensure maximum follow-up with program participants.

5. Liaise with Environ and share the findings of this report with the auditors in hopes that it will improve the service they provide to Terasen's customers.

<u>The over-arching recommendation of this report is that the Commercial Energy Assessment Program be continued but modified to maximize its cost-effectiveness and reach.</u>

STATUS OF RESEARCH

Friuch Consulting's services were retained in May, 2008 by Terasen Gas to complete a program evaluation of the Commercial Energy Assessment Program between the periods of January, 2005 and June, 2007.This research took place as outlined below:

Table 1: Research Schedule

Research Design and Consultation with Terasen Gas	May, 2008
Customer Audits/Interviews	May-June, 2008
Analysis	July, 2008
Reporting	August, 2008

Note: An extension was requested and granted in mid-July when it became clear that additional analysis of the consumption data was required. Due date for final report moved to mid-September, 2008.

Field research was completed on June 26, 2008 and met the requirements as laid out in Terasen's RFP. The methodology for collecting the data was as follows:

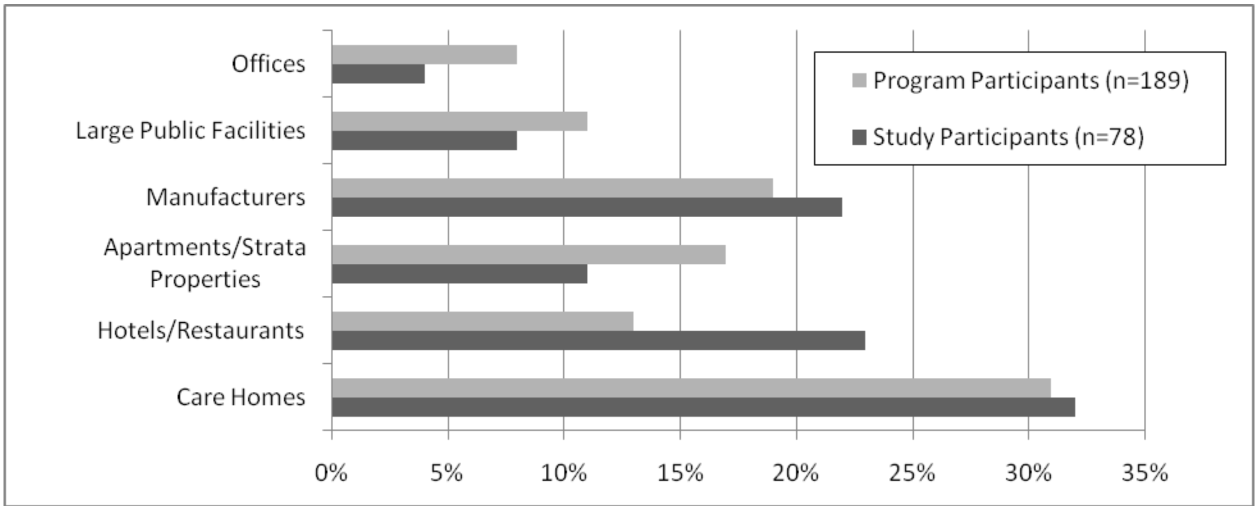
1. Aaron Cruikshank obtained copies of the audits conducted on all 189 properties prior to the start of field research.
2. Cristina Ambrosi (sub-contractor to Friuch Consulting) randomly called Commercial Energy Assessment Program participants that had audits between mid-2005 and June, 2007 to solicit their participation in a follow-up interview with Aaron Cruikshank of Friuch Consulting.
3. Aaron Cruikshank would request the historical billing records in advance of a telephone interview or face-to-face interview from Terasen Gas staff.
4. The interview followed a series of questions developed in conjunction with Terasen Demand Side Management and Marketing staff (see Appendix A).
5. Information from the interviews was entered into a spreadsheet for comparison and analysis with historical billing records.

Data collection from Terasen Gas to enable analysis of consumption data was completed on July 9, 2008. Interview analysis was completed on July 21, 2008. Consumption analysis was completed on August 13, 2008. Final findings of this report were validated by Bill Hennessey – the consultant that conducted the majority of the audits looked at by this study – in a phone interview.

In May, 2008, Terasen Gas provided contact information for 189 customer sites (some customers had multiple facilities that were reviewed with different accounts). Of these 189 customer sites, 50 customers representing 78 sites were audited/interviewed (hereafter: "interviewed") by Friuch Consulting. Thirty five interviews were conducted in the Metro Vancouver area – 15 of which were conducted face-to-face in accordance with the RFP guidelines. Fifteen interviews were conducted in the Interior – six of which were conducted face-to-face (Prince George and Quesnel).

Figure 1 (next page) shows that there was equal representation from Hotels/Restaurants and Manufacturers in this study but that Hotels/Restaurants may have been over-represented in the study compared to program participants. There was one customer with over 10 sites (Sandman Inn) that was interviewed by Aaron Cruikshank, effectively counting as one respondent towards the study quota but representing many more properties that each received an individual audit. Offices and Apartments/Strata properties may have been under-represented in this study compared to their program participation. In both of these cases, the researchers were dealing with property managers – many of whom did not want to participate in this study.

Figure 1: Study and Program Participation, by Type of Business



The low participation rate of property managers in this study representing Offices and Apartments/Strata Properties is attributed to the fact that it is unlikely that these managers were paid to respond to inquiries from Terasen Gas or contract researchers. It is thought that those property managers that did respond did so on their own time. Some property managers may have been able to claim the time they talked to Friuch Consulting against the customer in question. Operations managers and administrators/maintenance staff at Care Homes, Hotels, Manufacturers and Large Public Facilities would have, in most cases, been paid for any time they spent talking to Friuch Consulting.

Note that complete interview data has been submitted in an electronic format as an appendix to this report. It is not suitably formatted for print display but will be referenced throughout the report.

LIMITATIONS OF THIS STUDY

There are two primary limitations to this study:

1. There was no control group of customers. This means that any consumption reductions seen in program participants who did not make recommended changes cannot be attributed to the Commercial Energy Assessment Program.
2. The sample size is small and cannot yield statistically accurate findings. The findings from this report need to be interpreted as qualitative, not quantitative. Terasen was aware of the small sample size and accompanying limitations when the RFP for this project was issued.

A control group was not utilized by this study because it would have increased the cost of the study considerably and was not required by the original RFP. By not having a control group, the findings of this report (which deal exclusively with insights gained from analyzing customers who did make recommended changes to their gas-burning equipment) are still valid. What this study cannot address is what caused the gas consumption of some program participants who did not implement recommended changes to fall when they were expected to remain the same as they were before the audit.

This information, if obtained, would only add minor incremental insight to the entire study but would not likely alter the recommendations at the end of this report.

FINDINGS

This part of the report summarizes the findings as they match the deliverables specified in the RFP. Analysis of these findings and recommendations to improve on the Commercial Energy Assessment Program will follow in subsequent sections of this report.

AUDIT COMPLETION

During the process of sourcing interviewees for this project, none of the respondents indicated that they had not participated in the program. While not conclusive, it is a good indicator that all of the audits that were said to have been completed between January, 2005 and June, 2007 were completed.

There were some additional findings that question the quality of follow-up during program execution:

- 65% of customers interviewed for this study say that they did not hear from Terasen or their auditor following their original audit
- 22% of customers interviewed claim that they never received a copy of their audit after the site visit

This finding was validated in a phone interview with the principal auditor at the time – Bill Hennessey. Mr. Hennessey indicated that "follow-up [with customers] was a poorly executed before Environ took over delivery of this program".

It should be noted at this point that in many cases, the interviewee that talked to Friuch Consulting during field research was not the same person who participated in the original audit. It is feasible that a predecessor in many of these cases actually did receive the report and did not see fit to keep that report for their replacement. One could also assume that the interviewees were not aware of the study being conducted or the audit report was lost.

There is no indication that a lack of follow-up by Terasen led to the relatively low implementation rate amongst program participants. In fact, in the following sections, it will become clear that other factors had a bigger influence in the willingness of a customer to implement recommended changes to their gas infrastructure and usage.

IMPLEMENTATION OF RECOMMENDATIONS

As was mentioned in the Executive Summary, only 35% of the customers who participated in the Commercial Energy Assessment actually implemented any of the gas savings measures recommended by Bill Hennessey. This is not to suggest that a full 65% of program participants did not implement recommended changes. A full 9% of program participants were told in their assessments that there were no possible improvements to their current setup. This leaves only 56% of program participants that did not implement recommended changes.

Figure 2 (next page) shows what respondents cited as their reasons for not making recommended changes when asked. The majority (71%) of respondents who did not make recommended changes cited expense-related issues ("ROI too long" and "too expensive"). Return on Investment (ROI) concerns are closely related to sticker shock in that when someone cites length of ROI as an issue, it's typically because they need to borrow capital to invest and their concern is about how expensive that capital will be in terms of interest and the ability of that company to pay it off.

Figure 2: Respondents Who Did Not Make Recommended Changes, Reason for Not Making Changes (n=52)

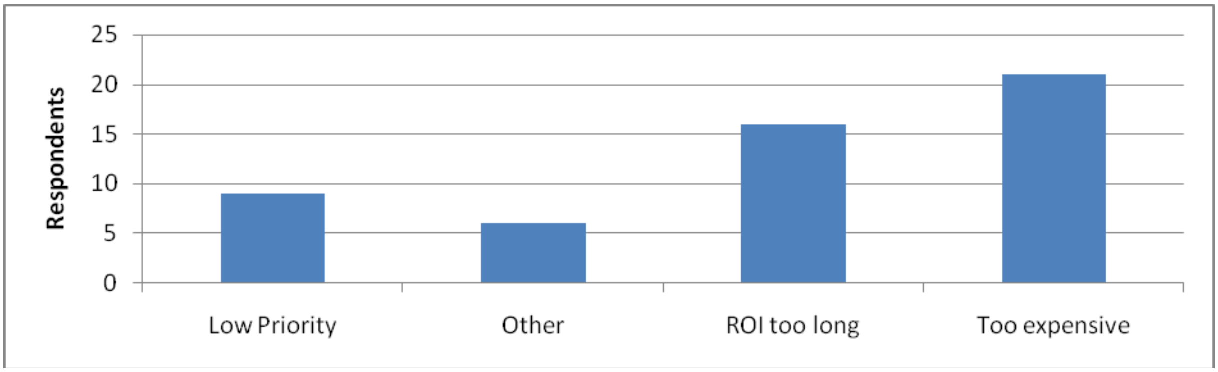


Figure 2 represents responses to question 6c from the customer questionnaire (see Appendix A).

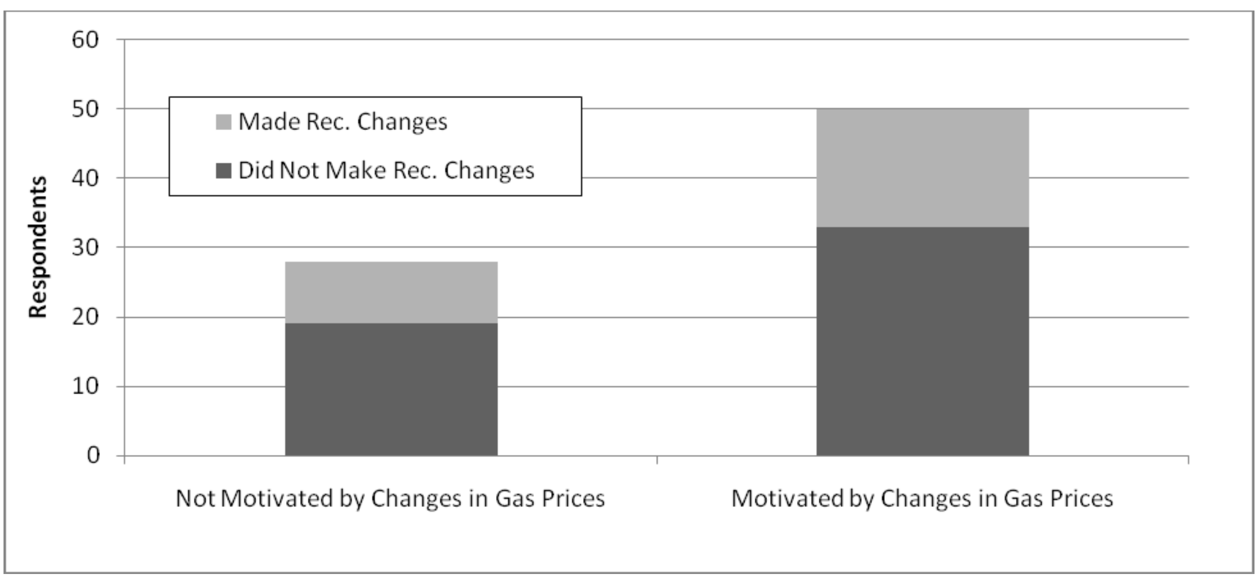
When a recommendation was made to replace a boiler immediately or when the current boiler fails, respondents who did not make the recommended changes were twice as likely to cite expense or ROI issues rather than other reasons when asked why they did not make the changes. This finding was obtained by examining the reported reasons for not implementing recommended changes and comparing the un-coded reasons given.

Fluctuations in gas prices did not appear to have a major impact on a company's decision to implement recommended changes or not. Sixty-four percent of respondents indicated that they are motivated by fluctuations in natural gas prices. Figure 3 shows that those respondents who made recommended changes represent approximately one third of respondents motivated by changes in gas prices and one third of respondents not motivated by changes in gas prices. This validates the finding that the primary driver of the decision to make changes or not is most likely the sticker price of the recommended upgrades and, by extension, the ROI of the recommended changes. Figure 3 represents responses to questions 11 and 6 (see Appendix A).

Figure 3: Respondents, Sensitivity to Natural Gas Prices, by Respondents who Made Recommended Changes and Those Who Did Not (n=78)



Most economists familiar with heating fuel stocks such as natural gas agree that the biggest determinant of demand for gas is the weather, as measured by Heated Degree Days[1] (HDDs). Demand for gas is relatively inelastic to the market price at any given time (at least, at its current price point).

Figure 4 shows the graphical representation of the billing analysis for a customer who did make the recommended changes. Their audit was conducted in June, 2006. This customer only uses natural gas for radiant tube heaters that provide space heating for the production floor. Bill Hennessey recommended the installation of timers on the radiant tube heaters so that they didn't continue to heat the shop floor when operations were shut down for the night. Figure 4 clearly shows that this customer has subsequently reduced their consumption, most noticeably in response to the winter HDD spikes. Also note that their consumption has gone down while market prices for gas went down.

Figure 4: Billing Analysis, Great Little Box Company (Manufacturing Company)

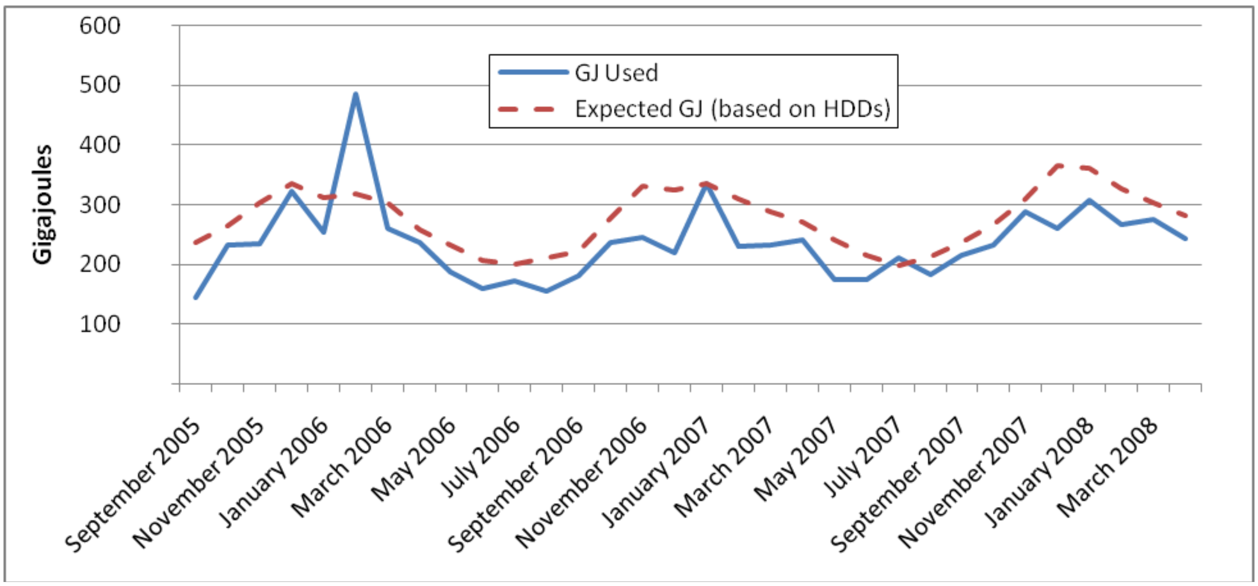


Figure 5 (next page) shows the graphical representation of the billing analysis for a customer who did not make the recommended changes. Their audit was conducted in February, 2006. Bill Hennessey recommended to this customer that they insulate the water pipes in the boiler room and install low-flow shower heads/faucet aerators throughout their facility. He estimated that they could save up to 25% of their hot water heating costs using these measures. Figure 4 shows that this customer's consumption is closely tied to HDDs with actual consumption (GJ used) exceeding expected consumption every winter heating season. They did not reduce their consumption following the audit.

[1] Source: Environment Canada

Figure 5: Billing Analysis, the Chateau (Care Home)

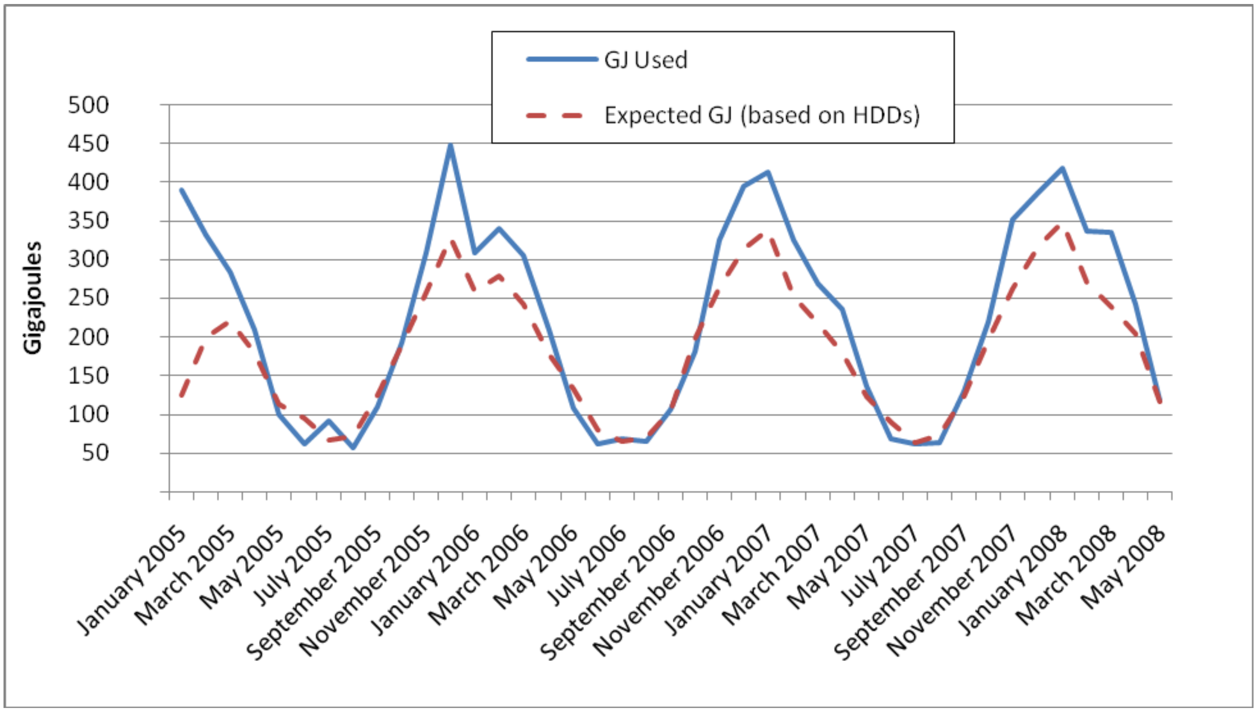

Table 2 shows the frequency that respondents made recommended changes by specific changes recommended. These recommendations have been coded for simpler analysis. Clearly cheaper, shorter-ROI options such as adjusting boiler/ heating, ventilating, and air conditioning (HVAC) settings or replacing old thermostats with new digital thermostats are the most popular options. Simple modifications to HVAC equipment (such as routing exhaust from one system to heat another room) were also popular. All of the top four recommended changes are potentially very short ROI solutions.

Please note that totals for the second column in Table 2 add up to more than the total sample size of 78. The consultants conducting the audits made more than one recommendation in most cases and respondents for this study were not restricted to one answer for question 6a – “Did your company implement any of the changes recommended in the audit” and “if yes, which changes were implemented?” (see Appendix A).

Table 2: Frequency of Recommended Change Implementation, by Type of Change Recommended (n=71)

Recommended Change	# of respondents this change rec. to	# of respondents who made change	Percentage
Replace Thermostats/Timers on HVAC systems	6	2	33%
Tweak boiler/HVAC settings	19	6	32%
Modify HVAC equipment	20	5	25%
Insulate water pipes in boiler room	20	4	20%
Replace boilers with high efficiency unit(s)	24	2	8%
Replace Makeup Air Units	12	1	8%
Install Low-flow shower heads/aerators on faucets	15	0	0%

ENERGY SAVINGS

This part of the analysis was the most complicated due to the high number of variables that had to be considered. To facilitate some type of analysis, Friuch Consulting obtained historical billing records showing GJs of Natural Gas used by each customer on a monthly basis during the study time period. While the quality of some of the historical consumption data was variable, it gave a relatively clear picture of consumption trends. GJs of gas used were compared with "expected" usage.

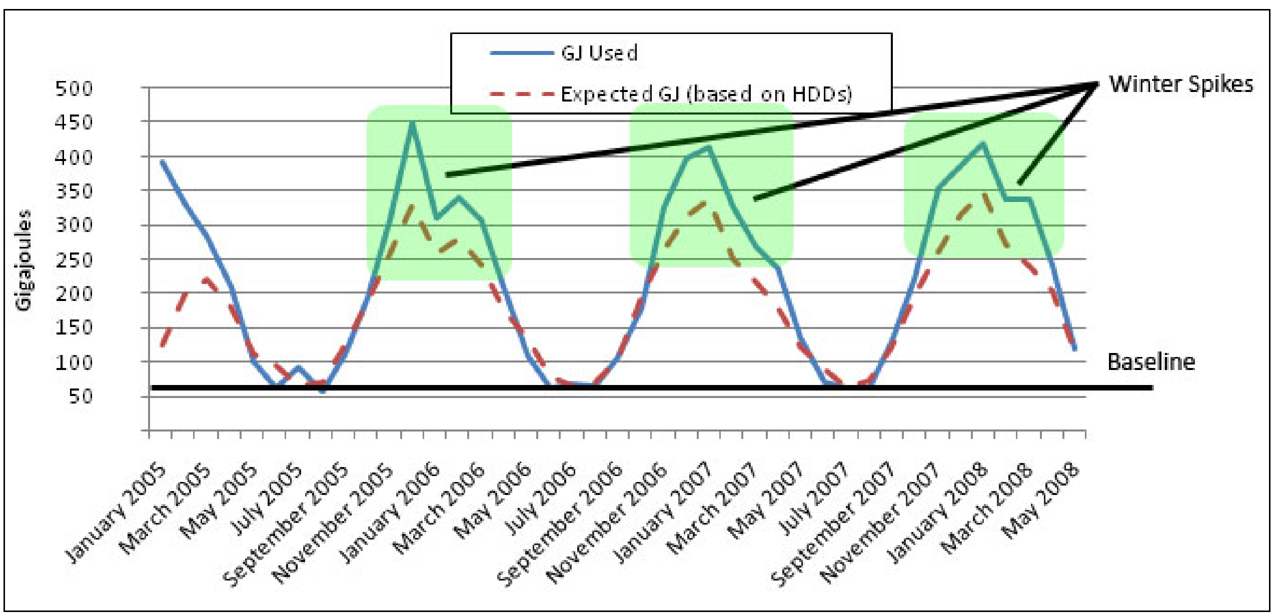
Put simply, here is how expected usage was calculated:

1. The researcher established a "baseline" of gas usage for each customer in the study. This baseline is the amount of gas that the company uses during months where they should not need to turn on the boiler for space heating. Space heating to compensate for outside temperature changes is the biggest cause of consumption variation from month to month.

   Figure 6 (below) illustrates how a baseline is established. In July of 2005, 2006 and 2007, both the GJs used and the expected GJs used bottom out at around 60 GJs for those months. This is what the customers' gas consumption looks like when they don't turn on their furnace for a month. All gas consumption that occurs above the baseline is attributed to consumption changes to address colder outside temperatures.

   In this specific example, the customer uses more than the expected amount of gas during the winter spikes. This is not uncommon since most customers are not using digital control systems which ramp up heating more incrementally than a person in control of a normal thermostat would. When it's very cold, many people turn the thermostat to a level that is much higher than is necessary to heat a room faster. The increased demand for gas places on the system by such behavior is illustrated in Figure 6.

Figure 6: Typical Billing Analysis Chart, Showing Baseline and Winter Spikes



2. Once the baseline was established, the amount of gas used during winter spikes was compared to the baseline. This gave a range of consumption that a business uses based on changes in outside temperature. After looking at the change between low and high heating seasons and comparing to HDDs for those seasons, a multiplier factor can be established to predict how much a customer will turn up the heat when

winter cold spikes hit. This information gives the researcher enough data to plot an "expected GJs used" line for each customer to compare against their actual consumption.

3. To compensate for production changes, the expected GJs line was multiplied by 1.n over time where "n" is the percentage increase or decrease in production.

4. The degree to which a customer's actual consumption is above or below the expected GJ use line is compared before and after the Terasen audit. If the customer's consumption rose against expected levels after the audit, it was assumed that the customer did not successfully reduce their natural gas consumption.

5. Customers who have lower consumption against expected levels after implementing recommended changes are counted as having successful outcomes for this program and the amount of GJs they saved below what was expected was counted towards the total GJs saved for this project. For customers who implemented recommended changes but saw an increase or no change in consumption were not counted in this study because their choice to consume more cannot be attributed to the Commercial Energy Assessment Program.

6. Once the analysis showed what customers in each of the different business types saved over what period of time, annual consumption reduction numbers for each category of business could be calculated. Table 3 (below) shows how the total GJs of gas consumption averted is calculated. For example, the research indicates that 12 out of the 59 program participants in this business type would actually decrease their consumption after implementing the recommended changes by Terasen.

   These 12 customers will reduce their consumption by an average of 473 GJs per year. Multiply program participants who are expected to have successful outcomes by the average annual gas savings for the category leading to a total annual gas consumption reduction by customers in this category of 5,676 GJs. Multiply this amount again by the average number of years since these customers had their audits to get the total amount of natural gas consumption averted by Terasen Gas during this study period.

Table 3: Commercial Energy Assessment Program Outcomes, by GJs of Natural Gas Consumption Averted (program participants who received audits between mid-2005 and June, 2007)

Type of Business	# of Program Participants	# that decreased consumption after implementing changes	Average Annual Gas Savings (GJ)[2]	Annual Gas Savings, program participants, this category (GJ)	Average Time (years) since audit	Total gas savings resulting from audits conducted mid-2005 to June, 2007 (GJ)
Care Homes	59	12	473	5,676	2.6	14,757
Manufacturers	**35**	**7**	**5,574**	**39,018**	**2.1**	**81,937**
Apartments/Stratas	33	11	591	6,501	2.7	17,552
Hotels/Restaurants	25	4	351	1,404	2.3	3,229
Large Public Facility	21	3	1,319	3,957	2.9	11,475
Offices	16	0	0	0	2	0
Totals	***189***	***37***		***56,556***		***128,950***

[2] Note that these amounts are averages and cannot be totalled.

By multiplying average consumption in a business type category by the estimated number of program participants who made the changes before seeing a drop in their consumption, by the number of years on average since this business type participated in the program – this study can arrive at a defensible number of GJs directly averted by the Commercial Energy Assessment program. This number appears to be roughly 129,000 GJs since these audits were conducted (see Table 3 on the previous page for details).

Put another way, program participants who implement the recommended changes are saving an average of 1,500 GJ per year. This is a substantial reduction and one that will continue to provide return on investment for Terasen for years to come.

SUCCESS OF RECOMMENDED MEASURES

The section above on Implementation touches on the issue of implementation rates of certain measures but does not discuss how effective each of these measures was in terms of reducing consumption. This analysis is difficult because in some cases, respondents made more than one of the recommended changes and could not attribute specific decreases in consumption to those changes. Because only a small percentage of respondents in this study implemented each recommended change, quantitative analysis is impossible.

Table 4: Relative effectiveness of recommended measures (n=28)

Recommended Change	% of respondents who implemented this change	Effectiveness
Replace Thermostats/Timers on HVAC systems	**33%**	This measure has a large impact in applications where there is a large area requiring space heating but not always in use. Best example is a manufacturing company that installed timers on their radiant tube heaters and saved 10,000 GJ over the past 17 months. For larger, open spaces with a low number of controls needed, this is a very low-cost upgrade.
Tweak boiler/HVAC settings	**32%**	Several of the respondents who implemented small changes to the settings of their boilers or HVAC equipment experienced immediate savings in their gas consumption for very little capital outlay.
Modify HVAC equipment	**25%**	In some cases, a simple modification of the boiler or process heat made a big difference in consumption. For example, one company used heat exhaust from a gas-fired process oven to heat another part of the shop instead of increasing boiler load.
Insulate water pipes in boiler room	**20%**	This measure is hard to isolate from other changes. Very few customers implemented this change alone. One of the customers that did implement this change in isolation from other changes saw a very modest 900 GJ of gas saved over the past two and a half years. The cost of insulating the pipes can be high if professional HVAC contractors are used.
Replace boilers with high efficiency unit(s)	**8%**	Most respondents who made this change saved about 1,000 GJ per year. This recommended change was not implemented often with most respondents citing cost as the number one issue. The ROI on a full boiler replacement is often 8-10 years.
Replace Makeup Air Units	**8%**	Several respondents made this recommended change and are saving, on average, 600 GJ per year. The ROI for these units can be fairly long so, like new boilers, few respondents made these changes.
Install Low-flow shower heads/aerators on faucets	**0%**	This measure was recommended to a fair number of respondents (15) but not implemented by any of them. In all cases, the recommendations were made to apartment buildings, care homes or hotels. It's possible that this is not a popular option because the cost of upgrading all taps and shower heads is relatively high (once parts and labour are factored in across 100+ units).

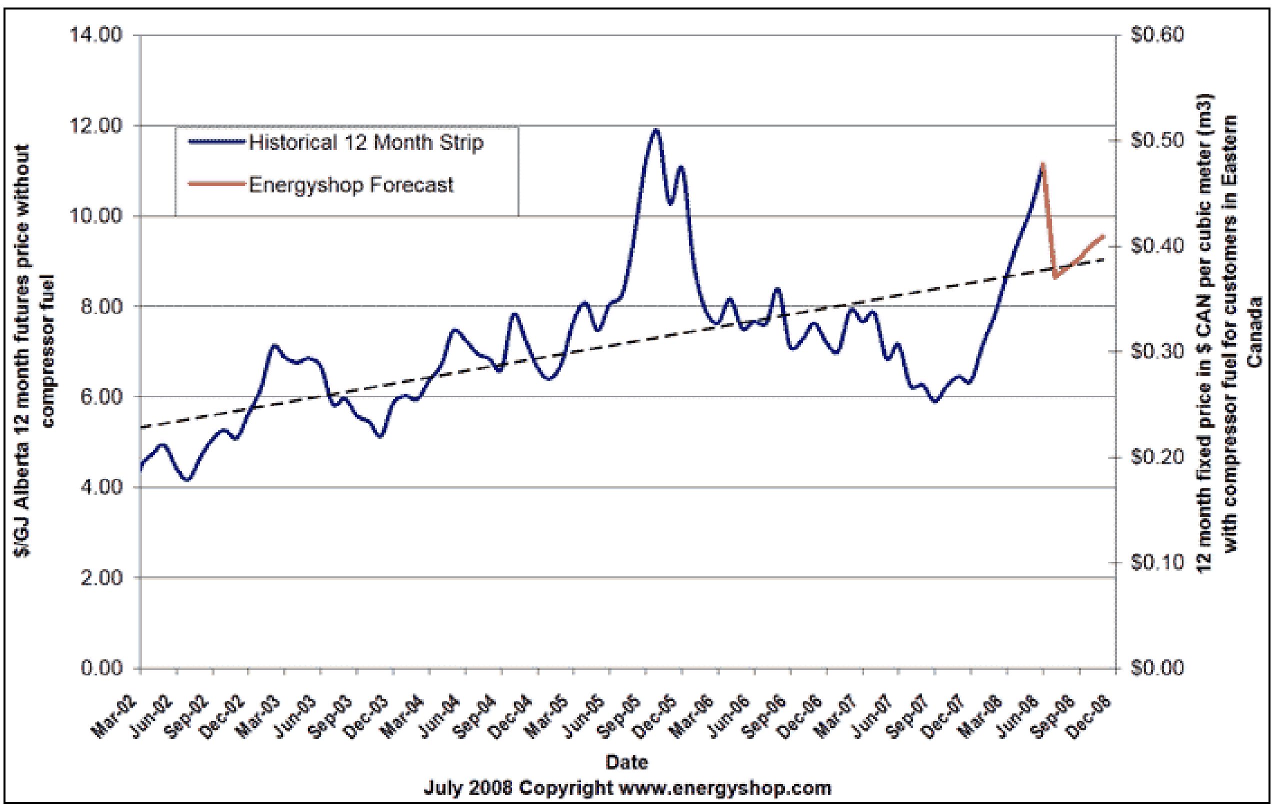
Table 4 (above) details the relative effectiveness of the recommended measures. Again, quantitative comparison is not possible due to the low sample size (28). There is a pattern in their uptake and relative effectiveness. New thermostats/timers, tweaking boiler/HVAC settings and modifications to HVAC equipment are the low-hanging fruit. These relatively cost-effective measures produce very short ROI for the customers and require small up-front capital expenditures. Replacing boilers, makeup air units and a large number of faucets/shower heads can be very costly with longer ROI.

Overall, 42% of respondents did not feel that the recommendations given to them were "reasonable". Respondents who did not feel the recommendations were reasonable were half as likely as respondents who liked the recommendations to actually implement the recommended changes.

OTHER FACTORS CONTRIBUTING TO CONSUMPTION DECREASES

Figure 7 (below) shows the historical market price of natural gas (per GJ) between March 2002 and December 2008 (estimated). Even though two-thirds of respondents claim to be motivated by changing prices in natural gas, those respondents who are price-sensitive and made changes to their consumption have done so during a period in which gas prices have dropped from a peak in the Q3 2005. This is a strong indicator that despite their claims of price-sensitivity (see question 11, Appendix A), there are other factors motivating their behavior – effectively ruling out price-sensitivity as a factor.

Figure 7: Market Price for Natural Gas ($CAD), March 2002 - December 2008 (estimated)



Twenty nine per cent of program participants who did not implement gas-saving measures suggested by Terasen Gas consultants still reduced their consumption after their audit. This number is calculated after factoring in staffing changes, changes in hours of operation or production increases and decreases at the customers' location.

Since consumers claim to be price sensitive when it comes to natural gas but their consumption behavior does not match fluctuations in the market price of gas, it is possible to rule out "real" price-sensitivity to market prices in gas and changes in the customers' operations. One possible factor that has caused this consumption decrease in program participants who did not make the recommended changes is that their very participation in the program is an indicator of a pre-existing interest in reducing consumption. The motivations for reducing consumption will vary – some program participants will be looking at opportunities to reduce consumption from an environmental standpoint while others will be looking for effective ways to reduce their operating expenditures. In any case, it is possible that there is a self-selection bias present amongst program participants which has led to this unexplained skew in the findings.

OVERALL EFFECTIVENESS OF THE PROGRAM

There are two measures of effectiveness to consider for this study:

1. Did the program get customers to reduce their consumption?
2. Was the program cost-effective?

It is clear from previous sections in this report that a significant number of program participants did reduce their natural gas consumption as a direct result of this program. Research shows that 57% of program participants who implemented the recommended changes saw a distinct decrease in their natural gas consumption not attributable to other factors.

However, this effectiveness was not spread evenly amongst the different business sectors represented by this study.

For the sake of discussion, let's look at the program cost from a pure consulting fees perspective. In discussions with Terasen Gas and its contractors, a number of different costs per audit were discussed – all of them in the neighborhood of $1,200. For the purposes of this part of the report, the cost per audit is assumed to be $1,200. The cost of a GJ of natural gas not saved is assumed to be the transportation fee for this rate class – approximately $2/GJ.

Table 5 shows that while 71% of Care Homes that implemented changes saw decreases, there were also 29% that saw increases in their consumption. Moreover, these businesses returned very modest average annual gas savings.

Table 5: Effectiveness of Program, by Participants who Implemented Recommended Changes and by Type of Business

Type of Business	# of Program Participants	# in study	% that implemented changes	Consumption post-implementation	Average[3] Annual Gas Savings (GJ)
Care Homes	59	25	28%	71% decreased, 29% increased	473
Manufacturers	35	17	35%	60% decreased, 40% no change	**5574**
Apartments/Strata Properties	33	9	56%	60% decreased, 20% no change, 20% increased	591
Hotels/Restaurants	25	18	28%	60% decreased, 40% no change	351
Large Public Facility	21	6	50%	33% decreased, 66% increased	1319
Offices	16	3	0%	*Insufficient data*	
Total	**189**	**78**			

[3] Average savings were taken by dividing the sum of total consumption reductions by the number of program participants in that company category.

Table 5 shows familiar figures but compares the types of business and whether or not they implemented the changes recommended by Terasen Gas and its consultants. The percentage of customers that implemented changes is taken straight from the interview data. The column showing "consumption post-implementation" is showing the outcomes of historical billing analysis and "Average Annual Gas Savings" looks at 12-month rolling average consumption for customers in these different business type categories and averages the savings achieved.

Manufacturing customers, as shown in Table 5, saw 60% of respondents who implemented recommended changes decrease their consumption while the rest saw no change. The biggest metric of effectiveness is how much natural gas these businesses saved, on average – over 3300 GJs per year. This is ten times that of nearly every other category of business in this study.

From this perspective, it is obvious that the program is more effective for some types of businesses than others. This dovetails into a discussion about the cost-effectiveness of the program.

For the sake of analysis, we'll calculate the cost-effectiveness of the program based on its cost vs. GJs of gas consumption averted. Based on 189 completed audits during the study period, the total cost of the audits was roughly $227,000. Table 6 shows that while the Commercial Energy Assessment managed a very modest 14% return on investment, the majority of that load was carried by businesses in the manufacturing sector.

Table 6: Cost-effectiveness of Commercial Assessment Program, by Business Type

Type of Business	# of Program Participants	# that decreased consumption after implementing changes	Average Annual Gas Savings (GJ)[4]	Average Time (years) since audit	Total Value of Gas Savings over average time since audit ($2/GJ)	Cost of Audits ($1,200 per)	ROI
Care Homes	59	12	473	2.6	$29,515	$70,800	(58%)
Manufacturers	**35**	**7**	**5574**	**2.1**	**$163,875**	**$42,000**	**290%**
Apartments/Strata Properties	33	11	591	2.7	$35,105	$39,600	(11%)
Hotels/Restaurants	25	4	351	2.3	$6,458	$30,000	(78%)
Large Public Facility	21	3	1319	2.9	$22,950	$25,200	(9%)
Offices	16	0	0	2	$0	$19,200	(100%)
Totals	***189***	***37***			***$257,903***	***$226,800***	

Table 6 further validates the findings that the most success in this program was found amongst program participants with manufacturing businesses. The sample size for offices was very low. While it appears that from cost-effectiveness perspective, this sector was a total loss, it's possible that if all 16 program participants were examined, at least a few would have seen decreased consumption. Hotels, restaurants and care homes saw dismal returns on investment.

The metric $2/GJ was used in the analysis for Table 6 because it is the easiest way to calculate the value of gas consumption averted (avoided cost). $2 is approximately how much Terasen charges for the transportation fees to Commercial/Light Industrial customers and represents a cost-recovery.

Overall, the Commercial Energy Assessment was moderately successful (keeping in mind that those businesses who implemented changes will continue to have lower-than-expected gas consumption for the foreseeable future) but if taken alone, the manufacturing customers that participated in this program carried the weight of the program. If they were not involved, the program would have suffered from significant negative returns on investment.

[4] Note that these amounts are averages based on the GJs saved, based on billing analysis undertaken on customers who participated in this study.

FREE RIDERS

One measure of the cost effectiveness of a program is a "free rider" analysis looking at program participants who accepted the audit service from Terasen at no cost to them when they would willingly pay for the service if it were not free. Note that as with all other methods of evaluating free ridership, the validity of this cost-benefit test is highly debatable. In this case, energy savings can be calculated from billing analysis alone.

In the case of the Commercial Energy Assessment Program, accurate free rider analysis is clouded by Terasen's business practice of offering free audits partly as a customer satisfaction tool. It is likely that the majority of customers in this study likely participated in the program because Terasen Gas and its sub-contractors pushed this free program on them. The option to pay for the audits was not made available to customers. The method by which customers found out about the program and agreed to participate is validated in responses to question 3 of the interview guide (see Appendix A). The majority of respondents found out about the program from their Account Manager or one of the contract auditors delivering this program. Very few of the study respondents found out about the program through Terasen's website or bill inserts.

For these reasons, it is the belief of Friuch Consulting that any conclusions drawn from this free rider analysis are notional at best.

Table 7 shows the percentage of "free riders" in each business category. This number is derived by dividing the number of study respondents who conducted other assessments on their business that were not subsidized at all by the number of study participants in a specific business type contacted for this research. See questions 4 and 4a in Appendix A. For example, a customer who participated in the Commercial Energy Program might have also conducted a self-funded lean manufacturing assessment to reduce operating costs or increase operating efficiencies. In either case, the customer shows a willingness to invest resources in efficiency and productivity increases. That percentage of free riders is extrapolated into a total number of free riders by business type in the last column by multiplying the number of program participants (n=189) by the percentage of free riders for that category.

Table 7: Free Ridership, by Type of Business (n=189)

Type of Business	# of Program Participants	% free riders	# free riders (mid-2005 to June 2007, est.)
Care Homes	59	4%	2
Manufacturers	35	29%	10
Apartments/Strata Properties	33	0%	0
Hotels/Restaurants	25	6%	2
Large Public Facility	21	0%	0
Offices	16	33%	5
Totals	***189***	***10% (avg.)***	***19***

Table 7 shows that Manufacturing and Office Building Management companies, as sub-groups of Terasen's Commercial Energy Assessment Program participants, have the highest incidence of free riders. In the case of Offices, it is appears that 33% of program participants would have paid for a Commercial Energy Assessment if Terasen had not offered it for free. Overall, it appears that roughly 10% program participants are free riders in that these 19 program participants (out of 189) would have paid for the assessment if it was not free.

ANALYSIS

This section of the report goes into more depth where there are interesting or puzzling findings. Analysis is done in the context of Terasen Gas' operational realities – the Commercial Energy Assessment Program needs to achieve the outcomes it is designed to achieve and it needs to do so in a cost-effective manner.

THE DECISION TO IMPLEMENT RECOMMENDED CHANGES OR NOT

The decision to implement recommended changes all appears to come back to the up-front cost and expected return on investment timescale for the recommended changes. This is not unexpected. For companies with complex financial considerations, the decision to make a costly upgrade to HVAC equipment is simple. To explain why facilities like Provincially-funded Care Homes do not often implemented recommended changes, a more in-depth analysis of these facilities and their relationship to funders is warranted:

1. In many cases, the operations staff (including maintenance) is not led at the executive level by someone with operations subject matter expertise. For this reason, upgrades to heating systems are placed in competition with other, more noticeable areas for improvement around the property such as new beds, maintenance of furniture for tenants, etc… Little or no consideration is given to the fact that if money was saved in the energy department, more money would be available for what are usually cosmetic repairs to furniture and the building itself.

2. The funding for these Care Homes comes through the Ministry of Health and then through the department responsible for Care Homes before getting to the Care Home Executive Director who then assigns a budget to maintenance. This means that there are a number of steps and series of approvals that any major infrastructure upgrade would need to go through before it could get implemented. Capital expenditures would have a direct impact on operating costs, potentially putting management at the Care Home in violation of their arrangement with the Province.

In the case of most manufacturing companies where the owner of the company is also the major shareholder, it is easier to justify large capital expenditures as long as the net present value (NPV[5]) is high over the short-term for the company. Improvements to the facilities can also be a beneficial expense for the company at tax time. The levels of approvals that a new equipment requisition must go through at most manufacturing companies are much fewer than they are for a Provincially-funded Care Home. Small to medium-sized manufacturing companies in BC tend to also have very flat hierarchies where an Operations Manager could typically go straight to the CFO or CEO to get new HVAC equipment approved.

<u>In conclusion, it seems clear that manufacturing companies have the motivation and the ability to make the changes recommended by Terasen Gas through the Commercial Energy Assessment Program more easily than other types of businesses</u>. This conclusion was validated by Bill Hennessey in a phone interview.

[5] Net present value is the standard method for using the time value of money to appraise long-term projects. Used for capital budgeting, and widely throughout economics, it measures the excess or shortfall of cash flows, in present value terms, once financing charges are met.

ENERGY SAVINGS

The assumptions behind the calculations of energy savings are defendable but not perfect. There were a number of issues with the data quality both from Terasen Gas and from Environment Canada (regional HDD statistics). For example, some of the historic billing records for the customers in this study only covered billing intervals up to November, 2007. When looking at customers whose audits were conducted in mid-2007, this did not provide sufficient post-audit data for an accurate analysis. In other cases, the billing records do not go much further past the audit while some records go back nearly 10 years.

On the Environment Canada front, HDD data for the Metro Vancouver area was available well beyond the study period for this program evaluation – ideally, this study was to review historical billing records two years before the audit took place. Outside of the Metro Vancouver area, monthly HDD summary statistics for regions like Quesnel and Kelowna are only available after January, 2005. For audits conducted in 2005 in these regions, the HDD data was not available to calculate expected consumption two years in advance of the audit.

Despite these challenges, every effort was made to compensate for data quality variability. The fact that customers who did not make the recommended changes and those who did were not compared with a control group of customers who did not participate in the program means that the calculation of total energy savings could only look at companies who made the recommended changes.

It is the belief of Friuch Consulting that customers who did not make the recommended changes were influenced by the audit process and while they might not have made significant equipment upgrades, may well have changed their operational practices following the audit. This would account for the customers who participated in the program, chose not to make the recommended changes but saw a significant drop in gas consumption following audit.

<u>In conclusion, it is clear that the program led to gas savings for customers who did implement the recommended changes.</u>

SUCCESS OF RECOMMENDED MEASURES

This is a relatively simple analysis. It is clear from the findings that low-cost, short ROI solutions are favoured over high-cost, long ROI options. This finding was not unexpected. Any customer doing a net present value (NPV) analysis (consciously or sub-consciously) will steer away from options that have an ROI of three years or longer. Long ROI options typically lead decision-makers to investment opportunities over infrastructure upgrades.

Setting popularity aside for a moment, it's also clear that these low-cost, short-ROI measures have had big impacts in the energy consumption of the companies that chose to implement them. One customer – a manufacturing customer – managed to save over 10,000 GJ of gas in the last 17 months by putting timers on their radiant tube heaters so that they don't run when the production floor is closed for the night. Replacing a boiler with a higher efficiency unit only appears to save most customers 1,000 GJ per year.

It is doubtful that most customers that participated in this program after receiving their audits took the time to calculate the actual NPV for the proposed solutions. It's more likely that the decision makers have an intuitive feel for NPV or simply relied on the ROI estimates provided in many of the audits and made their decision based on current cash-flow issues.

The 42% of participants who felt that the recommendations given were "not reasonable" are likely disappointed that the energy assessment did not take into consideration basic economic principles for small- to medium-sized businesses where a new boiler is not a viable option.

In conclusion, it appears that most customers who participated in the Commercial Energy Assessment Program gravitate towards low-cost, short-ROI solutions because they have more important short-term priorities for spending within their company. They clearly also expect Terasen to understand this dynamic when coming in to audit their business.

OVERALL EFFECTIVENESS OF THE PROGRAM

Clearly, this program was most effective amongst manufacturing companies – not just because of their modest uptake rate but because of the high ROI this group provides for Terasen Gas in the maintenance of this program. Upon reviewing program costing and ROI from these customer groups in Table 6, it is clear that manufacturing customers are largely responsible for the program making a 14% ROI overall.

In conclusion, these findings clearly indicate that the program was most effective amongst manufacturing clients; therefore, from a cost-effectiveness perspective, it was only cost-effective to deliver the program to this group. All of the other businesses types had negative ROI at the end of the study.

However, there are some public relations "optics" reasons why it would be a good idea to continue to offer free Commercial Energy Assessments to Large Public Facilities like malls, sports arenas and colleges – these high-profile facilities often have ties to government agencies and providing good services to these companies creates good will in the community that can be "cashed in" during regulatory filings or normal rate increases. Moreover, these companies use large volumes of gas and even if they cannot effectively reduce their consumption, it is in Terasen's best interest to keep them as a customer long-term.

CONCLUSIONS

The conclusions of this study are straightforward:

- **All of the audits conducted by Bill Hennessey and Peter Hill appear to have been successfully completed on 189 properties**
- **Only 35% of customers audited actually implemented any of the recommended changes**
- **It is estimated that nearly 129,000 GJ of natural gas was saved as a direct result of Energy Assessments conducted during the study period as calculated by the sum of actual consumption decreases against expected usage for customers who implemented recommended changes**
- **The best recommended measures were ones that either had short return on investment for the customer and low up-front costs OR ones that replaced equipment at the end of its operational life-span with high efficiency boilers.**
- **The program was most effective with manufacturing customers in the rate classes that were eligible to apply for this program**
- **29% of respondents who did not make recommended changes also saw a decrease in their consumption after the audit – no attributable factor is known**
- **Overall, the program was effective in getting commercial customers to use less gas but the program was most cost-effective amongst customers in the manufacturing sectors which saw a nearly 300% return on investment**
- **Roughly 10% of program participants are "free riders"**

This leads to the overall conclusion that the program has been a success to date but that it needs to focus on customer segments with the highest ROI for Terasen (manufacturing companies) and customers where there is a public relations reason for offering free energy assessments despite low ROI for Terasen. Terasen could offer a different slate of demand side management programs for customer segments that have low ROI for Terasen (apartments, care homes, hotels, restaurants and offices).

Specific recommendations for changes to the program are covered in the next section.

RECOMMENDATIONS

The conclusions from this study indicate that a diversified portfolio of demand-side management programs available to commercial and light industrial customers is warranted. The big picture implication of this reality is that some customers should receive more one-on-one attention from Terasen while groups with lower successful outcome rates should receive more general information (and more cost-effective communications) about demand-side management.

This is not suggest that non-manufacturing customers would no longer receive audits under any circumstances – just that they would need to be pre-qualified before participating to ensure that they are the type of customers that is more likely to invest in infrastructure upgrades to reduce gas consumption.

The recommended improvements to the Commercial Energy Assessment Program are as follows:

1. **Spend more time nurturing and providing free Commercial Energy Assessments to manufacturing customers.**
    a. Ensure the follow-up is done with each of these customers because that may have an impact on their willingness to make recommended changes to their HVAC systems.
    b. Consider providing more in-depth assessments for these customers including some advice on sourcing the recommended infrastructure upgrades.
    c. Be pro-active in seeking out these customers.
2. **Do not conduct Commercial Energy Assessments with non-manufacturing customers unless:**
    a. The customer has been through a series of free public workshops on demand side management measures and understands what these measures cost, the potential benefit to the company and if they have the ability to make these changes at this time.
    b. There is a public relations reason to do so.
3. **For low-ROI customers, develop public workshops that teach basic consumption reduction techniques.**
    a. Be sure to target the decision-makers in each sector… not necessarily the operations/maintenance manager.
    b. Workshops are a lower-cost way of pre-screening companies that are committed to making operational changes to reduce natural gas consumption.
4. **Account managers and the consultants conducting the audits clearly need to have some kind of Customer Relationship Management (CRM) solution in place** so that everyone who touches these customers from Terasen knows when each customer was last contacted and knows the context of that contact.
5. **Communicate with Environ and the auditors currently delivering the Commercial Energy Assessment Program and ensure that they pay special attention to low-cost, short-ROI solutions more often than costly upgrades such as boiler replacements.**

The following page details two specific DSM Program delivery vehicles that Terasen could consider developing to improve the overall effectiveness of the program. The expected outcomes of implementing these recommendations are:

1. **Vastly improved cost-effectiveness of program**
2. **Bigger reach into the customer base with less effort**
3. **A more streamlined process of tracking customers who leverage this program.**

IN-DEPTH COMMERCIAL ENERGY ASSESSMENTS FOR MANUFACTURING CUSTOMERS

The findings of this study show that the Commercial Energy Assessment Program (as delivered between mid-2005 and June, 2007) was most effective amongst customers in the manufacturing (light industrial) sector. The recommendation from Friuch Consulting is to "spend more time nurturing and providing free Commercial Energy Assessments to manufacturing customers." While acknowledging that the program has been successful with this sector, it is also important to remember that only 35% of program participants in this sector actually implemented the recommended changes. While that 35% of program participants generated some significant energy savings, even more savings could be achieved by this program if more customers in this sector had successful outcomes in reducing gas consumption.

Any changes to the Commercial Energy Assessment Program for this sector should focus on how to reach the 65% if program participants that did not make recommended changes can be encouraged to do so. For most of the respondents in this study in the manufacturing business that did not make recommended changes, they cited ROI issues. In these cases, equipment upgrade subsidies should be considered in cases where there is a great opportunity for gas savings.

In other cases, manufacturing customers might simply require more in-depth information such as specific equipment specs, suppliers and recommended installers. Other customers in this sector might be willing to ignore long ROI if there was a publicity/marketing benefit to going "green" with their HVAC systems. For example, one customer in the Apartment sector claimed to have initiated a pilot project on-site with Terasen Gas and IBC Boilers.

This category of customer is worth spending additional time and resources on because the return on investment for Terasen is so high.

SECTOR-SPECIFIC WORKSHOPS

For those customers who are least likely to implement recommended changes from the Commercial Energy Assessment Program, public workshops might be the best solution. These workshops would target specific customer groups such as apartment building managers, care home operations managers and property managers. In a telephone interview with Bill Hennessey – who was a Commercial Energy Assessment Program auditor and is currently an auditor through Environ – Bill validated Friuch Consulting's assessment of groups who have a low implementation rate as well as the recommendation to offer public workshops to these groups.

Bill Hennessey also indicated that he would be well positioning to provide the content for these workshops as he has already established "normal" gas consumption profiles for these customers based on his audit experience. Similarly, he has seen the most common areas for improvement in specific properties. This kind of information, paired with more general DSM information could provide the foundation for a successful public workshop.

The cost of one workshop would exceed the cost of a single audit but could reach dozens of customers in that sector. For the same expenditure, a public workshop campaign could expand the reach of the Demand Side Management program. There is support for this recommendation amongst the study respondents – 81% of respondents said that they would be interested in "educational seminars to learn more ways to reduce gas consumption" (see question 7b in Appendix A).

The content of these workshops should focus on informing customers what a normal gas consumption profile looks like, the many reasons why a customer's gas consumption might be above average and a number of pointers on how to reduce consumption. Customers that are very keen to do everything they can to reduce their consumption could apply for a Commercial Energy Assessment of their own. For most customers, this would not be necessary.

APPENDIX A: INTERVIEW SCRIPT

Interviewee:____ **Date:** _________________

Terasen Gas Commercial Energy Assessment Review – Customer Interview Script v.3 (Final)

Terasen Gas, as a Provincially regulated utility company, must ensure that expenditures for energy efficiency related programs are done prudently such that Terasen Gas can defend the programs to the regulator as well as the customer and the shareholder. Terasen Gas has not completed a comprehensive review of the Commercial Energy Assessment program in recent years and as such has hired Friuch Consulting to review the effectiveness of the program.

1. What is the nature of your business?

2. What does your company use natural gas for?
   a. Space heating?
   b. Vehicle Fuel?
   c. Water heating?
   d. Electricity co-generation?
   e. Manufacturing process?

3. How did you become aware of the Commercial Energy Assessment program? DO NOT READ, CHECK ALL THAT APPLY

   ☐ Insert in Terasen Gas Bill
   ☐ Direct mail from Terasen Gas
   ☐ Terasen Gas Website
   ☐ Through heating or furnace contractor
   ☐ Word of Mouth
   ☐ Account Manager
   ☐ Trade show or consumer event
   ☐ Other websites
   ☐ **Other (list)**

4. During the past five years, has your company conducted any assessments of other areas of the business with an eye to find ways to save money and/or increase return on investment? Eg. Waste reduction programs, electricity audits, lean production analysis?

   a. If yes, were these studies internally funded or did your company leverage government programs?

5. Did you receive a copy of your Energy Assessment after it was completed?
   a. <go over the audit with them to re-cap what was recommended>
   b. Were the recommendations reasonable?

6. Did your company implement any of the changes recommended in the audit?

   a. If yes, which changes were implemented and when?

   b. If yes, on a scale of one to five, where one is not at all important and five is very important, how important was the Terasen Gas free Energy Assessment in your decision to make these changes?
   ☐ 1 ☐ 2 ☐ 3 ☐ 4 ☐ 5 ☐ Don't know
   c. If no, why did your company decide not to make any of the recommended changes?

7. Was there any follow-up from Terasen Gas staff or the auditor since your Energy Assessment?

   a. If no, would you like someone from Terasen Gas to follow up with you?
   b. Would you be interested in educational seminars to learn more about ways to reduce your gas consumption? Online vs. Face to face?

8. <if changes were implemented> Did you do an analysis of your energy savings after you implemented recommended changes?

   a. If yes, were the results what you expected?
   b. If no, did you notice an overall decrease in your Terasen Gas bill?

9. Did your company's production increase/decrease after your energy assessment? Eg. Did you ramp up production? Did you expand your operation?

10. Did your company change owners since the energy assessment?

11. At any point before or after the energy assessment, did an increase in natural gas prices motivate your company to examine its natural gas consumption?

12. Have you done any major equipment upgrades since the energy assessment?

13. Did you make any structural changes to your facility since the energy assessment?

    a. Are you still in the same building as you were when the energy assessment was conducted?
    b. Have you increased the floor space of your company since the energy assessment was conducted?

14. How many employees does your company have at the moment?

    a. Has the number increased or decreased since the Energy Assessment?
    b. Have you changed your hours of operation since the Energy Assessment?

15. What was your overall satisfaction with the audit?

    a. Would you have liked any other information on the audit?

16. Additional comments about the Energy Assessment Program.

Commercial Energy Assessments

Program Evaluation

Friuch Consulting

This report outlines and reports the outcome of work done between January and March, 2010 by Friuch Consulting for Terasen Gas, Demand Side Management and Marketing Department under the direction of Michelle Petrusevich and Ramsay Cook. **Note that Friuch Consulting is now known as Ignitia Consulting as of March, 2010.**

Friuch Consulting

friuch.com

CONTENTS

EXECUTIVE SUMMARY

Friuch Consulting's services were retained in January, 2010 by Terasen Gas to complete a second evaluation of the Commercial Energy Assessment Program looking at program participants between the periods of July 2007 and July 2009. A previous review of the program was conducted in August, 2008 by Friuch looking at program participants between the periods of June 2005 and June 2007. The program was created to help Terasen's commercial and small industrial customers identify inefficiencies in their energy consumption, and provide them with an action plan to reduce their natural gas consumption.

This program offers energy assessments at no cost to qualifying participants. Similar versions of this program have been offered to Terasen's commercial and small industrial customers since 2001. The current version of the program was launched in mid-2005 and provides free energy audits, conducted by third-party energy consultants to qualified program participants. The program is open to commercial and small industrial customers in the Lower Mainland, Squamish and BC Interior customers who spend more than $20,000 per year on natural gas.

There is a formal application process to qualify for the program but in practice, customers have liaised with their Account Manager who determines if an audit is warranted. Once an application is approved, a third-party energy efficiency consultant visits the customer's site and performs an evaluation. Site visits are typically completed within two hours and the third-party consultant produces a report summarizing the audit as well as any recommendations to increase energy efficiency.

Third-party energy consultants carried out this work on behalf of Terasen Gas between July 2007 and July 2009 and completed 158 audits. Customers were to receive a written assessment and recommendations within two weeks of the visit and then a follow-up letter at a later date to verify what, if any, recommendations were implemented.

The specified deliverables for this study are:

1. Determine whether customers acted on recommendations provided in the energy audits
2. Estimate of energy savings (planned and achieved)
3. Determine the percentage of measures that were implemented by the customers and estimate energy savings based on findings
4. Determine other factors that might have affected a customer's energy usage after recommendations were put forward
5. Provide feedback on overall effectiveness of program
6. Perform a free-rider analysis on the assessments, i.e. what percentage of customers would have undertaken an energy audit in the absence of the free assessment program
7. Provide recommendations on further improvements of the program

All of the above deliverables were achieved and are covered in detail in the following sections. At a high-level, the findings are:

- It is estimated that 43% of program participants made some or all of the recommended changes.

- 52% of program participants saw a positive outcome (demonstrable reduction in gas consumption) whether they made the recommended changes or not.

- 13% of program participants made the recommended changes but saw no decrease in consumption. It is estimated that nearly 250,000 GJs of natural gas was saved as a direct result of Energy Assessments conducted during the study period.between July 2007 and November 2009.

- Manufacturing companies outperformed every other business type in terms of making recommended changes and seeing a substantial decrease in consumption. Offices, Apartments/Stratas and Hotels/Restaurants performed very poorly in terms of making the recommended changes and reducing their consumption.
- 24% of customer premises that did not make recommended changes also saw a decrease in their consumption after the audit. We are giving Terasen credit for 10% of this reduction as per a study by Sarah Darby[1] which proves demand-side management energy audits achieve modest reductions in consumption even when no major changes are made by introducing a "conservation culture" to the organization. These numbers are included in the total GJs saved above.
- Overall, the program was effective in getting commercial customers to use less gas but the program was most effective in the "manufacturing" sector which saw 92% of the total GJs reduced in this study while representing only 23% of the total program participant premises.The study has determined that roughly approximately 35% of program participants are "free riders" – defined as customers who would have paid for a Commercial Energy Assessment if it was not free. Statistics on how much these participants would be willing to pay are not available. Most participants determine the value of such programs in terms of how much ROI they can produce – not a flat fee for the service.

Note that data tables from this study were provided to Terasen in a digital format (Microsoft Excel) and will not be appended to this report.

Friuch Consulting believes that Terasen Gas can improve upon the success of the Commercial Energy Assessment Program by changing the program requirements for customers to receive free audits, offering new programs such as public workshops on demand-side management (DSM) and review some of the policies and procedures of the program overall.

Specific recommendations for improving the program include:

1. Move the minimum amount of gas purchased to participate in the program to $75,000 per year.

2. For customers spending less than $75,000 per year on gas, develop public workshops that teach basic consumption reduction techniques.

The over-arching recommendation of this report is that the Commercial Energy Assessment program be continued but significantly modified to maximize its cost-effectiveness and reach.

STATUS OF RESEARCH

[1] Darby, Sarah (2001) "Making it obvious: designing feedback into energy consumption". *Energy Efficiency in Household Appliances and Lighting* (30 January 2001), pp. 685-696.

Friuch Consulting's services were retained in January 2010 by Terasen Gas to complete a program evaluation of the Commercial Energy Assessment Program between the periods of July 2007 and July 2009.This research took place as outlined below:

Table 1: Research Schedule

Research Design and Consultation with Terasen Gas	January, 2010
Customer Audits/Interviews	January – February, 2010
Interim Report	Completed February 22, 2010
Analysis	March, 2010
Reporting	March-May, 2010

Field research was completed on February 9, 2010 and met the requirements laid out by Terasen at the beginning of the project. The research methodology for the study was as follows:

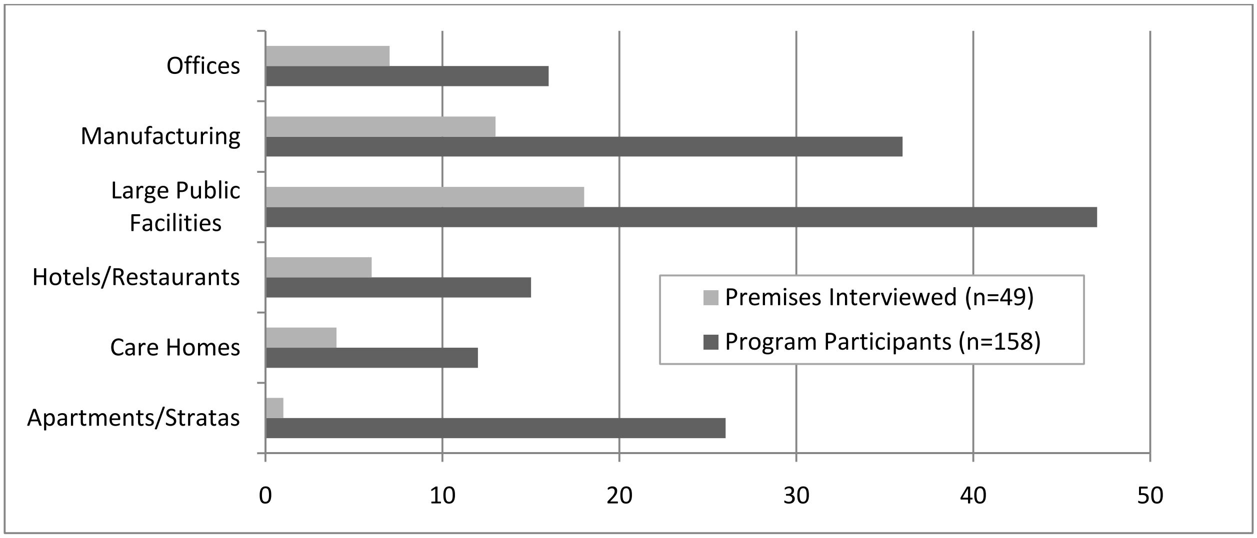
1. Aaron Cruikshank obtained copies of the audits and historical billing data for all 158 properties prior to the start of field research.
2. Min Soo Kim called program participants that had audits between July 2007 and July 2009 to solicit their participation in a follow-up interview with Aaron Cruikshank or Sean Peters of Friuch Consulting.
3. The interview followed a series of questions developed in conjunction with Terasen Demand Side Management and Marketing staff (see Appendix A).
4. Information from the interviews was entered into a spreadsheet for comparison and analysis with historical billing records.

Copies of all 158 assessments were provided to Friuch by Terasen on January 8, 2010. Friuch received very high quality historical billing data for all 158 program participants in our study period on February 1, 2010. Interviews were completed on February 9, 2010. Consumption Analysis was completed on February 22, 2010. Interim findings on overall program savings and return on investment were submitted to Terasen on February 23, 2010.

Of the 158 customer premises (some customers had multiple facilities or "premises" that were reviewed with different accounts), Friuch interviewed 30 program participants (respondents) representing 49 customer premises.

Figure 1 (next page) shows that there was reasonable representative samples of all business types except "other", and Apartments/Stratas. The response rate for Apartments/Stratas was very poor in terms of the interviews. The researcher scheduling the interviews was unable to find a sufficient number of property managers to speak with in this category. There were 26 apartment/strata customers in the study sample – all of whom were contact multiple times to complete this research.

Figure 1: Study and Program Participation, by Type of Business



Most of the respondents for the Apartments/Stratas category are professional property managers. Many of these property managers booked appointments to speak with Friuch staff, but on multiple occasions these appointments were left unattended by the property managers despite attempts to re-schedule interviews. The low participation rate of property managers in this study representing Apartments/Strata Properties is attributed to the fact that it is unlikely that responding to inquiries from Terasen would have been billable as per their contract with the building owners.

Those property managers that did respond likely did so on their own time. Operations managers and administrators/maintenance staff at Care Homes, Hotels, Manufacturers and Large Public Facilities would have, in most cases, been paid for any time they spent talking to Friuch Consulting.

<u>Note that complete interview data has been submitted in an electronic format as an appendix to this report. It is not suitably formatted for print display but will be referenced throughout the report.</u>

LIMITATIONS OF THIS STUDY

There is one primary limitation to this study:

1. The sample size is small and cannot yield statistically accurate findings. The findings from this report need to be interpreted as qualitative, not quantitative. Terasen was aware of the small sample size and accompanying limitations when the RFP for this project was issued.

METHODOLOGY FOR CALCULATING GJS SAVED

Most economists familiar with heating fuel stocks such as natural gas agree that the biggest determinant of demand for gas is the weather, as measured by Heated Degree Days[2] (HDDs). Demand for gas is relatively inelastic to the market price at any given time (at least, at its current price point).

Figure 2 shows the graphical representation of a typical billing analysis for a program participant who did make the recommended changes. This example audit is from the 2005-2007 program review and was conducted in June, 2006. This manufacturing company uses natural gas for radiant tube heaters that provide space heating for the production floor. The recommended change was to install timers on the radiant tube heaters so that they did not continue to heat the shop floor when operations were shut down for the night. Figure 2 clearly shows that this customer has subsequently reduced their consumption, most noticeably in response to the winter HDD spikes.

Figure 2: Billing Analysis, Manufacturing Company that Made Recommended Changes

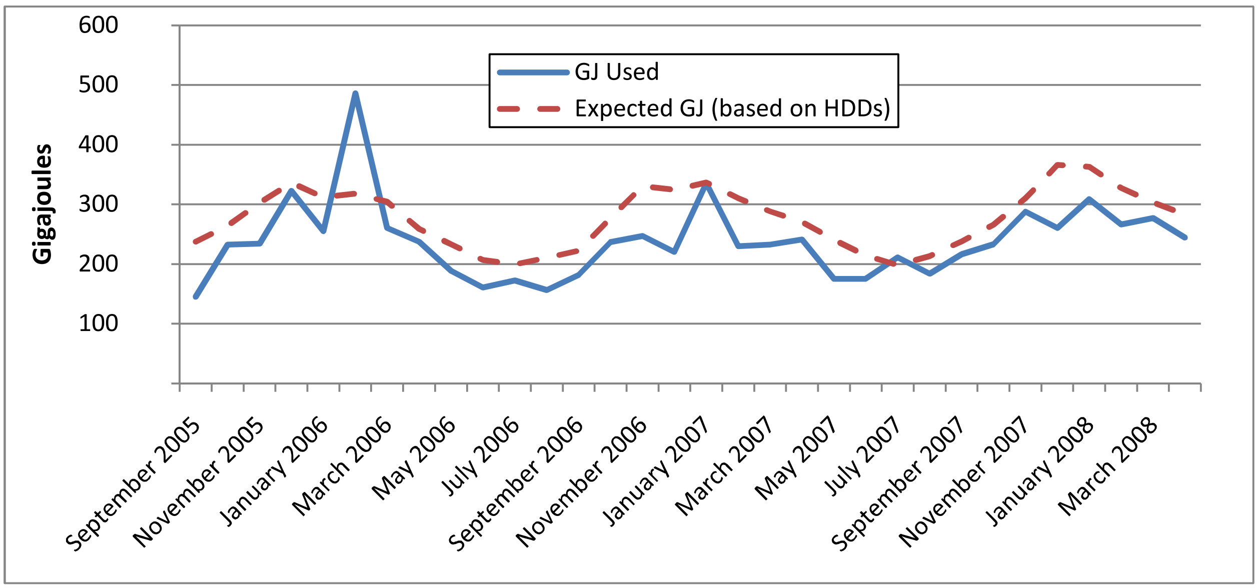


Figure 3 (next page) shows the graphical representation of a billing analysis for a Care Home customer from the 2005-2007 program review who did not make the recommended changes. Their audit was conducted in February, 2006. Figure 3 shows that this customer's consumption is closely tied to HDDs with actual consumption (GJ used) exceeding expected consumption every winter heating season. They did not reduce their consumption following the audit.

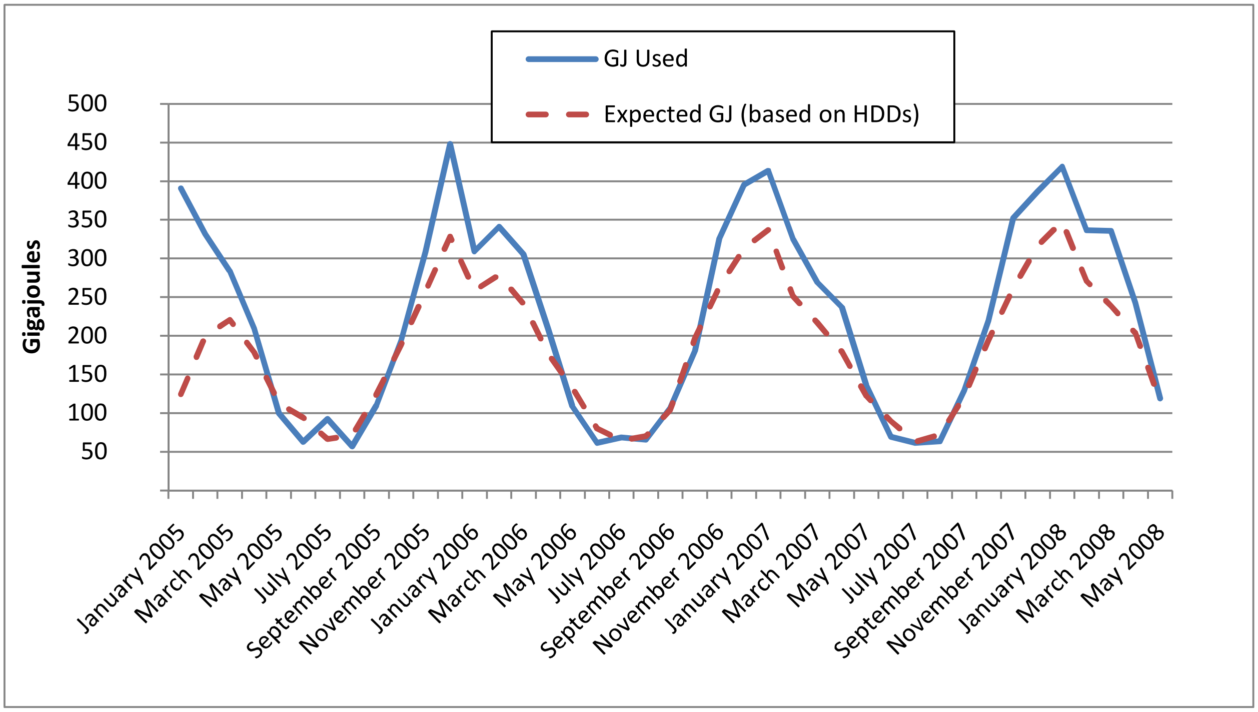
[2] Source: Environment Canada

Figure 3: Billing Analysis, Care Home, Did Not Make Recommended Changes



Calculation of these findings was complicated due to the high number of variables that had to be considered. To facilitate some type of analysis, Friuch obtained historical billing records showing GJs of Natural Gas used by each customer on a monthly basis during the study time period. While the quality of some of the historical consumption data was variable, it gave a relatively clear picture of consumption trends. GJs of gas used were compared with "expected" usage.

Put simply, here is how expected usage was calculated:

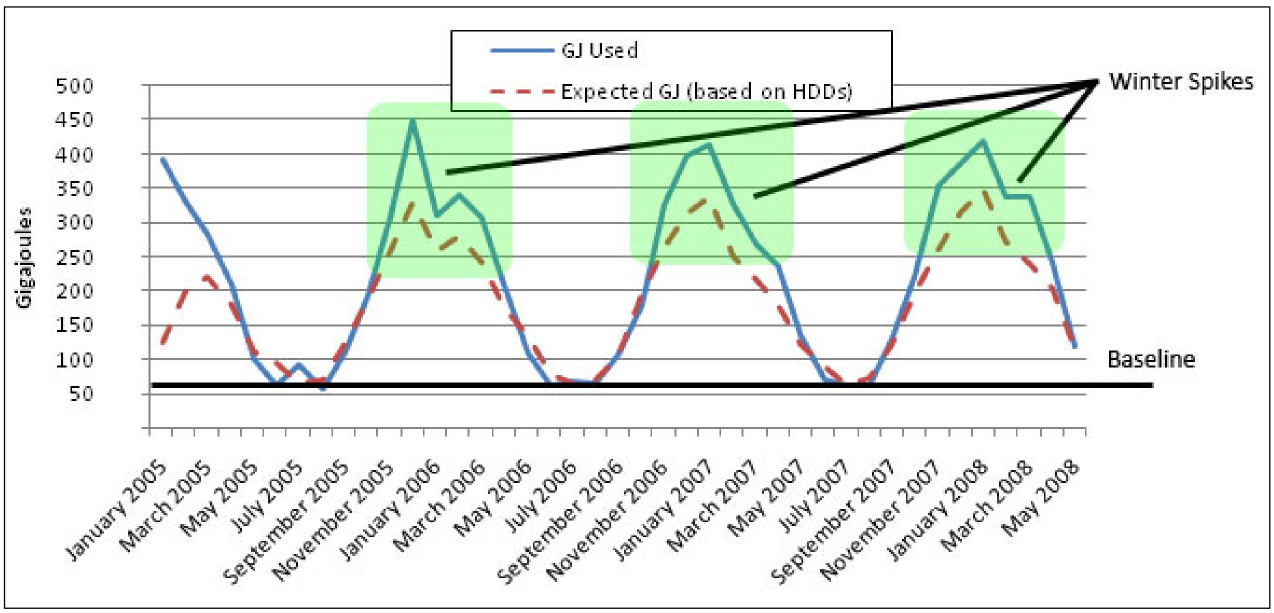
The researcher established a "baseline" of gas usage for each customer in the study. This baseline is the amount of natural gas that the company uses during months where they should not need to turn on the boiler for space heating. Space heating to compensate for outside temperature changes is the biggest cause of consumption variation from month to month.

Figure 4 (below) illustrates how a baseline is established. In July of 2005, 2006 and 2007, both the GJs used and the expected GJs used bottom out at around 60 GJs for those months. This is what the customers' gas consumption looks like when they don't turn on their furnace for a month. All gas consumption that occurs above the baseline is attributed to consumption changes to address colder outside temperatures.

In this specific example, the customer uses more than the expected amount of gas during the winter spikes. This is not uncommon since most customers are not using digital control systems which ramp up heating more incrementally than a person in control of a normal thermostat would. When it's very cold, many people turn the thermostat to a level that is much higher than is necessary under the mistaken impression that it will heat a room faster. The increased demand for gas places on the system by such behavior is illustrated in

Figure 4.

Figure 4: Typical Billing Analysis Chart, Showing Baseline and Winter Spikes



1. Once the baseline was established, the amount of gas used during winter spikes was compared to the baseline. This gave a range of consumption that a business uses based on changes in outside temperature. After looking at the change between low and high heating seasons and comparing to HDDs for three consecutive heating seasons, a multiplier factor can be established to predict how much a customer will turn up the heat when winter cold spikes hit. This information gives the researcher enough data to plot an "expected GJs used" line for each customer to compare against their actual consumption.

2. To compensate for production changes, the expected GJs line was multiplied by 1.n over time where "n" is the percentage increase or decrease in production.

3. The degree to which a customer's actual consumption is above or below the expected GJ use line is compared before and after the Terasen audit. If the customer's consumption rose against expected levels after the audit, it was assumed that the customer did not successfully reduce their natural gas consumption.

4. Customers who have lower consumption against expected levels after implementing recommended changes are counted as having successful outcomes for this program and the amount of GJs they saved below what was expected was counted towards the total GJs saved for this project. For customers who implemented recommended changes but saw an increase or no change in consumption were not counted in this study because their choice to consume more cannot be attributed to the Commercial Energy Assessment Program.

5. Customers who had lower consumption against expected levels but did not implement recommended changes were also counted as having successful outcomes for this program but only 10% of their reduction was added to the total program savings as per the Darby (2001) study[3].

6. Once the analysis showed what customers in each of the different business types saved over what period of time, annual consumption reduction numbers for each category of business could be calculated.

By multiplying average consumption in a business type category by the estimated number of program participants who made the changes before seeing a drop in their consumption, by the number of years on average since this business type participated in the program – this study can arrive at a defensible number of GJs directly averted by the Commercial Energy Assessment program.

FINDINGS

This part of the report summarizes the findings as they match the deliverables specified by Terasen. Analysis of these findings and recommendations to improve on the Commercial Energy Assessment Program will follow in subsequent sections of this report. Where possible, this report will make direct comparisons to the previous program review (completed in August, 2008) – hereafter "the 2005-2007 program review".

Note any distinctions between **respondents** (n=30) and **premises** (n=49) because there were some respondents that gave us information on multiple premises that had received energy assessments.

THE AUDIT EXPERIENCE

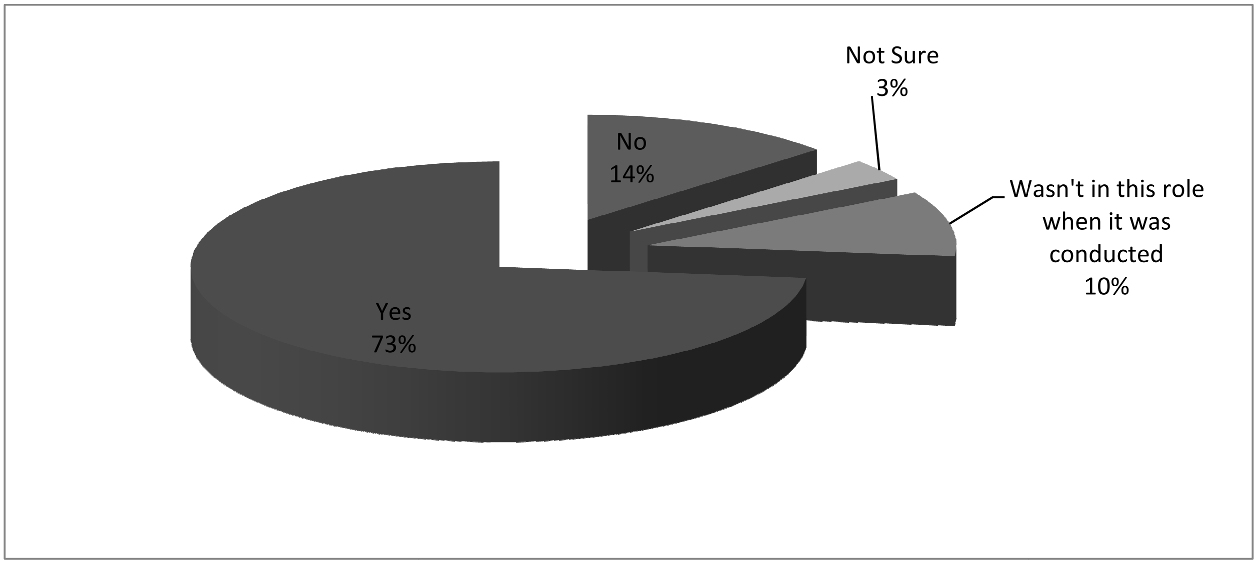
During the process of sourcing respondents for this project, none of the respondents indicated that they had not participated in the program. While not conclusive, it is a good indicator that all of the audits that were said to have been completed between July 2007 and July 2009 were completed.

As part of the follow-up procedure for the audit process, each audit client was to receive an electronic copy of their energy assessment report as well as a follow up phone call from their energy auditor. We interviewed 30 respondents about 49 premises and of these 30 respondents, 22 (73%) stated that they had received their energy assessment report after the completion of their energy audit. Only 14% responded that they hadn't received a copy

[3] Darby, Sarah (2001) "Making it obvious: designing feedback into energy consumption". *Energy Efficiency in Household Appliances and Lighting* (30 January 2001), pp. 685-696.

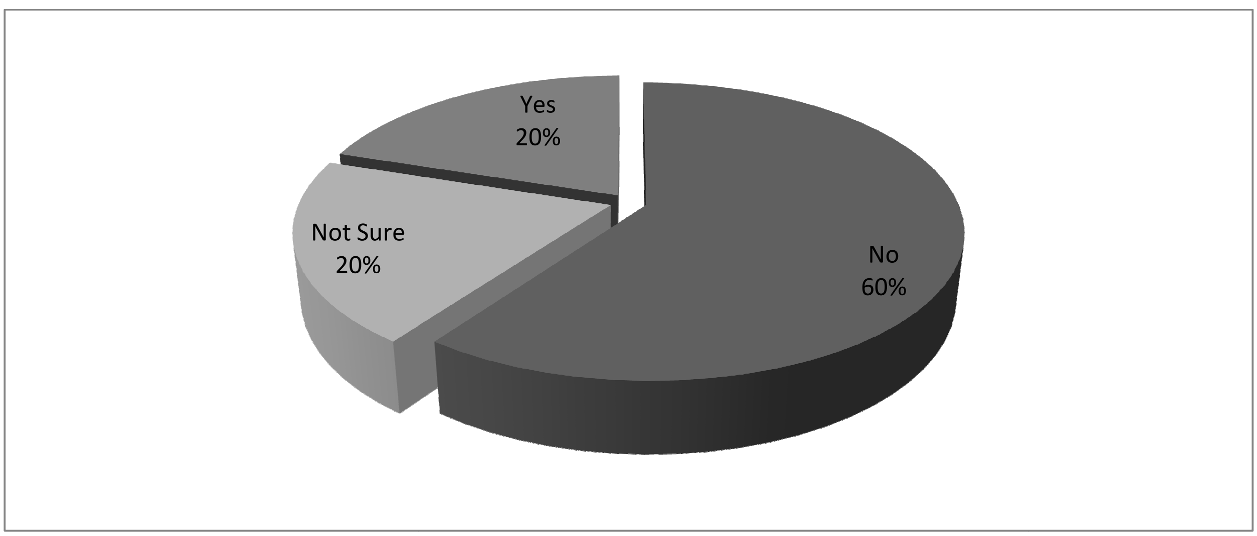
of their energy assessment report. This is an improvement from the 2005-2007 program review, where we had previously found that 20% of respondents hadn't received a copy.

Figure 5: All Respondents; Did You Receive Your Audit Report After The Audit Was Conducted? (N=30)



In terms of follow-up, 6 of 30 respondents (20%) said that they had received a follow-up call from Terasen Gas; 18 respondents (60%) said that they had not (see Figure 6). This is a slight improvement from the 2005-2007 program review, where a full 65% of respondents failed to receive a follow-up after the audit process was completed.

Figure 6: All Respondents; Was There Follow Up from Terasen After The Audit Was Completed? (N=30)



In many cases, the respondent that talked to Friuch Consulting was not the same person who participated in the original audit. This data was captured by asking if the respondent was in the same role as they were when the audit was conducted.

It is worth noting that for those respondents that reported they had not received their audit, it is possible they lost their energy assessments, or that it was delivered to a different department, or filed away and forgotten about. Some of these energy assessments were conducted over two years ago, and many of the respondents are busy building managers who receive a lot of paperwork from different departments. Similarly, it is possible that after the audit a follow-up phone call from Terasen or the Auditor was made and then forgotten about, or that the auditor left messages for the client that weren't returned.

Overall opinions of the audit varied, but generally fell into four categories:

1. **Those who felt the audit was too high level**
2. **Those who were generally satisfied with the overall audit process**
3. **Those who found inaccuracies or generally felt the audit quality was poor**
4. **Those who were not present for the audit process or had a different role in the company at the time of the audit.**

The majority of people audited were satisfied with their audit experience and many said that they had really appreciated the program even if changes weren't made, as it helped present options for them to work towards in the future.

At least one study has shown that the simple act of participating in an energy audit like the Terasen program can introduce a "conservation culture" into a company and result in an average 10% decrease in energy consumption[4]. This phenomenon will be described in greater detail in the section describing our analysis methodology.

However, a significant segment of respondents (13%) felt that the audit process did not meet its full potential because the analysis provided was too high level and/or did not provide enough detail to allow for the smooth implementation of the recommendations. These criticisms were only coming from large public facilities and manufacturing customers. Many of these customers found that they had to hire energy consultants to complete more detailed analyses in order to make the recommended changes. Others felt that the quotes estimating cost of implementation provided were not realistic or lacked enough information to act upon. Many respondents who felt the audits were a bit lean also had positive things to say about the audit but felt the lack of details limited the usefulness of the report.

There were only four (4) respondents who felt the quality was report was "poor". They explained that they found errors in the final report, and were disappointed with the costing calculations that were included. Again, these respondents were in manufacturing and large public facility businesses.

There is no indication that there is a correlation between the 60% of respondents that did not receive any follow-up from Terasen and the relatively low implementation rate amongst program participants (43%). The following sections will demonstrate that there are a number of factors that have an influence in the willingness of a program participant to implement recommended changes to their gas infrastructure and usage.

[4] Darby, Sarah (2001) "Making it obvious: designing feedback into energy consumption". *Energy Efficiency in Household Appliances and Lighting* (30 January 2001), pp. 685-696.

ENERGY SAVINGS

Table 2 gives a high level overview of the energy savings and outcomes experienced by program participants during the study period.

Table 2: Overview of energy savings and outcomes, all groups (n=152)

	Program Participant Premises	Participant Premises Interviewed	Total GJs Saved	Average Savings Per Premises	Premises that experienced a reduction in consumption after audit	%Premises that made recommended changes	% Premises that made recommended changes but did not see a decrease in consumption	% of Premises that did not make recommended changes but saw a decrease in consumption
Apartments/Stratas	26	1	3,064.6	2.60%	insufficient data			
Care Homes	12	4	3,634.1	2.10%	25%	50%	25%	0%
Hotels /Restaurants	15	6	1,089.1	0.68%	50%	50%	0%	0%
Large Public Facilities	47	18	9,901.1	2.19%	55%	44%	22%	33%
Manufacturing	36	13	231,303.9	5%	62%	54%	8%	23%
Offices	16	7	755.5	0.84%	43%	0%	0%	43%
Total	**152**[5]	**49**	**249,748.3**	**2.63%**	**52%**	**43%**	**13%**	**24%**

The above table illustrates how Manufacturing customers far outstripped the other sectors combined in terms of GJs of energy saved. The manufacturing sector is responsible for 92% of the total GJs reduced in this study while representing only 23% of the total program participant premises. This sector also had the highest implementation rate of recommended changes. The following sections will dive into the findings for each business types with regards to GJs of energy use averted.

[5] Npte: This total excludes "warehousing" and "other" respondents. There was insufficient data to analyze these business types.

APARTMENTS/STRATAS

The response rate for this category was very poor. The researcher tasked with scheduling interviews was unable to find a sufficient number of property managers to speak with in this category. There were 26 apartment/strata customers in the study sample – all of whom were contacted multiple times to complete this research.

The target for this category was to speak to eight (8) customers out of 26 (~30%) and Friuch was only able to contact one (1). Seven (7) interviews were scheduled but a number of them did not make their interview appointment and in all cases, did not make re-scheduled interviews. While this is not a good outcome, it does not mean that the findings for this business type are useless.

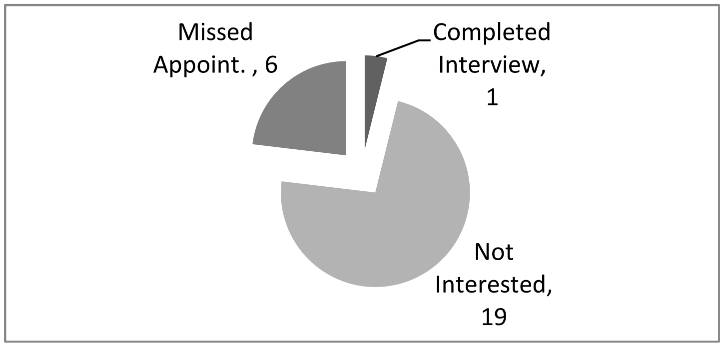


Figure 7: Response rate statistics - Apartments/Stratas (N=26)

During the 2005-2007 program review, this respondent group had a relatively high rate of implementing changes (56%) but had very little impact in terms of GJs of gas saved for two reasons: first, the average annual consumption for these program participants is very low compared to other program participants – in manufacturing, for example. Secondly, many of these kinds of properties lack healthy capital budgets to fund the recommended upgrades. Only 60% of Apartments/Stratas from the last study managed to reduce their consumption after making changes.

While it would be easier to apply the same change metrics from the previous study to this under-represented group in this study, there are a number of factors that lead the researchers to believe this would not result in an accurate review:

1. One of the most cited reasons for not doing major changes in the previous study was that major upgrades would require a special assessment fee to residents/owners that they were unwilling to pay. Given the province-wide decline in home values in 2008/2009 and the economic downturn of 2009, home owners may have been more resistant to spending money on major heating infrastructure upgrades during the study period.

   Put another way, the economic downturn may have made customers less willing to pay for new boilers and other upgrades. None of the respondents indicated that their "operations" were impacted by the economic downturn but that has a much different connotation for property managers of residential buildings than it does for the manufacturing companies interviewed.

2. 85% of the recommendations made to Apartments/Stratas in this study period were for "minor tweaks" (e.g. adjusting boiler settings, resetting thermostats, monitoring usage, etc…) or to replace a functioning boiler with a higher efficiency one when it fails. These recommendations are easy to follow and are more oriented towards introducing a "conservation culture" to the customer than making any major changes. . Studied have shown that the simple act of

participating in an energy audit like the Terasen program can introduce a "conservation culture" into a company and result in an average 10% decrease in energy consumption[6]. We did not account for this in our previous study but did in this study.

Comparable data from the previous study from which to make a direct comparison is not available. In the last study, Friuch only collected consumption data for respondents. After going back and running a more detailed analysis on the data from the previous study, it was discovered that Apartments/Stratas from the 2005-2007 program review reduced their consumption by an average of 2.88% after participating in the program. The sole apartment/strata respondent (who did not apply the recommended changes to their premises) saved 2.6% of their average annual consumption. This reduction percentage has already factored in the 10% of the GJ reduction Terasen can take credit for according to the Darby study. Total GJs below expected consumption post-audit was 524.83 GJ. Terasen is only taking credit for 52.483 GJs.Table 3: Data collected from respondents: Apartments/Stratas (n=1)

Participant ID	Months since audit to Nov. 2009	Implemented Changes?	Consumption Up/Down?	Raw GJs Saved	Average GJs Saved per year	Average Consumption Per Year Prior to Audit	Average GJ Savings %
113	12	No	Down	52.5	52.5	2020	2.60%

We are assuming an average savings since audit of 2.6%. Despite a sample size of only one, we are confident in this rate of savings because it is roughly in keeping with the average savings from the last study of 2.8%. The following table shows what happens when we apply this rate evenly to the program participants from the study period that we did not interview.

Table 4: Application of Average Savings to non-respondent program participants (n=25)

Participant ID	Date of Audit	Average Annual Consumption (GJs)	GJs Consumed since audit	Raw GJs Saved Since Audit	Average Annual GJs Saved
1	Jul-07	2033.8	4305.0	111.9	48.0

123	Nov-08	2688.7	2929.4	76.2	76.2
124	Nov-08	2860.2	3414.2	88.8	88.8
125	Nov-08	7623.6	8810.8	229.1	229.1
127	Dec-08	3667.0	4346.7	113.0	123.3
134	Jan-09	4514.0	4165.1	108.3	130.0
137	Feb-09	9887.0	8721.3	226.8	302.3
146	Apr-09	3356.9	1811.0	47.1	80.7
147	May-09	4552.2	2625.8	68.3	136.5
150	Jun-09	2352.8	1048.8	27.3	65.4
151	Jun-09	13097.0	4591.9	119.4	286.5
152	Jun-09	3195.8	1588.6	41.3	99.1
153	Jun-09	7625.1	2932.6	76.2	183.0
157	Jul-09	2949.5	1182.1	30.7	92.2
	Totals	**110735.0**	**115848.4**	**3012.1**	**3163.3**
	Average	**4429.4**	**4633.9**	**120.5**	**126.5**
	Median	**3356.9**	**3709.4**	**96.4**	**99.1**

If we add these totals together, we see that the raw savings for this business type during the study period was 3,064.6 GJs. The difference in consumption between these customers is likely the result of the size of the complexes which can range from 60 units (with gas used only for hot water and hallway heating) to 161 units (with an inefficient system used for unit space heating and hot water heating).

CARE HOMES

The response rate for this business type was adequate. The target for this category was to speak to four (4) customers out of 11 (~36%) and Friuch was able to interview four (4). 50% of the respondent premises for this category made some or all of the recommended changes resulting in an average consumption reduction of 8.39%. Average reduction from the previous study is 4.39%.

Table 5: Data Collected from Care Homes (n=4)

Participant ID	Months since audit to Nov. 2009	Implemented Changes?	Consumption Up/Down?	Raw GJs Saved	Average GJs Saved per year	Average Consumption Per Year Prior to Audit	Average GJ Savings %
4	28	No	Up	0			
5	28	No	Up	0			
7	28	Yes	Up	0			
14	27	Yes	Down	2239.3	995.3	11861	8.39%

Table 5 reveals that despite a 50% implementation rate, only 25% of respondents experienced a positive outcome (reduced GJs). The one respondent did experience an average savings of 8.39% but since only one out of four respondents actually experienced a positive outcome, that reduction will be multiplied by the positive outcome rate to generate a reduction percentage specific to program participants who did not get interviewed: **(8.39% * 25%) = 2.1%.** The following table shows what happens when we apply this rate (2.1%) evenly to the program participants from the study period that we did not interview:

Table 6: Application of Average Savings to non-respondent program participants (n=8)

Participant ID	Date of Audit	Average Annual Consumption (GJs)	GJs Consumed since audit	Raw GJs Saved Since Audit	Average Annual GJs Saved
6	Jul-07	2234.7	5188.0	108.9	46.7
13	Aug-07	3960.0	9860.3	207.1	92.0
15	Aug-07	2581.0	8669.6	182.1	80.9
18	Aug-07	5922.9	15062.4	316.3	140.6
39	Nov-07	3594.0	6483.6	136.2	68.1
57	Jan-08	4409.9	13309.0	279.5	152.4
58	Jan-08	1707.1	4547.3	95.5	52.1
64	Apr-08	2082.5	3299.8	69.3	43.8
Totals		**26492.1**	**66420.0**	**1394.8**	**676.6**
Average		**3311.5**	**8302.5**	**174.4**	**84.6**
Median		**3087.5**	**7576.6**	**159.1**	**74.5**

If we add these totals together, we see that the raw savings for this business type during the study period was 3,634.1 GJs.

HOTELS/RESTAURANTS

The response rate for this business type was adequate. The target for this category was to speak to five (5) program participants out of 15 (~30%) and Friuch was able to interview six (6) program participants. 50% of the respondents for this category made some or all of the recommended changes resulting in an average consumption reduction of 1.36%. Average reduction from the previous study is 2.5%.

Table 7: Data Collected from Hotels/Restaurants (n=6)

Participant ID	Months since audit to Nov. 2009	Implemented Changes?	Consumption Up/Down?	Raw GJs Saved	Average GJs Saved per year	Average Consumption Per Year Prior to Audit	Average GJ Savings %
9	28	Yes	Down	204.9	87.81	5869	1.50%
10	27	No	Up	0			
19	26	Yes	Down	206.9	95.49	10463	0.91%
40	24	No	Up	0			
41	24	No	Up	0			
45	23	Yes	Down	208.55	108.81	6502	1.67%
			Totals	**620.4**	**292.1**	**22834.0**	
			Average	**206.8**	**97.4**	**7611.3**	
			Median	**206.9**	**95.5**	**6502.0**	

Table 7 (above)Table 5 shows what we would expect to see for most categories – a direct relationship between premises that implemented recommended changes and a corresponding positive outcome (reduced GJs). That reduction (1.36%) will be multiplied by the positive outcome rate to generate a reduction percentage specific to program participants who did not get interviewed: **(1.36% * 50%) = 0.68%.** The following table shows what happens when we apply this rate (0.68%) evenly to the program participants from the study period that we did not interview:

Table 8: Application of Average Savings to non-respondent program participants (n=9)

Participant ID	Date of Audit	Average Annual Consumption (GJs)	GJs Consumed since audit	Raw GJs Saved Since Audit	Average Annual GJs Saved
38	Nov-07	7131.4	15669.6	106.6	53.3
46	Dec-07	2756.8	5964.7	40.6	21.2

47	Dec-07	4742.1	10830.7	73.6	38.4
56	Dec-07	3866.5	7814.9	53.1	27.7
77	May-08	4321.9	6449.5	43.9	29.2
78	May-08	2073.9	3671.8	25.0	16.6
92	Aug-08	3142.0	6900.6	46.9	37.5
93	Aug-08	5172.0	7065.4	48.0	38.4
95	Sep-08	3816.1	4558.2	31.0	26.6
	Totals	**37022.7**	**68925.4**	**468.7**	**289.0**
	Average	**4113.6**	**7658.4**	**52.1**	**32.1**
	Median	**3866.5**	**6900.6**	**46.9**	**29.2**

If we add these totals together, we see that the raw savings for this business type during the study period was 1089.1 GJs.

LARGE PUBLIC FACILITIES

The response rate for this business type was good. The target for this category was to speak to 15 customers out of 47 (~30%) and the researchers were able to interview 18. 44% of the respondents for this category made some or all of the recommended changes resulting in an average consumption reduction of 3.98%. This average reduction is in sharp contrast to the reduction from the previous study - 12%.

Table 9: Data Collected from Large Public Facilities (n=18)

Participant ID	Months since audit to Nov. 2009	Implemented Changes?	Consumption Up/Down?	Raw GJs Saved	Average GJs Saved per year	Average Consumption Per Year Prior to Audit	Average GJ Savings %
11	27	Yes	Down	275.9	122.6	719.0	0.2

If we add these totals together, we see that the raw savings for this business type during the study period was 9901.1 GJs.

MANUFACTURING

The response rate for this business type was good. The target for this category was to speak to 11 customers out of 37 (~30%) and the researchers were able to interview 13.

Table 11: Data collected from manufacturing premises (n=13)

Participant ID	Months since audit to Nov. 2009	Implemented Changes?	Consumption Up/Down?	Raw GJs Saved	Average GJs Saved per year	Average Consumption Per Year Prior to Audit	Average GJ Savings %

			Median	**68.9**	**59.1**	**4073.0**	

Table 13 (above)Table 5 is a prime example of this often-seen phenomenon in this study – respondents who did not implement any of the recommended changes but still saw positive outcomes in the form of reduced gas consumption. Even without instances of implemented changes, we can base our analysis on the positive outcomes experienced by respondents. The 1.96% average reduction in consumption experienced by respondents that is attributable to the influence of the audit will be multiplied by the positive outcome rate to generate a reduction percentage specific to program participants who did not get interviewed: **(1.96% * 43%) = 0.84%**

The following table shows what happens when we apply this rate (0.84%) evenly to the program participants from the study period that we did not interview:

Table 14: Application of Average Savings to non-respondent program participants (n=9)

Friuch ID	Date of Audit	Average Consumption Per Year	GJ Cons since audit	Raw GJs Saved	Average Savings per year
3	Jul-07	2114.5	4664.1	39.2	16.8
71	May-08	3527.1	5837.6	49.0	32.7
72	May-08	1576.1	2038.9	17.1	11.4
76	May-08	24238.3	27607.0	231.9	154.6
86	Jul-08	377.2	976.9	8.2	6.2
88	Jul-08	4878.1	7080.7	59.5	44.6
89	Jul-08	2337.5	4415.8	37.1	27.8
90	Aug-08	2586.1	3081.6	25.9	20.7

143	Mar-09	10542.3	3575.7	30.0	45.1
	Totals	**52177.3**	**59278.3**	**497.9**	**359.8**
	Average	**5797.5**	**6586.5**	**55.3**	**40.0**
	Median	**2586.1**	**4415.8**	**37.1**	**27.8**

If we add these totals together, we see that the raw savings for this business type during the study period was 755.5 GJs.

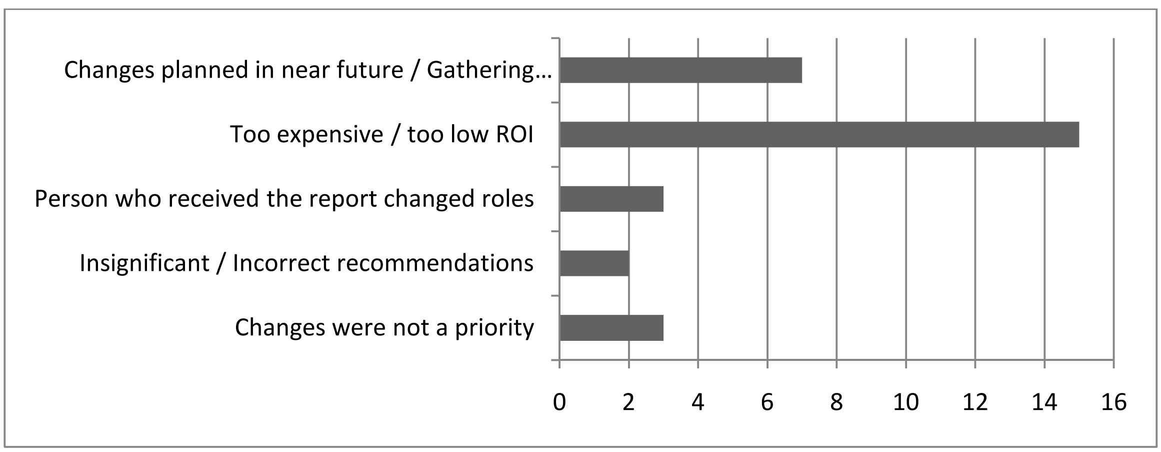
QUALITATIVE DATA

This section of the report reports on the coded findings derived from qualitative data collected during the interviews. The main source of this qualitative data is clarifying questions that were asked during the interviews.

Respondents who did not make changes listed a variety of reasons for why changes were not made: Fifteen (15) respondents found that the recommended changes were too expensive or had an ROI that was simply too low to take on the capital expense. Seven (7) respondents were in the process of making changes or gathering more information in preparation for a change in the near future.

In cases where audits were completed in the summer of 2009, the process of purchasing capital expenses like a new boiler may fall under a one year plan and may not yet have been implemented. In three (3) cases, despite a reasonable ROI, the recommended changes failed to be a priority for respondents due to more pressing issues. In one of these cases, the economic downturn had created enough uncertainty in the company such that all major expenses were frozen so as to keep the company as liquid as possible. In these cases, short term survival is more pressing then long term investment.

Figure 8: Respondents Who Did Not Make Recommended Changes, Reasons for Not Making Changes, by premises (N=30)



Many respondents who could not make substantial capital investments recommended in the energy assessment report did in fact make small improvements due to the audit process. For example, one post-secondary institution was not able to make any of the large changes recommended due to budget constraints, but following the assessment did end up making a significant effort to make small, less capital-intensive changes such as reviewing the schedules on their HVAC systems and adjusting their makeup air units.

In another example, a hotel could not justify the cost of a thermostat upgrade that was recommended but has been instead been manually turning down the roof heating system as a way to save money. Yet another example saw a manufacturing company that was not able to afford the upgrades recommended but did weather-strip all the doors and windows in their facility to save energy after the audit. From speaking with those who went through the process, it seems that even if the recommended changes couldn't be implemented, the audit process had a secondary benefit of stirring discussion on sustainability and the potential to save money by saving energy, heat and gas.

As mentioned earlier in the report, there is a precedent to assume that the introduction of a "conservation culture" during the assessment process will cause some participants to reduce their consumption by a noticeable amount. The abstract of the Darby (2001)[7] paper reads:

> The paper reviews the literature on the effectiveness of three types of feedback to domestic consumers: direct feedback in the home, indirect feedback via billing and 'inadvertent' feedback (a by-product of technical, household or social changes). The lessons learned on the importance of clear, immediate and user-specific information are then applied in a survey of the opportunities for better feedback to consumers in terms of technology, design and location of meters and display panels, energy billing **and services such as audits and advice programmes**.
>
> The paper concludes that feedback has a significant role to play in raising energy awareness and in bringing about reduced consumption of the order of 10%; and that opportunities exist for designing it into energy-related systems which have yet to be realised.

This should account for circumstances where a participant claims to have not implemented any of the recommended changes but manages to reduce their natural gas consumption by a significant amount.

Those respondents who did make changes were generally very satisfied with their results. Out of the 19 respondent premises that made significant changes, 16 said that they were very happy with the changes that they had made. The remaining three (3) firms said that they were not yet sure if they were happy because they were still waiting on more information as to the extent of their energy savings. As some of these implementations were still quite recent (less than six months), some of the respondents had yet to see full results from their investments.

Table 2 shows the frequency that respondents made recommended changes at their premises by specific changes recommended. These recommendations have been coded for simpler analysis as follows:

1. **Major Upgrade**. This refers to a major capital investment to upgrade or retrofit a piece of HVAC hardware or process heating system. For example: "replace aging boilers with staged, wall-mounted boilers" or "replace direct-fired drying oven furnace with redirected waste heat from main process heat boiler".
2. **Minor Tweaks**. This refers to minor adjustments to existing equipment. For example: "calibrate thermostats" or "reset timer on makeup air unit so that when it comes one, it only runs for 15 minutes instead of 30".
3. **No Recommendations**. This is when an assessment comes to the conclusion that there are no possible improvements to recommend.
4. Replace Boiler with Higher Efficiency Boiler when Fails. These are recommendations made about existing boilers that are, while inefficient, relatively new and in good working order. It's meant to say that when the boiler does fail (even if it is in 20 years); there is an incentive to upgrade to a higher efficiency boiler with a shorter ROI payback than replacing a working boiler with a new one.

Despite the apparent impact of the economic downturn, this study saw more participants making major upgrades to their HVAC and process heating equipment than the 2005-2007 program review. Obviously, when no changes are recommended, there is no opportunity to change.

Table 15: Frequency of Recommended Change Implementation, by (Coded) Type of Change Recommended (N=49)

Recommended Change	# of respondent premises where	# of respondent premises where	Percentage

Minor Tweaks	13	4	31%
No Recommendations	3	0	0%
Replace Boiler with highE Boiler when fails	15	3	20%
Total	**49**	**15**	

BARRIERS TO IMPLEMENTING RECOMMENDED CHANGES

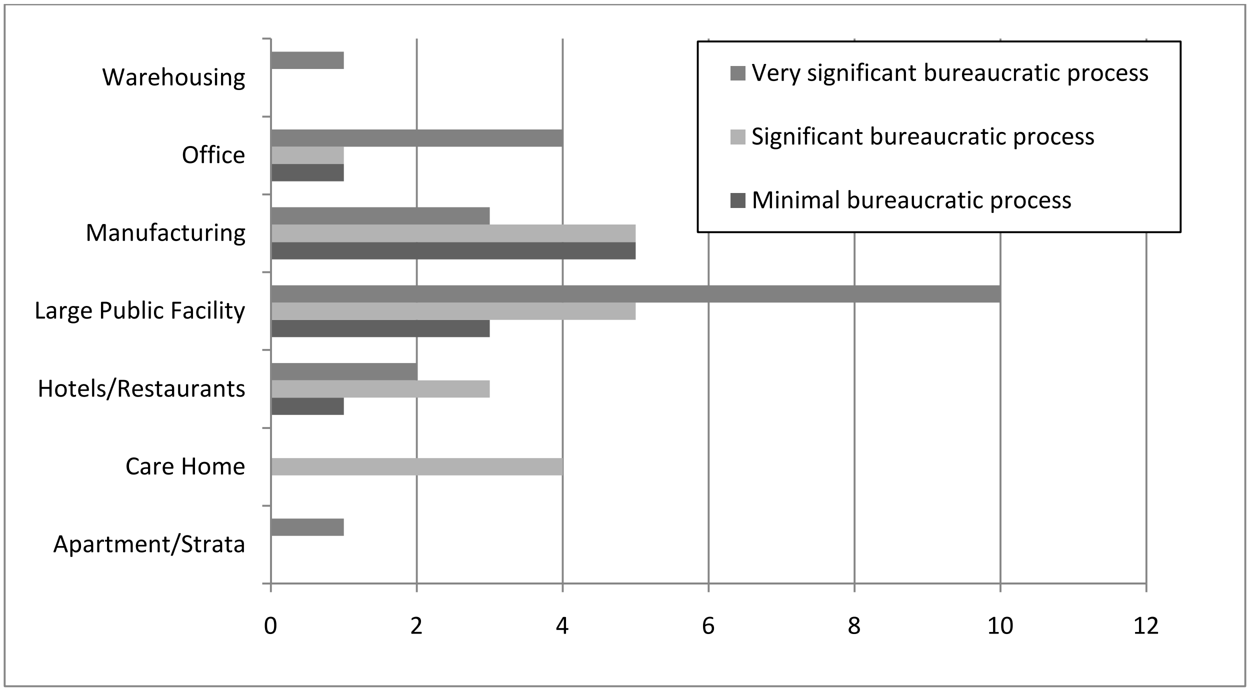
In most cases, managers who participated in the Terasen assessments had no direct authority over capital expenditures. In order to implement the recommended changes company owners, senior managers or (in the case of public facilities) government offices must be petitioned by a strong organizational champion who can articulate why and how the changes should be implemented. There are two main barriers to this process:

- **The ability of the organizational champion to promote this cause, and**
- **The level of bureaucracy to implement a capital purchase**

Organizations who put forward respondents in a significant position of authority and who had the time to champion the cause of implementing the audit recommendations were met with higher levels of success. For example, a post-secondary education institution had a specific groundskeeper who was focused on sustainability and conservation that championed all activities designed to save gas, energy and money around campus. This individual contributed to the success of this participants energy conservation measures by applying for government funding for the recommended changes. Other post-secondary institutions lacked a strong internal advocate in this kind of a position and found they were unable to access the same funding.

In terms of organizational bureaucracy, (as assessed by responses to an interview question which asked participants to describe the process through which their organization must go through to get an upgrade like the one recommended to them implemented) those organizations that have a less bureaucratic process for making capital purchases will have a higher chance of the audit recommendations being implemented. As can be seen in Figure 9 below, the manufacturing industry has a consistently lower bureaucratic decision-making structure, and as can be seen in **Error! Reference source not found.** above, when broken down by business type, "manufacturing" had the highest level of implementation.

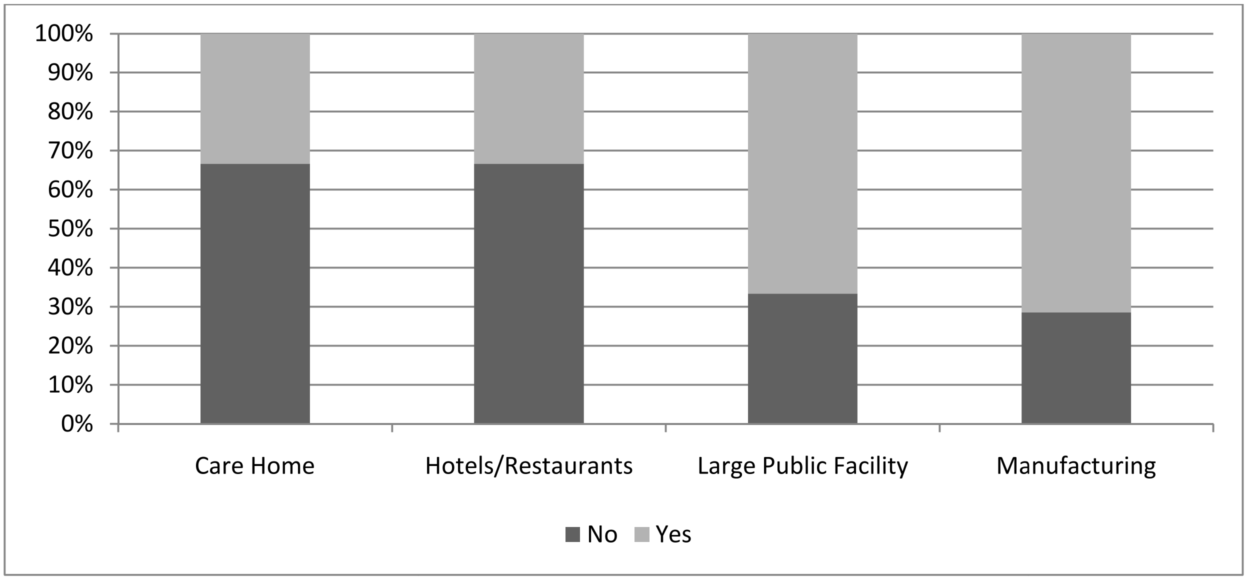
Figure 9: All Respondents, Degree of Bureaucracy in Making Capital Expenditures; By Industry (N=49)



58% of respondents who had made changes also tracked their energy savings after changes were made. Manufacturing industries and large public facility were most proportionately concerned with tracking their savings after changes were implemented, which suggests that in these industries ROI was more frequently a significant factor in making changes than in other industries. In businesses where the customer uses more GJs of gas per month than others, small efficiencies gained on the shop floor can dramatically affect the marginal cost of the product being produced.

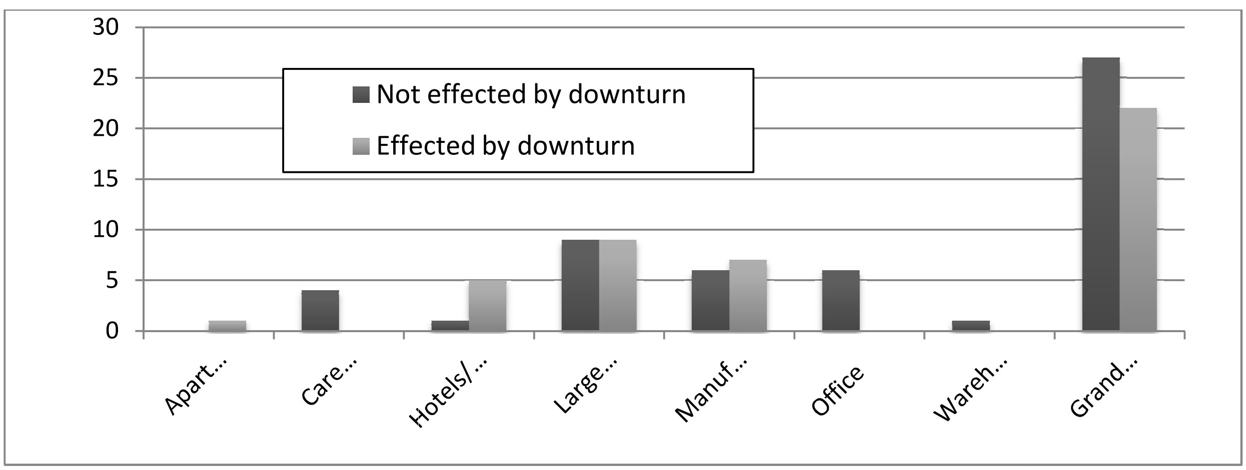
As such, manufacturing companies and any customers that use closer to $100,000 worth of gas per month have the most to gain from these kinds of programs because the ROI on any changes would be much shorter than it would be for care homes and apartments. In the case of a care home or a hotel, changes are likely made on the basis of a proposal that lists a very short ROI (less than three years) or based on need if a boiler breaks down and a new one needs to be installed. These energy savings are incidental to the core business at hand and so therefore for many managers, the task of monitoring gas usage reductions will not be a high priority.

Figure 10: Premises That Made Changes, Frequency of Tracking Energy Savings After Changes Were Made; By Industry (N= 19)



One of the questions in the interview asked if respondents' premises had been affected by the economic downturn. Their responses (see Figure 11) show that Large Public Facilities and Manufacturing customers were nearly evenly divided in their responses. Hotels/Restaurants were deeply impacted by the economy while Offices and Care Homes were largely unaffected.

Figure 11: Respondent Premises, Affected by Economic Downturn or Not (N=49)



The researchers tried to correlate the impact of the economic downturn to respondents' answers about production and operations fluctuations but there was none to be found. For example, some manufacturing companies who claimed to be negatively impacted by the economic downturn saw major production increases – a counterintuitive result.

FREE RIDERS

One measure of the cost effectiveness of a program is a "free rider" analysis looking at program participants who accepted the audit service from Terasen at no cost to them when they would willingly pay for the service if it were not free.

For the purposes of this study, energy savings can be calculated from billing analysis alone. In the case of the Commercial Energy Assessment Program, accurate free rider analysis is clouded by Terasen's business practice of offering free audits partly as a customer satisfaction tool. It is likely that the majority of customers in this study likely participated in the program because Terasen Gas and its sub-contractors encouraged customers to participate in the program.

The option to pay for the audits was not made available to customers. For these reasons, it is the belief of Friuch Consulting that any conclusions drawn from this free rider analysis are notional at best.

Table 16 shows the percentage of "free riders" in each business category. This number is derived by dividing the number of study respondents who conducted other assessments on their business that were not subsidized at all by the number of study participants in a specific business type contacted for this research. See question 15 in Appendix A.

For example, a customer who participated in the Commercial Energy Program might have also conducted a self-funded lean manufacturing assessment to reduce operating costs or increase operating efficiencies. In either case, the customer shows a willingness to invest resources in efficiency and productivity increases. That percentage of free riders is extrapolated into a total number of free riders by business type in the last column by multiplying the number of program participants (N=158) by the percentage of free riders for that category.

Table 16: Free Ridership, by Type of Business (n=158)

Type of Business	# of Program Participants	% free riders	# Free riders (mid-2005 to June 2007, est.)
Care Homes	11	0%	0
Manufacturers	27	62%	17
Apartments/Strata Properties	*26*	*100%*[8]	*26*
Hotels/Restaurants	15	66%	10
Large Public Facility	58	38%	22
Offices	16	43%	7
Warehousing	5	0%	0
Totals	**158**	**35%**[9]	**56**[10]

Table 16 shows that Manufacturing companies and Hotels/Restaurants, as sub-groups of Terasen's Commercial Energy Assessment Program participants, have the highest incidence of free riders. Overall, it appears that roughly 35% program participants are free riders in that these 56 program participants (out of 158) would have paid for the assessment if it was not free.

OVERALL EFFECTIVENESS OF THE PROGRAM

[8] This number should not be considered reliable because of the sample size of one (1) interviewee.
[9] Excluding Apartments/Stratas
[10] Excluding Apartments/Stratas

The best measure of overall effectiveness for this program is whether or not the program convinced customers to reduce their consumption.

It is clear from previous sections in this report that a significant number of program participants did reduce their natural gas consumption as a direct result of this program. The findings show that 68% of program participants who implemented the recommended changes saw a distinct decrease in their natural gas consumption not attributable to other factors. However, 32% of program participants who implemented changes saw their consumption rise, instead of fall, even after factoring in reduced demand due to production decreases or operations changes.

When we also look at respondent premises where recommended changes were not implemented (29 premises), we see that 44% of these non-compliant program participants managed to decrease their consumption. From this perspective, **the program could be considered effective in getting certain types of customers to reduce their consumption** – the details of which will be outlined in the Analysis section of this report.

As mentioned in the Executive Summary, only 43% of respondent premises actually implemented any of the gas saving measures recommended by the energy assessment report. This is an increase from the 2005-2007 program review where only 35% of respondents implemented the recommended changes.

As you can see from Table 17, the program overall is performing well but the entire weight of that performance is being carried by one category of customers – manufacturing companies. Without this category's participation in the program, the program could not be considered a success.

Table 17: Summary of Energy Savings

	Program Participant Premises	**Total GJs Saved**	**Average Savings Per Premises**	**%Premises that made recommended changes**	**% Premises that made recommended changes but did not see a decrease in consumption**	**% of Premises that did not make recommended changes but saw a decrease in consumption**
Apartments/Stratas	26	3,064.6	2.60%			
Care Homes	12	3,634.1	2.10%	50%	25%	0%
Hotels /Restaurants	15	1,089.1	0.68%	50%	0%	0%
Large Public Facilities	47	9,901.1	2.19%	44%	22%	33%
Manufacturing	**36**	**231,303.9**	**5%**	**54%**	**8%**	**23%**
Offices	16	755.5	0.84%	0%	0%	43%
Total	**152**[11]	**249,748.3**	**2.63%**	**43%**	**13%**	**24%**

Overall, the Commercial Energy Assessment Program was successful with the participation of Manufacturing companies. Taken alone, the manufacturing customers that participated in this program carried the weight of the program. If they were not involved, the program would not have been able to make any claims of success.

ANALYSIS

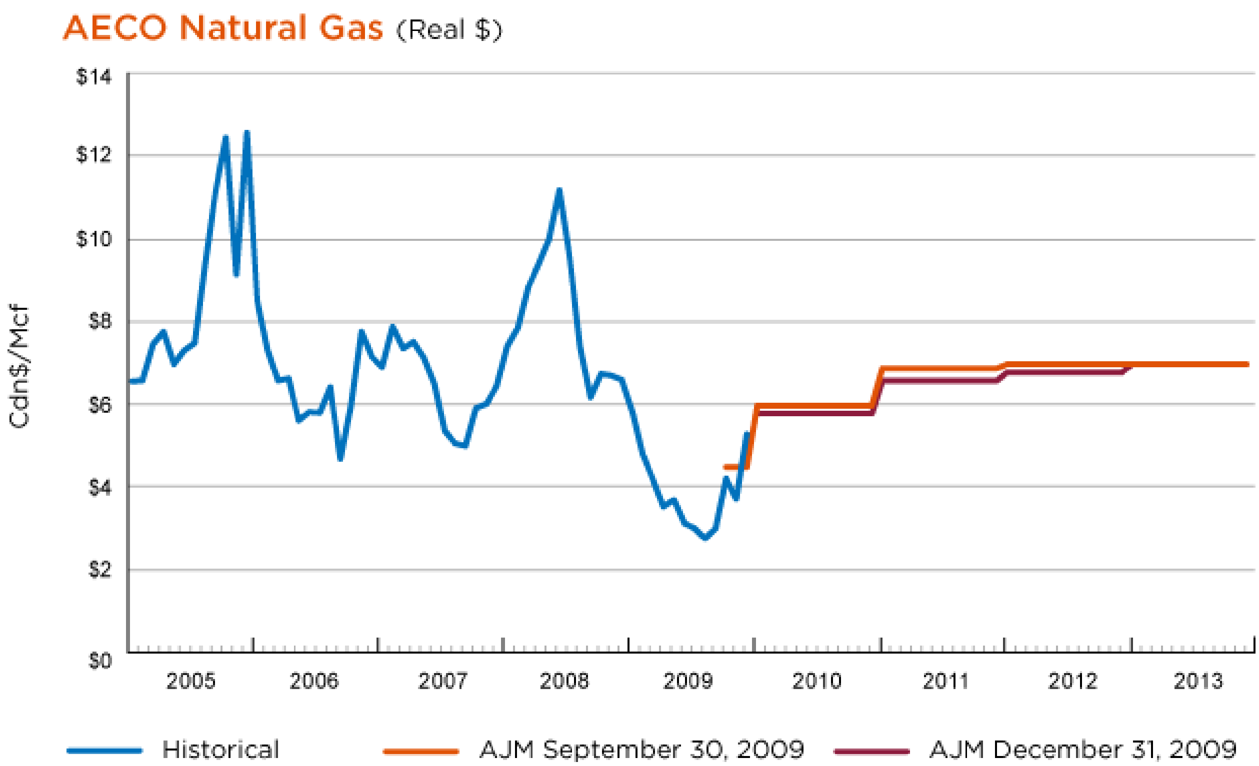
[11] Npte: This total excludes "warehousing" and "other" respondents. There was insufficient data to analyze these business types.

This section of the report goes into more depth where there are interesting or puzzling findings. Analysis is done in the context of Terasen Gas' operational realities – the Commercial Energy Assessment Program needs to achieve the outcomes it is designed to achieve.

OTHER FACTORS CONTRIBUTING TO CONSUMPTION DECREASES

Figure 12 (below) shows the historical market price of natural gas (per thousand cubic feet – roughly 1 GJ) between January, 2005 and December, 2009 with estimations on prices out to 2013. Notice that the market price of gas drops in conjunction with general Canadian commodity prices during the same time period (see Figure 13 – next page).

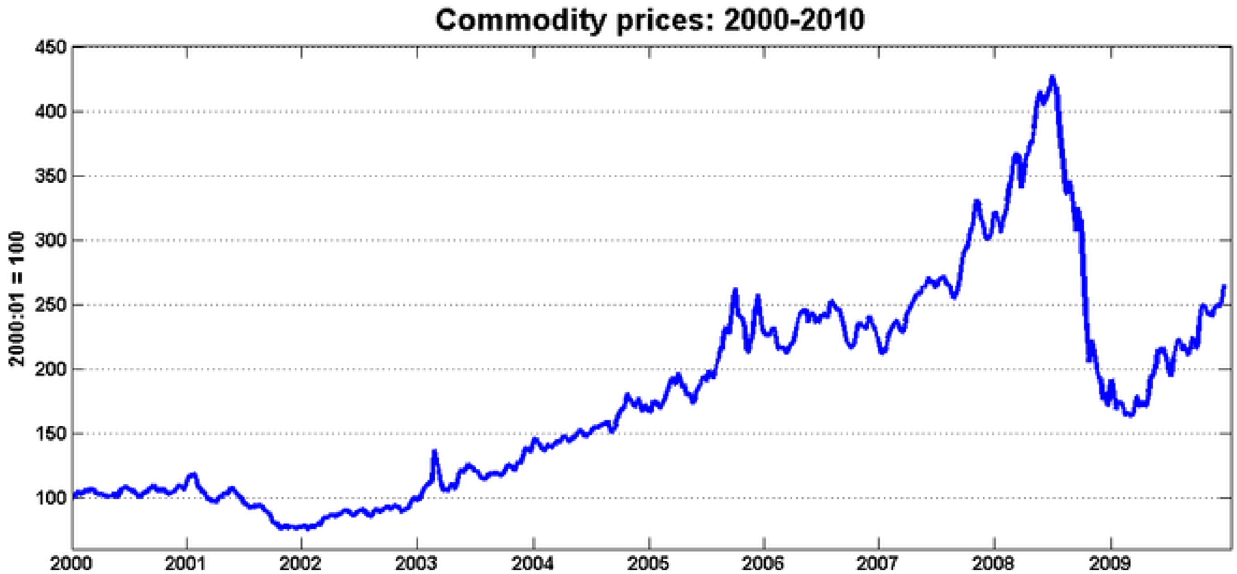
Figure 12: Market Price for Natural Gas ($CAD), 2005 – 2013 (estimated)[12]



In practical terms, this means that for the second half of this study period, the declining price of natural gas would not have motivated program participants to reduce their consumption. For this reason, this paper concludes that the price of gas was not a contributing factor to the findings.

[12] Source: AJM Petroleum Consultants

Figure 13: Canadian Commodity Prices[13]



45% of program participants who did not implement gas-saving measures suggested by Terasen Gas consultants still reduced their consumption after their audit. This number is calculated after factoring in staffing changes, changes in hours of operation or production increases and decreases at the customers' location post-assessment. As mentioned earlier, we attribute this change to the introduction of a "conservation culture" to the program participants (Darby, 2001) and expect to see a 10% average reduction in consumption as a result. The actual reduction seen in this study due to "conservation culture" was a modest 1.4%.

The economy certainly has a role to play in customers' price sensitivity regarding natural gas but as was mentioned in a previous section, this study saw almost equal numbers of companies who claimed to be negatively impacted by the economy see their production go up and down.

In conclusion, it appears that all of these external factors appear to have no bearing on the consumption behavior of program participants. Economic incentives and heating degree days appear to be the dominant drivers of reduced consumption.

THE DECISION TO IMPLEMENT RECOMMENDED CHANGES OR NOT

The decision to implement recommended changes is more complex during this study period than it was during the 2005-2007 program review. The economic downturn of 2008 and 2009 forced many businesses to make drastic changes to their operations to stay in business. This includes putting off capital infrastructure investments for years when the finances of these customers are in better shape.

Some companies chose this time period to do upgrades – possibly to leverage tax write-offs that could reduce their overall tax burdens.

At a high level, it is most likely that the decision to implement or not is based on how the expected return on investment timescale for the recommended changes. For example, three of the four companies that saw the largest

[13] Source: Bank of Canada

reduction in gas consumption are customers that use between $68,000 and $3.3 million worth of natural gas per year (compared to the study period median of $28,000 worth of gas per year).

The higher the annual gas consumption of a program participant, the quicker they will realize positive ROI for their capital upgrades – making them more likely to make the recommended changes than those companies with relatively low annual gas consumption.

In the case of most manufacturing companies where the owner of the company is also the major shareholder, it is easier to justify large capital expenditures as long as the net present value (NPV[14]) is high over the short-term for the company. The levels of approvals that a new equipment requisition must go through at most manufacturing companies are much fewer than they are for a Large Public Facility.

In conclusion, it seems clear that manufacturing companies consuming closer to $100,000 worth of gas per year have the motivation and the ability to make the changes recommended by Terasen Gas through the Commercial Energy Assessment Program more easily than other types of businesses.

ENERGY SAVINGS

Unlike the 2005-2007 program review, researchers for this study had access to much better quality data. Historical billing records from Terasen were accurate, complete and paired with regional HDD statistics matched to the billing period. Researchers also had the results of the previous study for comparison as well as the additional justification for bringing in GJs saved when no recommended changes were made (Darby, 2001).

While still not statistically valid, the findings are defendable and in keeping with Terasen's own methodologies for calculating energy savings. In conclusion, it is clear that the program led to gas savings for customers who participated in the program.

OVERALL EFFECTIVENESS OF THE PROGRAM

Clearly, this program was most effective amongst manufacturing companies. These respondents were responsible for 92% of the total GJs reduced in this study while representing only 23% of the total program participant premises.. In conclusion, these findings clearly indicate that the program was most effective amongst manufacturing clients

[14] Net present value is the standard method for using the time value of money to appraise long-term projects. Used for capital budgeting, and widely throughout economics, it measures the excess or shortfall of cash flows, in present value terms, once financing charges are met.

CONCLUSIONS

The conclusions of this study are straightforward:

- 43% of program participants made some or all of the recommended changes.
- It is estimated that nearly 250,000 GJs of natural gas was saved as a direct result of Energy Assessments conducted during the study period
- Manufacturing companies outperformed every other business type in terms of making recommended changes and seeing a substantial decrease in consumption.
- 45% of respondents who did not make recommended changes also saw a decrease in their consumption after the audit.
- The study has determined that roughly approximately 35% of program participants are "free riders" – defined as customers who would have paid for a Commercial Energy Assessment if it was not free.

This leads to the overall conclusion that the program has been a success to date but that it needs to focus on customer segments with the best reduction outcomes. The next section contains recommendations for changes to the program.

RECOMMENDATIONS

It is clear from the findings that the manufacturing industry has the highest potential to generate positive outcomes for the Commercial Energy Assessment program. The manufacturing industry has lower levels of bureaucracy that facilitate quick decisions on capital expenditures that make a large impact. Ensuring that recommendations result in short ROI for program participants is key when marketing this program and reporting on its effectiveness.

The conclusions from this study indicate that since a diversified portfolio of demand-side management programs available to commercial and light industrial customers is not a realistic policy option, the minimum requirements for participating in the program need to be reviewed.

Our recommendation is to move the minimum consumption rate to qualify for participation in the program to $75,000 per year in gas or more. For example, if this program had excluded customers with less consumption from the current study set (mid-2007 to mid-2009):

- **The average GJs of gas consumption reduced per month per program participant would grow from 142 to 711**
- **52% of Manufacturing companies in the study period would still be eligible**

This is not to suggest that companies with less than $75,000 in natural gas consumption per year would no longer receive assessments under any circumstances – just that they would need to be pre-qualified before participating to ensure that they are the type of customers that is more likely to invest in infrastructure upgrades to reduce gas consumption.

The recommended improvements to the Commercial Energy Assessment Program are as follows:

1. **Move the minimum amount of gas purchased to participate in the program to $75,000 per year.**
2. **For customers spending less than $75,000 per year on gas, develop public workshops that teach basic consumption reduction techniques.**

The following page details two specific DSM Program delivery vehicles that Terasen could consider developing to improve the overall effectiveness of the program. The expected outcomes of implementing these recommendations are:

1. **Vastly improved cost-effectiveness of program**
2. **Bigger reach into the customer base with less effort**

RAISE THE MINIMUM REQUIREMENTS FOR PROGRAM PARTICIPATION

The findings of this study show that the Commercial Energy Assessment program (as delivered between mid-2007 and mid-2009) was most effective amongst customers in the manufacturing (light industrial) sector. These clients tend to spend much more than the median gas spend and will experience significant position ROI in a short span of time.

In most cases, the companies with the most flexibility to reduce their consumption are those with larger utility bills in the first place. While Terasen cannot exclude participants from the program, raising the program requirements may reduce the amount of companies that report a negative outcomes after their assessment.

SECTOR-SPECIFIC WORKSHOPS

Once the Commercial Energy Assessment program admission requirements are adjusted, a new program for those customers who are least likely to implement recommended changes from the Commercial Energy Assessment can be built. Public workshops might be the best solution. These workshops would target specific customer groups such as apartment building managers, care home operations managers and property managers.

The cost of one workshop would exceed the cost of a single audit but could reach dozens of customers in that sector. For the same expenditure, a public workshop campaign could expand the reach of the Demand Side Management program. The 2005-2007 program review saw support for this recommendation amongst the study respondents – 81% of respondents said that they would be interested in “educational seminars to learn more ways to reduce gas consumption”.

The content of these workshops should focus on informing customers what a normal gas consumption profile looks like, the many reasons why a customer’s gas consumption might be above average and a number of pointers on how to reduce consumption. Customers that are very keen to do everything they can to reduce their consumption could apply for a Commercial Energy Assessment of their own. For most customers, this would not be necessary.

APPENDIX A: INTERVIEW SCRIPT

Terasen Gas Commercial Energy Assessment Interview Script

Friuch ID (number from first column of calling list)		Interviewee Name	
Interviewer (Sean or Aaron)		Company Name	
Date		Phone Number	

"We are calling on behalf of Terasen Gas. We wanted to follow up on the audit that was conducted on Date. Terasen is interested in helping their customers to reduce gas consumption and your feedback will help us to determine the effectiveness of our Commercial Energy Assessment program."

1. What was your opinion of the audit that was done on <insert date on file for their Energy Assessment>?

2. Did you receive a copy of your Energy Assessment after it was completed?

3. Are you still in the same building as you were when the energy assessment was conducted? **(If no, full stop interview and track those who have moved but do not count them towards the final count)**

4. Did your company implement any of the changes recommended in the audit?

    a. If yes, which changes were implemented and when?

    b. If no, why did your company decide not to make any of the recommended changes?

5. <if changes were implemented> Did you do an analysis of your energy savings after you implemented recommended changes?

    a. If yes, were the results what you expected?

    b. If no, did you notice an overall decrease in your Terasen Gas bill?

6. <if changes were implemented> Are you satisfied thus far with the changes made?

    a. If not, why?

7. Can you describe the process your organization must go through before making a major capital equipment purchase? i.e. if there is a need to upgrade to a new boiler, what is the process?

    a. How many people are involved in this decision-making process?

8. Was there any follow-up from Terasen Gas staff following your Energy Assessment?

    a. If no, would you like someone from Terasen Gas to follow up with you?

9. What does your company use natural gas for?

    a. Space heating?

    b. Vehicle Fuel?

    c. Water heating?

    d. Electricity co-generation?

    e. Process Heating?

    f. Other?

10. Did your company's production increase/decrease after your energy assessment? E.g. Did you ramp up production? Did you expand your operation? By what percentage? What date did these changes take place?

11. Was your organization/company impacted by the economic downturn of the past few years? i.e. Were work hours at your company reduced? By what percentage? What date did these changes take place?

12. Did your company change owners since the energy assessment?

13. Have you done any major equipment upgrades since the energy assessment?

14. Did you make any structural changes to your facility since the energy assessment?

    a. Have you increased the floor space (for example) of your company since the energy assessment was conducted?

15. During the past five years, has your company conducted any assessments of other areas of the business with an eye to find ways to save money and/or increase return on investment? E.g. Waste reduction programs, electricity audits, lean production analysis?

    a. If yes, were these studies internally funded or did your company leverage government programs?

16. Thinking about how much a commercial energy assessment like the one Terasen conducted for your company should cost if you had to pay for it, please answer the following questions:

    a. At what price would a commercial energy assessment be so expensive that you would not consider doing it? (too expensive)

b. At what price would a commercial energy assessment be so low that you would feel like the quality of audit is questionable? (too cheap)

c. At what price would a commercial energy assessment start to look expensive but not out of the question, but you would have to think hard before scheduling the audit? (expensive/high side)

d. At what price would a commercial energy assessment be a bargain – a great buy for the money? (cheap/good value)

17. If Terasen Gas no longer provided free Commercial Energy Assessments to businesses like yours, would you pay a third party (such as a heating/ventilation/air conditioning engineering consultant) to do these audits for you if you had to pay its full value of $1,500?

    a. Yes

    b. No, if not why not?

18. How many employees does your company have at the moment?

    a. Has the number increased or decreased since the Energy Assessment?

    b. Have you changed your hours of operation since the Energy Assessment?

Finally, we'd like to let you know that Terasen is launching a new program aimed at high efficiency commercial hot water heaters.
