December 14, 2017

British Columbia Utilities Commission
Suite 410, 900 Howe Street
Vancouver, BC
V6Z 2N3

Attention: Mr. Patrick Wruck, Commission Secretary and Manager, Regulatory Support

Dear Mr. Wruck:

Re: FortisBC Energy Inc. (FEI)

2017 Long Term Gas Resource Plan

On December 3, 2014, the British Columbia Utilities Commission (the Commission) issued Order No. G-189-14 accepting the FEI[1] 2014 Long Term Resource Plan. By Order G-99-17, the Commission approved FEI's request to extend the submission deadline for its next Long Term Gas Resource Plan to November 30, 2017.

In accordance with the Commission's Resource Planning Guidelines and Section 44.1(2) of the *Utilities Commission Act* (UCA), FEI respectfully submits the attached 2017 Long Term Gas Resource Plan (LTGRP) for the Commission's review.

There are no approvals being sought by FEI as part of this LTGRP submission. The LTGRP presents a 20-year view of the demand- and supply-side resources identified to meet expected and future natural gas demand and reliability requirements at the lowest reasonable cost to FEI's customers. The LTGRP includes an action plan that identifies the activities that FEI intends to take during the first four years of the 20-year planning horizon. FEI will file separate applications for Certificates of Public Convenience and Necessity, if and as necessary, for any of the identified activities in accordance with the Commission's guidelines.

[1] The FortisBC Energy Utilities (comprised of FortisBC Energy Inc., FortisBC Energy (Vancouver Island) Inc. and FortisBC Energy (Whistler) Inc.) were amalgamated into FortisBC Energy Inc. as of January 1, 2015 per Commission Order G-21-14 approving FortisBC Energy Utilities' Common Rate, Amalgamation and Rate Design Application.

FEI seeks acceptance of this LTGRP in accordance with Section 44.1(2) of the UCA. A discussion of how the LTGRP addresses the requirements of the UCA is included in various sections throughout.

If further information is required, please contact Ken Ross at (604) 576-7343 or ken.ross@fortisbc.com.

Sincerely,

FORTISBC ENERGY INC.

FortisBC 2017 Long Term Gas Resource Plan

Table of Contents

List of Appendices

Index of Tables and Figures

EXECUTIVE SUMMARY

1. Introduction

This 2017 Long Term Gas Resource Plan (LTGRP) is FortisBC Energy Inc.'s (FEI, the Company or the Utility) long-term resource plan as required by the *Utilities Commission Act* (*UCA*). The 2017 LTGRP presents a long term view of the demand- and supply-side resources[1] identified to meet expected future natural gas demand and reliability requirements at the lowest reasonable cost to FEI's customers over the 20-year planning horizon (2017-2036). Table ES-1 provides a summary of FEI customer, demand and pipeline characteristics.

Table ES-1: FEI Service Statistics

	2015	2016
Number of Customers	979,000	994,000
Annual Demand (TJ)	186,000	197,000
Peak Day Demand (TJ/d)	1,074	1,334
Length of Transmission Pipeline (km)	2,958	2,959
Length of Distribution Pipeline* (km)	45,242	45,741

** Includes both low and intermediate pressure pipelines*

The resource planning process begins by closely examining the planning environment in which the Company operates and by identifying expectations for future customer and demand growth. The demand- and supply-side resource alternatives for meeting future demand are then assessed, and actions recommended to ensure that the proper resources are in place to deliver the preferred energy solutions to meet future customer needs. Finally, a four-year action plan, which identifies the near term activities needed to meet the long term resource requirements identified in the LTGRP is prepared. FEI's LTGRP objectives are to: ensure cost effective, secure and reliable energy for customers; provide cost effective Demand Side Management (DSM) initiatives; and ensure consistency with provincial energy objectives.

FEI submits this 2017 LTGRP under Section 44.1(2) of the UCA and is **not seeking approval of any particular elements of the plan**. Any requests for approval of specific resource needs that are identified within this plan will be further evaluated and brought forward through a separate application to the British Columbia (BC) Utilities Commission (the Commission or BCUC) if warranted in the future.

[1] The British Columbia Utilities Commission Resource Planning Guidelines define resources as indivisible investments or actions by the utility to modify energy and/or capacity supply, or modify (decrease, shift, increase) energy and/or capacity demand. Within the context of FEI, such resources typically refer to FEI's own infrastructure (pipelines, natural gas compression equipment, natural gas storage equipment), natural gas supply arrangements, and demand side management initiatives.

2. Planning Environment

A wide range of factors influence FEI's long term analysis and planning decisions. FEI is submitting this 2017 LTGRP during a time of continued change and uncertainty in market forces, energy technology and government policy.

Price: The North American natural gas market remains in a low commodity pricing environment which is expected to continue for several years to come. These low commodity prices have created opportunities for increased natural gas use, particularly in power generation, liquefied natural gas (LNG) export potential, and the use of natural gas by the transportation and industrial sectors.

Supply: Improvements have been made to two essential technologies, horizontal drilling and hydraulic fracturing[2], that are used to unlock natural gas trapped in shale formations. These technological achievements have resulted in major production cost reductions, allowing producers to continue to drill despite the lower natural gas price environment. Market analysts believe a rig operating in 2016 delivers over two times as much gas as a rig operating in 2013. Not only is gas supply abundant, shale gas supplies are located throughout North America, providing cost effective supply within close proximity to many major load centres. However, due to increasing industrial demand for natural gas in the Pacific Northwest (PNW), upstream infrastructure on which FEI relies to get natural gas onto its distribution system is becoming fully contracted.

Demand: Over the past several years in North America, growth in industrial demand, specifically from the petrochemical sectors and United States (US) gas exports to Mexico, has been increasing demand for natural gas. The market is also seeing increased natural gas demand from the power sector due to more switching from coal to natural gas electricity production, as well as from the retirement of coal plants. Furthermore, new incremental demand from US LNG being exported overseas will continue to increase in the coming years.

Competition: Low commodity costs have improved the price competitiveness of using natural gas over electricity on an operating cost basis, though natural gas direct use applications (such as space and water heating) typically require higher capital, installation and maintenance costs than electric appliances. A multitude of factors beyond those relating to commodity cost influence consumer, builder and developer preferences relating to the use of natural gas versus other sources of energy. Capital costs, installation requirements, operating and maintenance costs, government policies and public perception all play a role in this regard.

Policy: The energy and emissions policy environment throughout North America and in BC remains uncertain and changing. In the US, federal policies are shifting away from carbon regulation under the current administration, while many states, including those on the west coast are continuing to strengthen carbon emission policies and initiatives. The Canadian government has set Greenhouse Gas (GHG) emissions targets and introduced a number of emissions reduction initiatives, including a carbon tax to be implemented where provinces fail to

[2] Appendix D-1: https://www.eia.gov/todayinenergy/detail.php?id=2170.

do so. Yet there is continued federal support for natural gas production, exporting and domestic use where doing so displaces higher emitting fossil fuels. A new BC government is likely to make amendments to existing energy and emissions policies and may be weighing many factors including the challenge of reducing GHG emissions against cost and employment issues. Finally, municipalities across the Province are considering initiatives like enacting the voluntary step codes put forth by the Province to increase efficiency requirements for new residential and commercial buildings.

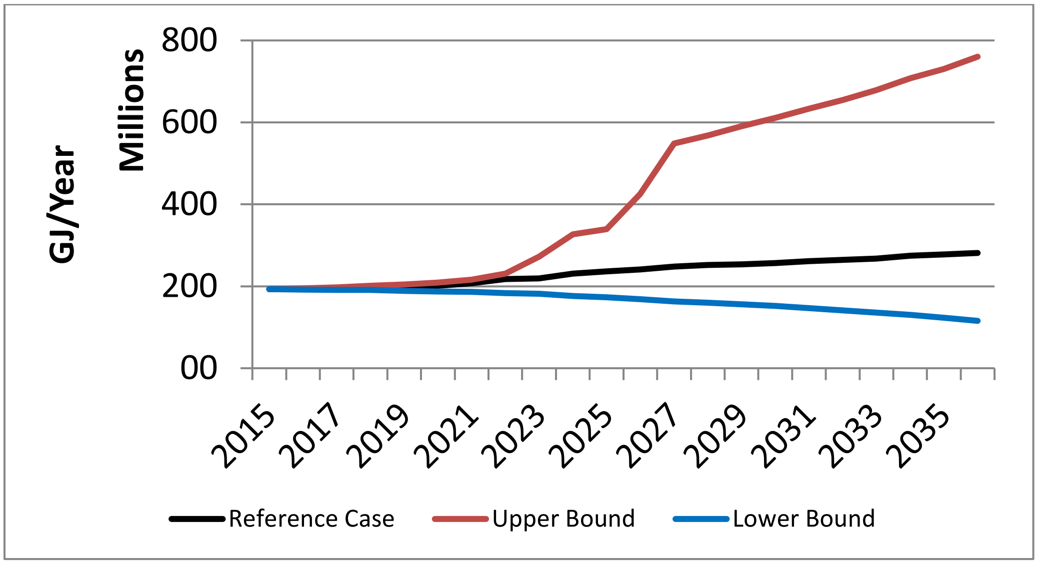
Customer Solutions: FEI believes that developing innovative and integrated customer solutions is an important part of positioning natural gas services competitively within BC's energy marketplace for the benefit of all customers. Using the right fuel effectively for the right end use and developing customer-driven energy services remain a key focus of FEI's customer solutions activities. Natural Gas for Transportation (NGT), Renewable Natural Gas (RNG) and Conservation and Energy Management (C&EM) are initiatives that FEI is currently undertaking toward this goal while helping to meet provincial goals for emissions reductions. FEI is also working with other entities to examine the potential for new technologies to reduce carbon emissions from the natural gas stream in order to help to meet provincial emission targets while maintaining throughput on the natural gas system and allowing customers to continue taking advantage of lower cost natural gas.

3. Annual Energy Demand Forecasting

Two key elements that underpin FEI's resource planning activities are the forecasts of annual demand and peak demand for natural gas. The annual demand forecast represents annual consumption by Rate Schedule and allows the Company to determine directional rate impacts and annual gas supply needs in the Company's long term planning efforts. The peak demand forecast provides an estimate of the maximum daily natural gas demand that expected under extreme weather conditions. The annual demand forecast is presented in Section 3 and discussed in Section 5 as it relates to securing gas supply. System-wide peak demand and its implications for securing supply resources to meet peak demand is discussed in the gas supply planning section, while regional peak demand forecasts are presented in Section 6 (System Resource Needs and Alternatives) where FEI's own infrastructure requirements for meeting regional peak demand are discussed.

FEI recognizes that its customers are using natural gas in different ways and amounts than they did in the past. Heating equipment installed in new buildings and in retrofit situations is more efficient and, in some cases, results in a different demand profile than the older equipment it replaces. FEI now uses an end-use, bottom up approach to demand forecasting for these customers in order to address these changing trends. New demand from the transportation sector will also impact the Company's overall demand profile. Figure ES-1 shows the total range of annual demand forecast for all customer groups, including NGT customers, for the Reference Case demand forecast as well as the highest (Upper Bound) and lowest (Lower Bound) of the various alternate future scenarios examined.

Figure ES-1: End-Use Total Annual Demand Forecast



FEI plans for the Reference Case demand, but will remain vigilant for indicators that suggest demand requirements might be unfolding more toward the Upper Bound scenario (driven largely by higher than expected NGT demand) or the Lower Bound scenario (driven largely by climate policy and regulation that favours displacing natural gas with other fuels for space heating and hot water). FEI does not assign probabilities to any particular forecast outcome.

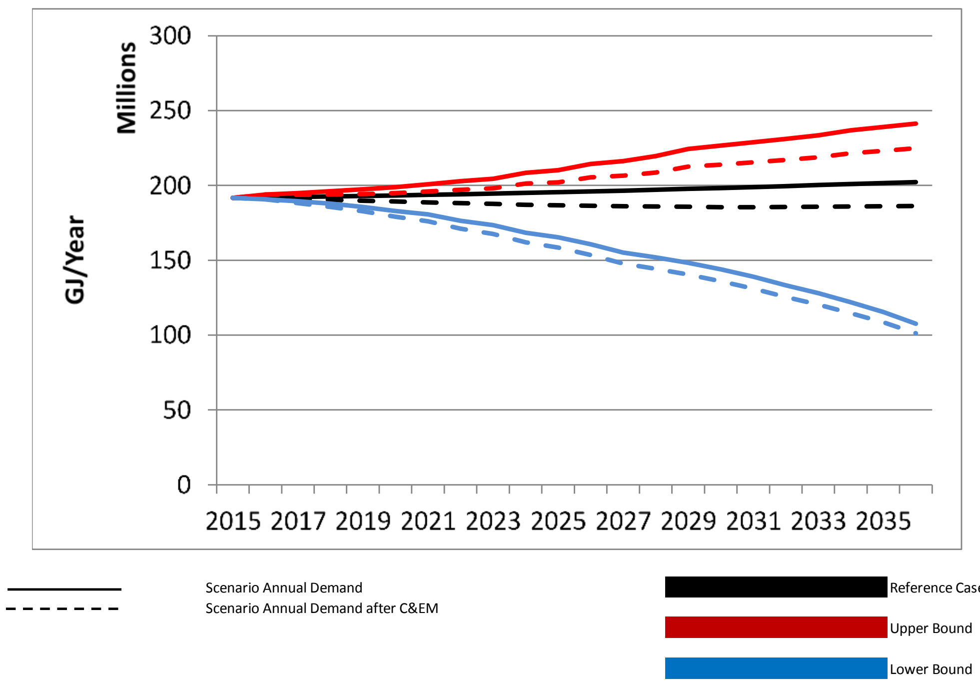
FEI also recognizes the potential for the addition of one or more large industrial customers over the planning horizon. If such large point source load additions were to occur in addition to demand in the Upper Bound scenario, demand could be pushed higher than that shown in Figure ES-1. Because the nature, size and location of such large industrial customer additions could vary widely and are subject to uncertainty, FEI generally does not plan for these load additions until a firm decision and a commitment by the customer for natural gas service is in place. Instead, in its 2017 LTGRP, FEI presents the Woodfibre LNG Project as an example to describe how it addresses such load additions while maintaining safe and reliable service to all customers.

4. Demand-Side Resources

Once an estimate of the demand for natural gas in FEI's territory is developed, the next step in long-term resource planning is to assess the impact of DSM activities on the demand forecast. In its LTGRP, FEI discusses both those DSM activities that fall strictly under the definition of demand-side measure under BC's Demand-Side Measures Regulation (DSM Regulation) as well as other demand side measures that do not fall under this strict definition. Yet these other demand side activities are recognized, industry-accepted utility practices important for FEI and its customers as well as for helping to meet BC Government energy and emissions objectives.

Under DSM activities defined by the DSM Regulation, FEI has estimated C&EM expenditures and energy savings from all cost effective measures identified through the Company's results from the BC Conservation Potential Review (BC CPR) study (undertaken between 2015 and 2017). This analysis was applied under FEI's Reference Case, Upper Bound and Lower Bound scenarios. The Upper Bound and Lower Bound scenario analyses ensure that FEI is considering its planning needs under the highest and lowest demand scenarios it reasonably expects could occur after energy savings from cost effective demand-side measures. Figure ES-2 presents energy savings for each of these scenarios before and after estimated C&EM savings amongst its residential, commercial and industrial customers. Reference Case incentive expenditures are estimated to reach a high of $46 million in 2023 based on cost effective measures known today.

Figure ES-2: Annual Natural Gas Demand Before and After Estimated C&EM Program Savings (Excluding NGT)



Since both the BC CPR and the 2017 LTGRP C&EM analysis investigate all cost effective C&EM measures already, FEI also conducted a sensitivity analysis to determine how the assumed level of incentive spending impacts forecast portfolio level C&EM expenditures and energy savings. The analysis, based on the BC CPR results, shows that as the level of incentives is increased, the portfolio expenditures rise much more quickly than do the portfolio energy savings. Conversely, as incentive levels are lowered, energy savings do not fall as quickly as portfolio expenditures.

Other demand side activities being undertaken by FEI include fuel switching to natural gas for space heating and hot water, NGT to shift fleets, heavy duty vehicles, marine and other vessels from higher carbon, petroleum based fuels to natural gas, and seeking to add new, large industrial customers. While these activities are not included in the DSM Regulation definition of a demand-side measure and are therefore not included in the C&EM activities described above, they are important for customers by adding throughput to the natural gas system and thereby reducing rates while also helping to achieve government energy and emissions policy objectives.

5. Gas Supply Portfolio Planning and Price Risk Management

FEI's gas supply planning activities ensure that the forecast normal and peak day demand of core market (Core) customers is appropriately planned for. FEI addresses how it plans to meet customer demand for natural gas over the long term via its gas supply arrangements. These arrangements encompass FEI's activities and means to contract for both the natural gas supply as well as the resources needed to bring this gas to the FEI pipeline system.

Key factors in FEI's gas portfolio planning include resource cost and availability, which are determined in the competitive natural gas marketplace. Consequently, gas supply portfolio planning activities must also consider marketplace developments throughout North America and particularly in the PNW that will affect traditional gas flows, supply and demand in the region, as well as the cost and availability of regional market resources for FEI. FEI has two primary means of managing these gas supply market dynamics in the medium and short term - the Annual Contracting Plan (ACP) and the Price Risk Management Plan (PRMP). Basic elements of the gas supply portfolio include the purchasing of gas commodity volumes, contracting on third party transportation pipelines that connect supply to market, and contracting for third party storage resources. Gas supply is also provided via FEI's own on-system LNG storage facilities.

It is critical that FEI's supply and resource portfolio incorporate a flexible variety of resources ranging from purchased term and spot gas supply, seasonal and short duration third party storage contracts, and high volume on-system resources. Accessing gas supply from a variety of locations and sources also provides FEI with a diverse pool of resources that is essential to help mitigate locational supply disruptions and price risk.

Gas supplies are plentiful throughout North America. This fact has caused western market prices to drop as producers seek to get supply from Northeast BC (NEBC) and Alberta onto a market that continues to develop more access to more producing regions. Although natural gas commodity prices are expected to remain low, interest from industrial users in natural gas is growing, as is the demand for regional storage and transmission resources to move gas from the producing areas to the demand areas.

Available capacity on these regional resources is becoming constrained. In today's competitive environment for regional gas supply resources, there is more risk of and a higher impact from FEI not having sufficient resources to meet forecast demand than from FEI finding itself long on supply resources. In the latter case, FEI's flexible portfolio will allow it to shed resources relatively quickly, whereas current trends in regional market factors may make it more difficult or even impossible to contract for critical additional resources on a firm basis should FEI find itself in need of more. For this reason, FEI's strategy is to be proactive in securing reliable and diversified gas supply cost effectively over the long term.[3] On behalf of its customers, FEI also closely monitors and participates in regulatory filings that could affect the availability of and costs for these resources, continues to establish key relationships with producers in the region and continues to evaluate opportunities within its own operating region to improve diversity and reliability within the gas supply portfolio.

Managing price risk in a marketplace with price volatility and competition for resources is also essential in helping to maintain affordable, competitive and stable rates for customers. FEI's price risk management objectives include mitigating market price volatility to support rate stability and capturing favourable prices to provide customers with more affordable rates. To meet these objectives, FEI has developed diversified procurement strategies through its PRMP to manage commodity price risk. FEI applies a range of price risk management strategies including various physical resource procurement strategies, managing locational basis risk and employing financial hedging tools. Today's low commodity price environment also provides opportunities for longer term strategies to meet PRMP objectives. FEI plans to continue to investigate longer term strategies such as investing in reserves and, if warranted, will bring forward any requests to the Commission for approval in the future.

6. System Resource Needs and Alternatives

A key aspect of ensuring safe, reliable and secure supply of natural gas to customers is identifying when and where any capacity constraints may appear and planning for the facilities that FEI needs to construct over the planning horizon to enable unrestrained delivery of natural gas to consumers. Growth in peak demand is among the most significant challenges for FEI's long term planning. When forecast peak demand exceeds available capacity, a gas system expansion is required.

There are three resource options to evaluate when planning system expansions: pipelines, compression and storage. To solve capacity constraints, each alternative is analysed with respect to overall cost, difficulty of implementation, operational flexibility, implementation time, and other factors within the overall philosophy of system sustainment and reliability. Often, some combination of the three resource options leads to an optimal solution.

Infrastructure projects on transmission systems to address system capacity constraints are often large and take many years to plan and execute. The location of customer demand on the system is a significant factor in determining the ability (capacity) of the system to deliver gas. To address the specific local and regional requirements, FEI builds regional peak demand forecasts from the bottom up, assembling the peak demand from the recent consumption and regional weather history of each customer within the system. The Company conducts this analysis for each of the three main transmission systems: Vancouver Island Transmission System (VITS); Coastal Transmission System (CTS); and Interior Transmission System (ITS).

[3] FEI has started to contract for some resources in excess of what Core customers are forecast to require in the short term. This approach is reasonable because the costs and ability to manage contract renewals within the portfolio of resources help to reduce the risk to Core customers.

Currently, FEI expects that capacity on the VITS will be exceeded in 2028 under expected load growth. Two primary options are identified to overcome this constraint. Option 1 involves adding compression along the transmission pipeline system near Squamish, while Option 2 includes some operational changes – increasing send-out and storage allotments from the Mt. Hayes storage facility to delay the need for additional compression near Squamish until 2030.

System expansion requirements on the CTS are highly dependent on the amount and nature of natural gas demand for use as a transportation fuel in either liquefied or compressed form. Compressed Natural Gas (CNG) demand could occur in many different locations across the CTS, while LNG demand would appear as a point source, industrial scale demand, most likely served by the Tilbury liquefaction and storage facility in Delta, BC. In the expected demand scenario, further expansion of the CTS (in addition to that currently under construction) would be needed at the end of the 20-year planning horizon (in approximately 2036).

The ITS peak demand will reach pipeline capacity when the system cannot maintain minimum system pressures near the high load centres in the Central Okanagan region. Expected load growth will cause an expansion requirement to address this constraint in 2022. FEI identified four reinforcement alternatives to meet the Traditional case demand forecast. Option 1 involves installing a 28 km transmission pipeline loop just north of Penticton and adding compression facilities at an existing station to move gas through the expanded pipe. Option 2 involves replacing a 9 km section of transmission pipeline between Penticton and Kelowna and adding the same compression as in Option 1. Option 3 entails approximately 52 km of transmission pipeline looping installed near Kamloops, BC. Option 4 is the installation of an LNG storage facility near Vernon BC, close to the load centre to bolster system delivery during times of high demand.

For each regional system, higher or lower than expected load growth could shift the timing of system expansion requirements either ahead or further out in time. The potential for additional new, large industrial demand could create a step change in load delivery requirements and a corresponding advancement of system expansion requirements. Because the location, size and nature of such potential new loads are often speculative, a myriad of potential impacts could occur, making it difficult to model these loads. FEI has used examples of potential loads to describe the impacts on system capacity that could result. For the VITS and CTS, the proposed Woodfibre LNG export facility near Squamish and potential additional demand at the Tilbury LNG facility to serve large increases in NGT demand, respectively, provide such examples. Based on these examples, expansion requirements on the VITS could be advanced to as early as 2021, and the CTS expansion could be advanced to as soon as 2024. The high and low demand scenarios, along with the large industrial customer addition examples presented in the LTGRP are used to identify contingency plans by advancing or delaying the timing of system constraints and resulting infrastructure needs.

In addition to the transmission pipeline expansion analysis, a number of other sizable expansion requirements on FEI's distribution and lateral transmission systems have been identified. FEI continues to examine the needs of the Revelstoke satellite propane distribution system and the potential to convert it to a natural gas system via a satellite LNG station. On the Cache

Creek/Ashcroft Transmission Lateral, FEI works closely with a firm transportation customer to manage peak demand and avoid the need for a pipeline loop. The company also explores several other significant projects that address needs other than system capacity. While these projects are not driven by capacity needs, FEI strives to ensure any projects integrate effectively with system capacity requirements of each system.

FEI plans to:

- Continue monitoring and studying the system capacity constraints identified to occur in 2028 on the VI Transmission System and complete the analysis of system reinforcement and load or supply reallocation alternatives;
- Identify system reinforcements that would be required to maintain system reliability and resilience for Core customers as LNG expansion or other large industrial loads are added on the CTS system;
- Continue to monitor and study the system capacity constraints identified to occur in 2022 in the Okanagan region of the ITS and complete the analysis of system reinforcement alternatives in anticipation of a Certificate of Public Convenience and Necessity (CPCN) application to the BCUC in the next two to three years; and
- Continue evaluating other major system projects and submit CPCN applications for these projects if required.

7. Stakeholder Consultation

Connecting with customers, communities and other stakeholders on long range planning issues is of critical importance to FEI. FEI undertook a number of initiatives to offer stakeholders the opportunity to participate in discussions to inform the 2017 LTGRP. These activities continued until the third quarter of 2017 and included:

- Workshops with the dedicated Resource Planning Advisory Group (RPAG) - the RPAG engages strategic representatives of municipalities, government, First Nations, customers, associations and organizations with interest, experience and/or significant industry knowledge in energy planning in the development of the LTGRP.
- Community Engagement workshops in communities served by FEI - recognizing the importance of considering diverse community perspectives when planning for the future, FEI has established resource planning Community Engagement workshops to gather feedback from stakeholders throughout FEI's service territories.
- Other activities that indirectly inform the resource planning process, including dialogue with First Nations, advisory groups, industry associations and other stakeholders.

Through the RPAG workshop sessions, stakeholders have been able to provide FEI with input on areas, such as demand forecasting and scenario analysis methods as well as annual demand drivers and scenarios. The Community Engagement workshops assisted FEI in identifying energy issues or planning opportunities in municipalities and communities throughout BC. The information gained through these activities informs FEI's market research and analysis, identifying long term planning issues of concern to a number of stakeholder groups, and identifying interested stakeholders who may become more engaged in the LTGRP process.

8. 20-Year Vision

FEI's long term vision is to continue to strive to be BC's trusted energy provider for safe, reliable and cost effective natural gas delivery services to its customers, and to be a healthy, growing contributor to the BC economy and to the well-being of communities in BC. Sustainability represents a key component of this vision and FEI considers all three pillars of this concept: social, environmental, and economic sustainability. FEI has developed the current 2017 LTGRP within a planning environment characterized by continued high policy uncertainty and rapid technological change. A long term vision thus cannot be made so specific that it does not allow for changes in the planning environment.

FEI discusses four key areas in which Market Transformation is occurring or may occur over the next 20 years, which could impact FEI's traditional business: NGT, C&EM technologies, low carbon thermal energy technologies, and RNG.

FEI examined NGT market capture scenarios of between 1 and 15 percent of the heavy duty and return to base fleet vehicles, and uses a Reference Case expectation of 4 percent market capture. All market sectors of potential NGT future demand - land transportation CNG and LNG vehicles as well as coastal freight vessels, domestic passenger ferries, locomotives, mine haul trucks and stationary power generation for industrial applications - are important in helping the Province meet its carbon emission reduction targets. The trans-Pacific marine segment, however, has the most significant potential impact on increased natural gas demand combined with reduced carbon emissions.

FEI expects to increase its C&EM activities with the overall goal of transforming the market from lower to higher efficiency technologies for use in the built environment. While FEI has not identified the extent of market transformation that will occur for each measure or technology via specific C&EM programs, the analysis results do represent an estimate of the amount of energy efficiency that can be achieved by the Company over the planning horizon.

Low carbon thermal energy solutions such as geo-exchange systems, waste heat recovery systems and solar thermal systems can displace both existing and future expected demand for natural gas. While FEI does not offer these services to its customers, the potential for other third party service providers to do so creates a risk to FEI's annual demand profile. This highlights the need for FEI to invest in other load building initiatives such as NGT and to support development of its RNG program and other technologies that enable FEI to meet market preferences while also helping to meet BC energy objectives.

Even annual demand forecast scenarios that assume a high level of RNG demand result in RNG accounting for a small proportion of FEI's total annual demand (less than three million GJ) by the end of the planning horizon. However, this analysis assumes current RNG supply technologies. If cellulosic biogas technologies become commercially scalable at reasonable cost, RNG demand may account for a significant share of FEI's demand within 20 years.

Table ES-2 compares forecast 2036 emissions reductions of FEI's initiatives with a 2036 target calculated by linear regression from the Government of Canada's 2017 Nationally Determined Contribution under the Paris Agreement (reducing GHG emissions by 30 percent from 2005 until 2030), and BC's legislated sector-agnostic 2050 emissions reduction target.[4,5]

Table ES-2: Comparison of FEI's Emissions Reduction Activities with the Calculated Emissions Reduction Target

GHG Reductions Required to Meet the Calculated 2036 Target ($MtCO_2e$, 2014 Base)	Forecast Emissions Reductions in 2036 ($MtCO_2e$, 2015 Base)		
29.3	**Reference Case**	**Upper Bound**	**Lower Bound**
RNG	0.04	0.14	0.01
C&EM	0.8	0.8	0.3
NGT	2.3	14.9	0.2

Note: Some forecast NGT emissions reductions are realized outside the current boundaries of the BC emissions inventory

Other technologies exist or are under development that may decarbonize the natural gas stream and enable the natural gas infrastructure to store electric energy (indirectly by injecting into the pipeline system hydrogen derived via electrolysis), decarbonize natural gas end-use appliances or increase beyond 100 percent the efficiency of natural gas appliances. FEI is monitoring and, where applicable, supporting the evolution of such technologies. If such technologies become commercially scalable at reasonable cost, they may mitigate policy-driven risks of downward pressure on natural gas demand (identified in Section 2) and create an investment opportunity for the Company. Within the context of a 20-year vision, FEI examined potential pathways through which emerging initiatives and technologies could help FEI lead efforts to pursue long term GHG emissions abatement. Please see Appendix E for this examination.

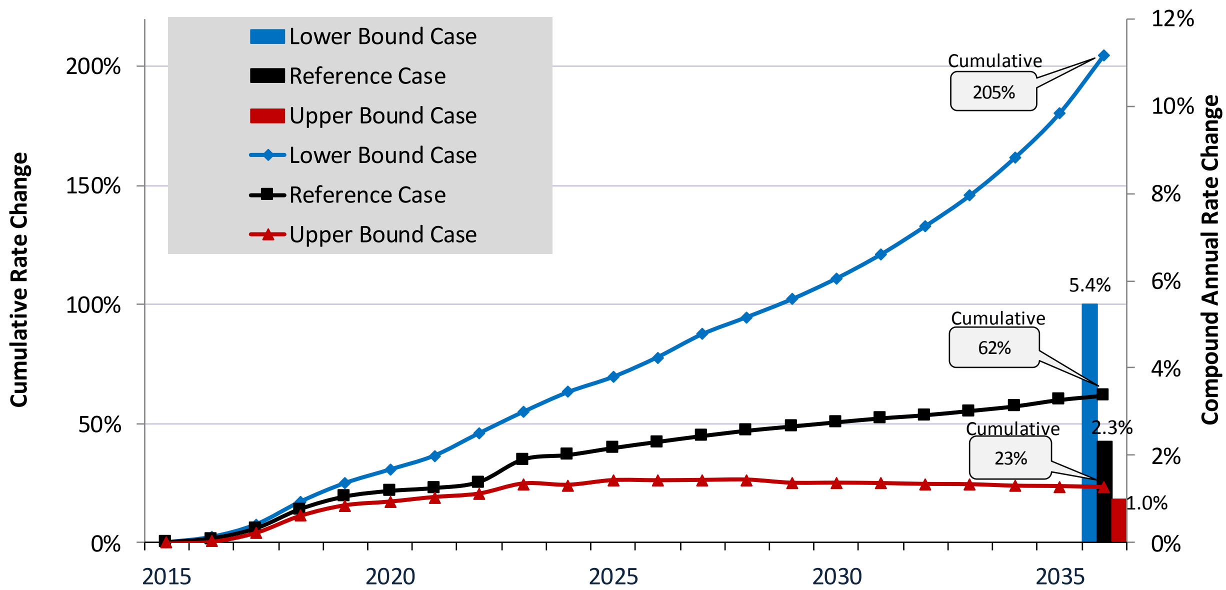
FEI also analyzes how variations in demand over the planning period can influence customer rates. Figure ES-3 shows that, holding all else constant, increasing delivery volumes (as demonstrated by the Upper Bound Case) has a downward impact on rates. This figure includes the impact of expenditures and demand impact for both the C&EM and the NGT initiatives,

4 FEI's RNG, C&EM and NGT initiatives each have their own merits and run under separate regulatory approval processes.

5 FEI received stakeholder support for using the Government of Canada's 2030 percentage reduction target as a reasonable alternative to the GGRA's 2020 target as part of a trajectory towards the GGRA's ultimate 2050 target.

however, FEI's analysis shows that individually, the C&EM initiative puts upward pressure on rates while the NGT initiative reduces rate pressure. Expanding the NGT market is an important opportunity for growth on the delivery system and underscores the importance for the Company to explore other opportunities for growth that will assist in mitigating upward pressure on delivery rates.

Figure ES-3: Delivery Rate Direction – All Rate Schedules with C&EM and NGT



9. Action Plan

The actions that FEI intends to pursue over the next four years based on the information and analyses provided in this LTGRP are to:

- Continue monitoring and analysing the energy planning environment including any market, policy and/or technology developments that may impact regional gas flows, supply, demand and pricing, or offer opportunities to improve on the secure, reliable and cost effective energy services that the Company provides to its customers.
- Continue exploring the application of projected changes across end-use patterns to peak demand forecasting and examining potential metering solutions that may allow FEI to field-validate the potential impact of end-use trends on peak demand.
- Protect and promote the interests of the Utility's customers by securing a reliable, cost effective long term gas supply. This includes participating in regional pipeline proceedings, evaluating opportunities within FEI's operating region to improve infrastructure, and exploring opportunities for longer term price risk management

strategies such as using fixed price purchases, building key relationships with producers, investing in natural gas reserves and continued financial hedging.

- Continue monitoring and evaluating system expansion needs in the Okanagan and Vancouver Island areas to maintain reliable and cost effective gas delivery to FEI's customers. Under the expected peak demand trajectory, FEI identifies a capacity constraint in the Okanagan occurring in 2022, for which four potential reinforcement options will be examined in more detail. A capacity constraint on the VITS is identified to occur in 2028 for which two reinforcement options will be examined in more detail if necessary. If peak demand trends are seen to be changing over the near to medium term, the timing of these constraints may change.
- Plan for and prepare CPCN applications for near-term system requirements to support safe, reliable and cost effective gas delivery to FEI's customers. The Company identifies a number of high priority projects on the CTS (including the Lower Mainland Intermediate Pressure System) and FEI's interior region infrastructure for which the Utility intends to submit CPCN applications. FEI will integrate its examination of these system upgrade requirements with the study of reinforcement options under consideration to meet FEI's capacity needs.
- Continue implementing the Company's NGT initiatives to meet market needs while capturing an important opportunity for load growth and GHG emissions reductions. This includes implementing any required expansions to the Tilbury LNG facility and FEI's CTS for meeting NGT and non-NGT LNG demand.
- Pursue approval of C&EM funding for the period beyond 2018 by submitting for BCUC approval a C&EM expenditure schedule in 2018. FEI will continue to examine the potential for all forms of DSM activity to optimize the use of BC's energy infrastructure by implementing programs that help meet customer energy needs while working toward BC energy objectives.
- Pursue approvals as necessary of a funding envelope dedicated to enabling FEI to further monitor and, where applicable, support the development of innovative natural gas technologies that have potential to help FEI meet market preferences while also supporting solutions for BC's emissions policy objectives.

1. INTRODUCTION

Long-term resource planning[6] is a tool for identifying long-range infrastructure requirements and resource acquisition strategies and for sharing this information with stakeholders; it is also a requirement of the UCA. This 2017 LTGRP[7] is FEI's[8] long-term resource plan as required by the UCA. The 2017 LTGRP presents a long term view of the demand- and supply-side resources[9] identified to meet expected future natural gas demand and reliability requirements at the lowest reasonable cost to FEI's customers over the 20-year planning horizon (2017-2036).[10]

The 2017 LTGRP analyzes the external regulatory, policy and planning environment within which FEI operates, compares annual and peak energy demand forecasts against current resource capabilities, and evaluates the potential for demand reduction with Demand Side Management (DSM) initiatives. This serves as a foundation for further evaluating gas supply and system infrastructure options for meeting forecast customer needs under different scenarios. This 2017 LTGRP includes an action plan that identifies the activities that FEI intends to take during the first four years of the 20-year planning horizon. This 2017 LTGRP will enable FEI to achieve its primary objective of providing cost effective, secure and reliable energy for its customers. The 2017 LTGRP is consistent with the applicable sections of the UCA and the British Columbia Utility Commission's Resource Planning Guidelines, and complies with directives from the Commission arising from the acceptance of FEI's 2014 Long Term Resource Plan (LTRP). These requirements are discussed further in Section 1.4.

FEI submits this 2017 LTGRP for acceptance under Section 44.1(2) of the UCA and is **not seeking approval of any particular elements of the plan**. Any requests for approval of specific resource needs that are identified within this plan will be further evaluated and brought forward through a separate application to the BCUC if warranted in the future. The LTGRP is not a substitute for the analysis done to support specific resource acquisitions or projects in the future but rather it helps to inform the acquisition process.

1.1 *RESOURCE PLANNING PROCESS*

The resource planning process begins by closely examining the planning environment in which the Company operates and by identifying expectations for future customer and demand growth.

6 The terms 'integrated resource planning,' 'long-term resource planning' and 'resource planning' are used interchangeably in this document.

7 FEI referred to the LTGRP as Long Term Resource Plan (LTRP) in previous filings but has updated this term to reflect the difference to FortisBC Inc.'s Long Term Electric Resource Plan (LTERP).

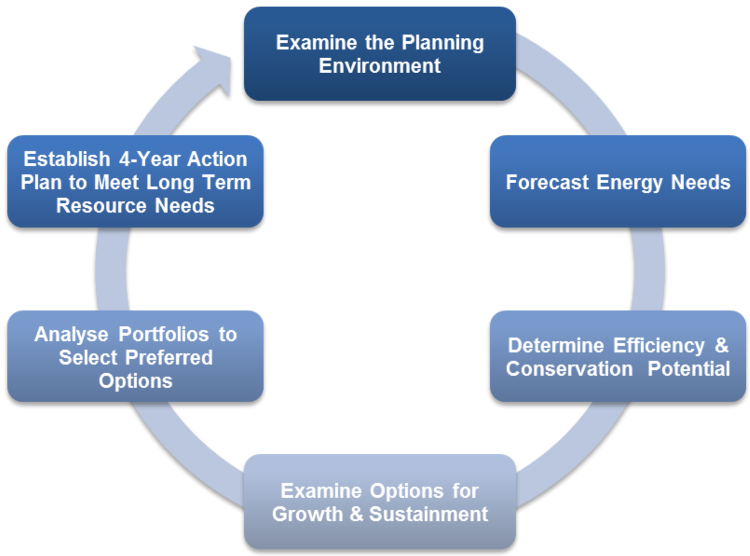
8 Where applicable, FEI's LTGRP analysis includes data for Fort Nelson. FEI does not expect any system capacity constraints in Fort Nelson during the 2017 LTGRP forecast horizon. FEI's gas supply portfolio planning and DSM activities do include Fort Nelson customers.

9 The British Columbia Utilities Commission Resource Planning Guidelines define resources as indivisible investments or actions by the utility to modify energy and/or capacity supply, or modify (decrease, shift, increase) energy and/or capacity demand. Within the context of FEI, such resources typically refer to FEI's own infrastructure (pipelines, natural gas compression equipment, natural gas storage equipment), natural gas supply arrangements, and DSM initiatives.

10 FEI submitted the 2014 LTRP as FortisBC Energy Utilities (FEU) which includes the now amalgamated FortisBC Energy Inc., FortisBC Energy (Vancouver Island) Inc., and FortisBC Energy (Whistler) Inc.

The demand- and supply-side resource alternatives for meeting future demand are then assessed, and actions are recommended to ensure that the proper resources are in place to deliver the preferred energy solutions to meet future customer needs. The final stage of the process is developing a four-year action plan which identifies the near term activities needed to meet the long term resource requirements identified in the LTGRP. Figure 1-1 below outlines FEI's resource planning process:

Figure 1-1: FEI Long Term Resource Planning Process



The Company continues to engage customers and stakeholders as a critical part of the LTGRP process. Furthermore, FEI believes that, as part of the planning process, it is important to also understand the planning issues, competitive environment and resource requirements for other utilities in the PNW region, due to common regional infrastructure used to serve both electricity and natural gas demand. As such, FEI actively participates as a stakeholder in the resource planning efforts of other gas and electric utilities in the region, such as British Columbia Hydro and Power Authority (BC Hydro), FortisBC Inc. (FBC), Puget Sound Energy (PSE), Avista and Northwest Natural Gas Company (NW Natural). To facilitate understanding and response to regional resource issues, FEI also participates in planning, resource assessment activities and events conducted by regional organizations including the Northwest Gas Association (NWGA), the Northwest Power and Conservation Council (NWPCC) and the Pacific Northwest Economic Region (PNWER). The regional outlooks provided by these organizations also inform the analyses and recommendations in this LTGRP.

1.2 *FORTISBC ENERGY INC.*

FEI is a subsidiary of Fortis Inc., the largest investor-owned gas and electric distribution utility company in Canada. FBC, which provides electric service in the British Columbia (BC) interior, is a separate Fortis Inc. subsidiary and sister company to FEI. The long term planning considerations and business activities of FBC are not included in this LTGRP.

FEI provides natural gas services to approximately one million residential, commercial, and industrial customers in more than 135 communities throughout BC. This puts FEI among the largest gas utilities in Canada and in the PNW. Table 1-1 provides a summary of FEI customer, demand and pipeline characteristics. Figure 1-2 shows the Company's service area locations.

Table 1-1: FEI Service Statistics

	2015	2016
Number of Customers	982,000	994,000
Annual Demand (TJ)	186,000	197,000
Peak Day Demand (TJ/d)	1,074	1,334
Length of Transmission Pipeline (km)	2,958	2,959
Length of Distribution Pipeline* (km)	45,242	45,741

** Includes both low and intermediate pressure pipelines*

Figure 1-2: Map of FortisBC Service Areas by Fuel Source

1.3 LONG TERM RESOURCE PLANNING OBJECTIVES

FEI's resource planning objectives form the basis for identifying and evaluating potential resources in the LTGRP, including major infrastructure projects, gas supply alternatives and demand side programs. These objectives reflect the Utility's commitment to providing customers with the highest level of quality energy services. FEI's key resource planning objectives are to:

1.3.1 Ensure Cost Effective, Secure and Reliable Energy for Customers

A secure energy supply is essential for all FEI customers. Ensuring a sufficient supply of gas and the capacity to deliver gas to customers during anticipated peak demand periods is an ongoing objective for the Utility. Acquiring resources that improve the reliability and security of supply will also help to reduce rate volatility and protect customers from potential outages.

1.3.2 Provide Cost Effective DSM Initiatives

Customers and regulators expect the Utility to procure and deliver energy in a cost effective and efficient manner. The most desirable resource options will provide cost effective service solutions and help to manage rate volatility both in the near term and into the future. Cost effective DSM strategies can add value to customers through more effective use of the gas delivery infrastructure and more efficient use at the burner tip. In addition to cost effective energy efficiency and conservation programming, FEI also delivers innovative energy solutions through natural gas initiatives for the transportation sector and carbon neutral biomethane for residential and commercial customers.

1.3.3 Ensure Consistency with Provincial Energy Objectives

FEI provides natural gas distribution service to 994,000 customers[11] across 135 communities in BC. This wide reach enables FEI to play a role in assisting customers to understand and reduce their energy consumption and GHG emissions. FEI's DSM activities, NGT[12] and RNG initiatives are key avenues through which FEI contributes to advancing BC's energy and GHG emission goals; the Company continues to examine and, where applicable, support potential programs, technologies and initiatives that will contribute to BC's energy and GHG emissions goals.

1.4 REGULATORY CONTEXT

In addition to being good utility practice, FEI has a regulatory obligation to file long-term resource plans under Section 44.1 of the UCA. The UCA and any directives from the Commission related to FEI's previously filed resource plans establish the requirements for what must be included in the plans. Additionally, the Commission has issued Resource Planning

[11] FEI 2016 customer count.
[12] NGT includes CNG and LNG supply for heavy duty on-road trucks, locomotives, marine vessels, mine haul trucks and remote power generation for industrial applications.

Guidelines which provide general guidance as to the BCUC's expectations of FEI's process and methods for developing the LTGRP.

1.4.1 *Utilities Commission Act*

The UCA provides the BCUC with the jurisdiction to regulate public utilities in BC and requires utilities to submit a long-term resource plan. Section 44.1(2) of the UCA, "Long-Term Resource and Conservation Planning," outlines the specific elements that are to be included in resource plans. Table identifies where each specific requirement is addressed.

Table 1-2: UCA Requirements and Areas Addressed in the 2017 LTGRP

Requirement of UCA Section 44.1(2)	Addressed in the 2017 LTGRP
a. An estimate of the demand for energy the public utility would expect to serve if the public utility does not take new demand-side measures during the period addressed by the plan;	See Sections 3.4.8 and 3.4.9
b. A plan of how the public utility intends to reduce the demand referred to in paragraph (a) by taking cost-effective demand-side measures;	See Section 4.2.4
c. An estimate of the demand for energy that the public utility expects to serve after it has taken cost-effective demand-side measures;	See Section 4.2.3
d. A description of the facilities that the public utility intends to construct or extend in order to serve the estimated demand referred to in paragraph (c);	See Section 6
e. Information regarding the energy purchases from other persons that the public utility intends to make in order to serve the estimated demand referred to in paragraph (c);	See Section 5
f. An explanation of why the demand for energy to be served by the facilities referred to in paragraph (d) and the purchases referred to in paragraph (e) are not planned to be replaced by demand-side measures; and	See Sections 6.2.1.3 and 6.3
g. Any other information required by the Commission.	Recent BCUC Directives from the 2014 LTRP Decision have been incorporated throughout this 2017 LTGRP. Directives relating to GHG reduction targets, DSM planning/funding scenarios and impacts of new initiatives are addressed in Sections 3, 4, and 8. Details of FEI's approach to demand forecasting are provided in Section 3; and Discussion of FEI's guiding principles for Price Risk Management is provided in Section 5.

In determining whether to accept a long-term resource plan, Section 44.1(8) of the UCA requires the Commission to consider:

- The applicable of BC's energy objectives (addressed in Section 8);
- The extent to which the plan is consistent with the applicable requirements under sections 6 and 19 of the *Clean Energy Act* (*CEA*) (addressed Section 1.4.2 below);
- Whether the plan shows that the public utility intends to pursue adequate, cost effective demand-side measures (addressed Sections 4 and 6); and
- The interests of persons in BC who receive or may receive service from the public utility (addressed throughout the 2017 LTGRP but primarily in Section 8).

The 2017 LTGRP meets the requirements of the UCA.

1.4.2 CEA Objectives

As set out in Section 1.4.1 above, two of the considerations in section 44.1(8) of the UCA relate to the CEA. This section provides background and discussion of the CEA and its relationship to the LTGRP.

In 2010 the Government of BC enacted the CEA. The CEA contains a set of sixteen specific energy objectives for the Province of BC. It provides a guide to help the Province meet its self-sufficiency goals and to reduce GHG emissions.

Table 1-3 below lists the CEA objectives that are directly applicable to the LTGRP and describes which section of the 2017 LTGRP supports them. It is important to note that these are provincial objectives and some of the objectives are specific to BC Hydro, as referenced in the CEA by the term 'the authority':

Table 1-3: Applicable CEA Objectives Directly Relevant to the LTGRP

CEA Section	CEA Objective	Supported in the 2017 LTGRP
2(b)	To take demand-side measures and to conserve energy, including the objective of the authority reducing its expected increase in demand for electricity by the year 2020 by at least 66%.	The 66 percent target applies to BC Hydro. Section 4 addresses FEI's DSM analysis.
2(d)	To use and foster the development in British Columbia of innovative technologies that support energy conservation and efficiency and the use of clean or renewable resources.	Sections 2, 3 and 8 address FEI's actions to support innovative and clean or renewable energy technologies. Section 4 addresses FEI's DSM analysis.

CEA Section	CEA Objective	Supported in the 2017 LTGRP
2(g)	To reduce BC GHG emissions: (i) By 2012 and for each subsequent year to at least 6% less than the level of those emissions in 2007, (ii) By 2016 and each subsequent calendar year to at least 18% less than the level of those emissions in 2007, (iii) By 2020 and for each subsequent calendar year to at least 33% less than the level of those emissions in 2007, (iv) By 2050 and for each subsequent calendar year to at least 80% less than the level of those emissions in 2007, and (v) By such other amounts as determined under the *Greenhouse Gas Reduction Targets Act*.	Section 8 addresses GHG emissions and emissions reductions from FEI's forecast energy demand and initiatives.
2(h)	To encourage the switching from one kind of energy source to another that decreases greenhouse gases in British Columbia.	Sections 2, 3, 4 and 8 address FEI's fuel switching initiatives within the umbrella definition of DSM.
2(i)	To encourage communities to reduce greenhouse gas emissions and use energy efficiently.	Section 4 addresses FEI's DSM analysis. Section 8 addresses GHG emissions and emissions reductions from FEI's forecast energy demand and initiatives.
2(j)	To reduce waste by encouraging the use of waste heat, biogas and biomass	Sections 2, 3, 5 and 8 discuss FEI's RNG initiative.
2(k)	To encourage economic development and the creation and retention of jobs	Section 8 summarizes FEI's 2017 LTGRP analysis results in light of BC's energy objectives.

1.4.3 Commission Resource Planning Guidelines and Directives

1.4.3.1 Resource Planning Guidelines

In 2003, the BCUC issued Resource Planning Guidelines which outline a process to assist in the development of resource plans to be filed with the Commission.[13] According to the guidelines, "resource planning is intended to facilitate the selection of cost-effective resources that yield the best overall outcome of expected impacts and risks for ratepayers over the long run." The guidelines do not distinguish between utilities that provide generation, transmission or

[13] http://www.bcuc.com/Documents/Guidelines/RPGuidelines_12-2003.pdf.

distribution services; therefore, some items (such as supply-side portfolio analysis[14]) apply more readily to integrated electric utilities. The BCUC reviews resource plans in the context of the unique circumstances of the utility in question. FEI adheres to the BCUC's planning guidelines where relevant and applicable to the Company's operating context. Table 1-4 below outlines the key elements of the Resource Planning Guidelines and the sections of the 2017 LTGRP in which they are addressed:

Table 1-4: Commission Resource Planning Guidelines

Resource Planning Guideline	Addressed in the 2017 LTGRP
1. Identification of the planning context and the objectives of a resource plan	See Sections 1.3, 1.4 and 2
2. Development of a range of gross (pre-DSM) demand forecasts	See Section 3
3. Identification of supply and demand resources	See Sections 2, 3, 4 and 5
4. Measurement of supply and demand resources	See Sections 3, 4, and 5
5. Development of multiple resource portfolios	As FEI is not a vertically integrated electric utility, it does not develop and compare multiple integrated resource portfolios. Rather, FEI plans to its forecast Reference Case but also prepares contingency plans. See Section 4 for the 2017 LTGRP's DSM analysis, Section 5 for the gas supply analysis, and Section 6 for FEI's system requirements and options.
6. Evaluation and selection of resource portfolios	As FEI is not a vertically integrated electric utility, it does not develop and compare multiple integrated resource portfolios. Rather, FEI plans to its forecast Reference Case but also prepares contingency plans. See Section 4 for the 2017 LTGRP's DSM analysis, Section 5 for the gas supply analysis, and Section 6 for FEI's system requirements and options.
7. Development of a four-year action plan, including contingency plans	See Section 9
8. Solicit stakeholder input during the planning process	See Section 7
9. Seek regulatory input from Commission staff	FEI met with Commission staff to discuss the resource planning process as well as some scope issues. Commission staff also attended FEI's external advisory group workshops (see Section 7) throughout the process.
10. Consideration of government policy	See Section 2.3
11. Regulatory review once a resource plan is filed	See Section 1.6

14 Supply-side portfolio analyses are conducted outside of FEI's LTGRP planning process and are submitted for approval to the BCUC through the Annual Contracting Plan (ACP) and Price Risk Management Plan (PRMP).

Where applicable, the 2017 LTGRP is consistent with the Resource Planning Guidelines.

1.4.3.2 Commission Directives

In the BCUC's acceptance of the 2014 LTRP (Order G-189-14), the Commission provided a number of directives and suggestions for FEI to integrate in future resource plans. These directives and related FEI actions are outlined in Table 1-5 below:

Table 1-5: List of Commission Directives and FEI Action Pursuant to Order G-189-14

Directive #	Commission Directive	FEI Action
5.	Therefore, the Commission Panel directs the FEU, to: • In its next LTRP filing, provide a detailed analysis of the relative benefits/shortcomings of their particular End-Use Method as compared to other end-use methods, and • Continue use of the Traditional Method as a parallel approach until such time as the Commission approves a new end-use method as a substitute.	Addressed in Section 3.4, report by an independent consultant in Appendix B-2, and further discussion in Appendix B-3. FEI continues using both the Traditional method as well as the end-use method for forecasting annual energy demand. Section 3.4.3 shows a comparison between both methods.

8.	The Panel therefore directs the FEU to include, in its next LTRP, the following information:
	• The development of DSM funding scenarios, reflecting the results of the most recent CPR. At a minimum, this should include a 'reference' DSM funding scenario with 'high DSM' and 'low DSM' scenarios that are relative to the reference scenario;
	• Analysis of each DSM scenario, at a portfolio level and for each DSM category (residential, low-income, commercial etc.), including:
	  ○ Total Resource Cost/Modified Total Resource Cost test results;
	  ○ Utility Cost Test result, expressed as a ratio and $/GJ
	  ○ Delivery rate impact;
	  ○ Estimated total bill impact
		Section 4.2 addresses FEI's forecast of C&EM activity, funding scenarios, and cost effectiveness test results.
		
		Sections 8.3 and 8.6 address the GHG emissions and projected delivery rate impact of the 2017 LTGRP analysis.
		
		FEI notes that the 2017 LTGRP provides a long term forecast of C&EM activity and that its next C&EM expenditure schedule (which FEI plans to submit after submission of the 2017 LTGRP), will determine and request approval for its specific program activity across the short and/or medium term.

Directive #	Commission Directive	FEI Action
	(including delivery and commodity), $ and %, with residential split between high and low use gas customers; and ○ Estimated gas (GJ) and GHG emission reductions.	
9.	Accordingly, in the next LTRP the FEU are directed to provide a more fulsome analysis of opportunities for DSM to be cost-effectively used to replace or defer infrastructure investments.	Section 6.2 addresses the potential impact of DSM as part of the 2017 LTGRP's discussion of system requirements and options.
11.	To ensure regulatory efficiency in the review of CPCN applications, the Panel directs that the FEU include in their next LTRP, a contingency plan(s) that outlines the impact(s) to FEU's System Resource Needs and Alternatives based on potential changes in supply, demand, market conditions and significant new developments in the industry that were not identified in the LTRP as being associated with the Reference Case or most-likely forecast.	Addressed in Section 6 by modulating FEI's Traditional peak demand forecast method and also reviewing results from a new exploratory peak demand forecast method.
12.	The Panel therefore directs FEU to include in the next LTRP a description of its long term vision for price risk management and provide broad principles which can be used to inform the PRMP.	Addressed in Section 5.5.
13.	the Commission Panel finds that (i) the FEU's objective of maintaining the competitiveness of natural gas with other energy sources is inappropriate and should not be included in a future PRMP, and (ii) while the Panel has no desire to close the door on the consideration of all future hedging options, the PRMP must show that this is the most cost effective approach or solution to moderating the volatility of natural gas prices or reducing risks related to price disconnects.	This directive relates to FEI's PRMPs specifically and is thus addressed in FEI's PRMPs when FEI submits these to the Commission for review and approval.

Directive #	Commission Directive	FEI Action
15.	The Panel determines that the FEU provided sufficient information in the LTRP to meet the 2010 LTRP requirements to provide: (i) an analysis of the GHG targets as set out in British Columbia's energy objectives and an estimate of the portion of the required reduction that the Company believes it can reasonably attain over time; and (ii) an outline of the impact of the implementation of new initiatives on the demand forecast and GHG emission reductions. The Panel directs the FEU to also provide this GHG related information in the next LTRP.	Section 8.3 continues to provide this information in the 2017 LTGRP. Based on current trends in the discourse on energy use and emissions policy (see Section 2.3) and with stakeholder support, Appendix E expands this analysis with an examination of possible wider GHG emissions abatement pathways.
17.	If, in the next LTRP, the FEU provides a demand forecast that includes the possibility of there being insufficient supply for both NGT BC customers and non-BC LNG export customers, then the Panel directs the FEU to address how it will insure compliance with section 44.1(8)(d) of the UCA.	Addressed in Section 5. Gas supply is abundant. Risk would arise related to ensuring sufficient storage and transportation infrastructure is available. For large LNG export projects, this relates to regional non-FEI infrastructure and may impact FEI indirectly only via price signals.
18.	The Commission Panel directs the FEU to file their next LTRP on or before June 30, 2017.	The Commission granted FEI an extension to this filing date to November 30, 2017 in Order G-99-17.

Please refer to Appendix D for excerpts of online sources referenced in footnotes throughout the 2017 LTGRP.

1.5 *STATUS OF THE 2014 LTRP ACTION PLAN*

In each successive resource plan, FEI presents a list of actions to implement the recommendations outlined throughout the plan. Table 1-6 below provides an update of the items identified in the Four-Year Action Plan of the 2014 LTRP.

Table 1-6: 2014 LTRP Action Items

Action Item	Status
1. Continue to monitor and analyze the energy planning environment.	FEI has continued monitoring and analysing the planning environment. To support its analysis of the policy planning environment, FEI, since the 2014 LTRP, has dedicated resources specifically to public policy analysis. Section 2 presents a snapshot of FEI's current analysis of the planning environment.

Action Item	Status
2. Continue to implement the Companies' NGT initiatives.	FEI has consolidated its NGT initiatives under a Director, NGT and Regional LNG. To date, FEI has invested $90.2 million in its NGT initiatives. From 2014 until 2016, FEI's annual NGT energy demand has increased by 53 percent.
3. Discontinue using the traditional annual demand forecasting method for residential, commercial and industrial customers.	In its decision on the 2014 LTRP, the Commission directed FEI to continue use of the Traditional method as a parallel approach until such time as the Commission approves a new end-use method as a substitute. FEI continues using both methods for forecasting annual energy demand; Section 3.4.3 shows a comparison between them.
4. Pursue approval of EEC[15] funding for the 2014-2018 period through the FEI 2014-2018 PBR application.	The Commission approved FEI's 2014-2018 expenditure schedule via its decision on FEI's 2014-2019 Performance Based Ratemaking Plan, as the application contained FEI's 2014-2018 DSM Plan.[16] [17,18] FEI is implementing this portfolio and delivers annual performance reports to the Commission.
5. Plan for and prepare CPCN applications for near-term system requirements identified in the FEU Five-Year Capital Plans.	Order C-11-15 approved the Lower Mainland Intermediate Pressure (IP) System Upgrade (LMIPSU) projects, which included two of the projects identified in the Action Plan: • Coquitlam Gate IP pipeline replacement; and • Fraser Gate IP pipeline replacement. Both projects are in progress. The remaining three projects which are components of the Coastal Transmission System (CTS), were authorized by Orders in Council[19] and are expected to be completed during 2017: • Nichol to Port Mann TP pipeline loop; • Cape Horn to Coquitlam TP pipeline loop; and • Nichol to Roebuck TP pipeline loop.
6. Expand the Tilbury LNG facility.	In accordance with the BC Government Special Direction No. 5, FEI implemented its first-stage expansion of the Tilbury LNG facility. This stage will be completed in 2017.
7. Continue monitoring and evaluating system expansion needs in the Okanagan area.	FEI continues to monitor and evaluate the Interior Transmission system and expects a system capacity constraint to occur in 2023, with contingency planning for 2021 and 2027. Section 6.3.3 discusses this analysis.

15 In 2014, FEI used the term Energy Efficiency and Conservation (EEC) to specifically refer to FEI programs whose expenditures fall under the BC Demand-Side Measures Regulation (DSM Regulation). FEI has updated this name to C&EM. Please see Section 4.1 for further details.

16 The 2017 LTGRP refers to FEI's future applications to the BCUC for approval of C&EM expenditures simply as the C&EM expenditure schedule.

17 FEI Application for Approval of a Multi-Year Performance Based Ratemaking Plan for 2014 through 2018 ~ Project No.3698715. http://www.bcuc.com/ApplicationView.aspx?ApplicationId=400.

18 http://www.ordersdecisions.bcuc.com/bcuc/orders/en/item/119195/index.do.

19 OIC 557 (BC Reg. 245/2013, Direction No. 5 to the Commission);
OIC 749 (BC Reg. 265/2014, amendment to Direction No. 5 to the Commission);
OIC 162 (BC Reg. 115/2017, amendment to Direction No. 5 to the Commission).

Action Item	Status
8. Protect and promote the interests of the Utility’s customers by securing a reliable, cost-effective long term gas supply.	• FEI has begun to secure the basis differential between the Station 2 and AECO/NIT price for term supply delivered at Station 2, for a period not exceeding three years, and within a confidential target pricing level. FEI’s strategy to layer in its monthly indexed gas over a period of time is important because the Station 2 to AECO/NIT monthly discount/premium can change significantly over the course of a few months, which is reflective of ongoing changes in the marketplace. • FEI actively participated as an intervener in a number of facilities applications proposed by NOVA Gas Transmission Ltd. (NGTL) for construction in Northeast BC (NEBC). After reviewing the North Montney Project and the Towerbirch Expansion Project, FEI raised concerns with the National Energy Board (NEB) about the lack of cost accountability by shippers requesting these facilities and the risk that supply could shift away from the Westcoast Energy Inc. (Westcoast) T-North system if these facilities were constructed. In the North Montney Project report, the NEB agreed with FEI, and other opposing interveners, that NGTL’s toll method does not properly price some new facilities. The NEB ordered NGTL to either develop and seek approval for a new toll method for the facilities or to toll these facilities on a stand-alone basis. Although the NEB did not agree with FEI’s objections to the Towerbirch Expansion project, it indicated that it was considering the potential for an inquiry into toll and competition matters in NEBC. If such an inquiry is held, FEI will be an active participant in that process. FEI continues to monitor developments in NEBC in order to identify issues with new proposed infrastructure and is working with regional stakeholders to develop suitable solutions. • The landscape of producers that are developing natural gas production in NEBC is continually changing. Many of the traditional gas producers that FEI had established relationships with have either sold their assets or reduced their development in NEBC. Over time, they were replaced by an influx of companies that acquired assets, specifically in the Montney Region. FEI has developed relationships with many of these companies and has successfully established multiple gas purchasing agreements with them. • FEI on a continuous basis evaluates the regional infrastructure that delivers natural gas to FEI’s system. This assessment of infrastructure in the regional marketplace has gained prominence over recent years as major industrial project proponents evaluate the south coast of BC and the US states of the PNW to set up plants to develop products such as LNG and methanol. Please see Sections 5.2 and 5.3 for FEI’s discussion of the potential regional impact of such projects.

The actionable items that FEI intends to pursue over the next four years are provided in Section 9 of this 2017 LTGRP.

1.6 *ORDER SOUGHT AND PROPOSED REGULATORY PROCESS*

FEI submits this 2017 LTGRP under Section 44.1(2) of the UCA. FEI is not seeking approval of any particular elements identified within the plan—any future requests for approval will be submitted under a different section of the *Act*. FEI submits that this 2017 LTGRP demonstrates that FEI has met the requirements of the UCA and the Commission's directives provided in the 2014 LTRP Decision and has followed the BCUC Resource Planning Guidelines. The Commission should accept this 2017 LTGRP under Section 44.1(6) of the UCA. A draft Order is attached as Appendix G-1.

The Company submits that a written hearing is appropriate for the review of the 2017 LTGRP and proposes the following regulatory timetable, which includes two rounds of Information Requests. An alternate timeline is also proposed in the event that interveners in the review of the 2017 LTGRP wish to file evidence. A draft Procedural Order is attached as Appendix G-2.

Table 1-7: Proposed Regulatory Timetable

ACTION	DATE	
	2018	
Commission Issues Procedural Order	Friday, January 5	
FEI Publishes Notice of Filing by	Friday, January 26

2. PLANNING ENVIRONMENT

2.1 INTRODUCTION

Like the 2014 LTRP, FEI is submitting this 2017 LTGRP during a time of continued change and uncertainty in market forces, energy technology and government policy. A wide range of factors influence FEI's long term analysis and planning decisions. This section discusses a number of the factors that the Company believes are among the most important. It provides relevant context for the analysis, results and recommendations that are made throughout the LTGRP to address the requirements for resource planning within the UCA. The remainder of this section is organized as follows:

- Section 2.2 discusses the competitive environment for natural gas which is influenced not only by regional energy markets and commodity pricing but also by supply infrastructure availability and end-use equipment installation and operations;
- Section 2.3 discusses the policy and regulatory context which provides the framework through which FEI's customers' energy needs are delivered and which can heavily influence the energy choices that consumers make.
- Section 2.4 discusses FEI's customer solutions.

The natural gas supply outlook looks different than it did even a few years ago. Horizontal drilling and hydraulic fracturing technologies have unlocked the potential of North America's vast shale gas deposits, which has led to a significant growth in supply and lower commodity prices than in recent years. As a result of the supply growth, governments across Canada, the PNW and North America more broadly, are looking to take advantage of the environmental, social and economic benefits of using natural gas. Natural gas is increasingly viewed as a fuel that can be used to help reduce GHG emissions by displacing more carbon-intensive coal-fired power generation, providing firm backup for renewable energy, and more recently, by displacing dirtier fuels such as diesel and gasoline in transport applications.

While governments across North America were keen to introduce climate and green energy policies in recent years, today's setting is more uncertain in light of a changed administration in the US. Uncertainty also exists about long term energy policy in BC after a 2017 provincial election and resulting change in government. This uncertainty is compounded, on the one hand, by discussions in various North American jurisdictions about energy affordability and potential negative economic impacts of stringent energy and emissions policies. On the other hand, this discussion also includes voices which support initiatives to mitigate emissions from natural gas upstream activities and which express concern about the long term climate impacts of methane emissions. Actions to address these latter issues pose the risk of upward pressure on natural gas prices.

New energy technologies and gains in energy efficiency have led the way to changing natural gas use, particularly as customers look for innovative solutions and improved information about energy and consumption patterns. Energy consumers are increasingly faced with numerous energy services and equipment choices, often with conflicting information with which to make decisions that have a long term impact on energy consumption. New energy technologies and energy production at or near the end use are also beginning to create challenges for the traditional utility model. These new, efficient technologies are changing energy use patterns, making it difficult to accurately predict how such factors may influence the demand for natural gas or its competitive position in the long term. To help maintain the competitiveness of natural gas rates for customers, FEI continues to focus on growing its customer base, adding efficient load to the natural gas system, and delivering energy solutions which address customers' GHG emissions concerns, such as through FEI's NGT and RNG initiatives.

2.2 *COMPETITIVE ENVIRONMENT FOR NATURAL GAS*

The competitive environment for natural gas is influenced by factors that affect the full value chain for energy services. Section 2.2.1 discusses issues that affect natural gas production and supply (upstream), infrastructure (midstream) and end uses (downstream). While technological advancements have contributed to a supply boom and low price environment, a number of other factors beyond commodity cost influence the competitive position of natural gas relative to other forms of energy.

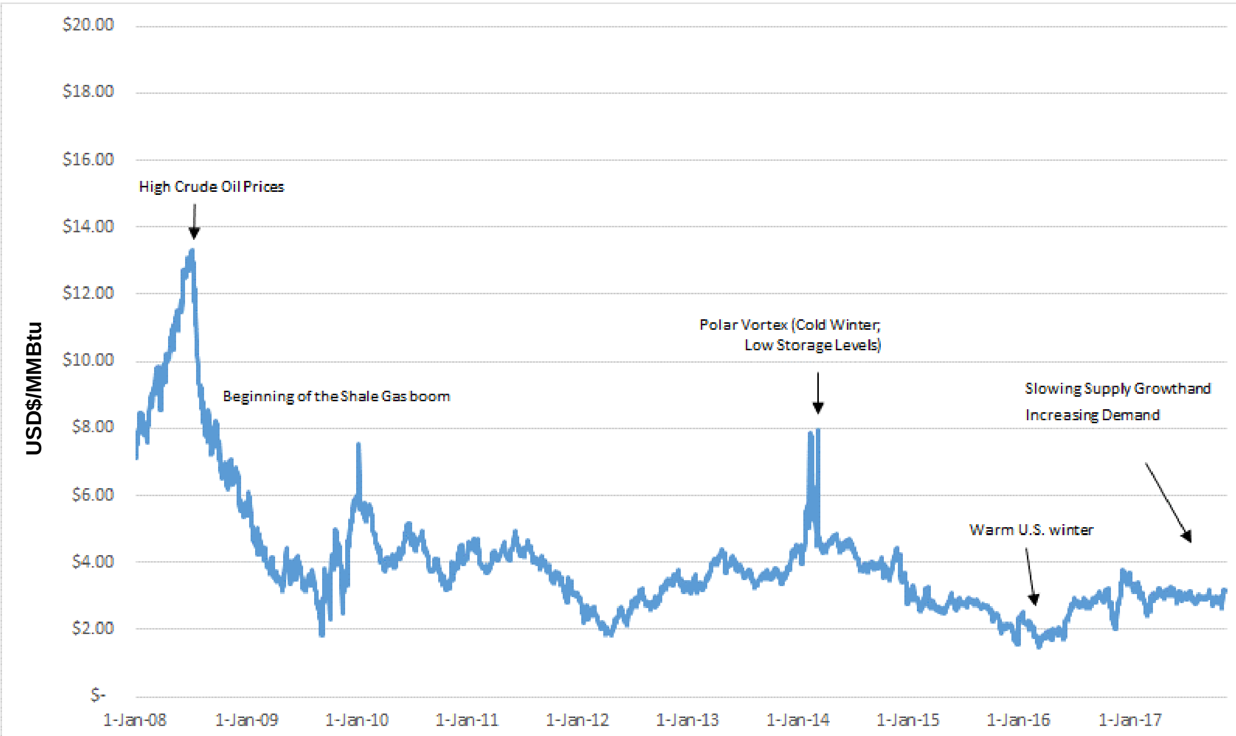
2.2.1 Market Dynamics and Commodity Pricing

The North American natural gas market remains in a low commodity pricing environment which is expected to continue for several years to come. These low commodity prices are attributed to significant changes that have occurred in the North American natural gas market since the temporary high market natural gas prices experienced in 2008. The advancement in drilling technology, specifically the use of hydraulic fracturing in conjunction with horizontal drilling, sparked an 'unconventional natural gas revolution' in the production of natural gas that has unlocked an abundance of gas supply. The surge in associated gas from liquids and oil production has also contributed to this gas supply growth. The dramatic increase in North American production has outpaced consumption, causing natural gas commodity prices to decline. Advancement in drilling technology has redrawn the North American supply map by increasing production in the US Northeast (e.g. in the Marcellus play), effectively decreasing demand for Canadian supply. The low commodity prices have created significant opportunities for increased natural gas use, particularly in power generation, LNG export potential, and the use of natural gas by the transportation and industrial sectors. In 2017, prices are rising due to some increased demand from these and other drivers as well as slowing supply growth.

Henry Hub is the official pricing point for natural gas futures on the New York Mercantile Exchange (NYMEX) and is used as the benchmark for the North American natural gas market. The significant growth of shale gas supply in recent years has resulted in a significant drop in natural gas prices. Prior to the shale gas revolution, NYMEX prices were typically trading above

USD$6.00 per MMBtu[20], however since then prices have dropped back down, currently trading around USD$3.00 per MMBtu as of June 1, 2017. This is illustrated in Figure 2-1.

Figure 2-1: Henry Hub Historical Natural Gas Spot Prices[21]



As Figure 2-1 shows, since the 2013/14 polar vortex, natural gas prices dropped to historically low levels, due to a significant imbalance in the supply/demand fundamentals. Gas production in North America increased significantly at a time when demand was relatively flat, resulting in an oversupply of gas. Natural gas prices dropped to as low as USD$1.48 per MMBtu on March 5, 2016, the lowest daily settlement price for NYMEX since 1998.[22] This oversupply of gas continued throughout the summer and fall of 2016, testing the limits of gas storage inventories in North America. The US Energy Information Administration (EIA) reported on November 17, 2016, that total US gas in storage reached a record high of 4,047 billion cubic feet (Bcf) for the week ending November 11, 2016.[23] However since that report, prices have recovered somewhat, as a slowdown in supply growth and increasing industrial demand, US LNG exports, and exports to Mexico, have started to re-balance the market.

NYMEX natural gas prices are expected to remain low over the medium to long term, ranging between USD$3.00 to USD$4.00 per MMbtu until 2025.[24] Regional prices may likely be even lower as Alberta (AECO/NIT) and BC (Station 2) prices are forecasted to continue to trade at a

[20] MMBtu is defined as one million British Thermal Units.
[21] Platts. “Platts Gas Daily Market Fundamentals”. https://www.platts.com/products/gas-daily.
[22] Ibid.

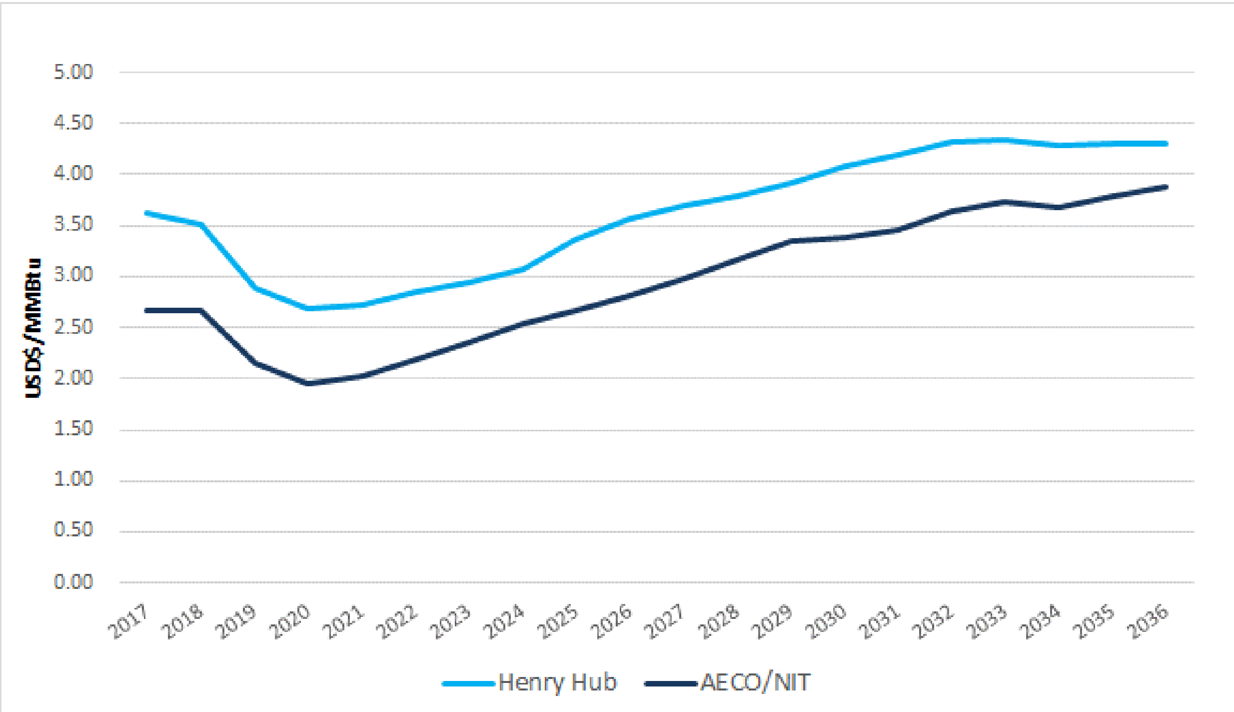
[24] Wood Mackenzie (Jan 2017). “United States gas long-term outlook H2 2016”.

significant discount to the Henry Hub price. One of the major reasons that prices are lower in Western Canada relative to the NYMEX is due to increasing supply coming from the US Northeast, which continues to displace traditional gas markets served by Western Canadian supply. (Regional gas market developments are discussed in more detail in Section 5.2). Figure 2-2 shows Wood Mackenzie's long term price forecast for natural gas based on the NYMEX and AECO/NIT market in nominal dollars.

Figure 2-2: Natural Gas Price Forecast (2016 USD$)[25]



With an abundance of gas supply, North American natural gas became more economically attractive relative to other fuel sources as it was significantly disconnected from other competing fuels, such as heating and fuel oil. This was particularly evident in 2012 when natural gas prices traded around USD$2.80 per MMBtu, while crude oil prices were trading over USD$100 per Barrel, which is equivalent to around USD$17.00 per MMBtu. However, a few years later this disconnect from other competing fuels decreased, as oil prices collapsed, dropping below USD$30 per Barrel (approximately USD$5.00 per MMBtu) in early 2016.[26] This narrowing spread between natural gas and competing fuels has had a major impact on both North American natural gas supply and demand.

Figure 2-3 sets out prices (historical prompt month and futures, on a USD$/MMBtu equivalent basis)[27] for various fuels that compete with natural gas, as of June 1, 2017. As Figure 2-3

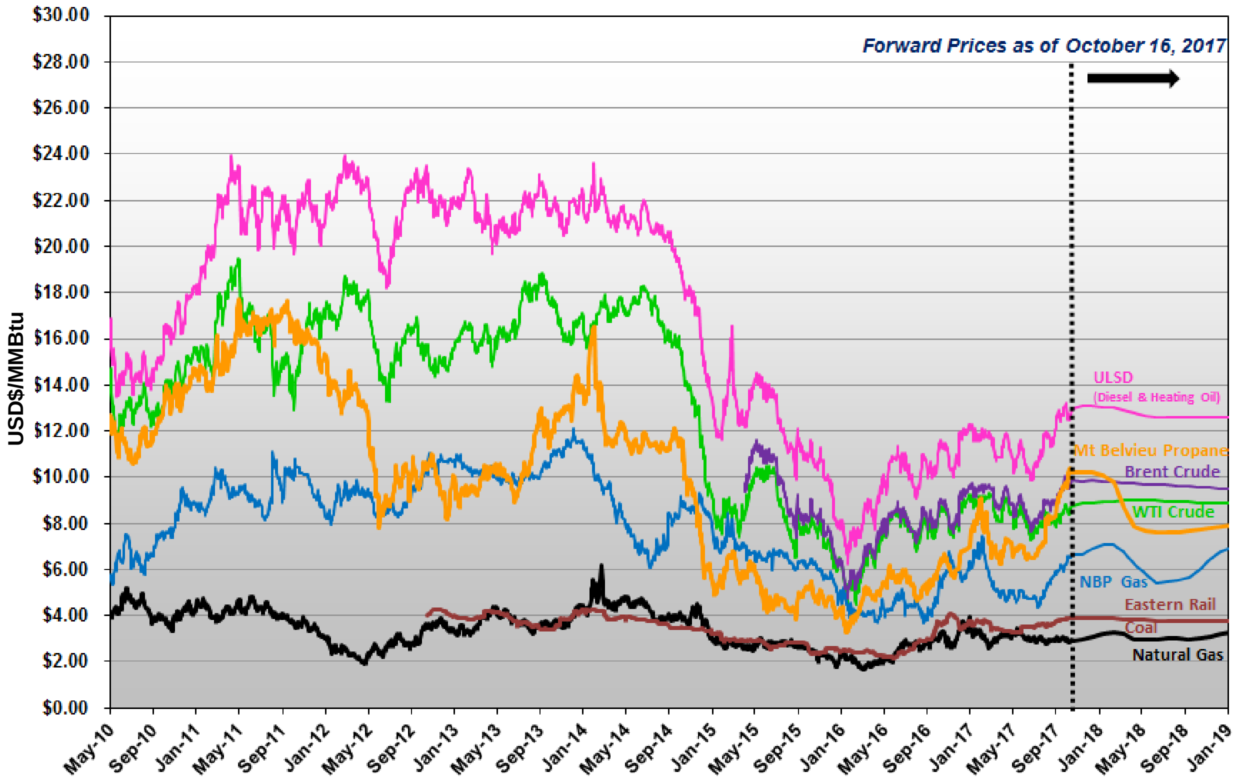
25 Wood Mackenzie (November 30, 2016). "United States gas long-term outlook 2016".

26 CME. http://www.cmegroup.com/trading/energy/.

27 Commodities futures are agreements to buy or sell a raw material at a specific date in the future at a particular price. Prompt-month prices refer to prices of the futures contract that is closest to expiration and is usually for

shows, prices have recovered somewhat since the winter of 2016. The increase in crude oil prices since early 2016 has been due to attempts by OPEC to re-balance the global supply and demand fundamentals by limiting production but recent US inventory levels continue to rise and mitigate the impact of OPEC production cuts. Due to the surge in North American oil production, it is not expected that oil prices will rise back to 2012 levels in the next five years.

Figure 2-3: Competing Fuel Prices[28]



2.2.1.1 Natural Gas Supply

The North American natural gas market continues to be influenced by the abundance of shale gas supply due to the rapid development of unconventional natural gas reserves. The rapid increase in domestic supply is a result of efficient drilling technologies and associated gas from oil and natural gas liquid plays. Significant improvements have been made to two essential technologies, horizontal drilling and hydraulic fracturing[29], that are used to unlock natural gas trapped in shale formations. These technological achievements have resulted in major production cost reductions, allowing producers to continue to drill despite the lower natural gas price environment. Market analysts believe a rig operating in 2016 delivers over two times as much gas as a rig operating in 2013. The use of horizontal drilling and hydraulic fracturing will

---

delivery in the next calendar month; historical prompt-month data thus records the actual historical prices of these prompt-month contracts.

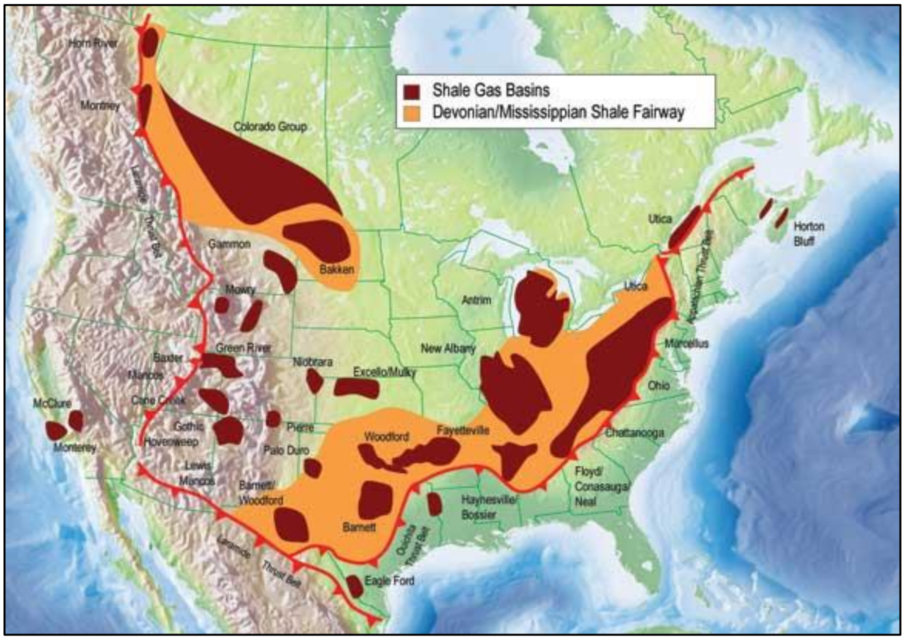
[28] US EIA & CME Group. (March 31, 2017).

[29] Appendix D-1: https://www.eia.gov/todayinenergy/detail.php?id=2170.

be increasingly critical in the future for accessing the natural gas potential of North America's shale basins. The potential resource in these basins will be needed in order to continue maintaining production growth in the future.

The shale gas potential in North America is significant. Not only is gas supply abundant, shale gas supplies are located throughout North America, providing cost effective supply within close proximity to many major load centres. Figure 2-4 shows the key North American shale gas regions.

Figure 2-4: North American Shale Gas Plays[30]



There is tremendous shale gas potential in Canada and it ranks globally in the top five countries with recoverable shale gas reserves. The majority of it is located in the Western Canadian Sedimentary Basin (WCSB), which extends from NEBC to southwest Manitoba. This area includes Horn River, Montney, Liard, Cordova, and Duvernay gas plays. In a joint study conducted by Canada's National Energy Board (NEB), Yukon Geological Survey, the Northwest Territories Geological Survey, and the British Columbia Ministry of Natural Gas Development it was reported that the estimated total potential of marketable gas in the WCSB (discovered and undiscovered) is now 1,051 trillion cubic feet (Tcf).[31] This estimation is 230 Tcf higher than the NEB's previous estimate in 2013 of 821 Tcf.[32] This number could continue to climb, as additional unconventional potential may be found in other formations over time.

In the US, the supply increase will be driven by the Mid-Atlantic's Marcellus shale formation. Output from the Marcellus continues to grow and will likely continue to increase as new and

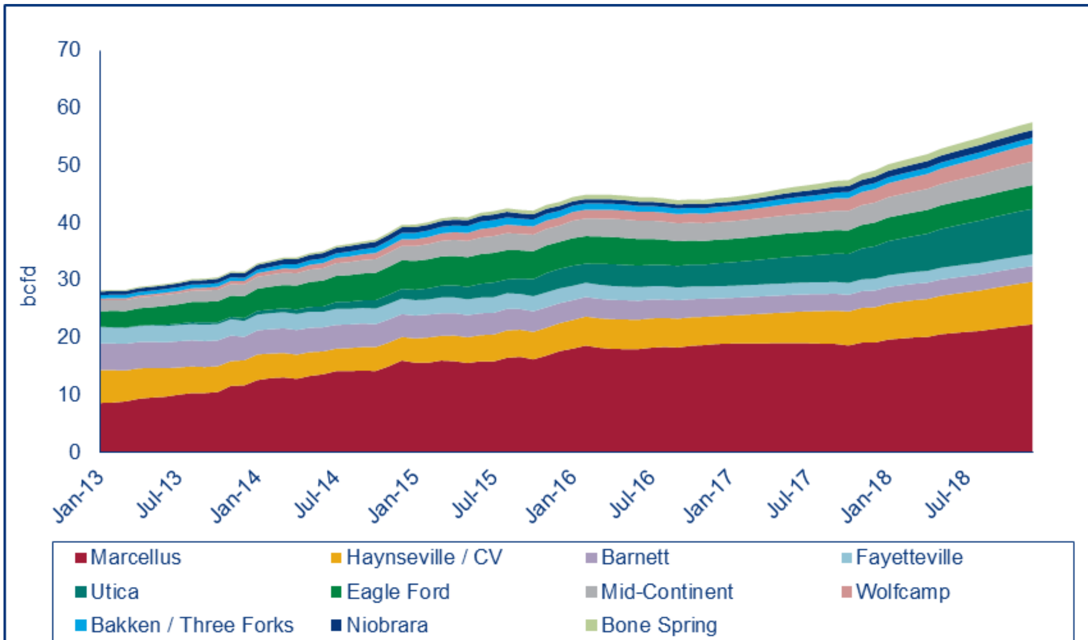
planned pipeline transport capacity and processing plants allow for more Marcellus gas to come online. Figure 2-5 shows how quickly the Marcellus production capacity has expanded since 2013.

Figure 2-5: US Natural Gas Production[33]

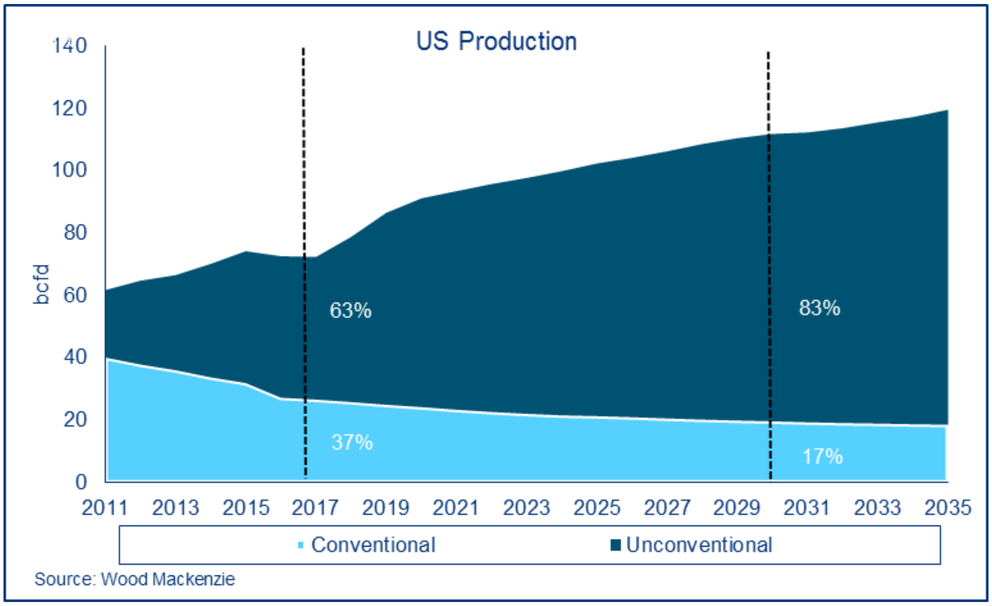


Source: Wood Mackenzie

Supplies from unconventional resources, specifically shale gas, have quickly become the most significant contributor to growth in production. As illustrated in Figure 2-6 below, unconventional gas, which accounted for 35 percent of US natural gas production in 2011, now accounts for 63 percent and is forecasted to account for 83 percent of US natural gas production by 2030. Contributions from conventional gas plays are expected to decline from 37 percent in 2016, to less than 17 percent by 2030.

[33] Wood Mackenzie (Jan 2017). “North American Gas Short Term Energy Outlook”.

Figure 2-6: US Production by Type[34]



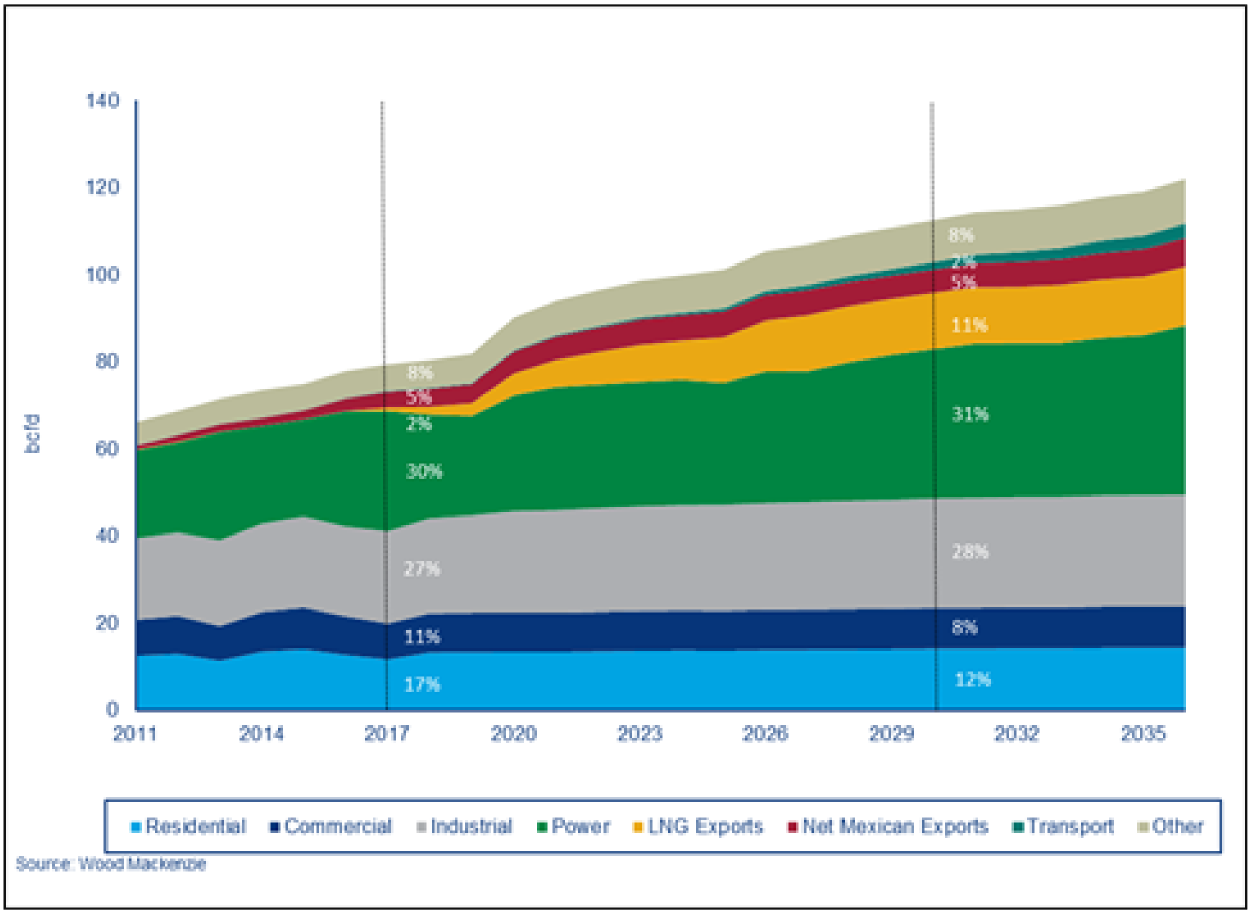
2.2.1.2 Natural Gas Demand

The low price of natural gas in recent years has been a key driver for its increased usage across North America. Over the past several years, industrial demand, specifically from the petrochemical sectors and US gas exports to Mexico, has been increasing the demand for natural gas. The market is also seeing increased natural gas demand from the power sector due to more switching from coal to natural gas electricity production, as well as from the retirement of coal plants. Furthermore, new incremental demand from US LNG being exported overseas will continue to increase in the coming years.

Figure 2-7 provides a demand forecast for US residential, commercial, industrial, power, NGT, other demand components (including lease, plant, and pipeline fuel), and LNG export demand out to 2035. Demand in the longer term is expected to grow steadily, with gas demand for power generation expected to be the largest contributor by 2030. In addition, the development of the LNG export sector is expected to eventually account for about 11 percent of total US gas demand by 2030. The overall increase in US gas demand is being met with supply from the US Northeast and is resulting in less demand for Canadian regional market exports to the US. This pushback of supply in Canada has resulted in lower natural gas prices for BC and Alberta, relative to most market prices in the US, which is discussed further in Section 5.1 (Regional Market Developments).

[34] Wood Mackenzie (Nov 2016). “North America gas long-term outlook data 2016”.

Figure 2-7: US Natural Gas Demand[35]



2.2.2 Competitive Environment in BC for Energy End Uses

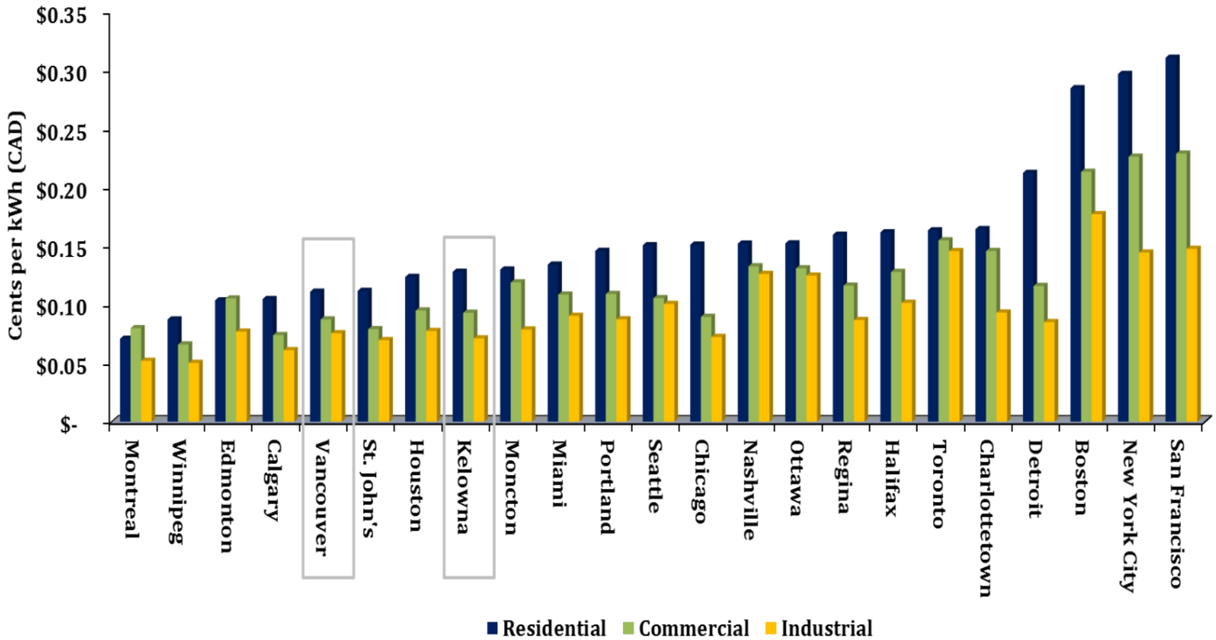
The relatively new abundance of natural gas supply in North America and recent low price levels have positively impacted the commodity's competitiveness with other sources of energy. The low price environment has improved the price competitiveness of using natural gas on an operating cost basis, though natural gas direct use applications (such as space and water heating) typically require higher capital, installation and maintenance costs than electric appliances. Since the competitiveness of low carbon thermal energy systems is determined on a case-specific basis as explained in Section 2.2.2.3, FEI needs to better understand how these new end-use technologies are impacting natural gas demand and use patterns (Section 3 provides information on how FEI is incorporating changing end-use trends into long term demand forecasts). A multitude of factors beyond those relating to commodity cost influence consumer, builder and developer preferences relating to the use of natural gas versus other sources of energy. Capital costs, installation requirements, operating and maintenance costs, government policies (outlined in Section 2.3) and public perception all play a role in this regard.

35 Wood Mackenzie (November 2016). "North America Natural Gas Long-Term View".

2.2.2.1 Natural Gas and Electricity Rates

Electricity rates in BC are among the lowest in North America (illustrated in Figure 2-8) and since 2010, the province's CEA has defined a provincial objective to "ensure the authority's rates remain among the most competitive of rates charged by public utilities in North America."

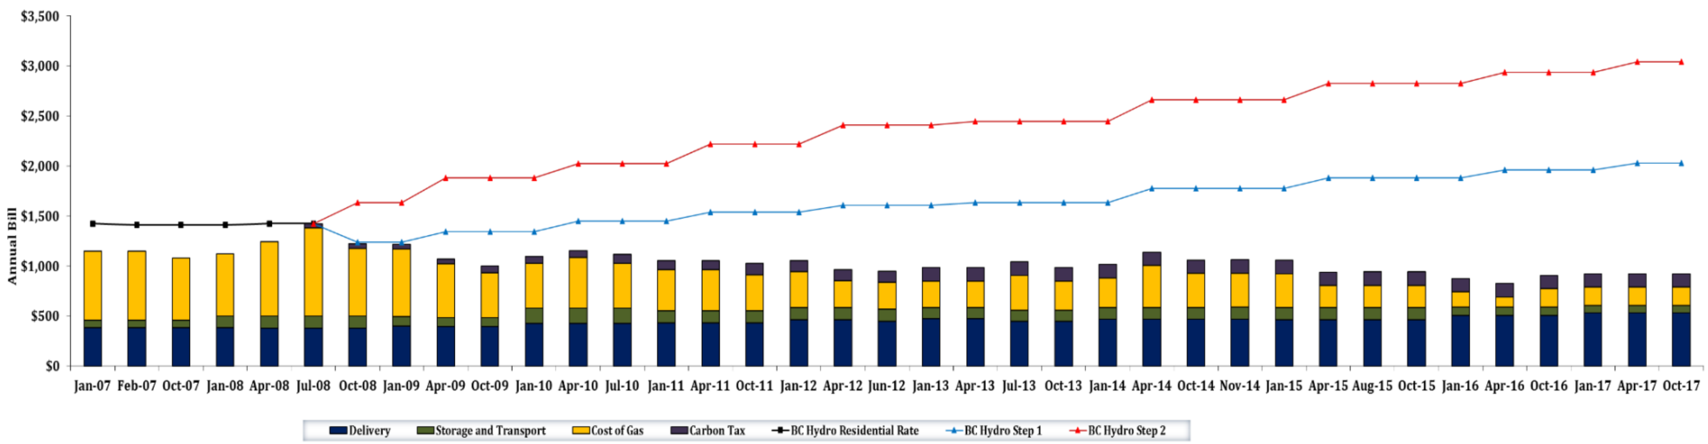
Figure 2-8: Electricity Rate Comparison Across Jurisdictions in North America[36]



In the past, low electricity rates have contributed to a competitive challenge for natural gas in BC, but the decline in gas commodity cost and increases to electricity rates in BC in recent years has helped to improve the competitiveness of natural gas. Figure 2-9 provides a historical comparison of the cost for space heating and domestic hot water for natural gas (based on consumption of 90 gigajoules (GJ) per year and 90 percent efficiency) versus electricity (assuming 100 percent efficiency) for an FEI residential customer in the Lower Mainland. This chart demonstrates that today's natural gas rates are cost competitive with electricity rates.

36 Hydro-Québec's Comparison of Electricity Prices in Major North American Cities, effective April 1, 2017; FEI added comparable Kelowna (FBC) rates.

Figure 2-9: FEI Lower Mainland Residential Natural Gas Cost for Space Heating and Domestic Hot Water[37]



37 This illustration assumes natural gas use of 90 GJ and the efficiency of gas equipment is 90 percent relative to 100 percent for electric equipment. FEI amount includes the basic charge; BC Hydro amount does not include basic charge since a household already pays the basic electric charge for non-heating use. The annual amounts include only space heating and water heating load. For the BC Hydro Step 1 annual amount, all natural gas-equivalent electricity consumption is assumed to be accounted for under Step 1; similarly, the BC Hydro Step 2 annual amount assumes all natural gas-equivalent electricity consumption to be accounted for under Step 2. Pleas note that households may actually experience a blended rate, depending on their total electricity consumption.

Figures 2-10 and 2-11 below illustrate the price difference per kilowatt hour energy unit between FEI natural gas, a 100 percent blend of FEI RNG, and BC Hydro's commercial general service and residential Step 1 and Step 2 electricity rates, respectively. RNG is more costly than conventional natural gas but it is also a clean and renewable fuel type that is less expensive than the electric alternative.

Figure 2-10: Lower Mainland Residential Energy Cost Comparison ($/kWh)

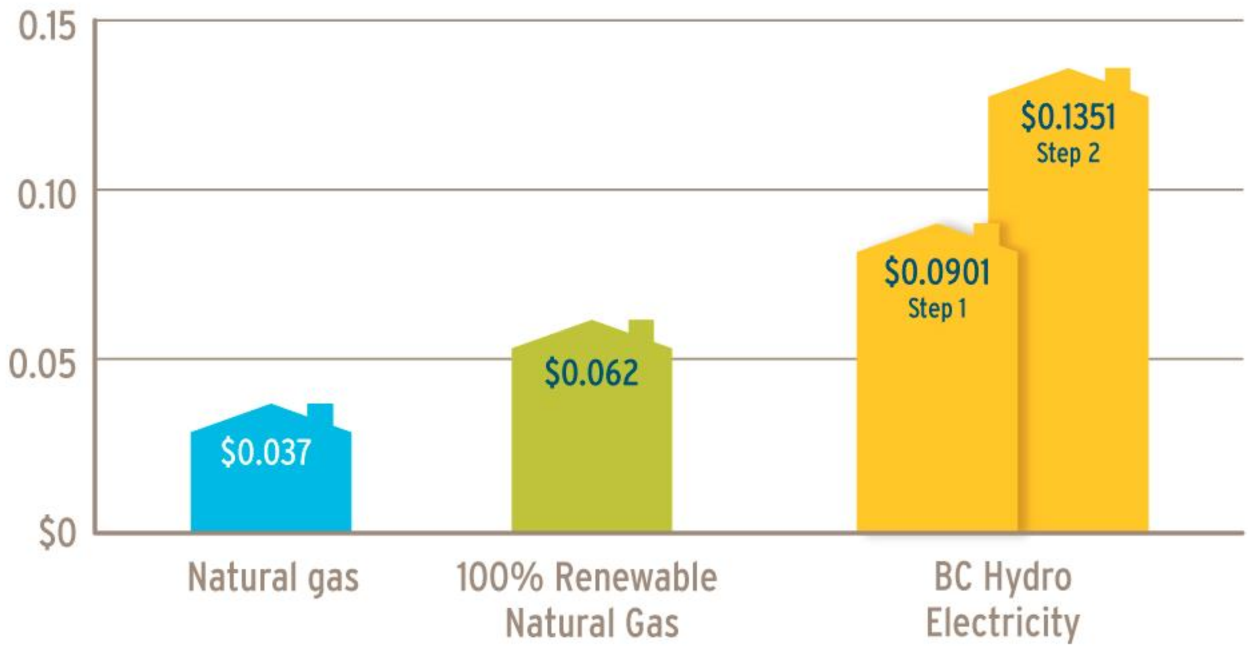


Figure 2-11: Lower Mainland Commercial Energy Cost Comparison ($/kWh)

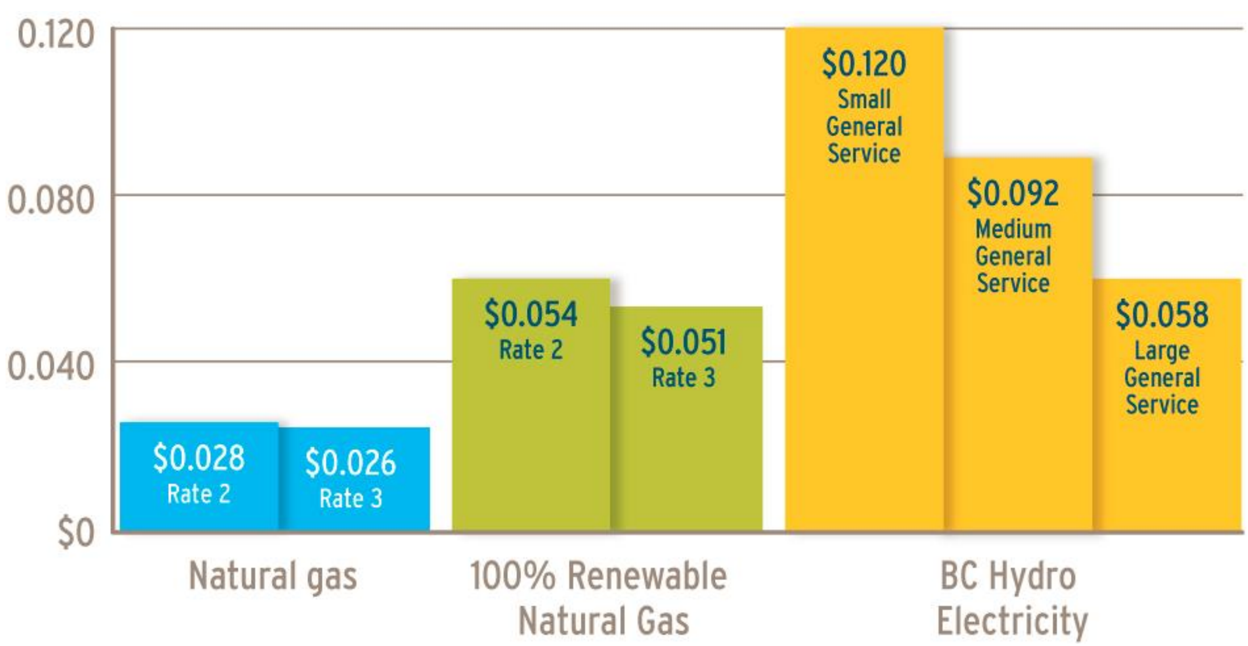


While today's low natural gas rates contribute to a natural gas operating cost advantage relative to electricity, FEI believes that commodity price is only one factor that impacts the price competitiveness of natural gas in BC relative to electricity. Other factors include natural gas price volatility (discussed in the Regional Market Overview, Appendix A) and the installation costs of natural gas appliances relative to electric appliances.

2.2.2.2 Installation and Operation

Capital costs related to natural gas equipment (such as furnaces, ducting and hot water tanks) tend to be costlier than those relating to electric resistance heating equipment (such as electric baseboard heaters and hot water tanks). In retrofit situations, ducting requirements for high efficiency equipment are making the installation of natural gas equipment more difficult and costly. In both retrofit and new construction situations, venting requirements may also increase the difficulty and cost of installing high efficiency natural gas equipment. In addition, it is often not the end user that makes decisions regarding energy sources installed in the home: builders and developers are the primary decision makers regarding the choice of energy and equipment used in new construction. As builders and developers do not ultimately pay operating costs, they tend to be more influenced by capital costs alone. In addition, builders and developers typically aim to maximize the useable square footage available in a development to maximize the return on investment, particularly for multi-unit residential developments. Thus, capital cost savings and the ability to sell more useable living space incents developers and builders to install electricity equipment over natural gas equipment in new developments. The upfront capital cost difference for installing natural gas equipment has been identified by the American Gas Association as the "primary impediment to natural gas use in residential and commercial buildings if service can be made available."[38]

Table 2-1 provides an example of the upfront installation (capital) cost difference associated with natural gas versus electricity for a space heating furnace and hot water tank in new construction for FEI residential customers. The difference in upfront capital costs between gas and electricity means that over the life of the appliance, the operating cost advantage of natural gas over electricity must be significant ($13.84/GJ for space heating and $5.25/GJ for water heating) for the equipment to be economic to the consumer. As outlined in Figure 2-10 above, the current price differential between natural gas and BC Hydro Step 1 is $14.75 per GJ; this differential increases to $27.85 per GJ when compared to BC Hydro Step 2. When comparing a 100 percent nominal blend of RNG to BC Hydro Step 1, the differential declines to $7.81 per GJ but increases to $20.31 per GJ when compared to BC Hydro Step 2.

[38] American Gas Association (2012). "Squeezing Every BTU: Natural Gas Direct Use Opportunities and Challenges". p. 32.

Table 2-1: Capital Cost Difference for Space and Water Heating – Natural Gas vs. Electricity[39][40]

	Space Heating	Water Heating
Capital costs for natural gas	$9,000	$2,000
Capital costs for electricity	$4,435	$1,000
Upfront capital cost premium for natural gas compared to electricity	**$4,565**	**$1,000**
Annual difference in capital costs[41]	$422	$116
Annual difference in maintenance costs	$100	$0
Total annual difference in capital and maintenance costs	**$522**	**$116**
Energy consumption per year (GJ)	38	22
Difference in capital and maintenance costs over measurable life ($/GJ)	**$13.84/GJ**	**$5.25/GJ**

The higher upfront capital cost of natural gas end-use applications reduces the cost advantage of natural gas compared to electricity and plays an important role in influencing customer energy choice. FEI recognizes that factors other than pure economics can influence customer decisions. Nevertheless, FEI expects the capital cost difference between natural gas and electricity to continue into the foreseeable future, which highlights the need to develop solutions (such as working with key energy influencers and contributing to the commercialization of innovative natural gas use technologies, discussed in Section 2.4) to address this challenge.

2.2.2.3 Competition from Low Carbon Thermal Energy Systems

Numerous new end-use technologies have entered the energy services marketplace in recent years and will likely continue to do so throughout the 20-year planning horizon of this LTGRP. In addition to advancements on both natural gas- and electricity-based heating equipment, advancements in low carbon thermal energy solutions have emerged to take a small but growing slice of the market. Examples of low carbon thermal solutions include air and ground source heat pumps for single family residences; geo-exchange and biomass energy systems that can serve one or more multi-family developments; and district energy systems that can employ one or more renewable energy systems such as waste heat from industrial processes, geo-exchange technologies, or biomass solutions often in combination with natural gas-fired heating solutions. FEI needs to continue to monitor how these low carbon thermal solutions are impacting natural gas demand (outlined in Sections 3 and 8) and how they are

39 Assumptions based on the new construction of a 3,000 sq. ft. home in the Lower Mainland.

40 FEI explored expanding this comparison to include electric heat pumps. It is important to note that the performance of heat pumps greatly varies depending on the manufacturer, especially over a seasonal profile. This also explains why a simple comparison using the printed chart is not an appropriate comparison and shall not be used to draw conclusions as to how a natural gas based system performs against a heat pump system.

41 Represents the difference in capital costs per year, assuming a stream of equal annual payments with an interest rate of 6 percent and measurable life of 18 years for a space heating furnace and 13 years for a hot water tank.

changing the way FEI's customers are using natural gas. These growing changes indicate that the traditional utility model may potentially shift over the long term.

The competitiveness of any given low carbon thermal energy system with that of a natural gas only system is case-specific. In some cases, high quality renewable energy sources are readily available and in close proximity and match the needs of a residential or commercial development. In other cases, the low carbon thermal energy source may not be as well-matched or close to the energy plant, which increases the costs of installation and operation. Generally speaking, capital costs for low carbon thermal systems are higher than capital costs of non-renewable systems, while the commodity cost can range from zero for heat extracted from the ground, to much higher for biomass, depending on market conditions. These and other factors can result in a low carbon thermal solution being more cost effective than a natural gas system in some cases, and less so in other cases. Adding to the difficulty in understanding how these solutions will impact natural gas demand over time, the decision to choose a low carbon thermal energy solution is often not purely based on cost of the system. A homeowner or developer might choose to invest in such a system based on air emission reductions, perceived impact on resale value, municipal development requirements or other reasons. The willingness of the system owner to incur higher capital costs at the outset versus potentially lower operating costs over the long run can also impact the decision to install these systems.

How these factors will affect the rate at which low carbon thermal systems enter the BC end-use energy market place remains unknown. This LTGRP has therefore incorporated a range of market penetration assumptions into the forecast scenarios for annual demand (described in Section 3).

2.2.3 Summary

The proliferation of shale gas development in North America and recent low price levels continue to influence the competitiveness of natural gas with other sources of energy. Changing market dynamics are likely to impact regional gas flows and prices, particularly as new industrial, power generation and oil sands demand have the potential to affect the availability and cost to obtain gas supply for BC and PNW markets. Although market developments have improved the competitiveness of natural gas on an operating cost basis, the higher upfront capital costs of natural gas installations and appliances can negatively influence the competitive position of natural gas relative to other energy forms, such as oil, propane, electricity and possibly low carbon thermal energy. These factors combine with government policy (discussed below) to influence customer perception, energy choice and energy technology adoption.

2.3 ENERGY AND EMISSIONS POLICY

2.3.1 Canada

Overall, the Government of Canada supports using natural gas for export markets but support for continued growth in domestic use is limited to market segments where natural gas can displace higher emitting fossil fuels. This creates risks of a downward pressure on demand in buildings but also generates opportunities for natural gas demand to grow in exports and other sectors such as transportation, where natural gas can displace more carbon intensive fuels.

The government's policy frameworks, budget documents and public statements reflect this approach. On January 19, 2017, in a response to the interim report of the Standing Committee on Natural Resources, the government notes:

> Resource industries have, and must continue to make vital contributions to the prosperity of Canadians. Today, Canada is among the world's largest oil and gas producers and exporters and we expect to continue to play a significant role in meeting global demand for energy. Accessing strategic markets ensures Canadians receive full value for our resources; resources which can fund the next generation of renewable energy. The Government believes that resource development and environmental protections must go hand in hand, and that collaboration with stakeholders is essential to developing resources in a manner that maintains public trust.[42]

In March 2016 at a First Ministers' Meeting, the government started developing the Pan-Canadian Framework on Clean Growth and Climate Change (the Framework). This Framework intends to support a path for Canada to reduce its GHG emissions by 30 percent below 2005 levels by 2030 (in May 2017, the Government of Canada reaffirmed its commitment to this reduction path under the Paris Agreement).[43] The Government of Canada and Canadian provinces (apart from Saskatchewan) formally adopted the Framework in October 2016.[44] The framework itself represents a planning document rather than mandatory regulation or statute.

The government expects emissions reductions within the Framework to break down as follows:

- 41 percent will derive from federal regulations and provincial measures that were announced by November 1, 2016, as well as international cap-and-trade credits. These include federal regulations for hydrofluorocarbons, heavy duty vehicles, and methane emissions as well as provincial renewables targets and climate action plans;

[42] Appendix D-4: http://www.parl.gc.ca/Content/HOC/Committee/421/RNNR/GovResponse/RP8710641/421_RNNR_Rpt02_GR/421_RNNR_Rpt02_GR-e.pdf.

[43] http://www4.unfccc.int/ndcregistry/PublishedDocuments/Canada%20First/Canada%20First%20NDC-Revised%20submission%202017-05-11.pdf

[44] Appendix D-5: https://www.canada.ca/en/services/environment/weather/climatechange/pan-canadian-framework.html.

- 39 percent will derive from measures in the Framework, such as phasing out coal-fired electric power generation by 2030, supporting building efficiency and transitions to electricity, and developing a federal clean fuel standard[45]; and
- The final 20 percent will derive from additional measures, such as investments in public transit, technology innovation and carbon stored in forests, soils and wetlands.

The Canadian government reinforced the Framework via its 2016 Mid-Century Long-Term Low-Greenhouse Gas Development Strategy.[46] This strategy includes the following substantiated actions:

- Enhancing inter-provincial interties to support decarbonisation of the electricity supply;
- Shifting end users, such as diesel-powered remote communities, to non-fossil energy sources;
- Encouraging building retrofits and behavioural changes; and
- Supporting development of cellulosic biogas as part of initiatives that target emissions reductions from land use and forestry.[47]

The Government of Canada's 2017 budget, tabled in the House of Commons on March 22, 2017,[48] provides further clarity on emissions reduction initiatives and reinforces the government's commitment to emissions reductions via electrification. This creates risk of downward pressure on natural gas demand. However, highlights from the budget also suggest opportunities for FEI's C&EM as well as CNG and LNG for Transportation programs:

- $182 million for advancing building codes and expanding Natural Resources Canada's mandate to support energy efficiency in buildings;
- Simplified and realigned technology innovation support programs, including re-capitalization of Sustainable Development Technology Canada with $400 million over five years and an additional $300 million in funding for renewable energy commercialization and demonstration;
- Doubled funding (from $60 million in 2016 to $120 million in 2017) for deploying alternative fuelling technologies;

[45] On December 13, 2017, the Government of Canada published a regulatory framework on the proposed clean fuel standard. The framework outlines the proposed scope, regulated parties, compliance options and regulation timing. The framework proposes for natural gas distribution utilities to be covered by the regulation. The framework proposes to select carbon intensity reduction targets after establishing baseline values. The Government of Canada plans to conduct additional consultations and aims for the regulation to come into force in mid-2019.

[46] Appendix D-6: http://unfccc.int/files/focus/long-term_strategies/application/pdf/canadas_mid-century_long-term_strategy.pdf.

[47] Appendix D-7: https://www.canada.ca/en/natural-resources-canada/news/2017/03/government_of_canadainvestsinrenewablenaturalgas.html?_ga=1.147080181.372773754.1489585450.

[48] https://www.budget.gc.ca/2017/docs/plan/budget-2017-en.pdf

- Approximately $60 million for Transport Canada to address GHG regulations in the marine, rail, aviation and vehicles sectors; and
- Approximately $18 million for Environment and Climate Change Canada and Transport Canada to develop heavy duty vehicle retrofit and off-road regulations as well as a clean fuel standard for reducing emissions.
- $160 million allocated to BC from the $2 billion Low Carbon Economy Fund to generate clean growth and reduce GHG emissions towards meeting or exceeding commitments under the Paris Agreement.

2.3.1.1 Canadian Carbon Price

As part of the Framework, the Government of Canada plans to implement a carbon pricing backstop mechanism. This mechanism sets the floor price of carbon at $10 per metric tonne in 2017 and increases to $50 per metric tonne by 2022. The backstop mechanism will be reviewed by 2022 (with a preliminary review by 2020) to confirm its path.

The backstop mechanism will apply to a common and broad set of sources which are substantively identical to the sources covered under BC's 2016 carbon tax. Provinces with existing cap-and-trade systems must set their 2030 target at least equal to the Canadian federal target from the Framework and their 2018-2022 emissions reductions trajectories must at least align with the reductions expected from the federal carbon price increases between 2018 and 2022.

On May 18, 2017 the Government of Canada released a technical paper on the backstop mechanism and invited commentary by June 30, 2017.[49] In addition to the backstop mechanism, the paper outlines an output-based pricing system for carbon intensive industries with annual emissions over 50 kilotonnes of CO_2 equivalent. The technical paper plans for this system to become effective in 2018.

At the time of writing, the federal backstop mechanism and the output-based pricing system have not been passed into law.

Outside of BC, six Canadian provinces have developed and implemented energy and emissions policy actions.

Section 2.3.3 discusses BC policy actions while Section 2.3.2 discusses the US and PNW policy context.

2.3.2 United States

The US policy context impacts the BC natural gas use environment in two ways. First, upstream natural gas resources in BC and Alberta serve US demand for natural gas for electricity

[49] Appendix D-8: https://www.canada.ca/en/services/environment/weather/climatechange/technical-paper-federal-carbon-pricing-backstop.html.

generation. However, increasing supply of natural gas from the US Northeast is expected to decrease demand for Canadian exports to the US as further discussed in Section 5.2. Second, US policy may influence Canadian policy due to potential impacts on the relative economic competitiveness of each jurisdiction.

Historically, US energy and emissions policy has influenced policy implementation in Canada. Canada signed the Kyoto Protocol but did not implement strong policy actions in pursuit of its Kyoto emissions reduction target during a time when the US withdrew from the Protocol.

Some uncertainty still exists about the direction of US energy and emissions policy under the current administration. The US administration has declared that it will facilitate energy infrastructure projects and reduce environmental regulations but has, at times, taken contradictory positions on energy and emissions policy. Some actions of the US administration indicate that the US intends to implement its declared goals on energy infrastructure projects and environment regulations. Such implementation will be intermediated by US states (e.g. in the case of infrastructure projects), federal regulatory bodies (e.g. the Federal Energy Regulatory Commission), and the US judiciary.

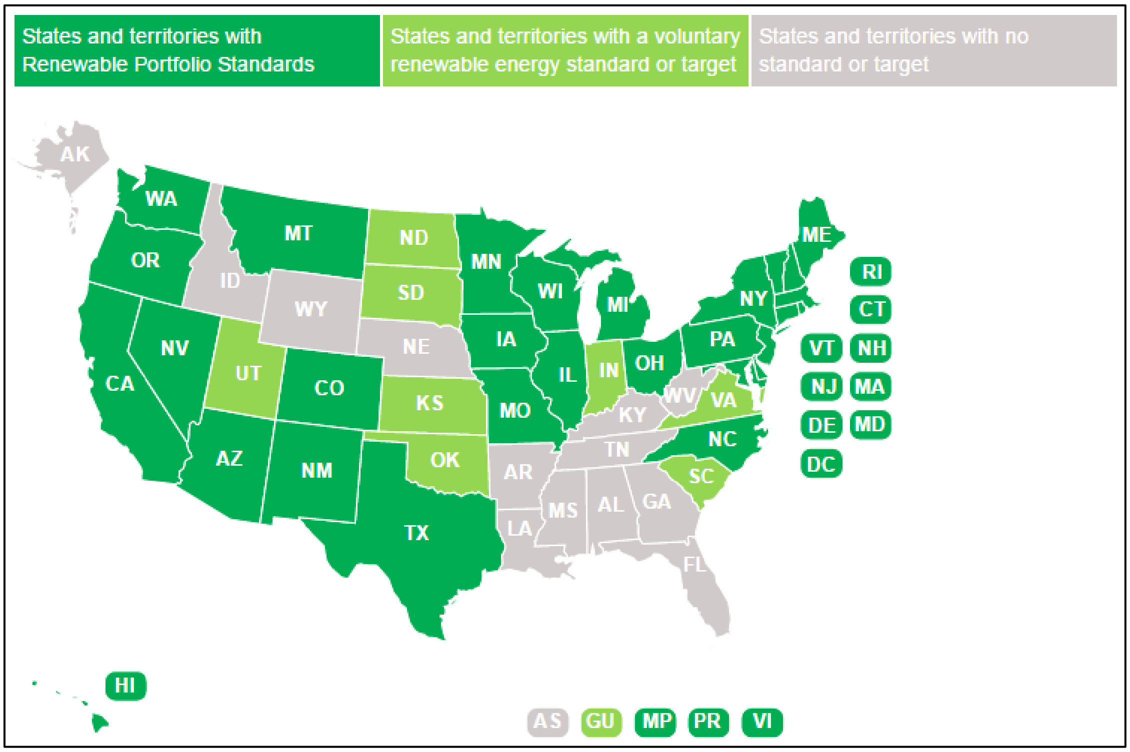
Sections 2.3.2.1 to 2.3.2.3 discuss the State-level Renewable Portfolio Standards (RPS) and Energy Efficiency Resource Standards (EERS) and the Clean Power Plan. Section 2.3.2.4 discusses energy and emissions policy action in the PNW as federal US policy uncertainty may leave regional and state entities leading these policy actions in the US.

2.3.2.1 Renewable Portfolio Standards

Renewable Portfolio Standards (RPS) are policies designed to increase generation of electricity from renewable resources. These policies require or encourage electricity producers within a given jurisdiction to generate and supply a minimum share of their electricity from designated renewable resources. Generally, these resources include wind, solar, geothermal, biomass, and some types of hydro-electricity. Some RPS policies may also include other resources such as landfill gas, municipal solid waste, and tidal energy.[50] Thirty states and the District of Columbia have enforceable RPS or Alternative Energy Portfolio Standards, and eight states have a voluntary Renewable or Alternative Energy Goal.[51] These programs vary widely in terms of program structure, enforcement mechanisms, size, and application. Figure 2-12 below shows the states with RPS or voluntary targets versus those without any standard or target.

50 Appendix D-9: http://www.eia.gov/todayinenergy/detail.cfm?id=4850.
51 Appendix D-10: http://www.ncsl.org/research/energy/renewable-portfolio-standards.aspx.

Figure 2-12: State RPS or Voluntary Targets[52]



According to the NWPCC's 7th Power Plan, 250 to 400 megawatts (MW) of installed capacity is expected to be required by 2035 to fulfil existing RPS.[53] Renewable development in the region has historically consisted primarily of wind resources. Implementing the RPS will impact natural gas demand for power generation in the US and PNW, which, in turn, impacts demand for Canadian (primarily BC and Alberta to serve the PNW) natural gas imports to the US. At the same time, the declining cost of utility-scale solar means that future increases in US renewable electricity generation may increasingly come from solar power sources. Although renewable generation resources will make a material contribution to the total installed generation capacity in the future, their contribution to the electricity system's ability to meet its peak demand is modest given the intermittent nature of wind and solar resources.

2.3.2.2 Energy Efficiency Resource Standards

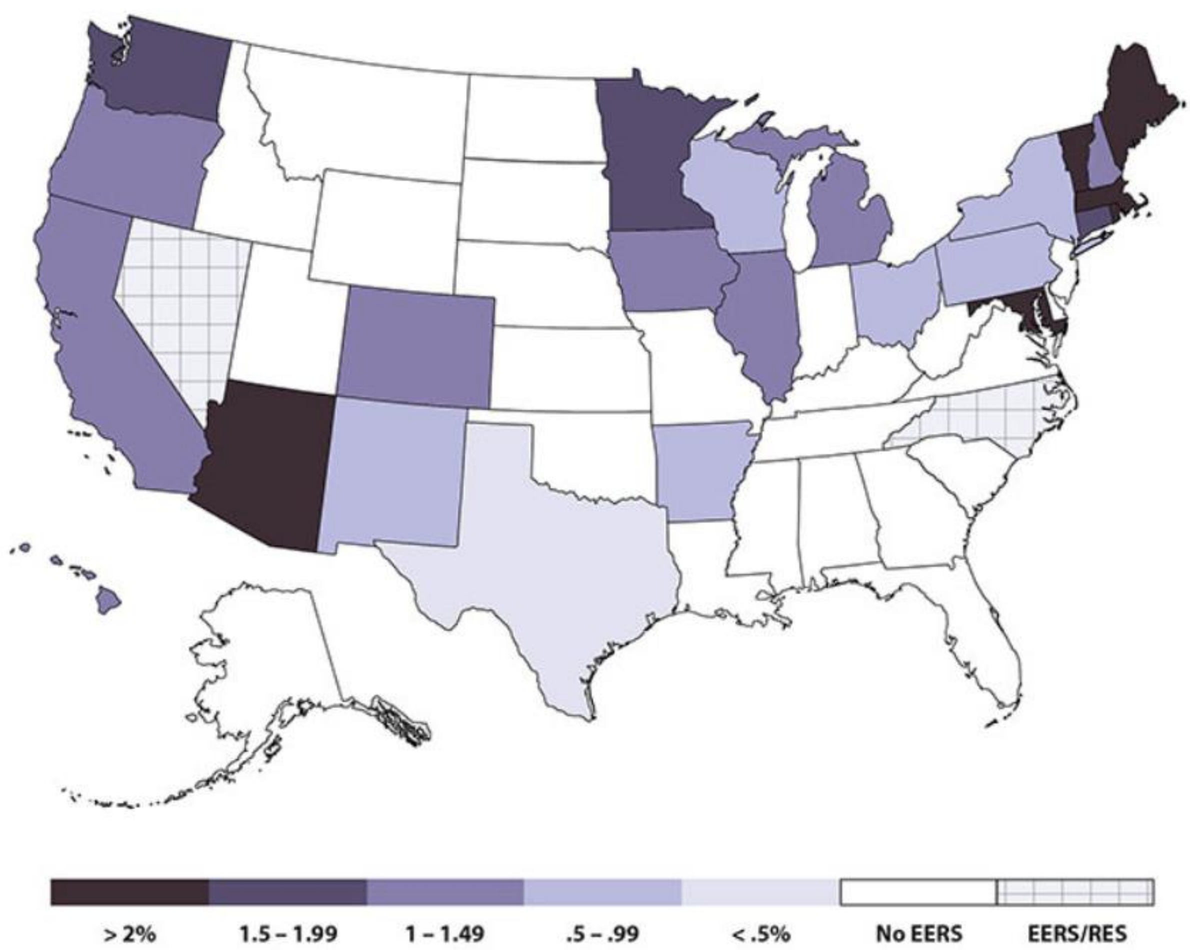
Energy Efficiency Resource Standards (EERS) aim to increase utility investment in energy efficiency measures to meet a share of their total load. Under an EERS, electric and gas utilities are regulated to demonstrate annual energy savings as a percentage of their total load. These savings are achieved through investment in utility energy efficiency programs. Annual savings targets range from 0.5 percent to 3 percent of total utility sales depending on the state. As of the end of 2016, 26 and 16 states in the US had implemented EERS for electricity and natural gas

[52] Ibid.

[53] Appendix D-11: Northwest Power and Conservation Council (2016). "7th Power Plan". p. 3-5. https://www.nwcouncil.org/media/7149940/7thplanfinal_allchapters.pdf.

utilities, respectively. States with an EERS achieved energy savings that were four times greater than states without this policy.[54] The scale of the savings from EERS on energy markets is currently small. Averaged over all state programs, EERS are saving an estimated 1.2 percent of utility load. However, should this annual savings rate persist, it would lead to a 15 percent reduction in utility energy demand by 2030, all else remaining equal. Figure 2-13 below shows the states with EERS targets versus those without any target.

Figure 2-13: State EERS Arranged By Annual Electric Savings Target[55]



2.3.2.3 Clean Power Plan

The US Environmental Protection Agency's (EPA) Clean Power Plan aims to reduce carbon dioxide emissions from power plants by 32 percent below its 2005 levels by 2030.[56] The Clean Power Plan sets emissions standards for electric generating units and provides a number of

54 Appendix D-12: http://aceee.org/sites/default/files/state-eers-0117.pdf.
55 Appendix D-13: http://aceee.org/topics/energy-efficiency-resource-standard-eers.
56 Appendix D-14: http://www2.epa.gov/sites/production/files/2015-08/documents/cpp-final-rule.pdf.

options for states to meet these standards, including inter-state collaboration to demonstrate emissions performance. This recognizes that electricity is transmitted across state lines.

As such, individual power plants can use out-of-state reductions (in the form of credits or allowances, depending on the plan type) to achieve required CO_2 reductions. This will provide a structural incentive for increased carbon trading activity. Renewable energy generated by sources outside of the US, such as hydropower from Canada, can qualify for emission reduction credits to be used to adjust a CO_2 emissions rate of a US generator, provided that they meet the eligibility requirements. This could provide opportunities for renewable energy projects in BC, or impact the prices and rates of electricity in BC.

One likely outcome of the Clean Power Plan, if it is implemented, includes less reliance on coal and more development of natural gas-fired generation. It could also provide states and developers additional incentives to rapidly expand their non-hydro renewable capacity to displace existing coal generation. The incremental increases in renewable generation would consist primarily of new wind and solar capacity.[57] This adoption of intermittent renewables could produce vulnerability to the power system through reliability issues. It could also provide market opportunities for exporters of renewable generation such as Canadian wind and hydro-electric generation.

However, a number of legal challenges are underway after the release of the final Clean Power Plan rule. Twenty-seven states and dozens of industry groups comprising almost 150 total identified parties have sued the EPA[58] to suspend the rule and ultimately have it invalidated. It will likely be several years before all the legal challenges and appeals are exhausted. Furthermore, additional uncertainty now exists over the future of climate action, including the Clean Power Plan rule, in the US as a result of the current administration's proposal to repeal the Clean Power Plan. On October 10, 2017, the EPA formally proposed to repeal the Clean Power Plan, will accept comment on the proposal for 60 days after publication in the Federal Register, and will hold a public hearing if one is requested.[59]

2.3.2.4 Pacific Northwest

Policymakers and utilities in the PNW region consider natural gas to be a viable solution to meet growing energy demands; due to high generation efficiency, relatively low carbon content and operational flexibility, natural gas provides an ideal source of base load and peaking electric power supply. Therefore, policies are aimed at moving away from coal-based electricity generation to natural gas and other renewable energy.

The NWPCC adopted its Seventh Power Plan (NWPCC Plan) on February 10, 2016. The NWPCC Plan indicates that natural gas-fired electricity generation is the lowest cost option for reducing regional carbon emissions. The NWPCC Plan also forecasts that, even without additional policy actions, aggressive pursuit of energy efficiency opportunities and expanded

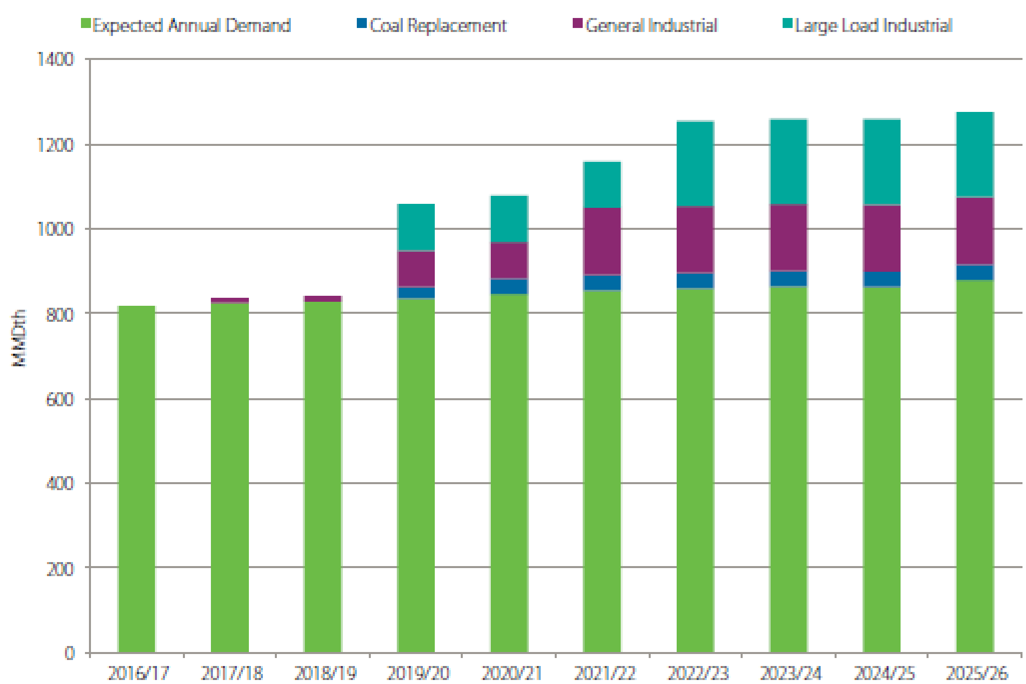
---

[57] Appendix D-15: https://www.epa.gov/cleanpowerplan/fact-sheet-clean-power-plan-clean-energy-now-and-future.
[58] Appendix D-16: http://www.eenews.net/interactive/clean_power_plan/fact_sheets/legal.
[59] https://www.epa.gov/sites/production/files/2017-10/documents/fs-proposed-repeal-cpp-final_oct10.pdf

natural gas-fired electricity generation (by retiring existing coal-fired power plants) would reduce PNW power system carbon emissions nearly 40 percent by 2035. This drop would meet the goals of the Clean Power Plan but uncertainty surrounding the Clean Power Plan or the replacement plan put forth by the current US administration remains a question going forward.[60]

New gas-fired generation demand continues to account for forecast load growth in the region, though at a slower pace than in years past. Figure 2-14 from the NWGA's 2016 Gas Outlook displays how replacing coal-fired electricity generation as well as additional industrial projects (including large methanol or LNG export plants) may drive regional demand for natural gas.

Figure 2-14: PNW Expected and Incremental Annual Natural Gas Demand[61]



At the same time, with the exception of Idaho, PNW states use RPS to promote renewable energy generation. Wind power is considered the most available and cost effective resource to meet these mandates; thus, electricity generation from wind energy has also grown in the PNW.

Within this context, Oregon's Clean Air and Coal Transition Plan commits to phase out coal-fired electricity generation and meet half of customer electricity demand with renewables by 2040. High penetrations of renewables electricity generation may require natural gas power plants as backup.[62]

The Washington Department of Ecology is implementing a binding carbon cap on major stationary emissions sources (factories, power plants, oil refineries) and residential households

[60] Appendix D-11: https://www.nwcouncil.org/media/7149940/7thplanfinal_allchapters.pdf.
[61] Appendix D-17: http://www.nwga.org/wp-content/uploads/2016/10/2016NWGA-Gas-Outlook.pdf.
[62] Ibid.

as well as businesses. In a fall 2016 referendum, Washington voters defeated proposals for a carbon tax to start at USD$ 15 per metric tonne and escalate to USD$ 100 per metric tonne across 40 years.[63]

The growing use of renewable, intermittent resources may change the way that the region's gas infrastructure will be called upon to meet the region's future energy needs – a possibility for which FEI must be prepared.

Natural gas in the PNW is also promoted for direct use applications. Direct use refers to natural gas consumed directly in appliances for space and water heating, cooking and clothes drying. Direct use of natural gas avoids the significant energy losses incurred in gas-fired generation of electricity; in total, electricity generation, transmission and distribution losses amount to nearly half the energy used in homes and commercial businesses.[64] Since using natural gas for space heating and thermal applications is more efficient than using it to generate electricity for use in these same applications, utilities such as PSE (which provide both electricity and natural gas), promote the direct use of natural gas to avoid new electricity demand—even in service territories where other utilities may benefit from increased natural gas demand.[65] The NWGA also advocates policies to promote the direct use of natural gas. Like other entities in the region, the NWGA sees gas as a pillar of the region's electricity resource strategy to reduce the use of coal-fired generation and to allow integration of a growing fleet of intermittent renewable resources.[66]

In BC, natural gas is gaining traction as a transportation and power generation fuel where diesel is the displaced incumbent fuel. FEI has seen continued growth in this market segment since the inception of FEI's NGT program for CNG and LNG supply for heavy duty vehicles, marine vessels and power generation applications.[67]

In the Port of Tacoma in Washington, PSE is developing an LNG production facility that will enable LNG supply for marine and transportation markets in the region. This LNG facility will incorporate LNG liquefaction, storage and bunkering (i.e. fuelling) to the marine market. PSE would provide LNG as a marine fuel to local vessels and could potentially also provide regional natural gas system peak support to gas customers of PSE. The project is scheduled to be completed in late 2019 and would compete with FEI's supply of LNG for over-the-road, rail and the marine transportation sectors.[68] An anticipated increase in natural gas demand within the PNW region will provide BC with an opportunity to leverage its natural gas supply resources to fulfill this anticipated market demand.

2.3.3 British Columbia

In the years between 2007 and 2010, the Government of BC stated its desire to become a leader of North America's GHG emissions reduction efforts with a number of key energy and emissions policy initiatives.

BC crystallized its comprehensive approach in the BC Energy Plan of 2007. This plan was followed by a number of legislative and regulatory acts which include the following:

- The 2007 *Greenhouse Gas Reduction Targets Act* (GGRA) sets a legislated target for BC to reduce its emissions by 33 percent below 2007 levels by 2020 and 80 percent by 2050;
- The 2008 *Carbon Tax Act* established a carbon tax rate of $10 per metric tonne of CO_2 for all fuels at the point of consumption. This tax increased by $5 per metric tonne until it reached $30 per metric tonne in 2012;
- The 2008 *Utilities Commission Amendment Act* encourages utilities to reduce GHG emissions and to promote energy efficiency and renewable energy sources;
- The 2008 Demand-Side Measures Regulation (DSM Regulation) sets the framework for the Commission to evaluate utility energy efficiency activities;
- The 2008 Emissions Offset Regulation and the Carbon Neutral Government Regulation set the foundation for public sector organizations' GHG emissions reduction targets and reporting on these targets;
- The 2008 Renewable and Low-Carbon Fuel Requirements Regulation established a schedule of reductions that will reduce the carbon intensity of the transportation fuel mix in BC by 10 percent by 2020 relative to 2010. This has helped stimulate the adoption of natural gas as a transportation fuel;[69] and
- The 2010 CEA focuses on exporting electricity, increases from 50 to 60 percent the goal of meeting new electricity demand from energy efficiency, increases from 90 to 93 percent to goal of electric power generation from clean resources, and encourages fuel switching that reduces GHG emissions. Excluding electricity-to-gas fuel switching as a demand-side measure may cloud customer and public perception of natural gas as an efficient fuel. This, combined with heavy government and media emphasis on BC's electricity as a clean, renewable energy source, may contribute to customer and stakeholder confusion regarding the role of natural gas as an efficient, affordable and reliable energy source. The Act also requires the BC Hydro to submit its integrated resource plan (IRP) to the Government of BC rather than the BCUC. This may diminish independent regulatory oversight of major energy projects and policies.

[69] Ministry of Energy, Mines and Petroleum Resources, 2017, Renewable and Low-Carbon Fuel Requirements Regulation Summary: 2010-2016. http://www2.gov.bc.ca/assets/gov/farming-natural-resources-and-industry/electricity-alternative-energy/transportation/renewable-low-carbon-fuels/rlcf-007-2016.pdf.

In March 2011, BC experienced a change in government which caused a further calibration of provincial energy and emissions policy. This calibration resulted in a further focus on NGT, natural gas exports, energy efficiency in buildings, RNG, and efficient electrification. This creates the risk of a downward pressure on natural gas demand from buildings in BC but also provides an opportunity for FEI's NGT, C&EM and RNG initiatives.

Figure 2-15 shows BC's transport-related GHG emissions and highlights the relative contribution of road transportation emissions. Transport emissions (37 percent of BC's total emissions), and road transportation emissions in particular (26 percent of BC's total emissions), make the largest contribution to BC's GHG emissions profile and emphasize a need to target emission reduction strategies in these areas in order to address the province's climate change goals.

Figure 2-15: 2014 Transport and Road Transportation GHG Emissions in BC[70]

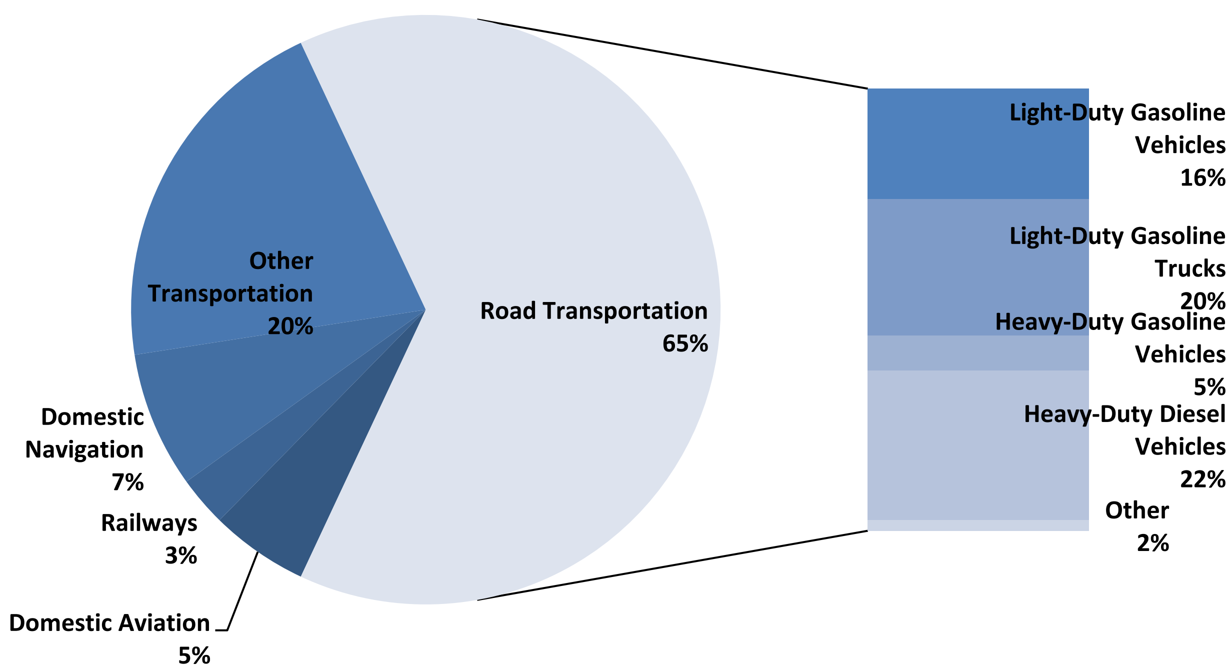

Figure 2-16 outlines the chronological development of BC's energy and emissions policy since the 2011 change in government. Black font denotes regulation or legislation whereas brown font denotes plans and general policy documents:

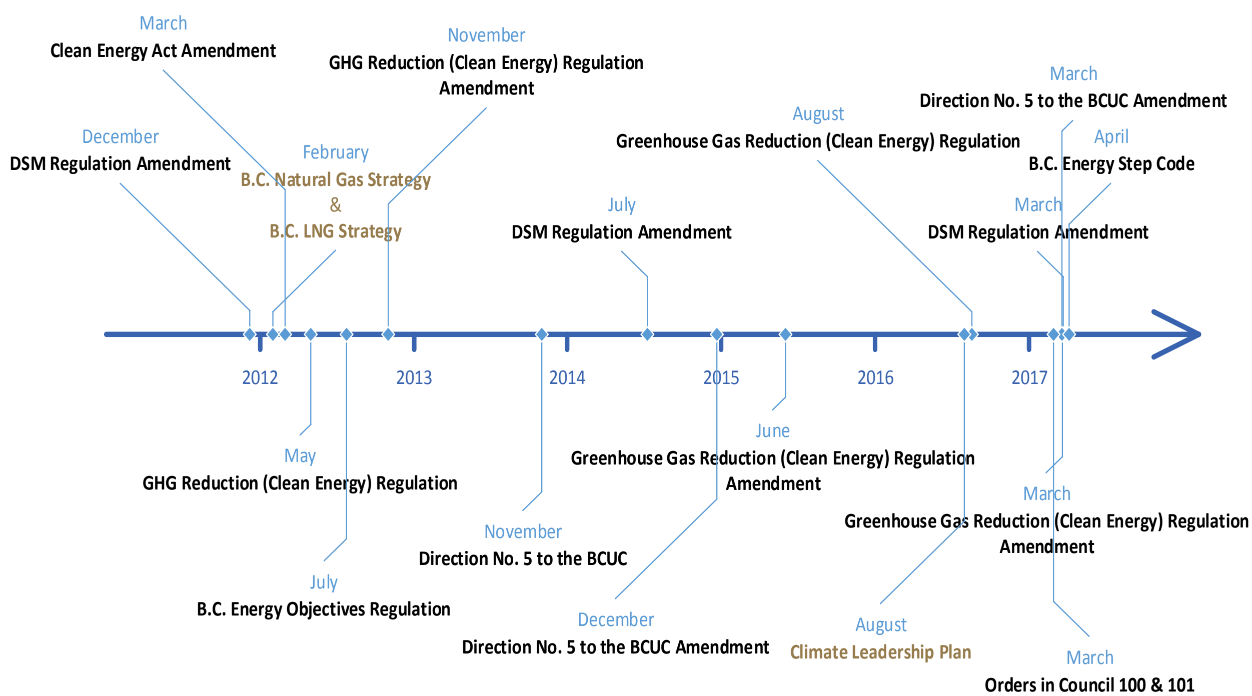
[70] FEI from "2014 BC GHG Inventory Report". BC Climate Action Secretariat.

Figure 2-16: BC Energy and Emissions Policy and Legislative Timeline



Sections 2.3.3.1 to 2.3.3.5 discuss the BC Climate Leadership Plan (CLP), the BC Natural Gas and LNG Strategies, the BC Energy Objectives Regulation, the Greenhouse Gas Reduction (Clean Energy) Regulation (GGRR), Government of BC Directions to the BCUC, and amendments to the DSM Regulation.

2.3.3.1 BC Climate Leadership Plan

The BC Government has signalled intent to remain committed to reducing GHG emissions and, in 2015, formed a Climate Leadership Team (CLT) comprised of leaders from the business, academic and environmental communities, including First Nations, to provide advice and recommendations to government on how to maintain BC's climate leadership.

In October 2015, the CLT released a report to the BC Government calling for increased action to reduce provincial GHG emissions with 32 policy recommendations. A key recommendation was to increase the carbon tax by $10 per year commencing in 2018 and to expand the application of the carbon tax to all sources of GHG emissions in the province including fugitive, flared and vented emissions from upstream oil and gas extraction and processing. The CLT report noted that with an increasing carbon tax, special consideration should be given to emission-intensive, trade-exposed industries. Additionally, the CLT recommended that if the majority of Canadian provinces opt for carbon pricing via emissions trading, a review should be undertaken of potential mechanisms to integrate a carbon tax with a cap and trade framework for the BC context and that BC should work closely with other jurisdictions in North America to achieve parity with BC's climate action policies. The CLT report also recommended the development of a low carbon transportation strategy, including establishing Zero Emission Vehicle targets to encourage greater adoption of electric vehicles.

In August 2016, the BC government released the CLP, which adopted some of the recommendations from the CLT's report. The CLP affirmed existing policy directions but also outlined goals for additional policy activity. The CLP included 21 action items intended to help put BC on course to meet the target of an 80 percent reduction in GHG emissions from 2007 levels by 2050. The CLP stated that the carbon tax rate could be increased from the current level ($30 per tonne) in the future but only once other jurisdictions catch up.[71]

The CLP included the following actions which, if implemented, may impact FEI and provincial natural gas use patterns:

- Encouraging commercial vehicle fleets to switch from diesel to natural gas and RNG, and amending the applicable regulations to enable utilities to double incentives for switching vehicles if such vehicles will use 100 percent RNG after their switch;
- Affirming existing amendments to the BC GGRR to enable utilities to provide incentives for marine, mining, and remote power generation to switch from higher emitting fuels to natural gas;
- Supporting energy efficiency initiatives via multiple actions:
  - Updating the DSM Regulation to support FEI with expanding its energy efficiency incentives by at least 100 percent;
  - Expanding the mandate for BC public utilities to meet demand growth via DSM and supporting GHG emissions reduction by advancing efficient electrification;
  - Introducing energy performance regulations for natural gas industrial package boilers in 2020;
  - Introducing updated energy performance regulations for heat pumps and natural gas fireplaces in 2018;
  - Introducing high efficiency energy performance regulations for natural gas space heating equipment in 2020 and 2025;
  - Allocating budget from the provincial Innovative Clean Energy Fund to support innovation and training;
  - Aiming for newly constructed buildings to be net zero ready in 2032;
- Pursuing multiple pathways for reducing the emissions intensity of natural gas:
  - Introducing regulation and an incentive program to reduce upstream vented and fugitive methane emissions by 45 percent by 2025;

[71] https://climate.gov.bc.ca/app/uploads/sites/13/2016/10/4030_CLP_Booklet_web.pdf

- Potentially supporting electricity capital projects to power upstream infrastructure in the Montney region; and
- Completing a review of the Low Carbon Fuel Standard.

The CLP's transportation and innovation actions provide an opportunity for FEI's NGT and RNG programs. The CLP's building sector actions present the risk of downward pressure on natural gas demand but also provide an opportunity for FEI's C&EM programs. The CLP's actions for reducing the emissions intensity of natural gas also provide an opportunity to increase the attractiveness of natural gas as a clean energy option.

2.3.3.2 BC's Natural Gas and LNG Strategies

On February 3, 2012, the Government of BC unveiled its Natural Gas Strategy[72] and LNG Strategy[73], which outlined a vision to become an international leader in LNG development and recognize the role of natural gas as a transition fuel to a low carbon global economy. BC's LNG Strategy committed the province to having three LNG facilities in operation by 2020 and represented an attempt to create a new industry that was intended to bring significant job creation and economic benefits to the province. Critical priorities that guide the strategies included: maintaining BC's competitiveness in global LNG markets; promoting natural gas as a transportation fuel; developing new markets for gas-related industries such as a gas-to-liquids, methanol and fertilizer production; and ensuring a reliable supply, available infrastructure and effective royalty regime to encourage investment in BC's natural gas sector. The current BC Government has affirmed its conditional support for the BC LNG industry; however some uncertainty exists on how the strategy will be implemented. The current BC Government's mandate to the BC Minister of Energy and Mines now requires that LNG project proposals should expressly guarantee jobs and training opportunities for BC residents, provide BC a fair return on its resources, respect and partner with First Nations, and protect BC's climate commitments.[74]

The Natural Gas Strategy also continues to build on BC's Bioenergy Strategy by reinforcing a commitment to encourage biomethane opportunities and offering consumers low carbon natural gas (Section 2.4.2 discusses FEI's initiatives to provide its customers with RNG).

As such, the province's energy demand and energy infrastructure needs are also set to expand. FEI is well-positioned to assist in meeting the government's objectives in BC's Natural Gas and LNG Strategies.

---

72 http://www.gov.bc.ca/ener/popt/down/natural_gas_strategy.pdf
73 http://www.gov.bc.ca/ener/popt/down/liquefied_natural_gas_strategy.pdf
74 Appendix D-20: https://www.bcndp.ca/latest/read-premier-john-horgans-mandate-letters-new-bc-ndp-government-ministers.

2.3.3.3 BC's Energy Objectives Regulation

Building on momentum from the BC Natural Gas and LNG Strategies, in June 2012, the Government of BC declared natural gas as a 'clean' fuel when used to generate power for BC's LNG export market (Appendix A provides further information on expected LNG projects, pipeline routes and implications for the regional gas marketplace). Using the Government's rationale that natural gas can be used to reduce global GHG emissions, FEI believes the efficient use of natural gas for heating applications in BC can provide a similar benefit for global emissions when displaced electricity load results in clean electricity supply available for export to offset coal and gas fired generation in neighbouring jurisdictions, or reduces the need to import electricity from neighbouring jurisdictions.[75]

The change to the designation of natural gas as a source of clean energy, made through BC's Energy Objectives Regulation, enabled production of relatively cheap and abundant electricity to fuel the LNG export market without compromising the requirements of the CEA. As a result, natural gas can be used for both liquefaction and as a power-generating fuel, and demand for natural gas in BC may increase.

2.3.3.4 Greenhouse Gas Reduction (Clean Energy) Regulation

As part of the province's strategy to encourage the use of natural gas as a transportation fuel, on May 14, 2012, the Provincial government introduced the GGRR through a "prescribed undertaking" under sections 18 and 35(n) of the CEA.

Through subsequent amendments to the GGRR, the regulation authorizes a utility to invest up to $331.500 million in NGT programs, with commitments for funding to be made by March 31, 2022 (when the GGRR expires), including[76]:

- Offering capital incentives to transportation fleets that use natural gas as a fuel in place of diesel (or other higher carbon emitting fuels) such as marine vessels, heavy duty trucks, locomotives, mine haul trucks, busses, or natural gas used to produce power for remote industrial applications;
  - Capital incentives are available to either CNG or LNG transportation fleets that consume gas supply that is derived entirely from biogas or biomass;
- Providing LNG bunkering infrastructure such as shoreside fuelling assets to the marine market;
- Building, owning and operating CNG and LNG fuelling stations; and

[75] This assertion is supported by comprehensive analysis conducted by the Center for Climate and Energy Solutions in its June 2013 report, "Leveraging Natural Gas to Reduce GHG Emissions". Appendix D-21: http://www.c2es.org/publications/leveraging-natural-gas-reduce-greenhouse-gas-emissions.

[76] First amendment to the GGRR was through OIC 297 on June 3, 2015, the second GGRR amendment was approved through OIC 609 dated August 19, 2016, and the third GGRR amendment was approved through OIC 161 dated March 21, 2017.

- Providing grants to meet safety guidelines for operating and maintaining natural gas vehicles.

The GGRR is designed to facilitate certain market segments to adopt natural gas as a transportation (or power generation) fuel to displace higher carbon emitting fuels such as diesel and heavy marine oil. For NGT customers, there are immediate benefits from adopting natural gas into their fleets, such as reduced fuel and operating costs, better air quality due to reduced emissions, and minimizing environmental hazards associated with diesel/oil storage tanks.

FEI's NGT efforts will assist BC in achieving its GHG reduction goals by converting the province's transportation fleet from more carbon intensive fuels, such as diesel and gasoline, to relatively cleaner burning natural gas. Further, the broader adoption of natural gas fuel in the transportation sector will also reduce air contaminants such as particulate matter (PM), sulfur oxides (SOx) and nitrous oxides (NOx).

For FEI's customers, CNG and LNG demand also adds value by increasing the year-round load on the gas distribution system, thereby reducing upward pressure on delivery rates for all natural gas customers.

In its March 22, 2017, amendment to the Regulation, the BC government also increased to $30/GJ the maximum rate at which FEI may acquire RNG. The amendment also enables FEI to acquire sufficient RNG to meet up to 5 percent of FEI's 2015 non-bypass annual demand (this equals approximately 8.9 million GJ).

2.3.3.5 BC Government Directions to BCUC

On November 27, 2013 through Order in Council 557/2013 (OIC 557), the BC Government issued Direction No. 5 to the BCUC under Section 3 of the UCA. This direction exempts from CPCN review expenditures on an expansion of the Tilbury LNG facility up to $400 million. OIC 557 also established the Rate Schedule 46 LNG Sales, Dispensing and Transportation Service tariff.

On December 19, 2014 the BC Government issued OIC 749/2014 (OIC 749) amending Direction No. 5, which established, among other things, investment parameters for an additional expansion of the Tilbury LNG facility beyond that approved in OIC 557 (i.e. Phase 1A permitted under OIC 557).[77] Specifically, OIC 749 permitted additional expenditures, exempt from CPCN review by the BCUC, of up to $400 million for Phase 1B expansions of the Tilbury LNG facility subject to overall contracting levels averaging 70 percent of the facilities production capacity over a period of 15 years. Additionally, OIC 749 also established a new Rate Schedule 50 Large Volume Industrial Transportation tariff. OIC 749 also exempted several transmission system projects from the requirement to undergo a CPCN review, including the Eagle Mountain

[77] OIC 749 also established spending limit exemptions for the FEI CTS and Eagle Mountain Gas Pipeline (EGP) project in addition to the LNG-related expenditure limits as referenced above.

to Woodfibre Gas Pipeline (EGP) project and three Coastal Transmission System (CTS) projects.

Subsequently, on March 21, 2017, the BC Government further amended Direction No. 5 through OIC 162/2017. The key amendments under OIC 162 were an increase to the Tilbury Phase 1A capital expenditure limit from $400 million to $425 million, removing the 70 percent average contracting requirement over 15 years pertaining to the Phase 1B expansion facility and removing the two lower priced tiers from Rate Schedule 46.

On March 1, 2017, the BC Government issued OICs 100/2017 and 101/2017. These orders enable BC public utilities to conduct efficient electrification programs and BC Hydro to charge the costs of these programs to its DSM deferral account.

In July 2014 and March 2017, the BC Government also amended the DSM Regulation to further encourage the efficient use of natural gas in BC and to enable a broader set of utility customers to participate in energy efficiency programs. These updates present an opportunity for FEI's C&EM programs. Please see Section 4.2.1.1 for further details.

2.3.3.6 2017 BC Election and Change in Government

BC conducted provincial elections in May 2017 which resulted in a new minority government forming in July 2017. The BC government's mandate letters to cabinet include the following key instructions that may impact the government's energy and emissions policy:

- Create a roadmap for the future of BC energy to drive innovation, energy efficiency, responsible and sustainable generation of new energy and create durable good jobs across the province;
- Boost investments in new energy technologies and climate solutions by reinvigorating the Innovative Clean Energy Fund;
- Implement a comprehensive climate action strategy that includes a new legislated 2030 reduction target and separate sectoral reduction targets and plans;
- Implement an increase of the carbon tax by $5 per year beginning in April 2018 to meet the federal carbon-pricing mandate and take measures to expand the carbon tax to fugitive emissions;[78] and
- Revitalize the Environmental Assessment process to ensure a transparent public process and that legal rights of First Nations are met.[79]

[78] In its September 11, 2017, BC budget update, the BC Government proposes a $5 per metric tonne annual increase to the carbon price, starting in 2018 and lasting four years. If this increase is maintained each year, as proposed in the updated budget, carbon tax will increase to $50 per tonne in 2021. Specific tax rates vary for each type of fuel, depending on the amount of CO_2 equivalent emissions released as a result of its combustion. At the current $30 per metric tonne level the tax adds $1.50 per GJ of natural gas, which is approximately half the price of the commodity itself. At $50 per tonne of CO_2 the additional cost will increase to $2.48 per GJ.

[79] Appendix D-20: https://www.bcndp.ca/latest/read-premier-john-horgans-mandate-letters-new-bc-ndp-government-ministers.

On October 23, 2017, the BC Government introduced the Climate Solutions and Clean Growth Advisory Council whose work will provide strategic advice to the BC Government on carbon pollution reductions as well as optimizing opportunities for sustainable economic development and job creation.[80]

The minority government status creates uncertainty as to what extent, how specifically, and the time frame that the BC Government will implement these mandates. The thrust of these mandates presents the risk of downward pressure on natural gas demand but also provides opportunities for FEI's C&EM, RNG and NGT initiatives.

2.3.4 Municipalities

Many municipalities in BC and across Canada are using their municipal powers to take policy actions aimed at reducing GHG emissions. This can range from building code and zoning by-laws placing restrictions around building energy use, to municipalities investing in energy efficiency and conservation programs, or municipal investments in renewable energy generation.

In order to support municipal energy efficiency and emissions reductions goals, the BC government enacted the BC Energy Step Code in April 2017. The step code represents a fuel-neutral voluntary set of energy performance variances from the prevailing *BC Building Code*. Under the 2015 *Building Act* and effective December 15, 2017, BC municipalities will be unable to pass bylaws that create variances in energy performance requirements from the prevailing BC Building Code, unless these variances enact specific steps from the BC Energy Step Code.[81] Under the *Act*, BC municipalities will still able to enact actions outside their bylaws as long as the Province has not already regulated the areas which are impacted by such actions. The BC Energy Step Code contains multiple steps for residential and commercial buildings that range from enhanced compliance with the prevailing provincial building code to net zero ready building performance. The BC Energy Step Code provides a consistent provincial standard for energy efficiency and replaces the various existing policies that various municipal governments had enacted previously. As such, the BC Energy Step Code poses a risk of downward pressure on natural gas demand but also provides an opportunity for FEI's C&EM programs.

Uncertainty exists regarding which municipalities will adopt what steps of the BC Energy Step Code and how quickly. While municipalities are cognizant of their legislated emissions reduction goals, they are cautious about their implementation approach. Some municipalities profess that they prefer to move in regional or economic groups in order to prevent economic leakage to other municipalities.[82]

Some municipalities are setting goals to supply 100 percent of their energy needs via clean and renewable sources by 2050. These goals focus on buildings, transport and municipal waste but are aspirational in nature as implementation pathways and municipal policy levers for achieving

[80] https://news.gov.bc.ca/releases/2017ENV0057-001797
[81] http://www.bclaws.ca/civix/document/id/complete/statreg/15002
[82] FEI received this feedback during its 2017 LTGRP stakeholder engagement efforts.

such goals are not clear yet. These municipalities include the City of Vancouver (COV), the City of Victoria, the District of Saanich, and various municipalities in the BC Kootenays. These municipal targets present a risk of downward pressure on natural gas demand but also provide an opportunity for FEI's RNG program and the Company's other initiatives for increasing the renewables portion of its energy supply.

The COV represents a special case among BC municipalities since COV has its own charter which confers regulatory powers that other BC municipalities do not have access to. The COV is moving forward with the Renewable Cities Strategy which includes the aspirational goal of consuming 100 percent renewable energy in all sectors by 2050 and reducing GHG emissions by 80 percent below 2007 levels by 2050. The COV's Greenest City Action Plan includes specific goals to reduce energy use and GHG emissions in existing buildings by 20 percent below 2007 levels, and require all buildings constructed from 2020 onward to be carbon neutral in operations. The COV also aims to increase public transit rideshare, expand the public transit system, and transition light-duty vehicles (cars and light trucks) to predominantly battery electric, plug-in electric, or sustainable biofuel powered models. On March 23, 2015, Vancouver City Council voted unanimously to support a shift toward the city deriving 100 percent of its energy from renewable sources, including energy for transportation and buildings.

In July 2016, the COV released the Zero Emissions Building Plan that aims for all new buildings to achieve zero operational GHG emissions by 2030.[83] The plan features GHG intensity (GHGI) targets for each major building type, complemented by Thermal Energy Demand Intensity (TEDI) targets to focus on building envelope performance improvements for all buildings. Section 2.2 of the plan states that its focus is on "reducing the demand for fossil fuel-based natural gas used primarily for space heating and hot water, and transitioning these functions to renewable sources such as electricity (including heat pumps), biogas and neighborhood renewable energy systems (NRES)."[84] The COV and FEI announced an agreement in November 2017, whereby the COV would amend the Zero Emissions Building Plan to include alternate compliance pathways that align with the BC Energy Step Code. This pathway does not require new buildings to achieve the GHGI target if they, instead, comply with a step of the BC Energy Step Code that achieves similar reductions in GHGs. Significantly reducing GHG emissions from new developments and new housing builds, and implementing an electrified transportation system, poses the risk of downward pressure on natural gas demand and could result in increased electricity demand in the COV.

2.3.5 Summary

Energy and emissions policy in Canada and the US is constantly evolving. While current legislation and the actions of municipalities to reduce the use of gas create risks for FEI as a result of potential residential, commercial and/or industrial demand reductions, natural gas is also increasingly recognized as playing an important role in BC's overall energy portfolio, resulting in the potential for demand growth. These countervailing forces create a measure of

[83] Appendix D-22: http://council.vancouver.ca/20160712/documents/rr2.pdf.
[84] Ibid.

uncertainty in the market and thus FEI must be prepared for a range of possible outcomes. Section 3 discusses how FEI's long term analysis accounts for these countervailing forces and resulting uncertainty

2.4 CUSTOMER SOLUTIONS

FEI believes that developing innovative and integrated customer solutions is an important part of positioning natural gas services competitively within BC's energy marketplace for the benefit of all customers. Using the right fuel effectively for the right end use and developing customer-driven energy services remain a key focus of FEI's customer solutions activities.

Following the BCUC Alternative Energy Solutions Inquiry in 2011-2012, FEI's new initiatives in thermal energy service projects are being undertaken by a separate FEI affiliate.[85] Some customers continue to seek out efficient, low carbon, integrated end-use energy solutions.

Although FEI is no longer delivering low carbon thermal energy alternatives, the Company is:

- Providing natural gas as a transportation fuel alternative and capturing carbon neutral biomethane sources to displace conventional natural gas;
- Exploring advanced metering and natural gas utilization solutions; and
- Improving the competitive position of natural gas service to better meet the needs of builders, developers and end-use customers.

The initiatives discussed below are provided to illustrate the types of activities that FEI continues to explore, implement and expand where there are benefits to customers and where they create an opportunity for the Company to assist in meeting government energy and GHG emission goals. Section 4 also discusses how the Company is enabling a number of customer solutions through programs to promote energy efficiency and conservation. There are no approvals sought by FEI within this LTGRP related to any new initiatives; such approvals, where required, will be sought prior to program implementation.

2.4.1 Natural Gas for Transportation

NGT and remote power generation are key opportunities for the Company to serve the energy needs of customers and help reach the ambitious GHG reduction targets legislated by the Province. In the NGT and remote power generation sectors, FEI is looking to displace petroleum fuels such as diesel with cleaner-burning natural gas. Natural gas is a lower carbon alternative to conventional transportation and remote power generation fuels and can play a significant role in reducing emissions, reducing reliance on petroleum-based fuels and supporting technology development in BC.

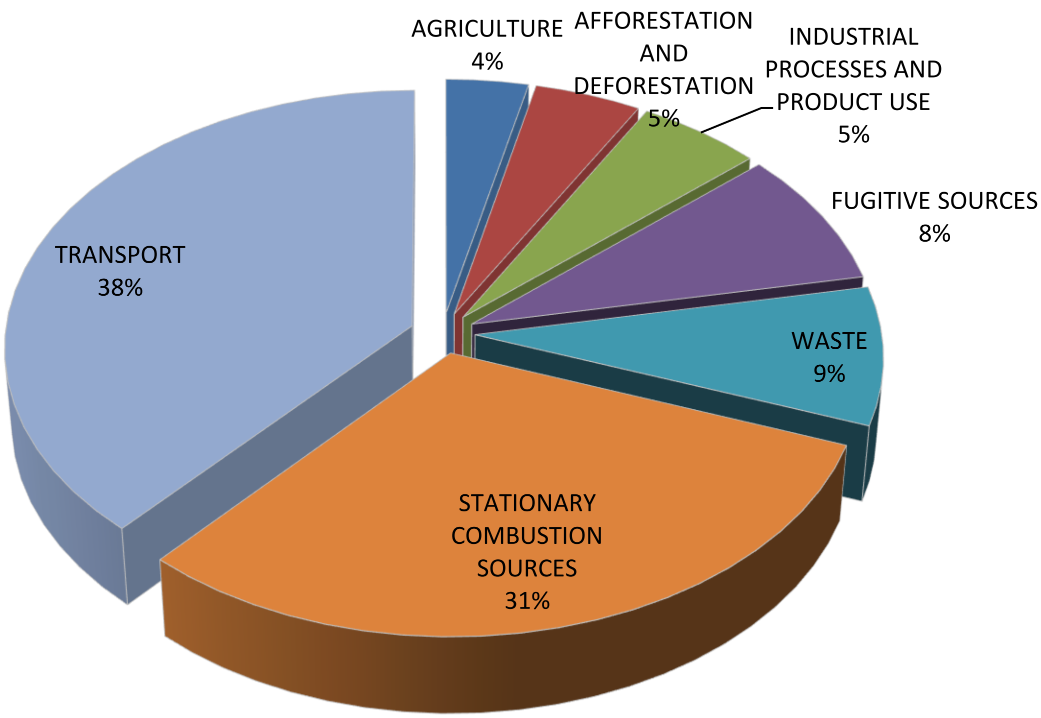
[85] BCUC report, "Inquiry into the Offering of Products and Services in Alternative Energy Solutions and Other New Initiatives". Dec. 27, 2012. http://www.bcuc.com/Documents/Arguments/2012/DOC_33032_12-27-2012-G-201-12_FEI-AES-Inquiry-Report_WEB.pdf.

To capture the NGT benefit, customers must make significant investments in vehicles, equipment and marine vessels designed to use natural gas. Given the significant investment dollars at stake for early adopters of natural gas as a transportation fuel, customers view FEI as a partner that can be depended upon to deliver the natural gas energy they need to facilitate the shift from conventional petroleum fuel to natural gas.

The GGRR is one mechanism that utilities in the Province can use to begin the market transformation process of converting applicable transportation and power generation applications to natural gas as a feedstock fuel.

The Company sees the development of natural gas use for these types of applications, programs and markets as a key part of its low carbon strategy to help meet changing customer needs and the GHG reduction targets legislated by the province. Shown in Figure 2-17, the on road and off road transportation sectors are responsible for more GHG emissions than any other sector. As such, these sectors provide BC's biggest opportunity to contribute to a reduction of GHG emissions and other air pollutants over the next 20 years. Note that the GHG emissions presented in the figure below include emissions for marine traffic operating in Provincial intercoastal waterways (i.e. such as domestic tug boats, BC Ferries and Seaspan vessels operating in domestic waterways). The data in Figure 2-17 is using the most current available information up to the end of 2014 from the Province of BC's GHG emissions inventory.

Figure 2-17: 2014 GHG Emissions by Sector in BC[86]



As discussed in greater detail in Section 3, natural gas is expected to emerge as a viable fuel for the global marine vessel market. As further discussed in Sections 2.4.1.1 to 2.4.1.3, there are global environmental regulations that are scheduled to be implemented in the next couple of years that are expected to materially impact the current mix of fuels that have traditionally been consumed by the global marine market. Due to these tighter restrictions on marine vessel emissions, natural gas in the form of LNG is expected to emerge as a choice alternative fuel for vessel operators to comply with these tighter restrictions.

2.4.1.1 Marine Bunkering Overview

Bunkering is the act of supplying a ship with fuel while vessels are berthed at port. Various incumbent fuels are used in marine transportation, including marine gas oil (MGO), marine diesel oil (MDO), intermediate fuel oil (IFO) and heavy fuel oil (HFO).[87] Currently, HFO accounts for the majority of the fuel used for tankers, bulk carriers and container ships globally. LNG is a relatively new fuel in the marine bunkering market whose adoption is being driven by its environmental and operating cost advantages compared to incumbent fuels.

[86] FEI from 2014 BC GHG Inventory Report, Climate Action Secretariat.

[87] These four marine fuels are ordered from lightest to heaviest in terms of density and weight (i.e. least emitting to highest emitting).

Capitalizing on the LNG marine bunkering opportunity is a key part of FEI's strategy to leverage pre-existing Company-owned assets and operational expertise to drive growth in new markets. While the Tilbury LNG facility primarily serves as a winter peaking facility, over time, the facility has also evolved to serve a variety of new LNG markets. Tilbury is a scalable LNG facility that, subject to any required regulatory approvals and the lead time for obtaining them, provides FEI with the flexibility to invest in new infrastructure in order to capitalize on load growth opportunities such as the marine bunkering market.

Due to the complexity of global ports, ships and fuelling (i.e. bunkering) requirements, numerous marine bunkering scenarios could unfold. In general, the ship requiring bunkering is either at the cargo loading/unloading berth or anchored at the port. LNG marine bunkering is performed by transporting LNG by a truck, through shoreside storage, or via an LNG ship to the marine vessel requiring refuelling. These three bunker delivery methods vary in complexity and the more complex bunkering solutions would involve the use of a LNG bunker barge or vessel whereby the bunker barge or vessel would be filled with LNG at a terminal (such as Tilbury) and then transported on the water to alongside the ship that requires LNG bunkering fuel.

FEI has had initial success advancing the LNG marine bunkering market in BC as evidenced in the milestones listed below:

- Tilbury Phase 1A expansion to be completed by the end of 2017 as a prerequisite to enable demand growth from LNG markets, such as marine bunkering;
- The GGRR supporting FEI's activity in developing the LNG marine bunkering market by providing capital cost incentives and bunkering/fuelling infrastructure for vessels to operate on LNG;
- LNG supply and delivery contracts are in place for three BC Ferries and two Seaspan Ferries vessels, with two more BC Ferries Spirit-class vessels expected to begin operational service, beginning mid-2018 for the first vessel and mid-2019 for the second vessel[88]; and
- The first ever global instance of an LNG tanker providing LNG bunkering by driving on-board the ship to refuel.

FEI will continue to advance its interests in the LNG marine bunkering market as an LNG fuel and logistics provider. The Company's early progress in this market, coupled with recent supportive market conditions, create a favourable environment for the Company.

2.4.1.2 Marine Market Overview

The International Maritime Organization (IMO) is scheduled to implement a global cap on sulfur emissions from the shipping industry to take effect on January 1, 2020. Vessels that operate in designated Emission Control Areas (ECA), which are 200 mile zones extending from all coasts

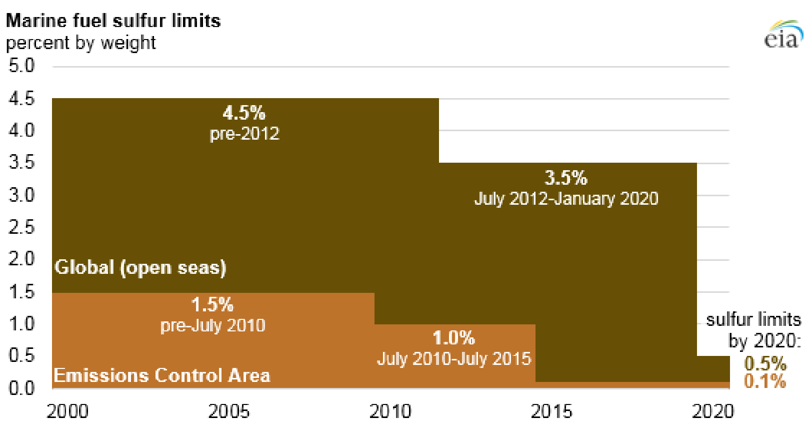
[88] Appendix D-23: http://www.timescolonist.com/news/local/b-c-ferries-will-head-to-poland-for-refits-1.2217288.

in North America and in Europe, are currently required to burn ultra-low sulfur MGO in order to comply with the current sulfur limit on emissions of 0.1 percent. Globally (outside of the ECA), the current limit is 3.5 percent. In 2020, this global sulfur limit will drop to 0.5 percent.

Figure 2-18 below illustrates the current ECAs. Figure 2-19 graphically outlines current and future legislated limits on sulfur for marine vessels operating within and outside of the designated ECA zones.

Figure 2-18: Designated ECA in North America and Europe

Figure 2-19: Designated ECA in North America and Europe



The global cap on sulfur in marine fuels is expected to have a material impact on marine vessel operators as they must weigh a number of options in order to comply with these emission limits.

For example, operators using higher-sulfur marine fuels such as IFO or HFO could install exhaust scrubbers that essentially scrub out the sulfur from the flue gas from a ship's exhaust. This is expected to be a temporary solution as the scrubbers do not remove other harmful emissions such as NOx and PM. Another option is for marine operators to consume more expensive low-sulfur MGO, which is what most vessels operating in the current ECAs are consuming today. Lastly, marine vessels could consume LNG, which is a cheaper fuel on a commodity cost basis, but the engines, on-board storage tanks and fuel delivery systems that are capable of consuming natural gas, are more costly than traditional marine petroleum fuelled engines. LNG would help vessel operators to comply not only with sulfur emission limits, but would also help dramatically reduce NOx and PM emissions.

2.4.1.3 GHG Emissions from the Global Marine Sector

The Provincial GHG emissions inventory (in Section 2.4.1) includes only marine emissions for vessels transiting intercostal provincial waterways. Marine vessels that regularly call BC ports that originate from ports of other countries (i.e. container ships, chemical tankers, car carriers, etc.) are not included in the Provincial emissions inventory, although these vessels emit large amounts of GHGs into the Province's atmosphere when in transit, and when berthed in domestic ports. It is FEI's view that these emissions should be considered as part of a global GHG reduction strategy through fuel switching from the incumbent petroleum marine fuels to natural gas.

For example, coastal freight vessels (which operate entirely within the currently-designated ECA zones) and trans-Pacific marine vessels (which operate a small portion of the total journey in the currently-designated ECA zones) are not included in the BC GHG inventory numbers. Specifically, emissions from shipping activities not included in the provincial GHG inventory amount to about 70 million metric tonnes of CO_2e per year, which is greater than the combined 64 million metric tonnes of CO_2e per year that the entire Province of BC emits per year.[89] It is FEI's view that emissions from the marine segment which are not currently included in the provincial GHG inventory numbers should also be considered in the context of global GHG emission reduction opportunities through the development of natural gas use for this market segment.[90]

Within the context of the planning environment of the LTGRP, a strategic focus on developing LNG for the marine segment is expected to have an impact in terms of total demand on FEI's distribution system as the marine market for LNG develops over time. The potential total LNG demand (as discussed in Section 3.4.7 of the LTGRP) that could materialize could be significant in the region and FEI will pay close attention to this demand as it develops over time to ensure that adequate resources are developed to continue to serve this key market segment.

The Company's CNG and LNG solutions are designed to capture the opportunity for emission reductions in the transportation and remote power generation sectors and provide an important source of load growth on FEI's systems. The Company is not asking for approval of any natural gas for transport programs as part of this LTGRP.

---

89 Stx Canada Marine: West Coast Marine LNG Supply Chain Project; prepared for Transportation Development Centre of Transport Canada; October 2013; Table 5-11.

90 The Provincial GHG emissions inventory only includes marine emissions for vessels transiting intercoastal waterways. Marine vessels that regularly call BC Provincial ports that originate from ports from other countries are not included in the Provincial emissions inventory and should be considered as a GHG reduction strategy through the use of natural gas.

2.4.2 RNG

In response to customer demand for sustainable energy options and to support the Province's energy and climate change goals,[91] FEI was the first utility in North America to offer an end-to-end RNG supply and service program. FEI initiated development of a low carbon natural gas product offering in June 2010 and today, the RNG Offering gives customers the means to support low carbon energy initiatives. Customers that elect to purchase RNG continue to receive natural gas supply from the FEI distribution system but notionally replace a percentage of their traditional gas supply with biomethane,[92] or RNG. Because the BC Government considers biomethane to be carbon neutral, customers with GHG emission reduction targets (such as public sector organizations or municipalities) can purchase a portion of their natural gas supply through the RNG Offering to offset their climate emissions. FEI customers that participate in the RNG Offering can elect to designate 5, 10, 25, 50 or 100 percent of the natural gas they use as RNG. These customers pay a premium on their natural gas bill dependent on the percentage level of RNG that they select (please see Figures 2-10 and 2-11 for an energy cost comparison of 100 percent FEI RNG with FEI natural gas and BC Hydro electricity). Participants in the RNG Offering also receive a credit on the BC carbon tax on their bill.

Though supply and demand for the RNG Offering is small when compared against FEI's traditional gas service, the program remains an important part of the Utility's customer offering. The 2017 LTGRP's RNG annual demand forecasts assume current RNG supply technologies. FEI is aware that pilot projects exist for expanding the base of RNG supply technologies. One example is a project that seeks to prove the commercial scalability of RNG from wood waste. If such cellulosic biogas does become available at reasonable prices, it would dramatically increase RNG supply and thus potentially enable FEI to substantially increase RNG annual demand via its RNG program. FEI will continue monitoring the progress of cellulosic biogas pilot projects.

The LTGRP does not contain any requests in relation to the RNG program. Section 3 discusses RNG impact on annual demand. Section 5 references RNG in relation to FEI's gas supply considerations. Section 8 outlines the RNG program's impact on FEI GHG emissions.

2.4.3 Others

The Company is improving customer engagement through education and awareness of the benefits of natural gas use, along with providing customers with energy management tools facilitated through multiple communication channels. As such, FEI continues to explore ways to engage a wider network of builders and developers along with other influencers of residential gas use including architects, engineers, contractors, manufacturers, dealers and homeowners.

[91] The BC Bioenergy Strategy aims to "launch British Columbia as a carbon-neutral energy powerhouse in North America [and] help BC achieve its targets for zero net greenhouse gas emissions from energy generation, improved air quality, electricity self-sufficiency and increased use of biofuels." BC Bioenergy Strategy, 2009.

[92] Biomethane is derived from biogas, which is produced from decomposing organic waste from landfills or agricultural waste. When captured and cleaned, biomethane is interchangeable with conventional natural gas and can be injected into the existing natural gas pipeline system. Biogas is readily available in BC and most importantly, it is a renewable fuel. Once upgraded, biogas is called biomethane or RNG.

This activity is aimed at building natural gas load, mitigating declining market share in some sectors, and improving customer and stakeholder engagement through opportunities to promote natural gas education, awareness and training.

To support the above goals, FEI is contributing to various projects that support commercializing innovative natural gas utilization technologies that will help FEI meet its customers' preferences for natural gas while also addressing societal plans for reducing GHG emissions. Such technologies achieve this goal by raising the efficiency of natural gas end uses and also reducing the GHG emissions intensity of both the natural gas stream as well as individual end uses. The initiatives include:

- Work with the Canadian Gas Association (CGA) and its member companies to explore injection of hydrogen into the natural gas pipeline system (hydrogen combusts without generating GHG emissions and can be derived via electrolysis which makes it a candidate for decarbonizing the natural gas stream while serving as a potential storage medium for electricity generated from renewable sources);
- Support for a project to capture and make commercially usable carbon emissions from commercial natural gas end-use appliances, such as commercial furnaces;
- Research into commercialization of gas-driven heat pumps which could help natural gas appliances exceed 100 percent end-use efficiency;
- Research into combined heat and power appliances that increase the aggregate energy use efficiency of natural gas end-use appliances by generating heat and power from the natural gas stream; and
- Support for commercializing small-scale residential natural gas end-use appliances that are designed to meet the reduced heating requirements of more energy efficient newly constructed buildings.

2.5 *CONCLUSION*

The development of unconventional natural gas supply has opened up vast reserves of natural gas throughout North America. Advances in drilling and well productivity have led to record high production and as natural gas supplies have grown, commodity prices have fallen. A low price environment is generating new sources of natural gas demand. The availability and cost to supply gas to traditional BC and PNW markets may change in the future as the commodity moves from production areas to areas of high demand growth.

Although the decline of natural gas commodity rates has improved the fuel's price competitiveness against electricity on an operating cost basis, this decline has been offset by the relatively higher capital, installation and maintenance costs for natural gas equipment and increasing end-use efficiency of electric appliances. Furthermore, the role of natural gas in its traditional use of space and water heating, which makes up over 80 percent of residential natural gas throughput, continues to be challenged by changing energy and emissions policies, appliance standards and regulations. These declining trends negatively impact throughput and load growth, and increase the importance of FEI's actions to mitigate this pressure. Though the evolving natural gas marketplace presents a number of utility challenges, FEI is also presented with opportunities to capitalize on new areas to add new system load.

To help maintain the competitiveness of natural gas rates, FEI is focusing on growing the customer base and increasing throughput on the natural gas system by developing new markets for natural gas use. FEI continues to develop sustainable energy solutions, such as NGT, RNG and C&EM programs, as well as to pursue innovative technologies, such as thermal metering or commercial appliance carbon capture, to help satisfy customer and stakeholder demand for new, innovative solutions while simultaneously reducing customers' energy costs and environmental impact. The Company continues to remain flexible in its service offerings in order to overcome the challenges presented by an evolving energy marketplace while capitalizing on opportunities to serve customer needs for safe, reliable, efficient and cost effective energy.

This LTGRP addresses the evolving elements of the planning environment discussed in this section by examining a range of possible scenarios in the Utility's analysis for annual and peak demand forecasting, DSM activities, system resource needs and gas supply portfolio planning:

- Section 3 provides a range of annual demand forecasts based on a number of future scenarios that incorporate a variety of outcomes based on these planning environment uncertainties;
- Section 4 examines a range of potential energy savings for FEI's C&EM programs based on consideration of the same potential outcomes that are used to examine demand forecasts;
- Section 5 includes consideration of how these planning environment uncertainties may impact resource cost and availability for FEI to secure a stable, reliable and cost effective source of gas supply; and
- Section 6 examines how a range of potential future peak demand scenarios could be influenced by these planning environment uncertainties and the effect that these could have on the timing to address future constraints on FEI's gas delivery system.

3. ANNUAL ENERGY DEMAND FORECASTING

3.1 *INTRODUCTION AND BACKGROUND*

Two key elements that underpin FEI's resource planning activities are the forecasts of annual demand and peak demand for natural gas. FEI's demand forecasts are used to ensure adequate system capacity, to plan gas supply resources, and also to provide a baseline against which to analyse the impact of proposed or potential future initiatives such as expanded energy efficiency and conservation activities or growth in natural gas sales for fuelling transportation.

The annual demand forecast discussed in this Section represents annual consumption by region and customer class, and allows the Company to determine directional rate impacts and annual gas supply needs in the Company's long term planning efforts. In contrast, the peak demand forecast provides an estimate of the maximum daily natural gas demand that would be expected under extreme weather conditions. Gas supply planning (discussed in Section 5) uses system-wide daily peak demand and also relies on the annual shape of the load curve to model prolonged periods of high demand throughout the year. In contrast, system capacity planning (discussed in Section 6), relies on regional peak day and, in certain cases, peak hour demand to design FEI's regional system infrastructure to be able to meet that peak day or peak hour demand.

The current planning environment is uncertain. The Company recognizes that its customers are using natural gas in different ways and amounts than they did in the past. Heating equipment installed in new buildings and in retrofit situations is more efficient and, in some cases, results in a different demand profile than the older equipment it replaces. Potential new demand from the transportation and industrial sectors may also impact the Company's overall demand profile. While recent demand history is appropriate for short term demand forecasting, a method which relies on modelling long range changes in energy end uses is more appropriate for longer forecast horizons.

This section of the 2017 LTGRP addresses Section 44.1(2)(a) of the UCA, which requires utilities to include an estimate of the demand for energy the utility expects to serve in the absence of taking new demand-side measures. This section is organized as follows:

- Sections 3.2 and 3.3 set the stage by outlining FEI's base year customer distribution and annual demand and by discussing FEI's customer forecast which serves as the basis for both of the 2017 LTGRP's two annual demand forecast methods;
- Sections 3.4.1 to 3.4.5 explain and compare FEI's traditional annual demand forecast method (Traditional Annual Method) with its end-use annual demand forecast method and outline FEI's end-use annual demand forecast scenario analysis (FEI uses the Traditional Annual Method to ground its end-use annual demand forecast method and uses the end-use annual demand forecast method to plan its resources across the 2017 LTGRP long term forecast horizon);

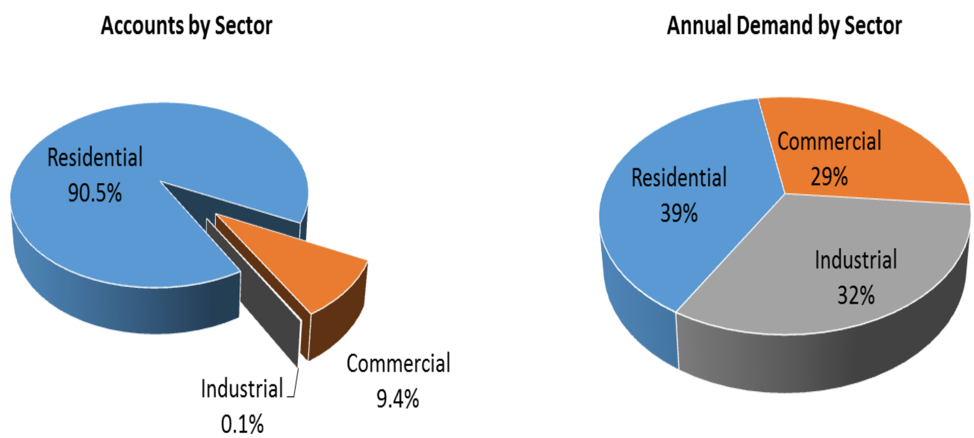
- Sections 3.4.6 and 3.4.7 discuss the annual demand impact of FEI's NGT and RNG initiatives; and
- Section 3.4.8 outlines FEI's total annual demand forecast while Section 3.4.9 discusses the impact of potential new large industrial point loads on this annual demand.

3.2 *EXISTING RESIDENTIAL, COMMERCIAL, & INDUSTRIAL CUSTOMER DEMAND*

The 2017 LTGRP uses a 2015 base year, starts its forecast in 2016 and ends the forecast horizon in 2036. The 2017 LTGRP selected the 2015 base year because FEI had not finalized its 2016 actuals in time for the 2017 LTGRP analysis to import this data while also being able to conclude in the 2017 submission year.

FEI's customer base includes approximately one million customers, consisting predominantly of residential customers that account for approximately 90 percent of the overall customer base (see **Error! Reference source not found.** below). However, on an annual demand basis, there is a more even split between the residential, commercial, and industrial groups. The makeup of the Company's customer base and demand patterns has implications for infrastructure requirements and conservation goals as discussed throughout this LTGRP.

Figure 3-1: FEI Customer Base and Demand Overview, 2015



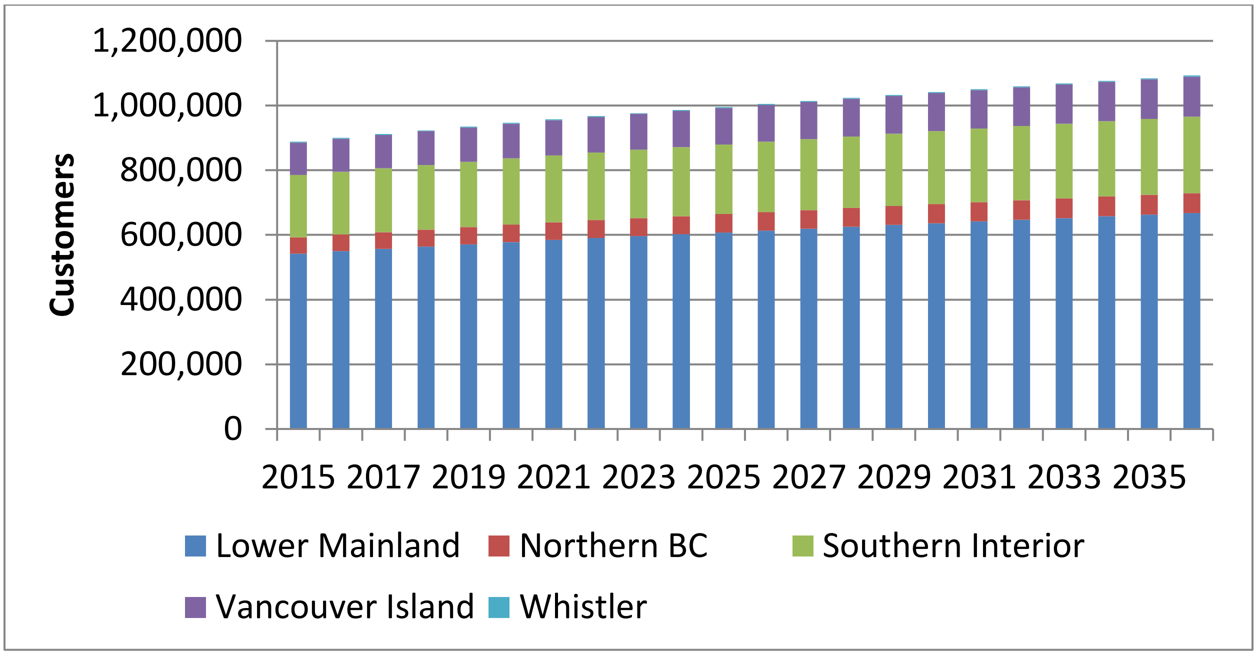
3.3 *CUSTOMER ADDITIONS FORECAST*

FEI uses a well-established method to forecast customer additions that remains consistent with previous LTRP filings. The forecast of residential customer additions is grounded in the Conference Board of Canada housing starts forecast for BC, while commercial customer additions are forecast based on recent trends in growth for the commercial customer group. In its decision on FEI's 2014 LTRP, the BCUC noted that it expects FEI's future LTRP filings to show "forecast variability in new customer additions for all scenarios based on different economic growth assumptions".[93] The 2017 LTGRP relies on a statistical method for altering the Reference Case customer forecast across the various scenarios such that the individual scenarios use different customer forecasts. Please refer to Appendix B-1 for an explanation of this method and illustrations of its impact on the Reference Case account forecast. Section 3.4.4 explains how the LTGRP treats different account growth trajectories as one of the critical uncertainties for its scenario analysis. Section 3.4.5 details the scenario analysis results.

3.3.1.1 Residential

Figure 3-2 shows the Reference Case forecast of residential customers for each of the Company's service areas, as defined for the purpose of this LTGRP. The Reference Case predicts growth of 23 percent across the 20-year planning period with regional distribution remaining relatively unchanged.

Figure 3-2: Long Term Customer Forecast by Region – Residential[94],[95],[96]



3.3.1.2 Commercial

Recent trends in commercial customer additions are used to forecast future additions. The net customer additions are estimated based on actual additions in the latest three years. Recent additions are stronger than in the period between 2010 and 2014 with annual new attachments averaging in the range of 1,400.

93 Decision and Order G-189-14, dated December 3, 2014. p. 16.

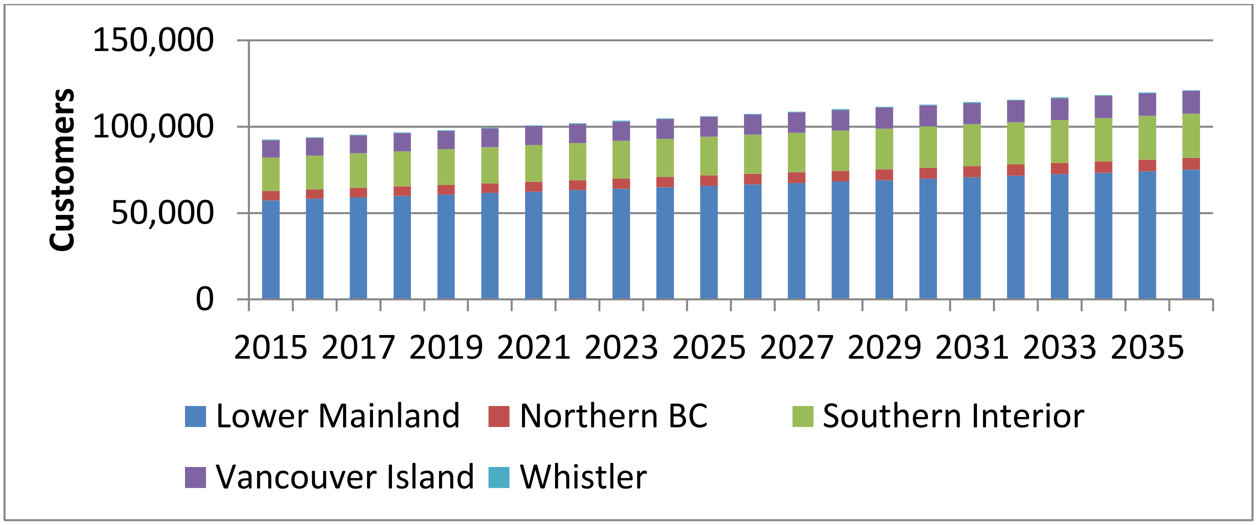
94 All 2017 LTGRP annual demand, customer, GHG, and rate impact graphs, tables, and results exclude data for Vancouver Island Joint Venture, BC Hydro Island Generation, and Company Use.

95 In the 2017 LTGRP analysis customer counts represent the number of FEI accounts.

96 The region names specified in FEI's end-use annual demand forecast method are independent from FEI's internal service areas that may appear in other regulatory submissions or short term forecasts.

Figure 3-3 shows the Reference Case long term account forecast for commercial rate schedule customers for each of FEI's service regions. The Reference Case predicts continued growth of 31 percent across the planning horizon with regional distribution remaining relatively unchanged.

Figure 3-3: Long Term Customer Forecast by Region – Commercial (Excluding NGT)



3.3.1.3 Industrial

The Company had 979 industrial customers in 2015. At the time the long term forecast was prepared, there were no firm commitments for new industrial customers to take natural gas service or for existing customers to close their accounts. Hence, no material growth or decline in industrial customers has been forecasted.

3.4 *FORECAST METHODS*

The amount of natural gas that the Company expects its customers to use over the course of a year determines both the amount of gas that FEI needs to acquire and transport on behalf of its customers on an annual basis, and the number of units of energy per year over which the Company is able to recover its cost of service. Hence, the forecast of annual demand is a key early step in identifying the resources the Company needs to put into place in order to meet customers' future energy needs.

Using historical data to prepare short term time series forecasts of future consumption is a common and accepted industry practice. This method provides a high level of confidence for near-term business and operational decision making. All short-term demand forecasts for revenue requirements at FEI rely on historical data and the short-term Forecast Information System (FIS), which has been in use for over a decade.

However, as described in Section 2, on-going changes in the end-use energy solutions available to customers and the way in which customers are using energy means that historical trends are not robust enough to provide the best basis on which to forecast the long term potential range of future demand. For this reason, the Company used an approach to demand forecasting in the 2014 LTRP that involved examining different ways that end-use trends in energy utilization could potentially impact future demand for natural gas. FEI refers to this newer method as the "end-use method" of demand forecasting. This method produces a Reference Case annual demand forecast but also enables FEI to examine alternate future scenarios. In contrast FEI's Traditional Annual Method provides one forecast trajectory only.

In its review of the 2014 LTRP, the BCUC and interveners recognized the value of the end-use method. The BCUC directed FEI to continue using its Traditional Annual Method as a parallel approach until such time as the BCUC finds the end-use method acceptable as a substitute.[97]

In its decision on the 2014 LTRP, the BCUC also directed FEI to provide a detailed analysis of the relative benefits and shortcomings of its particular end-use method as compared to other end-use methods. FEI commissioned Boreas Consulting Ltd. (Boreas) to prepare this analysis. Boreas concludes that almost half of the 30 surveyed North American entities use end-use models for all or part their long term forecasts. Entities that run DSM programs or exist within an uncertain or changing planning environment are more likely to use an end-use method. Boreas completed its review before FEI updated its end-use model for the 2017 LTGRP and at that time concluded that FEI's end-use model compares well with other North American end-use methods. Please refer to Appendix B-2 for the Boreas report.

In this 2017 LTGRP, FEI continues to improve on its end-use method as well as to use its Traditional Annual Method. Improvements for the 2017 LTGRP not only enhance FEI's ability to examine the end-use method Reference Case annual demand forecast but also to analyse how annual demand behaves across alternate future scenarios.

Section 3.4.1 below outlines FEI's approach to the end-use method. Section 3.4.2 discusses the end-use method Reference Case annual demand forecast results. Section 3.4.3 compares the end-use method Reference Case forecast results to the Traditional Annual Method forecast results. Based on this foundation, Section 3.4.4 subsequently discusses how end-use method annual demand behaves across alternate future scenarios.

Please refer to Appendix B-3 for more detailed results from the Traditional Annual Method.

3.4.1 End-Use Annual Demand Method – Residential, Commercial and Industrial

To prepare the 2017 LTGRP end-use forecast, the Company used the following data sources to calibrate[98] the forecast model to FEI's 2015 base year actuals and to identify Reference Case end-use changes across the forecast horizon:

[97] Decision and Order G-189-14, dated December 3, 2014.

[98] The calibration process ensures that the sum total annual natural gas demand of all base year end uses in the end-use demand forecast model matches FEI's base year actuals.

- The BC Conservation Potential Review (BC CPR) which represents a collaborative provincial forecast (sponsored by FEI, FBC, BC Hydro, and Pacific Northern Gas) of energy conservation potential and thus benefits from data supplied by all sponsors as well as the rigour of multiple entities acting as reviewers;
- FEI's 2012 Residential End-use Survey (REUS); FEI's 2017 REUS is not complete at the time of filing the 2017 LTGRP;
- FEI's 2015 Commercial End-use Survey (CEUS) which represents FEI's most recent study of its commercial customers; and
- Research and data analysis from the 2014 LTGRP which FEI included to utilize and build upon work that had already been completed for the 2014 LTRP.

FEI engaged Posterity Group (Posterity) to support FEI in preparing the end-use forecast for the 2017 LTGRP. Members of Posterity's team were instrumental in preparing FEI's 2010 CPR and 2014 LTRP end-use demand forecast. Posterity prepared an updated end-use forecast model for FEI based on lessons learned from the 2014 LTRP. As in the 2014 LTRP, the current end-use model provides raw data outputs to FEI which FEI further processes with the database infrastructure that it created for the 2014 LTRP.

The end-use forecast process starts with developing a Reference Case forecast. The Reference Case is based on end-use patterns observed in the base year and keeps these patterns constant throughout the planning period. The impact of C&EM programs up to and including 2015 are thus implicitly included in the end-use characteristics identified for the base year, but the existing program activity is assumed not to have any incremental impact through the planning period for the purpose of demand forecasting. Section 4 separately discusses the impact of FEI's forecast future C&EM activities.

3.4.2 Development of the Reference Case for Annual Demand

The Reference Case began with the development of a base year, in this case 2015. FEI provided Posterity with a database of accounts and weather normalized consumption data, categorized by region, rate schedule, and industry (for industrial and commercial customers). To further subdivide natural gas consumption by end-use, Posterity drew on the detailed customer knowledge assembled by the BC CPR and the 2014 LTRP, including end-use consumption, market saturation[99] and gas share.[100] As described in Section 3.4.1 above, some

[99] Market saturation is a percentage indicating what portion of the population of buildings has a given end-use. For end-uses such as space heating and water heating, this is assumed to be 100 percent of dwellings. For an end-use such as clothes drying, where the logical unit of analysis is the appliance, the percentage is the number of clothes dryers divided by the number of dwellings. Market saturation in the commercial sector is based on the percentage of building floor space with a given end-use, instead of percentage of dwellings. Market saturation is not employed in the industrial model – saturation is taken into account in the overall end-use consumption for a given plant type.

[100] Gas share is the percentage of the energy end-use that is supplied by natural gas. For clothes dryers, for example, this translates into the percentage of dryers that are natural gas-fired. Note that that gas share is based

of this information has been derived from end-use surveys commissioned by the Company, while other aspects emerged from detailed building modeling. The resulting model, calibrated to FEI's actual normalized sales of natural gas, is subdivided as follows:

- By region: Lower Mainland, Vancouver Island, Whistler, Southern Interior, Northern BC;[101]
- By sector: Residential, Commercial and Industrial;
- By segment (i.e. sub-sector):
    - In residential — three dwelling types, detachment type, dominant heating fuel, and vintage;
    - In commercial — seventeen building types, by predominant use and building size (office, retail, school, hospital, etc.);
    - In industrial — ten plant types;
- By rate schedule: one rate schedule in residential, six rate schedules in commercial, and nine rate schedules in industrial; and
- By end-use: twelve residential, five commercial and seventeen industrial gas end-uses.

Beginning with the calibrated base year, the Reference Case forecast was built using the Company's 20-year account forecast (discussed in Section 3.3), with new residential dwellings, commercial floor area and industrial facilities added based on the account growth rates. Anticipated efficiency improvements, such as the natural replacement of furnaces, were incorporated in both existing buildings and new construction. Anticipated changes in the saturation and gas shares for specific end-uses were also included. The end-use forecast model provides the forecast consumption values for each forecast year at the same level of granularity as the base year.

Figures 3-4 and 3-5 below display end-use demand forecast annual demand by sector and by region. Overall, Reference Case demand is expected to grow slightly, motivated by growth in the commercial and residential sectors.

---

on the percentage of useful energy supplied to accomplish the end-use (i.e. the tertiary load); actual energy consumption equals tertiary load divided by the efficiency of the appliance that meets this load.

[101] The region names specified in FEI's end-use annual demand forecast method are independent from FEI's internal service areas that may appear in other regulatory submissions or short term forecasts.

Figure 3-4: Reference Case Annual Demand Forecast by Rate Schedule – End-Use Method (Excluding NGT)[102]

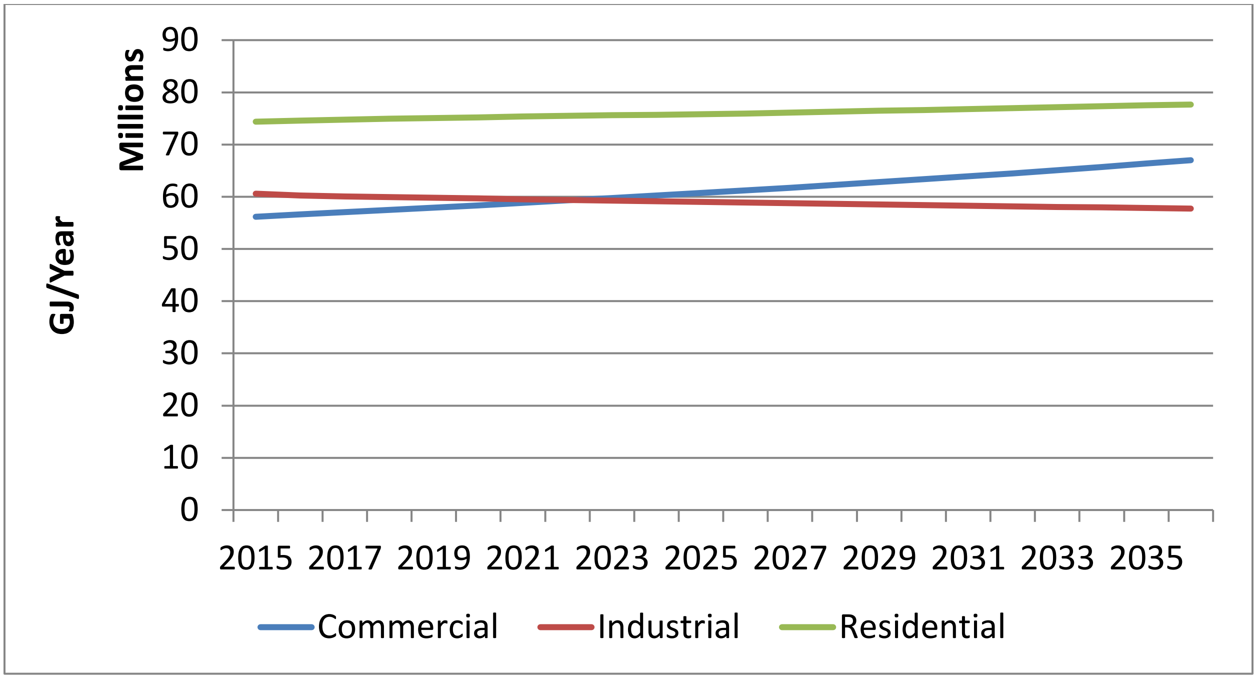


Figure 3-5: Reference Case Annual Demand Forecast by Region – End-Use Method (Excluding NGT)

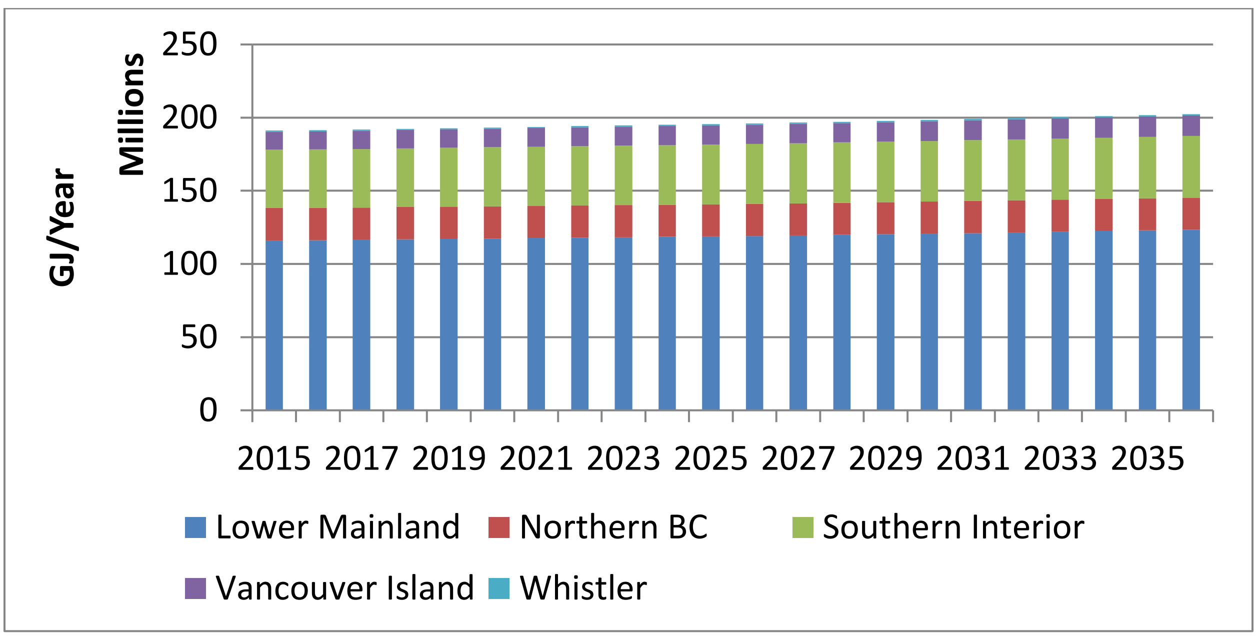


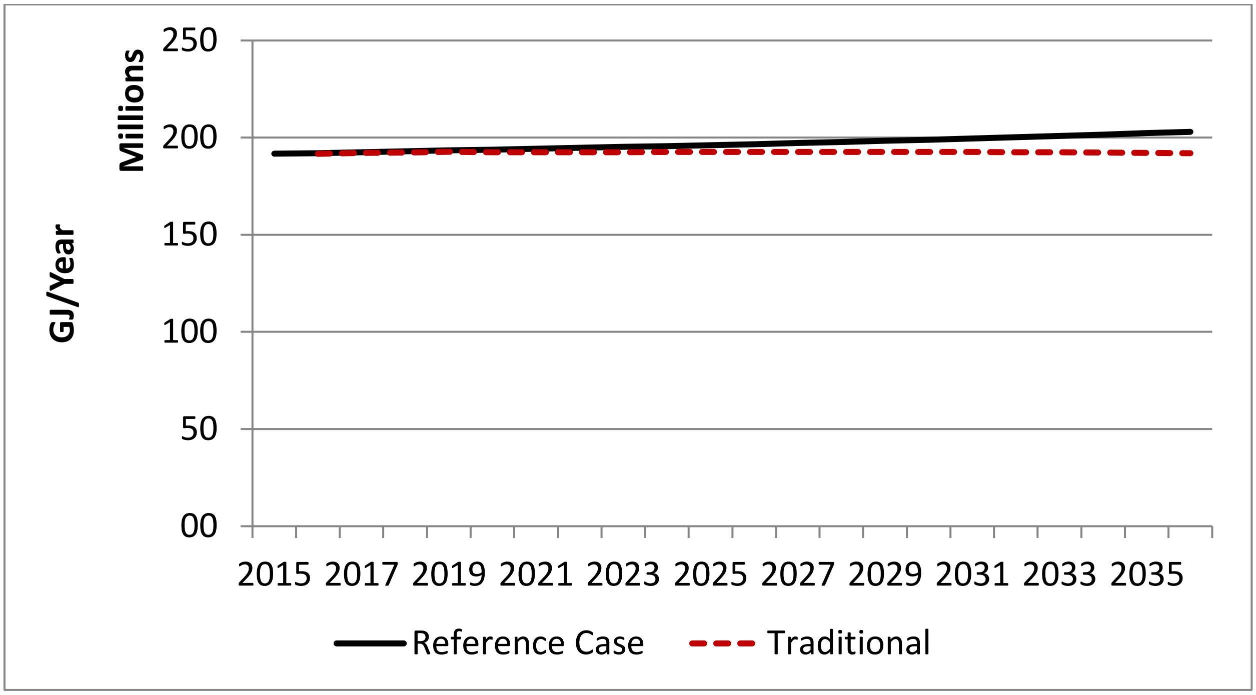
[102] This and the following figure exclude consumption of FEI's LNG customers.

3.4.3 Comparing the Traditional and End-Use Methods For Forecasting Annual Demand

As discussed above, FEI's end-use method differs in a number of ways from its time-series based Traditional Annual Method. Comparing the end-use method Reference Case results with the results of the Traditional Annual Method grounds the results of the end-use method before FEI proceeds to use this method for examining the impact on annual demand of alternate future scenarios. If the results of the Traditional Annual Method demand forecast and the end-use method Reference Case annual demand are reasonably aligned, then the end-use method provides a reasonable basis for developing alternate future scenarios.

Figure 3-6 below compares the annual demand results of the Traditional Annual Method with the results of the end-use method Reference Case. By the end of the planning period the two forecast methods differ by less than six percent. This variance is due to the various differences between the two methods. One of these differences is that the Traditional Annual Method includes intrinsic historical end-use trends, whereas the end-use method Reference Case limits itself to fully known, legally enshrined, and mandatory data. For example, the Traditional Annual Method includes historical change trends of energy performance codes and standards while the end-use method Reference Case only accounts for such changes that are already legally enshrined and are or will be mandatory during the forecast horizon. By the same token, the Traditional Annual Method includes historical C&EM program participation trends whereas the end-use method Reference Case relies on specific assumptions regarding future changes in equipment characteristics and adoption but not C&EM programs. Across the LTGRP planning horizon, FEI uses the end-use method Reference Case to plan for its forecast long term annual demand.

Figure 3-6: Comparison of Annual Demand Forecasts



3.4.4 Alternate Future Scenarios

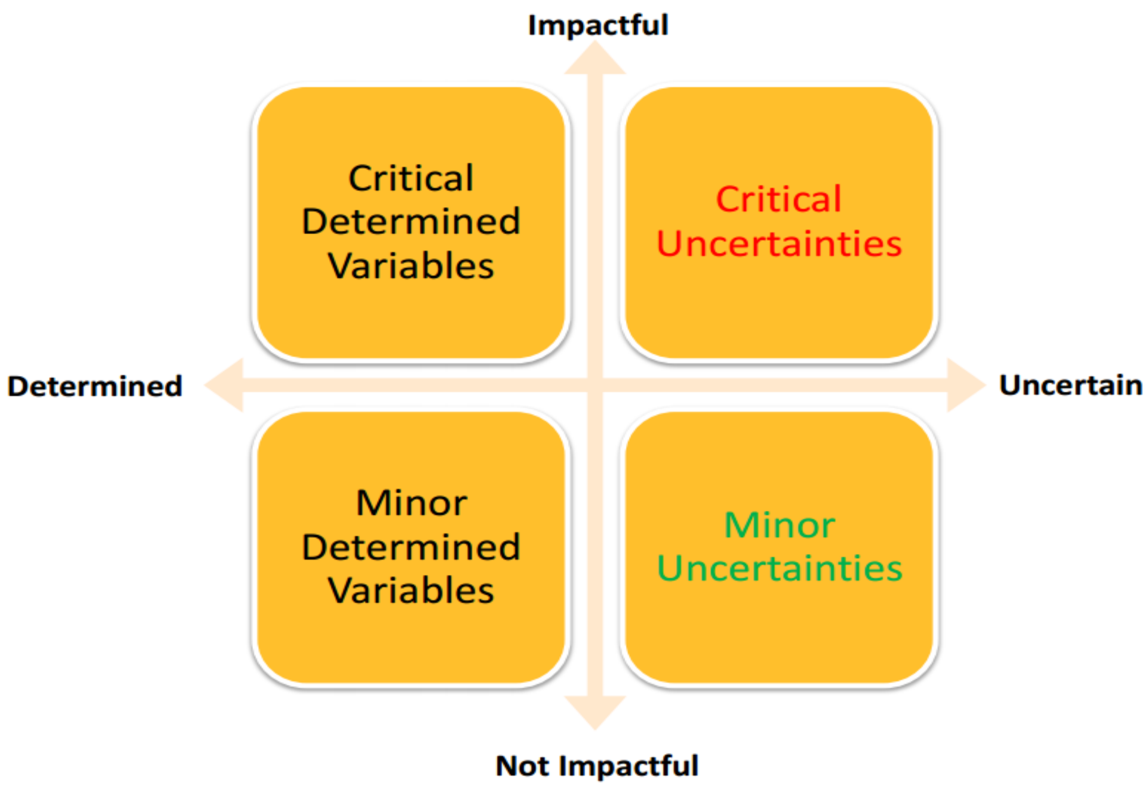
The Reference Case provides a baseline against which forecast demand under five different alternative future scenarios is examined. The five future scenarios are intended to provide insight into the impact on demand of a broader range of potential future conditions than has been examined in previous LTRPs. These five scenarios were developed based on critical uncertainties identified with input from the scenario analysis work for the 2014 LTRP, both internal FEI stakeholders and members of the external Resource Planning Advisory Group (RPAG), as well as themes that emerged from the 2017 LTGRP's community engagement workshops. The critical uncertainties represent those future conditions that FEI and stakeholders felt could have the biggest impact on FEI's business.

Following a standard scenario planning approach, FEI's scenario analysis proceeds in four steps:

1. Evaluating planning environment variables and identifying critical uncertainties;
2. Determining the number of outcomes and their broad qualitative boundaries for each selected critical uncertainty;
3. Determining plausible combinations of outcomes for each critical uncertainty and creating reasonable scenario plotlines; and
4. Populating quantitative data into the outcomes for each critical uncertainty and iterating with internal and external stakeholder feedback.

The first step in the above list intends to focus the scenario analysis by determining which of the manifold variables in the planning environment should be used to alter the Reference Case into various alternate future scenarios. This involves selecting the most impactful and most uncertain variables. Figure 3-7 below illustrates how FEI classified planning environment variables for this first step:

Figure 3-7: Classification of Planning Environment Variables



FEI intentionally held each step separate from the other steps. Selecting critical uncertainties first and then determining their qualitative boundaries before generating the plotlines and populating quantitative data guards against inadvertently favoring certain visions of the future over others by presupposing scenario results rather than focusing on inputs.

The 2017 LTGRP's critical uncertainties break down as follows:

- Economic variables:
  - Economic growth, represented by account growth values in the forecast model;
  - Natural gas commodity price, based on a multitude of third-party forecasts (this accounts for price changes motivated by various factors, such as demand-supply balance or upstream regulatory changes);

- Policy variables:
  - Carbon price, which accounts for provincial and federal carbon pricing actions and is agnostic to the specific pricing mechanism (the forecast model simply assumes a stream of price values without identifying, for example, whether these are the result of a carbon tax or a cap and trade system);
  - Non-price policy levers, which account for changes in the building code, energy performance standards, and any requirements for switching from one fuel type to another (e.g. district energy systems[103]); and
- The extraneous variables of RNG demand, NGT demand, and demand from large industrial point loads (FEI's scenario analysis assumes that the RNG and NGT markets are still emerging and thus primarily depend on policy and stakeholder action rather than other macroeconomic factors).

Table 3-1 below summarizes the five alternate future scenarios, their descriptions and input settings, and includes a brief discussion of each scenario's specific attributes. This table does not include the Reference Case because the Reference Case sets the baseline for the scenario analysis by using the Reference input setting for all critical uncertainties. Based on the Reference Case, the scenario analysis alters the outcomes of each critical uncertainty to be higher and lower, respectively, than their Reference outcome. Please see Appendix B-1 for a description of the scenario analysis method and the critical uncertainty parameters:

Table 3-1: Alternate Future Scenario Summary

Scenario	Description	Input Settings		Discussion
A (Upper Bound)	The BC economy experiences higher-than-average growth. Infrastructure development in other regions, coupled with extraction infrastructure development in BC, keep regional gas supply abundant. Continued political opposition to carbon pricing and non-price carbon policy action cause governments to focus on issues other than carbon policy but the BC government keeps supporting NGT and RNG as cost effective existing carbon solutions.	Economic Growth	High	In general, the outcomes of the multiple critical uncertainties can offset each other's impact on annual demand but this scenario combines all outcomes that would increase annual demand. As such, this scenario represents one of two boundary scenarios that frame the scenario analysis. The combination of outcomes on each critical uncertainty is plausible and has occurred in the past.
		Natural Gas Price	Low	
		Carbon Price	Low	
		Non-Price Carbon Policy Action	Delayed	

[103] As noted in Section 2.3.4, some BC municipalities are pursuing goals to supply 100 percent of their energy needs via clean and renewable sources by 2050. Some of these municipalities are encouraging deployment of district energy systems. In the near term, such district energy systems may rely on natural gas but municipalities may intend to shift these to other fuel sources in the long term.

Scenario	Description	Input Settings		Discussion
B (Local Growth & Constricted Supply)	The BC economy experiences higher-than-average growth. This is paralleled by moderate growth elsewhere which continues fuelling existing demand for natural gas and constricts BC's natural gas demand balance. High natural gas prices and continued political opposition to carbon pricing and non-price carbon policy action cause government policy to implement energy performance standards upgrades published in their existing vision documents but to avoid imposing carbon costs that exceed annual increases of $5 per metric tonne.	Economic Growth	High	This represents one of the three intermediate scenarios in which outcomes of the multiple critical uncertainties do offset each other's impact on annual demand. Economic growth creates upward pressure on annual demand which is more strongly felt in the commercial and industrial sectors than in the residential sector. Price signals counteract this upward pressure on annual demand (these signals, again, more strongly impact the commercial and industrial sector in relation to the residential sector). Carbon policy action also dampens annual demand. Non-price carbon policy levers more significantly impact residential sector demand than commercial and industrial sector demand.
		Natural Gas Price	High	
		Carbon Price	Medium Increase	
		Non-Price Carbon Policy Action	Accelerated	
C (Global Growth & Carbon Step Change)	The BC economy experiences higher-than-average growth as part of a global economic upturn. Infrastructure development in other regions (such as a strong focus on renewable fuel sources which reduces natural gas export opportunities), coupled with extraction infrastructure development in BC, keep BC's gas demand balance abundant. Global economic performance contributes to a political climate that is favourable to carbon pricing and non-price carbon policy action. This provides governments confidence to strongly focus on carbon policy.	Economic Growth	High	This represents the second of the three intermediate scenarios. This scenario differs from Scenario B in the natural gas and carbon price settings. The annual demand impacts in this scenario versus Scenario B show the trade-off between the natural gas and carbon price trajectories. The directional implications of each critical uncertainty on annual demand in this scenario are identical to Scenario B.
		Natural Gas Price	Low	
		Carbon Price	High Increase	
		Non-Price Carbon Policy Action	Accelerated	

Scenario	Description	Input Settings		Discussion
D (Global Economic Stagnation)	The BC economy experiences lower-than-average growth as part of global economic stagnation which also reduces excess regional demand for natural gas and keeps BC's gas demand balance abundant. Global economic performance contributes to a political climate that is not favourable to carbon pricing and non-price carbon policy action. This causes governments to focus on areas other than carbon policy.	Economic Growth	Low	This represents the third of the three intermediate scenarios and examines the possible impact of further economic stagnation. The annual demand impact of low economic growth is offset by low natural gas and carbon pricing and delayed carbon policy action. As in Scenarios B and C, price signals and the economy are more impactful for the commercial and industrial sector, whereas carbon policy action more significantly impacts the residential sector.
		Natural Gas Price	Low	
		Carbon Price	Low	
		Non-Price Carbon Policy Action	Delayed	
E (Lower Bound)	The BC economy experiences lower-than average growth as part of global economic stagnation. This reduces investment in regional gas supply so much that BC's demand balance becomes constricted. Global economic performance contributes to a political climate that is not favourable to carbon pricing and non-price carbon policy action in other jurisdictions but causes a counter-movement in BC. This causes the BC government to focus on carbon policy and electrification without support for NGT and RNG.	Economic Growth	Low	This represents the second of the two boundary scenarios. This combination of outcomes across the critical uncertainties is plausible but has not been prevalent in the past. Governments have typically been reluctant to impose taxes and other restrictions, including carbon pricing and carbon policy actions, during periods of economic stagnation.
		Natural Gas Price	High	
		Carbon Price	High Increase	
		Non-Price Carbon Policy Action	Accelerated	

The modeling process involved turning each of these assumptions into concrete changes to the input values for buildings in the three sectors. For example, in response to higher or lower gas prices, adjustments were made to the number of new buildings using natural gas for specific end-uses, or to the number of existing buildings whose owners might opt to change fuels when equipment needs replacement. The policy environment affects assumptions about the number of customers who would opt to install energy efficient equipment naturally, without influence from utility programs. Assumptions for developing district energy systems resulted in adjustments to the fuel shares for those options: increases in those fuel shares would generally displace the demand for natural gas. Renewable energy systems include systems such as geo-exchange, waste heat recovery, and solar thermal energy. This has the effect of displacing natural gas consumption, particularly for space and water heating in commercial buildings and apartments. With limited but growing market penetration of low carbon thermal energy systems, the Company must continue to monitor this growth to gauge its impact over time on the Utility's natural gas infrastructure, annual and peak day demand, system capacity needs and rate design.

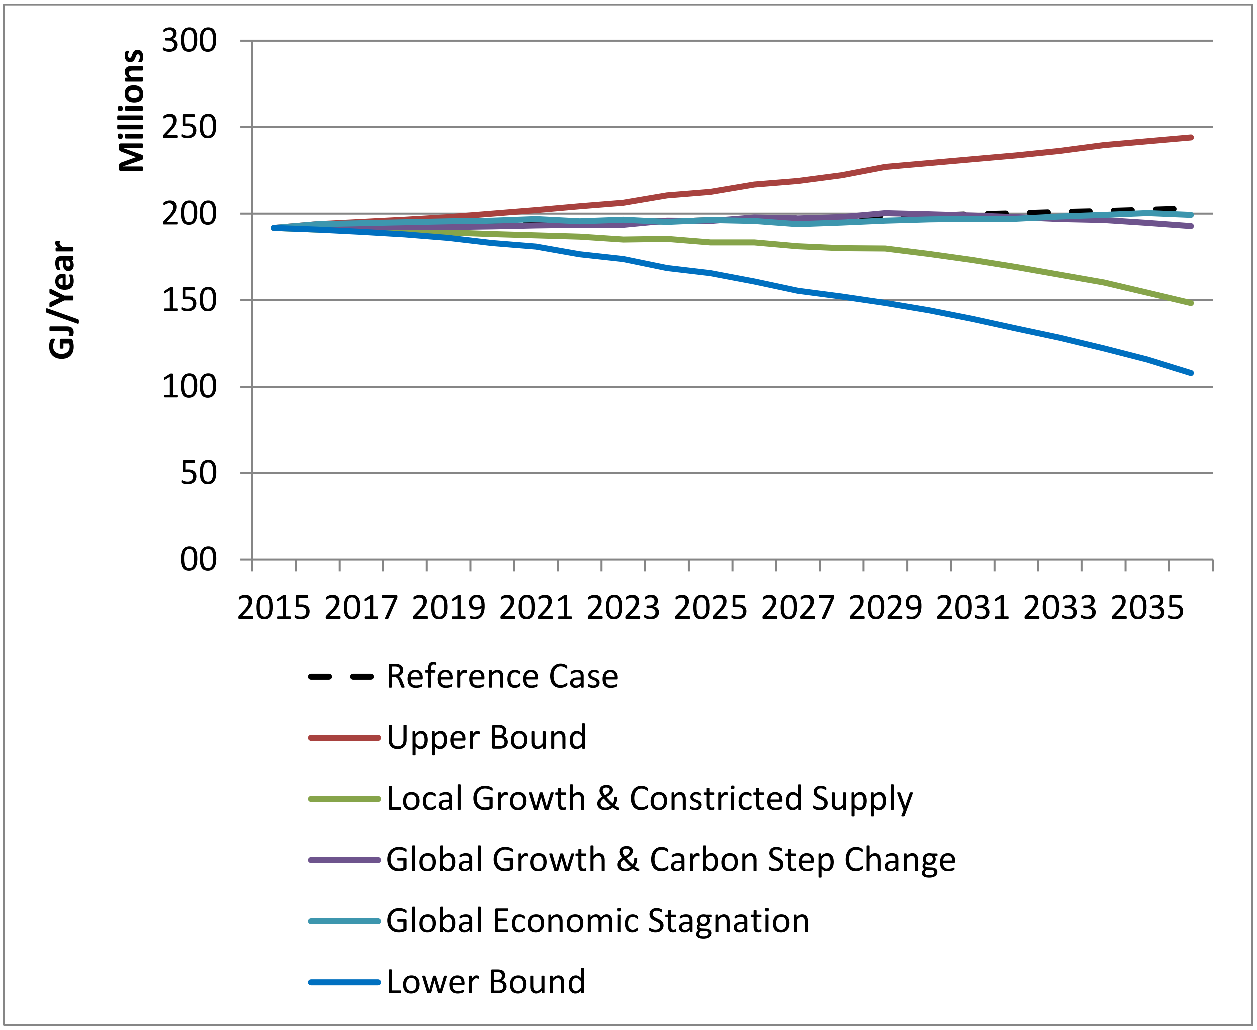
The model results for Scenarios A through E have the same level of granularity as the Reference Case. FEI does not predict which scenario will unfold in the future and does not assign probabilities to the scenarios. Rather, the five scenarios (considered together) provide a reasonable range of possible future demand that the Company will need to serve over the next 20 years.

Please refer to Appendix B-1 for a detailed explanation of the end-use demand forecast scenario parameters.

3.4.5 End-Use Demand Forecast Results by Scenario

Figure 3-8 below displays the end-use annual demand Reference Case and scenario results for all sectors and regions.

Figure 3-8: Annual Demand Scenarios – All Sectors (Excluding NGT)



As can be seen in Figure 3-8, the Upper and Lower Bound scenarios denote the range of the forecast. By the end of the planning period, this range accounts for a variation of 67 percent around the Reference Case. This range has widened since the 2014 LTRP due to increased policy uncertainty and FEI's updates to the scenario analysis inputs. Nevertheless, the majority of scenarios (and the Reference Case) cluster within a narrower annual demand range since outcomes across critical uncertainties offset each other's impact on annual demand.

Figure 3-9 below displays the same information for the residential sector.

Figure 3-9: Annual Demand Scenarios – Residential Sector

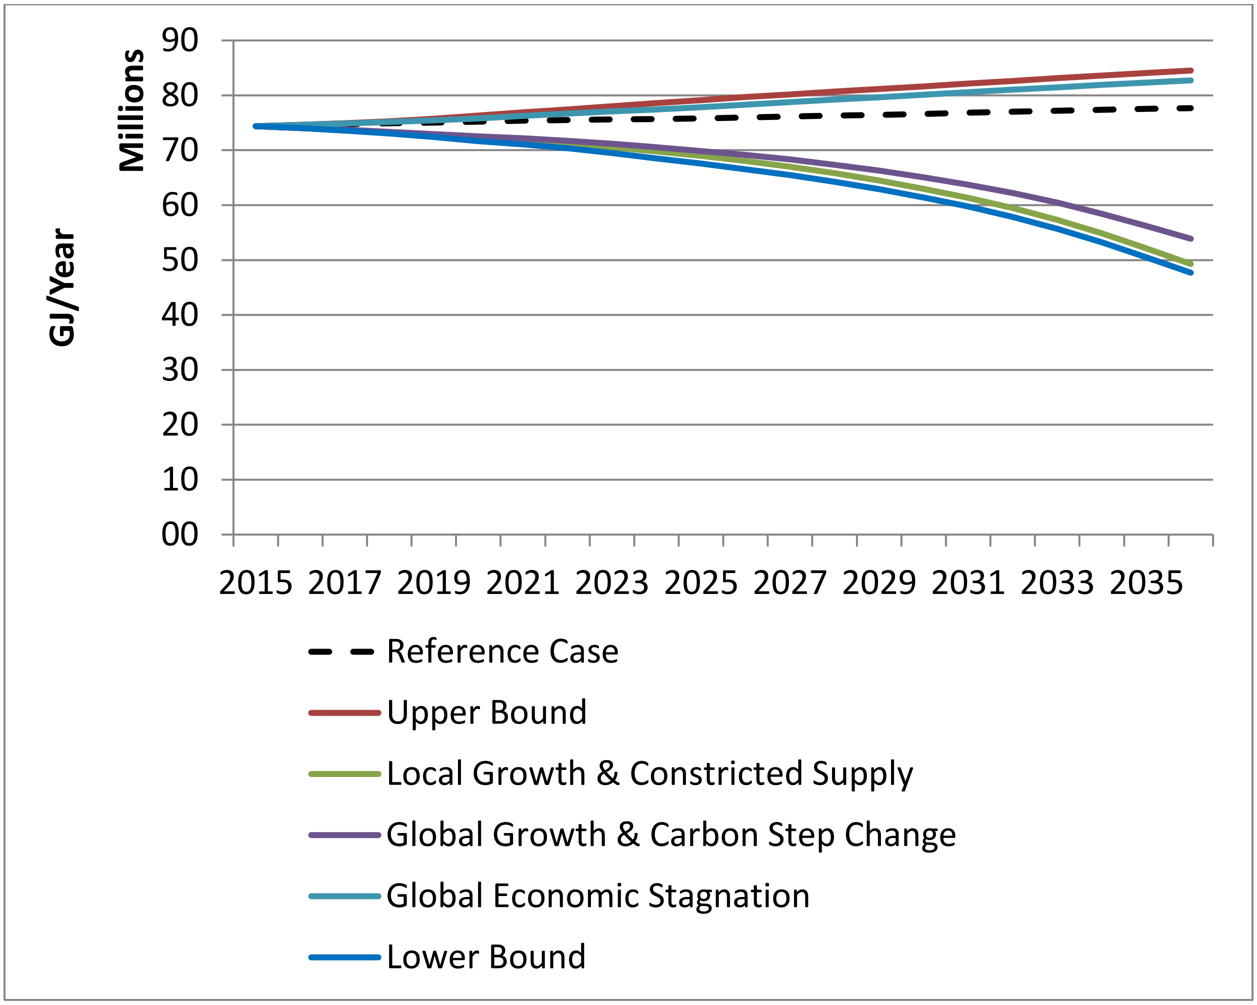


Figure 3-9 illustrates the following effects for the residential sector:

- The Upper Bound and Global Economic Stagnation scenarios differ in their economic growth assumption only. Annual demand for these two scenarios is aligned closely because, in FEI's forecast model, economic growth has a limited impact on residential sector customer numbers.
- The remaining three scenarios are also closely aligned. The difference between the Local Growth & Constricted Supply and Global Growth & Carbon Step Change scenarios highlight how the trade-off in natural gas versus carbon pricing between these scenarios impacts residential annual demand.

As illustrated for the Lower Bound scenario in Figure 3-10 below, the declining demand scenarios also involve a significant decline in space heating annual demand. Measured by annual demand, central space heating remains the top end-use until the end of the planning period. Domestic hot water end-use annual demand declines below fireplace annual demand near the middle of the planning period (this does not apply to the Reference Case and Upper Bound scenario). This observation represents one of the interesting results that can be extracted by utilizing the end-use method (in contrast to the Traditional Annual Method).

Figure 3-10: Lower Bound Annual Demand – Residential Sector (Excluding NGT) Top End Uses

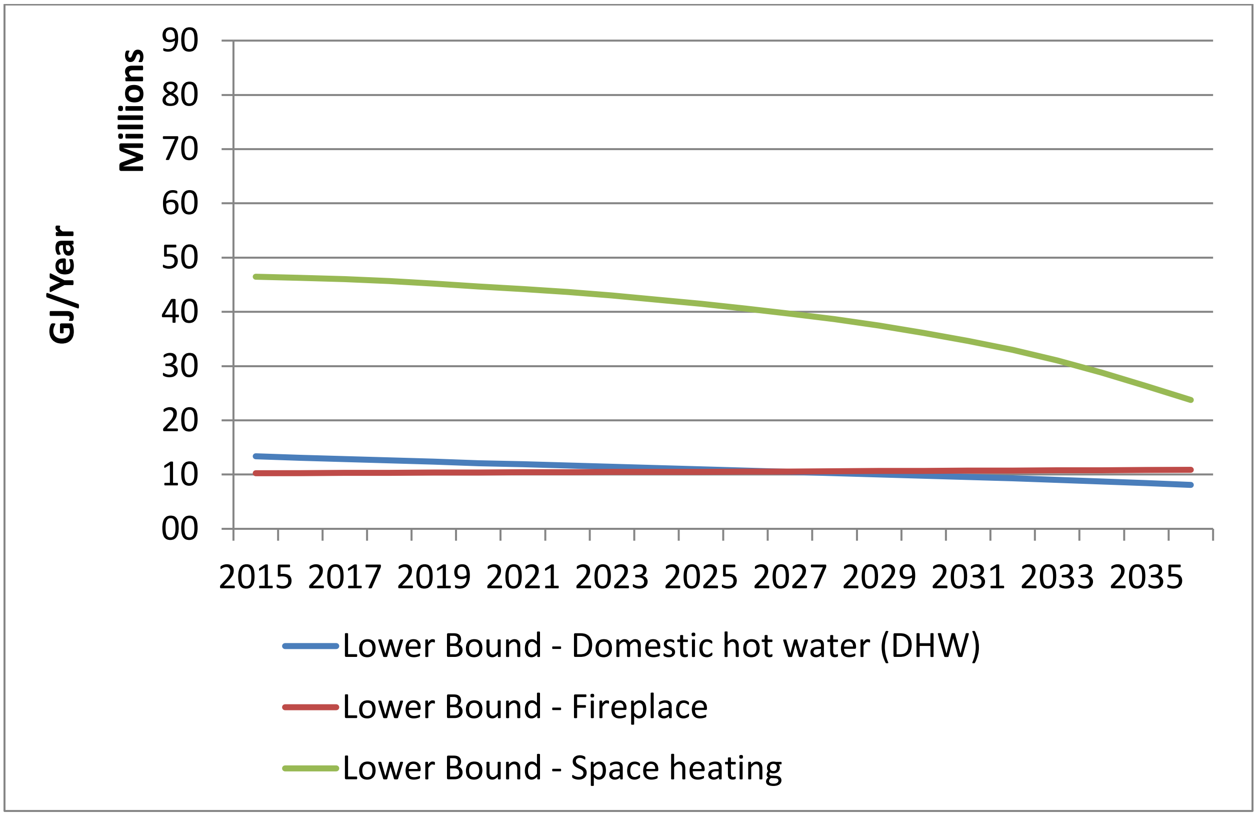

Figure 3-11 below displays the same information for the commercial sector in all regions.

Figure 3-11: Annual Demand Scenarios – Commercial Sector (Excluding NGT)

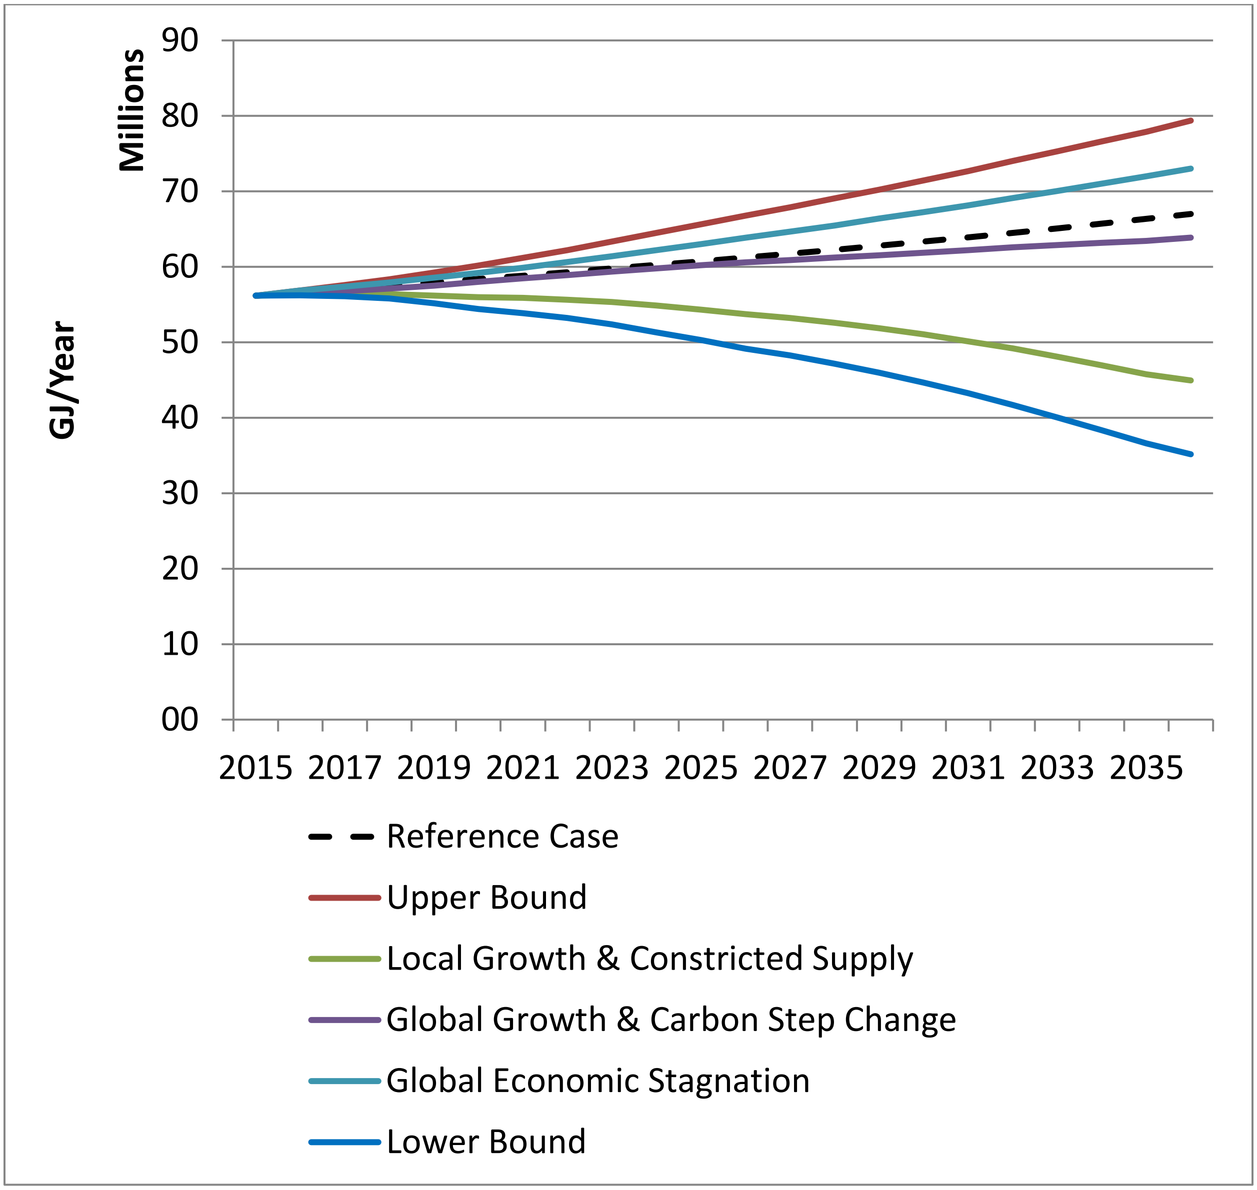

Figure 3-11 illustrates the following effects for the commercial sector:

- The annual demand difference between the Upper Bound and the Global Economic Stagnation scenarios illustrates the annual demand impact of the economic growth critical uncertainty on the commercial sector.
- The widened difference between the Local Growth & Constricted Supply and the Global Growth & Carbon Step Change scenarios highlights the increased annual demand impact of prices for the commercial in relation to the residential sector (price changes

are the result of the trade-off between natural gas and carbon pricing across the two scenarios).

- In the commercial sector, the Global Growth & Carbon Step Change scenario displays annual demand growth since the impact of high economic growth outweighs the impact of price signals and non-price carbon policy action.

Figure 3-12 below displays the same information for the industrial sector in all regions.

Figure 3-12: Annual Demand Scenarios – Industrial Sector (Excluding NGT)

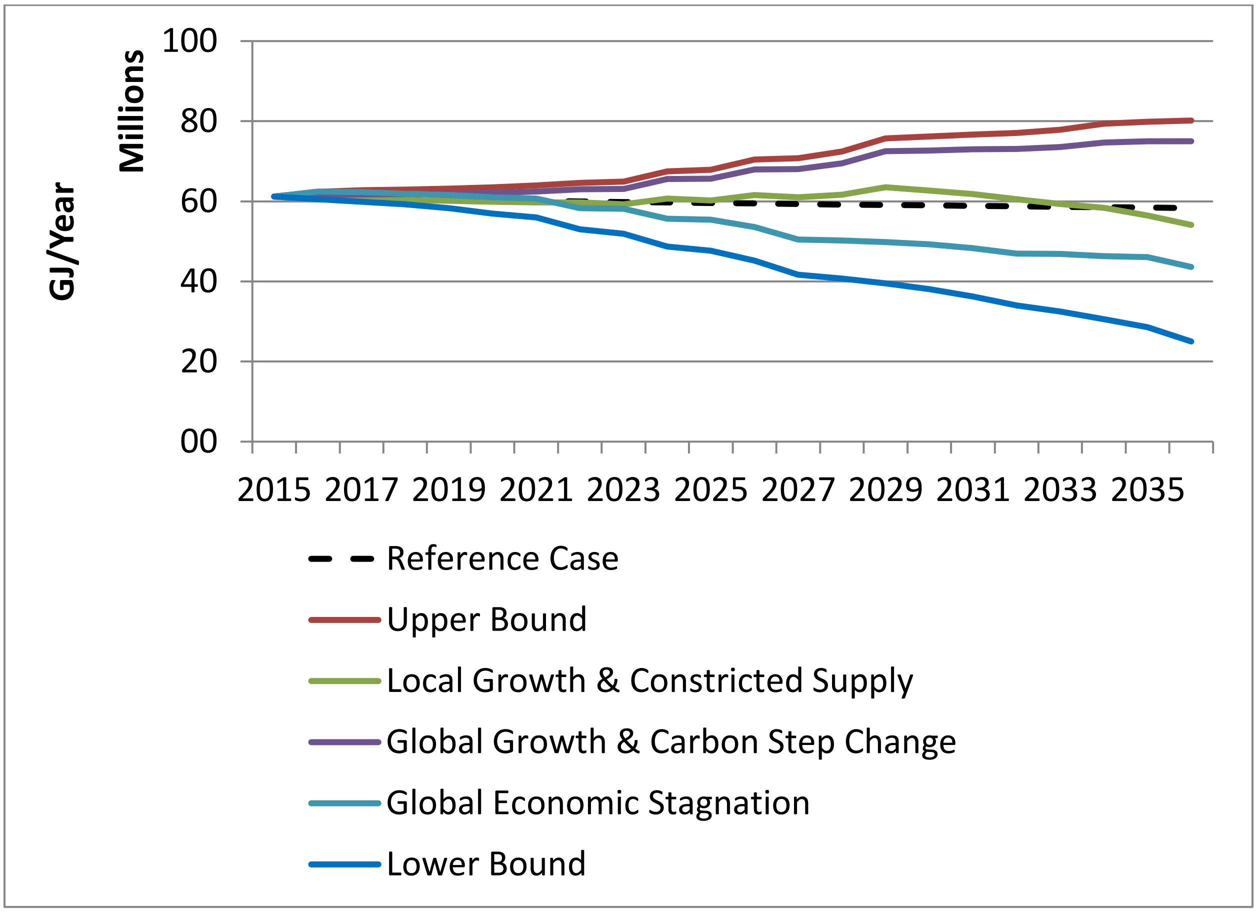

Figure 3-12 illustrates the following effects for the industrial sector:

- The annual demand trajectories are jagged because the economic growth critical uncertainty causes additions/removals of individual customers, and industrial customers typically have high annual demand.
- The annual demand difference between the Upper Bound and the Global Economic Stagnation scenarios illustrates the significant annual demand impact of the economic growth critical uncertainty on the industrial sector (in relation to the residential and commercial sectors).

- Again, the widened difference between the Local Growth & Constricted Supply and the Global Growth & Carbon Step Change scenarios highlights the increased annual demand impact of prices for the industrial in relation to the residential sector (price changes are the result of the trade-off between natural gas and carbon pricing across the two scenarios).
- Annual demand for the Global Growth & Carbon Step Change scenario is closely aligned with the Upper Bound scenario. These two scenarios differ in their carbon price and non-price carbon policy action critical uncertainties only. Since non-price carbon policy action has a limited impact on the industrial sector, this alignment illustrates the influence of carbon pricing on the industrial sector.
- Annual demand for the Global Economic Stagnation scenario initially exceeds the Local Growth & Constricted Supply scenario but falls below this over time. In the Global Economic Stagnation scenario, low natural gas and carbon pricing initially compensate for low economic growth but fail to do so throughout the remainder of the planning period.

3.4.6 RNG Demand

Based on the historical performance of the RNG program, FEI anticipated that the annual demand impact of this program across the planning period would be limited. FEI included a full quantitative RNG annual demand forecast in the 2017 LTGRP because of stakeholder interest in seeing this data. Stakeholders in both the RPAG and FEI's Community Engagement workshops voiced this opinion.

Figure 3-13 below displays the Reference Case share of RNG annual demand in relation to total natural gas demand. Customers that use RNG still utilize FEI's infrastructure. RNG annual demand displacing conventional natural gas demand for individual customers does not change the total volume of annual demand that FEI's infrastructure provides to such customers.

Figure 3-13: Reference Case Annual Demand – All Sectors (Excluding NGT), Data Labels Denote RNG Demand

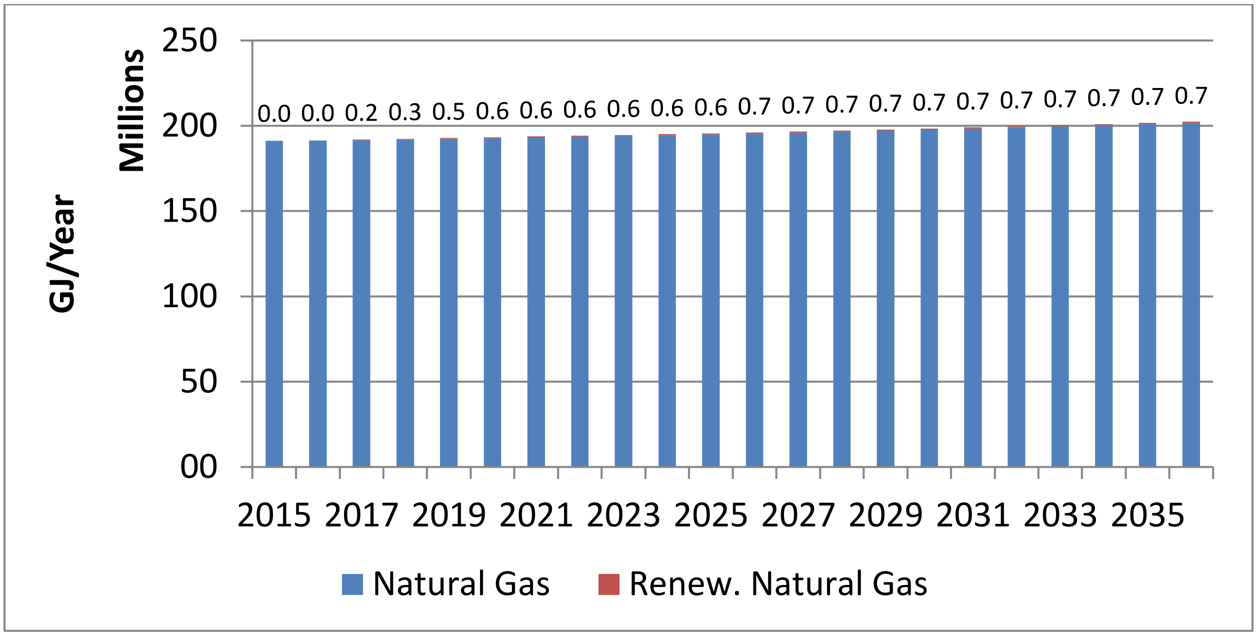

Figure 3-14 below displays how RNG annual demand changes across the 2017 LTGRP scenarios. In the Reference Case, RNG annual demand grows by 195 percent by 2036. This growth rate changes to 888 percent and 117 percent in the Upper and Lower Bound scenarios, respectively. The links between the core end-use forecast and the RNG annual demand forecast are qualitative only because RNG represents an emerging market. FEI provided the core end-use forecast scenario parameters to its RNG program team and requested this team to prepare three forecast trajectories (Reference Case, Low, High) based on these scenario parameters. FEI's RNG program team prepared the three forecast trajectories by altering expectations about committed projects, projects under negotiation, and assumptions about plausible future capture rates. FEI's RNG program team also shaped the resulting RNG annual demand forecast trajectories to align with expectations about RNG supply availability within the currently approved pricing model.[104] FEI's forecast trajectories assume current RNG supply technologies. FEI is aware that pilot projects exist for proving the commercial scalability of RNG from wood waste. If such cellulosic biogas does become available at reasonable prices, it could dramatically increase RNG supply and thus potentially enable FEI to substantially increase RNG annual demand via its RNG program. FEI will continue monitoring the progress of cellulosic biogas pilot projects.

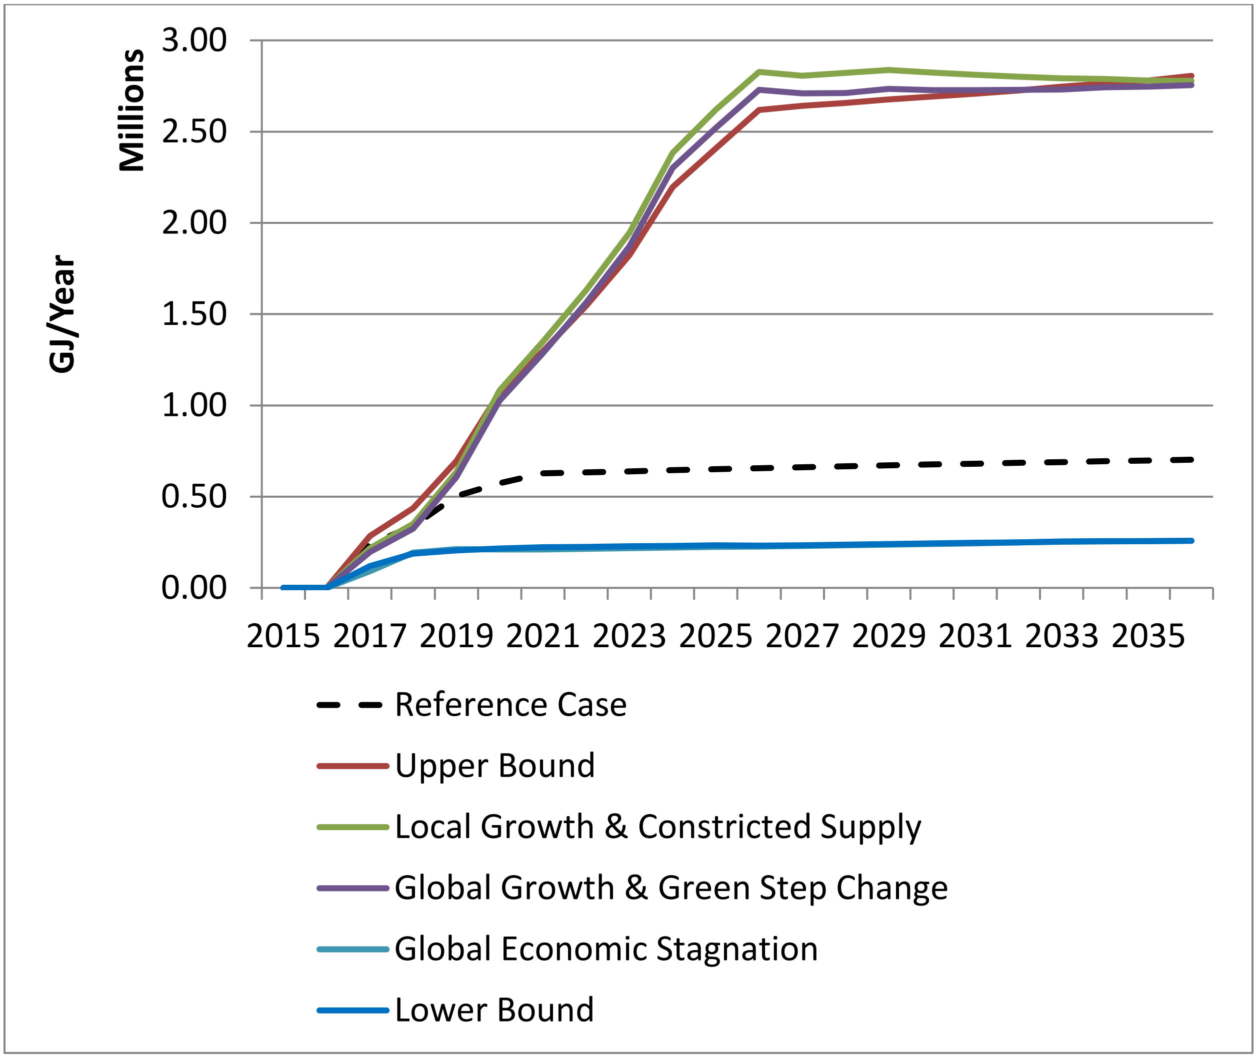
[104] RNG forecasts account for regulatory decisions up to the end of March 2017.

In the scenario analysis, shifts to RNG displace some fuel switching away from conventional natural gas to non-gas fuel types. For example, in the Global Growth & Carbon Step Change scenario, policy impels some customers to switch away from conventional natural gas. Across FEI's customer sectors, this switch away from natural gas is offset by the difference between the Reference Case RNG annual demand and the Global Growth & Carbon Step Change RNG demand.

Figure 3-14: RNG Annual Demand Scenarios – All Sectors



3.4.7 Forecast of Annual CNG and LNG Demand

Natural gas as a transportation fuel has emerged as a growing market in BC, both for CNG and LNG customers. As discussed in Section 2, the Company has established programs (incentive and infrastructure investment opportunities) that are enabled through the BC government's GGRR to assist customers with:

- Incentives toward the incremental cost of new natural gas vehicles (which includes marine vessels, mine haul trucks, on-road trucks, buses and locomotives) and remote power generation applications;
- Incentives toward upgrading maintenance shop facilities to service natural gas vehicles; and
- The construction of fuelling infrastructure that would service these natural gas applications.

The long term CNG and LNG demand forecasts presented in this section are based on three factors: (1) FEI's experience in the GGRR vehicle incentive applications that FEI conducts quarterly to solicit incentive funding interest from NGT customers, (2) industry research, and (3) policy changes that are expected to impact the demand for natural gas as a transport fuel in the future. Some other considerations are the allowed funding period permitted under the GGRR, actual NGT customer additions to date and the relative price of competing or incumbent fuels such as diesel fuel. Sections 3.4.7.1 and 3.4.7.2 further elaborate on these factors.

The natural gas demand forecasts were completed separately for CNG and LNG applications as each segment, utilizing natural gas in either CNG or LNG form, has distinct characteristics and different considerations. CNG is positioned as a fuel for on-road transport applications such as transit buses, waste haulers and heavy duty on-road trucks. LNG is positioned to emerge as a fuel for off-road and high horsepower applications such as marine vessels, locomotives, mine haul trucks and remote industrial power and heat generation applications.

Similar to the RNG forecast, the links between the core end-use forecast and the NGT annual demand forecast are qualitative only because NGT represents an emerging market. FEI provided the core end-use forecast scenario parameters to its NGT programs department and requested three forecast demand trajectories (Base, High, Low) based on these scenario parameters. Section 3.4.8 outlines how these NGT scenarios are incorporated into the 2017 LTGRP annual demand forecast.

3.4.7.1 CNG Demand Forecast Method

To formulate the different demand curves, FEI determined the eligible market size by first quantifying the size of the diesel fuel market for transportation in BC. This data was obtained from Natural Resource Canada's (NRCan) Transportation Sector – British Columbia and Territories database, which displays the 2014 fuel consumption for the transportation sector by fuel type[105]. This fuel consumption database provided the basis for the 2014 market size, which was then escalated by a forecasted growth rate.

The sectors included in the market size were passenger light trucks, freight light trucks, medium duty trucks, heavy duty trucks, school buses, urban transit, and inter-city buses. The forecasted

[105] Appendix D-24: http://oee.nrcan.gc.ca/corporate/statistics/neud/dpa/menus/trends/comprehensive/trends_tran_bct.cfm.

growth rate per year was derived from the NEB's report "An Energy Market Assessment – Canada's Energy Future 2016 Update"[106]. This report is a forecast of Canada's energy supply and demand projections to 2040.

Using the 2014 market size determined by the NRCan database, the growth rates of natural gas and diesel fuel consumption were used from the NEB's report to extrapolate out to 2036; utilizing the NEB and NRCan reports, the potential market in 2036 is approximately 76 million GJ.

Utilizing the above information, FEI developed a Base, Low, and High case scenario, described below.

3.4.7.1.1 CNG BASE SCENARIO DEMAND FORECAST

The CNG Base case forecast was derived in two parts: the number of vehicles that are expected to be in-service based on the GGRR incentive program,[107] and the estimated number of vehicles to come in-service after the GGRR program expires on March 31, 2022.

For the period of 2017 to 2020, the forecast includes incremental load growth based on known and expected customer commitments that FEI has made under the GGRR incentive program (current and expected). From 2021 and beyond, the forecast contains assumptions regarding incremental load generated per year. FEI has assumed an annual growth in vehicles of about 85 additional CNG vehicles to the road per year. These additional CNG vehicles translate to an approximate net incremental growth of 100 thousand GJ per year.

This method for the Base case assumes actual load from existing CNG customers in 2016 will continue throughout the term of the forecast period. This assumes that the existing customers are not retiring their CNG vehicles and will continue to renew or replace their CNG vehicles with a natural gas equivalent.

For the Base case scenario, based on the growth of CNG demand, FEI assumes that it will capture about 4 percent of the eligible market by the end of the forecast period of 2036. This level of market capture constitutes a growth rate of approximately 6 percent per year.

3.4.7.1.2 CNG LOW SCENARIO DEMAND FORECAST

The CNG Low case scenario is based on no expansion or advancements on natural gas engines, the spread between diesel prices and natural gas prices decreasing in favour of diesel, policies becoming unfavourable to natural gas adoption and the availability and efficiency of alternative energy engines increasing (i.e. electric vehicles).

This scenario assumes that minimal growth occurs and existing customers continue to renew their natural gas fleet vehicles with minimal additions to their natural gas fleet. As a result, the

[106] NEB (2016). "Canada's Energy Future 2016: Update – Energy Supply and Demand Projections to 2040 - Figure Data [EXCEL 651 KB]". Appendix D-25: https://www.neb-one.gc.ca/nrg/ntgrtd/ftr/index-eng.html.

[107] This represents FEI's initiative that seeks to engage customers in adopting natural gas as a transportation fuel. Please see Sections 2.3.3.4 and 2.4.1 for further details on the GGRR mechanism and regulatory context.

market share for the Low case scenario forecasts a market share of about 1 percent of the eligible market size by 2036, which results in an annual growth rate of about 1 percent per year or an average demand addition of approximately 8,000 GJ per year.

3.4.7.1.3 CNG HIGH SCENARIO DEMAND FORECAST

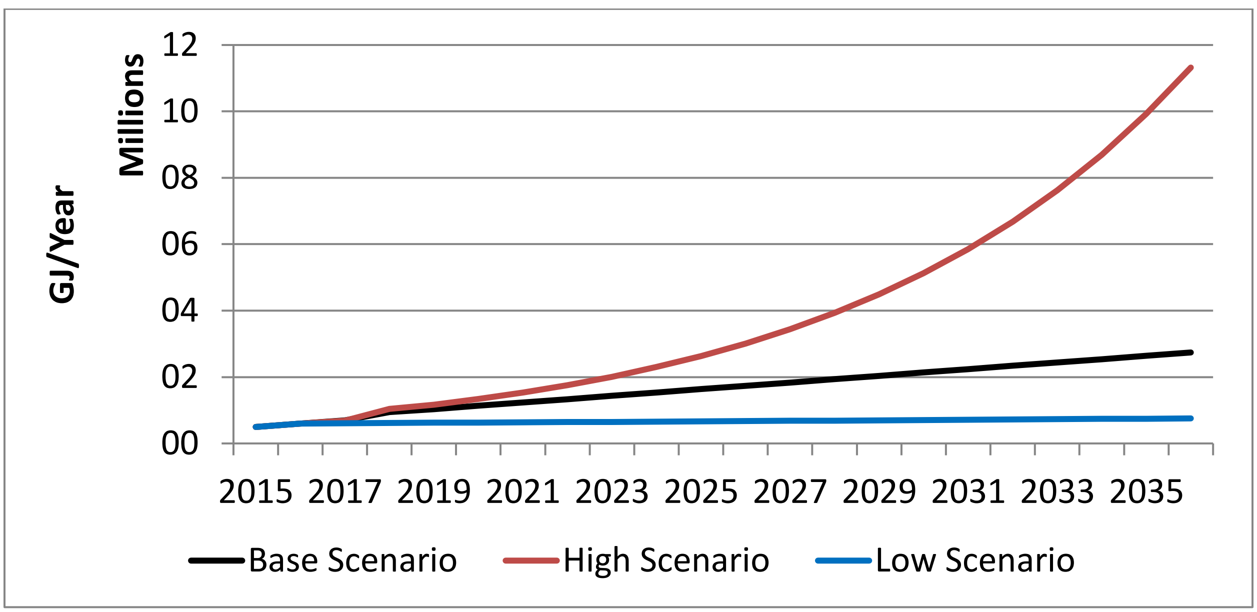
The High case scenario is predicated on expansion or advancements in natural gas engines (better efficiencies and availability), the spread between diesel prices and natural gas prices increasing in favour of natural gas, an increased spread in carbon pricing between diesel and natural gas, and policies favouring natural gas adoption.

It assumes the popularity of NGT vehicles will increase dramatically due to operating advantages over diesel and that the natural gas refuelling infrastructure is constructed over time, providing better access to fuel for CNG customers.

By 2036, for the High case scenario forecast, FEI expects to capture approximately 15 percent of the potential eligible market in BC, which equates to an average annual growth rate of about 16 percent per year or an average demand addition of approximately 532 thousand GJ per year from 2017 to 2036.

Figure 3-15 below displays a forecast of CNG demand growth on FEI's system over the planning period (2017 to 2036) across the three scenarios.

Figure 3-15: Forecast Annual Demand from Long Term CNG Adoption Scenarios (2017-2036)



3.4.7.2 LNG Demand Forecast Method

LNG is supplied under FEI's Rate Schedule 46 LNG Supply tariff (RS46). The LNG is provided by FEI from two LNG facilities: Tilbury in the Lower Mainland and Mt. Hayes on Vancouver Island.

The key early adopters of LNG in BC were on-road heavy duty trucking customers. However, after the preferred high horsepower Cummins-Westport 15 litre high pressure direct injection (HPDI) engine was discontinued in 2013, causing a technology gap in the market, LNG adoption for on-road trucking essentially halted. The key markets that have emerged over the past number of years as consumers of LNG fuel have been high horsepower applications such as marine vessels, mine haul trucks, locomotives, and remote power generation for industrial applications. Similar to the CNG demand forecasts, FEI formulated the LNG demand forecasts by accounting for commitments that have been made by customers to take LNG supply under RS46, then applying inflation and forecasting the impacts of a variety of factors. These factors include the availability of Original Equipment Manufacturer (OEM) technology capable of adopting natural gas, regulatory changes that are expected to drive natural gas adoption and assumptions regarding market size and adoption rates based on past experience for some of the market segments.

The LNG demand scenarios presented below include demand from a number of different market segments that are suited to adopt natural gas as a fuel.

LNG for the marine market could be the largest share of the overall demand if this market segment adopts natural gas over the forecast period. As such, any changes in these marine markets in terms of suitability of adopting natural gas will have a larger impact on the overall LNG demand forecasts as this market segment makes up a large share of the overall demand forecast.

3.4.7.2.1 LNG LOW SCENARIO DEMAND FORECAST

For the Low demand forecast scenario, FEI assumed that LNG demand would grow to about 13 million GJ per year by about 2025 through the capture of key LNG markets such as coastal freight vessels, domestic passenger ferries, locomotives, mine haul trucks and stationary power generation for industrial applications. Under this scenario, no growth is expected beyond this initial capture of 13 million GJ per year through to the end of the forecast period of 2036. This scenario also assumes that no trans-Pacific marine vessels adopt LNG as a marine fuel in response to the tighter emissions regulations that are expected to be imposed on the marine industry by the IMO beginning in 2020 (see Section 2).

3.4.7.2.2 LNG BASE SCENARIO DEMAND FORECAST

In the Base forecast scenario, FEI built upon the Low scenario but included some capture rate of trans-Pacific marine vessels as LNG fuel adopters. Through market intelligence and industry research, FEI has identified a certain segment of the trans-Pacific marine segment (international car and vehicle carriers) that would be ideal early adopters of LNG as a marine fuel. Over the forecast horizon to 2036, FEI assumed an annual growth rate of about 5 percent per year beyond 2028 as a Base case demand growth scenario.

3.4.7.2.3 LNG HIGH SCENARIO DEMAND FORECAST

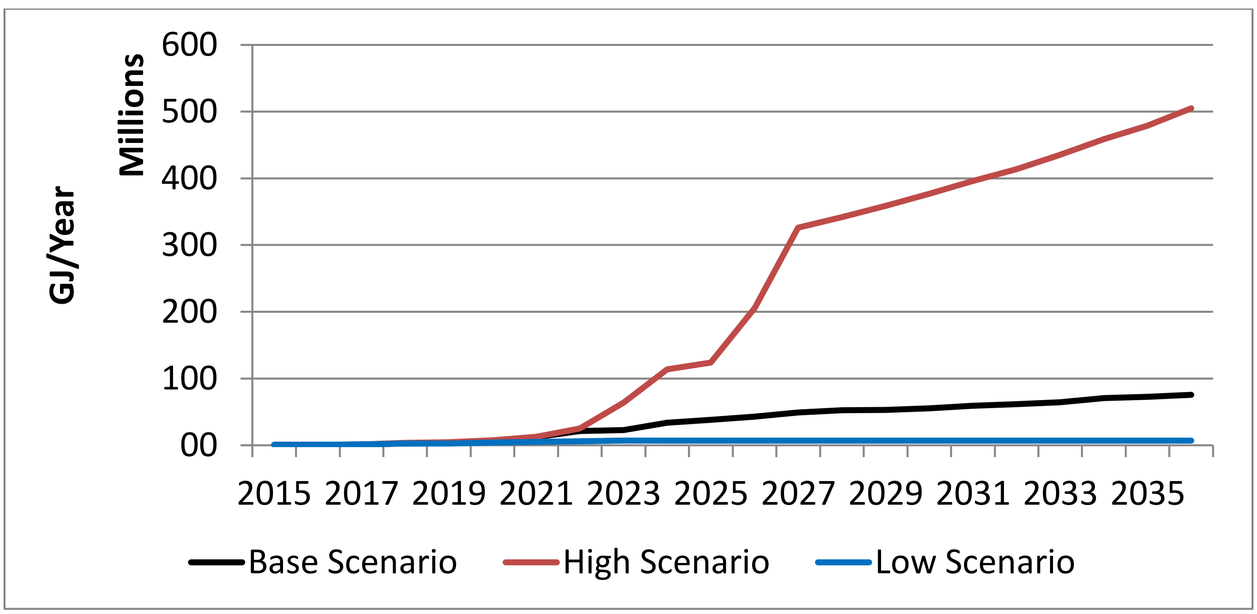
For the High forecast scenario, FEI further built upon the Base scenario but incorporated a more aggressive LNG adoption scenario, particularly from the trans-Pacific deep sea marine segment. In both the Base and High scenarios, the marine segment plays a crucial role in developing LNG demand on a material scale, beyond the capacity of the Tilbury Phase 1A Expansion.

For example, if LNG gains prominence as a maritime fuel and vessels begin to request LNG bunkers from West Coast ports, the High scenario assumes that in addition to the key marine segment identified in the Base case, other marine segments would also adopt LNG on a larger scale. For instance, LNG adoption for container marine vessels was not included in the Base scenario but is included in the High scenario.

The High scenario begins to diverge dramatically from the Base scenario beginning around the 2022/2023 time period due to the impacts from the imposition of the IMO sulfur cap on marine industry emissions beginning to be addressed by the market. This regulation is set to take effect in 2020, which is expected to favourably position natural gas as an alternative fuel to meet these tighter emissions restrictions. Although the IMO sulfur cap will take effect on January 1, 2020, there is much uncertainty as to whether this will be a 'soft cap' to allow marine vessel operators sufficient time to assess and adopt technologies or alternative fuels to meet the 0.5 percent sulfur emissions limit. Due to this uncertainty, FEI assumed that there would be a gradual ramp up in LNG adoption from 2020 to about 2025, at which time LNG adoption could accelerate as the full effects of the IMO sulfur regulation are realized by the maritime industry.

Figure 3-16 below provides a combined illustration of the three LNG adoption scenarios to the end of the forecast period of 2036.

Figure 3-16: Forecast Annual Demand from Long Term LNG Adoption Scenarios (2017-2036)



3.4.7.3 Combined CNG and LNG Demand Forecast

Figure 3-17 below illustrates the combined natural gas demand forecasts by scenario for both CNG and LNG, presented in the two sections above (Sections 3.4.7.1 and 3.4.7.2). FEI combines forecast annual demand from CNG and LNG since FEI's long term planning considers cumulative annual demand of FEI's customers and initiatives. While each fuel type has its own merit in the BC market, LNG accounts for a larger portion of forecast NGT annual demand than CNG and thus shapes the appearance of the combined annual demand graph.

Figure 3-17: Forecast Annual Demand from Long Term CNG and LNG Adoption Scenarios (2017-2036)

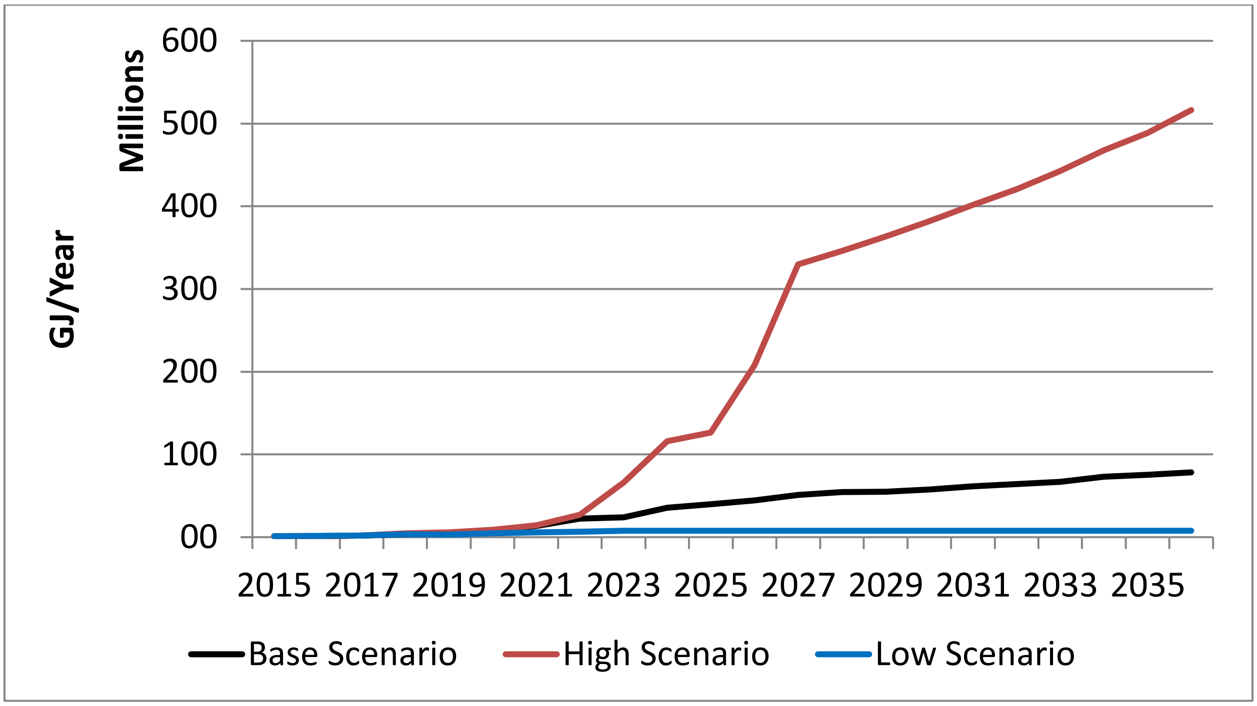


Figure 3-18 below provides a regional look at the CNG and LNG annual demand for natural gas. This graph depicts the effect of adding NGT load to the distribution system and reveals that the majority of NGT load is expected to come onto the system in the Lower Mainland.

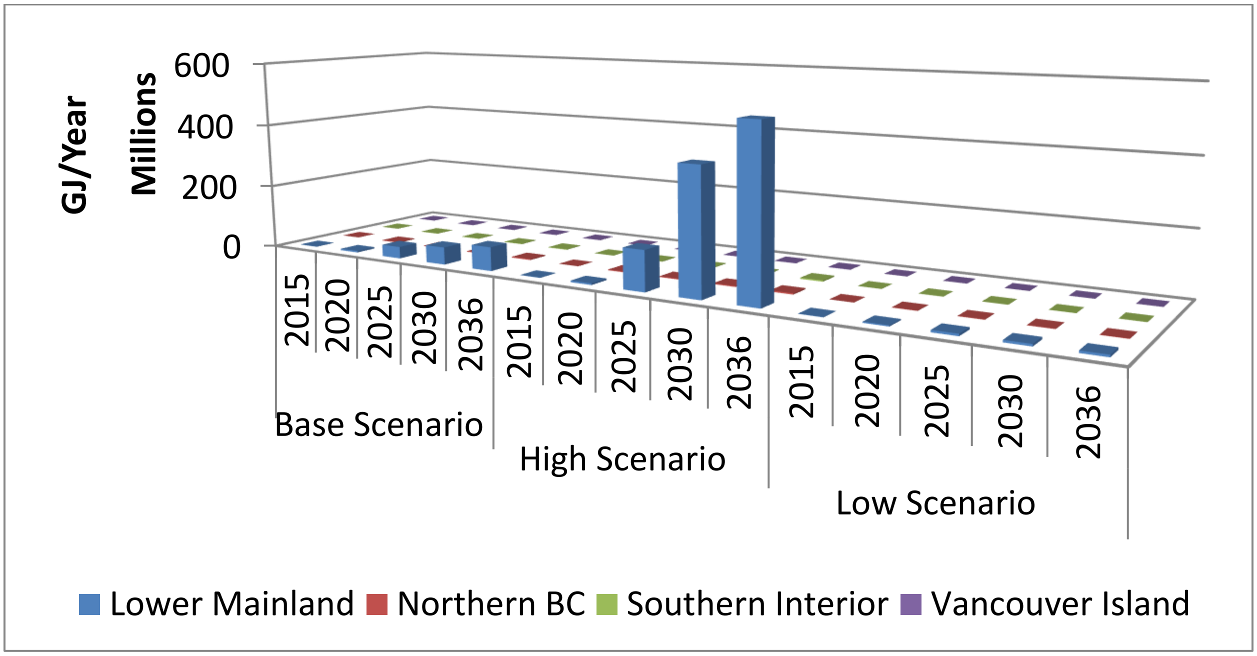
Figure 3-18: Forecast NGT Annual Demand (CNG & LNG) – by Scenario and Region

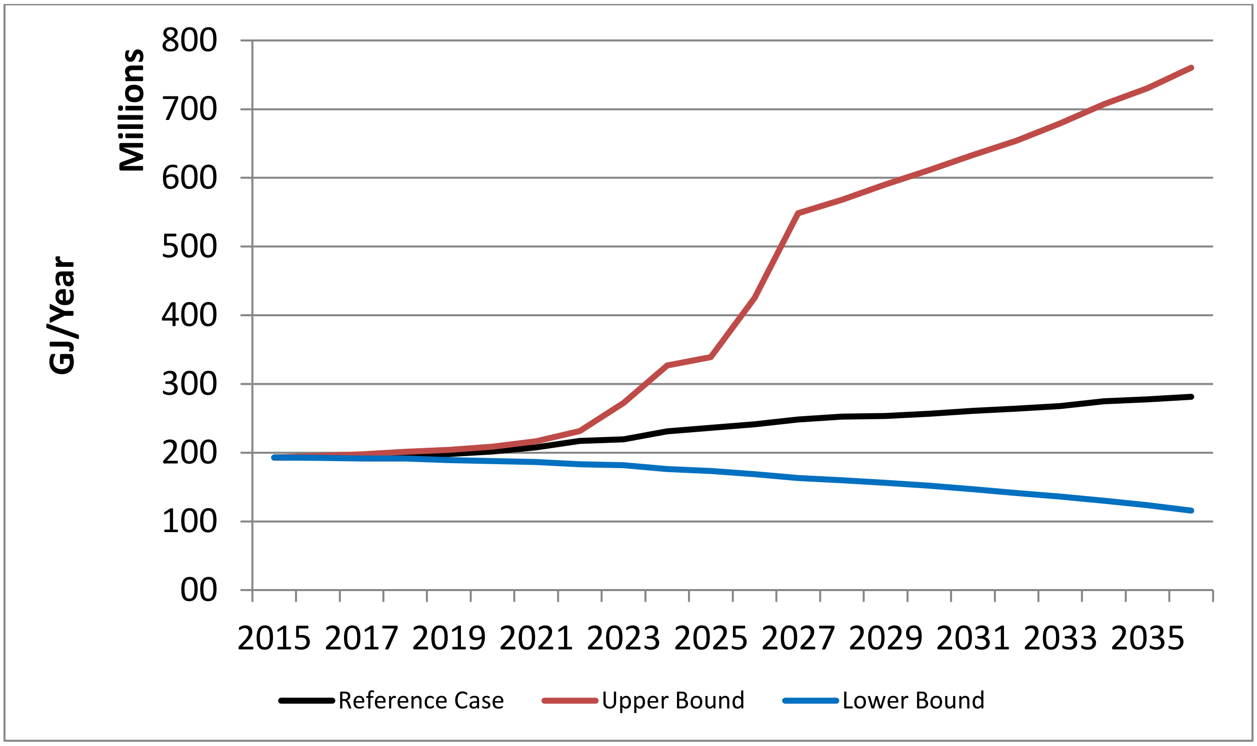


Note: Figure 3-18 displays milestones every five years only in order to fit the information to the report page; the forecast model contains information for all years of the planning period.

3.4.8 Total Annual Demand

FEI serves demand from the residential, commercial and industrial customer base as well as the CNG and LNG customer base. Therefore, to determine the lower limit to the total annual demand forecast, the Company summed the lowest demand scenario for residential, commercial and industrial customers (Scenario E) with the lowest CNG/LNG demand scenario. The same summation was conducted for the highest residential, commercial and industrial demand scenario (Scenario A) and the highest CNG/LNG demand scenario to establish the total annual demand upper limit. The Reference Case residential, commercial and industrial demand was added to the Base CNG/LNG demand to create an overall Reference Case annual demand forecast. Scenarios B, C and D were not examined further as these additional scenarios would result in a demand forecast that lies somewhere between the upper and lower demand forecast limits created by the other scenarios. Figure 3-19 shows the sum of total annual demand for the Reference Case, Upper Bound (Scenario A) and Lower Bound (Scenario E), plus the total annual NGT demand (Base, Low and High cases), and shows the range of total demand that may occur over the planning period. In the Reference Case, total annual demand grows by 46 percent across the planning horizon. This rate changes to a growth of 294 percent and a decline of 40 percent in the Upper and the Lower Bound scenarios, respectively.

Figure 3-19: Total Annual Demand Including NGT – All Sectors



Please see Appendix B-4 for tables that summarize the end-use method annual demand results and Appendix B-5 for a working MS Excel data file which contains annual demand results (sheet tab 1) and the critical uncertainty inputs (sheet tab 2) for natural gas and carbon prices.

3.4.9 Potential Large New Industrial Annual Demand

This section discusses the potential for large industrial point loads, outside of the impacts of CNG and LNG demand as articulated above, in relation to FEI's NGT programs. Customers of this nature which tend to consume more natural gas than FEI's existing industrial customers (e.g. pulp mills) could include LNG export terminals or other large industrial point loads, such as fertilizer or methanol plants.

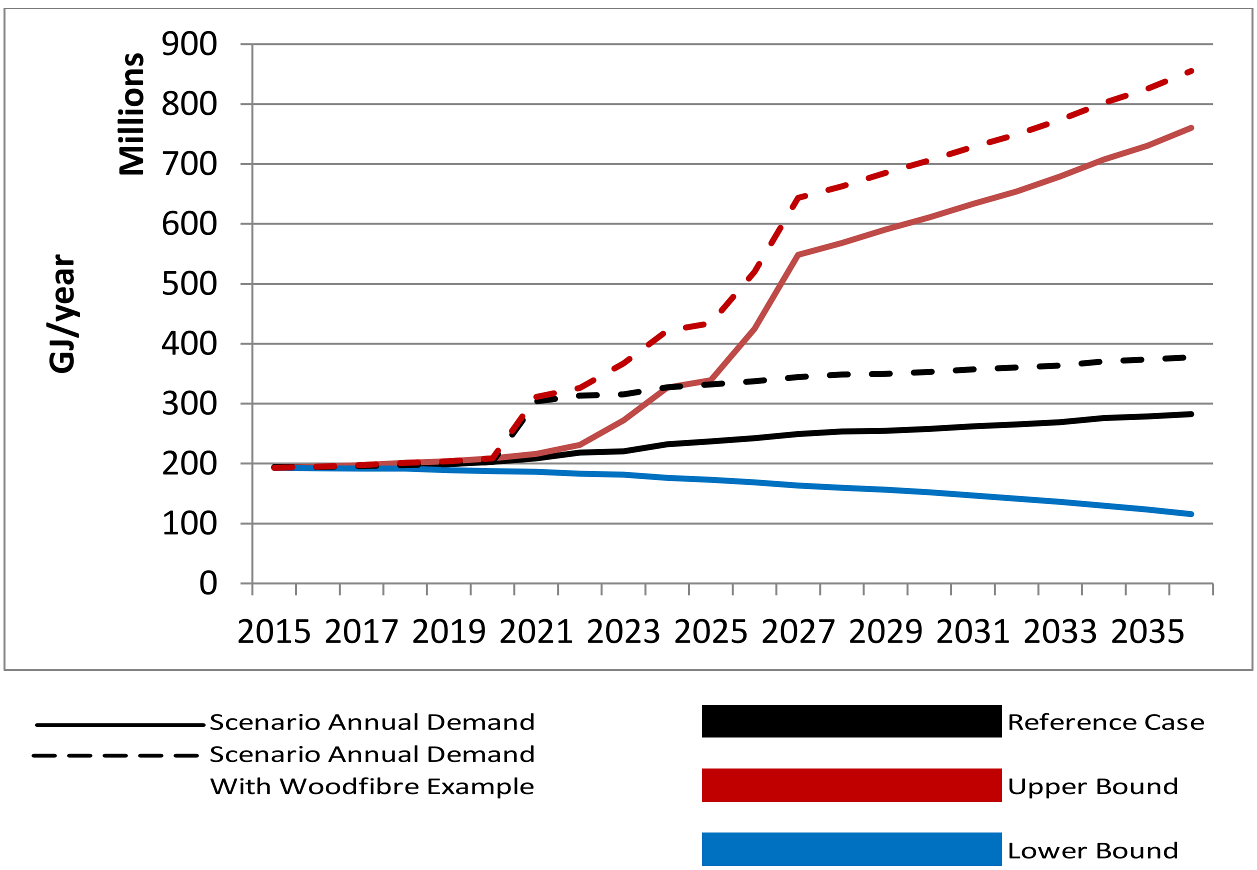
The 2017 LTGRP's results for and discussion of these customers is limited by three factors:

1. Significant uncertainty about when and where such demand would materialize in absence of FEI having firm commitments from prospective customers;
2. FEI must protect the confidentiality of negotiations with prospective large point load customers as a result of contractual obligations; and
3. The uniqueness of each such industrial point load customer, which makes extrapolating potential average impacts of such customers across the planning period difficult.

FEI's current experience indicates that most large scale industrial point loads that are proposed in the PNW will likely have their own pipeline connections to upstream/midstream resources rather than using FEI's pipeline network. In this case, such large industrial point loads would raise questions for regional gas supply and pipeline capacity rather than for FEI's annual demand and the capacity on FEI's system. Sections 5 and 6, respectively, discuss regional pipeline capacity and gas supply considerations as well as FEI's system capacity planning.

Figure 3-20 below displays the impact of the proposed Pacific Energy Corporation (PEC) small scale LNG export and processing facility located on the former Woodfibre pulp mill site near Squamish (Woodfibre LNG Project) on the 2017 LTGRP's total Reference Case and total Upper Bound scenario annual demand. The proposed Woodfibre LNG Project serves as an example to illustrate the potential impact on FEI's annual demand of large industrial point loads that are small enough to still be connected to FEI's system rather than having their own pipeline connection to midstream and upstream resources. For illustration purposes, FEI assumes that the Woodfibre LNG Project will come into service no sooner than 2021[108] and approximates that it will consume 95 million GJ annually[109].

Figure 3-20: Total Annual Demand Including NGT and Woodfibre LNG Project Example



[108] Appendix D-26: https://fortisinc.com/docs/default-source/investor-presentations/presentation-barclays-ceo-8-24-17.pdf.

[109] Woodfibre LNG Project annual demand represents an FEI estimate for illustration purposes rather than a firm commitment by the customer.

3.5 *CONCLUSION*

FEI has provided an estimate of the annual demand for natural gas that it expects to serve over the 20-year planning period, as required under Section 44.1(2)(a) of the UCA. This estimate is presented in Figures 3-19 and 3-20 as a potential range of future demand that can reasonably be expected to occur under differing potential future conditions impacting residential, commercial and industrial customers, as well as customers using natural gas as a transportation fuel. Since the likelihood of predicting actual future conditions is low, probabilities are not assigned to the different scenario outcomes; rather, the Company identifies and implements a set of cost effective resources to meet the Reference Case and establishes contingency plans for meeting the scenario range of potential future annual demand. FEI has based these estimates on the best available information at the time the forecast was prepared. Sections 5 and 6, respectively, of this LTGRP discusses the natural gas supply and FEI infrastructure physical resources required to meet this range of demand, including the timing of peak capacity requirements under higher or lower demand growth. The 2017 LTGRP presents the influence of different annual demand scenarios on customer rates in Section 8.

The end-use approach to annual demand forecasting, based on a plausible but varied range of potential future scenarios, provides an improved view of the way long term demand for natural gas could potentially unfold. FEI has examined future scenarios in which annual demand could dwindle considerably over the planning period, better capturing the risks that the Company is facing in the current planning environment, particularly with respect to carbon policy action and competition from other end-use energy types. At the same time, there are significant opportunities for demand growth while helping to meet provincial energy and economic objectives by facilitating the development of the natural gas for transportation market and by being responsive to potential new industrial demand.

In addition, FEI provides a comparative analysis of the end-use method with the Traditional Annual Method (Section 3.4.3), and includes an analysis of the impact of established new initiatives on demand and GHG emissions by including RNG and NGT in the demand forecast (Sections 3.4.6 and 3.4.7, respectively). The Company presents the GHG emissions from gas use in each scenario and emission reductions from RNG and NGT demand in Section 8.

4. DEMAND SIDE RESOURCES

4.1 INTRODUCTION

Once an estimate of the demand for natural gas in FEI's territory is developed (as has been presented in Section 3) the next step in long term resource planning is to determine what the impact of DSM activities will be on the demand forecast. Table 4-1 below outlines the requirements of Section 44.1(2) of the UCA for long term resource and conservation planning and indicates which items are applicable to and addressed in Section 4.

Table 4-1: UCA Requirements and Areas Addressed in Section 4

Requirement of UCA Section 44.1(2)	Addressed in Section 4
a. An estimate of the demand for energy the public utility would expect to serve if the public utility does not take new demand-side measures during the period addressed by the plan;	Not applicable to Section 4
b. A plan of how the public utility intends to reduce the demand referred to in paragraph (a) by taking cost-effective demand-side measures;	See Section 4.2.4
c. An estimate of the demand for energy that the public utility expects to serve after it has taken cost-effective demand-side measures;	See Sections 4.2.3 and 4.4
d. A description of the facilities that the public utility intends to construct or extend in order to serve the estimated demand referred to in paragraph (c);	Not applicable to Section 4
e. Information regarding the energy purchases from other persons that the public utility intends to make in order to serve the estimated demand referred to in paragraph (c);	Not applicable to Section 4
f. An explanation of why the demand for energy to be served by the facilities referred to in paragraph (d) and the purchases referred to in paragraph (e) are not planned to be replaced by demand-side measures; and	Section 4.2.3 outlines FEI's analysis and Section 4.2.2.1 explains that this incorporates all cost effective demand-side measure activity.
g. Any other information required by the commission.	As requested by Order G-189-14, dated December 3, 2014, Section 4.2 outlines multiple funding scenarios and provides utility cost effectiveness test results for these scenarios. Sections 8.3 and 8.6 address emissions as well as projected delivery rate and average bill impacts.

This section discusses FEI's long term expectations for DSM. Two distinctions are important for this discussion. First, FEI is a natural gas utility that, in contrast to electric utilities, is not vertically integrated and does not construct its own energy generation resources. As such, FEI's LTGRP DSM analysis does not weigh against the cost of DSM the need for procuring or constructing upstream energy generation resources to meet demand growth. Instead, FEI's LTGRP DSM analysis seeks to establish an adequate cost effective level of DSM activity and seeks to explore to what extent the peak demand implications of such DSM activity may defer FEI's requirements for downstream infrastructure upgrades.

Second, the term 'demand-side measure' has a statutory definition in BC in the CEA[110] that the Company must follow in developing a plan to reduce demand by taking cost effective demand-side measures as set out in Section 44.1(2)(b) of the UCA.[111] Across North America, DSM has a broader context that includes activities such as fuel substitution and load building, beyond the more limited statutory definition of demand-side measures that exists in BC. This section addresses both the statutory requirements for utilities within the narrower BC context, as well as broader types of DSM activities, within the broader North American meaning of the term, that are also important for FEI to consider for providing safe, reliable and cost effective energy to customers. A review of the energy planning environment in BC (Section 2) confirms that the Company needs to maintain a strong focus on a range of demand side activities to ensure that FEI is: providing the services that customers want, delivering demand side service offerings that help keep customers' energy costs down, helping to meet provincial emission targets, and playing a role in optimizing BC's energy infrastructure.

This section is organized as follows:

Section 4.2 addresses the utility demand-side measures as defined by the CEA that are being met through FEI's C&EM activities. A review of the statutory environment for demand-side measures in BC is followed by an analysis of the reductions in annual demand for natural gas that the Company expects to achieve under the range of future scenarios presented in Section 3. Section 4.2.3.6 specifically addresses the estimated long term impact of FEI's projected C&EM activities on peak demand and points to Section 6 for further details. Finally, the section presents the plan for how the Company will move forward to try to achieve these demand reductions over the planning horizon. Section 4.2 represents FEI's long term plan to reduce demand by taking cost effective demand-side measures as outlined in the provincial definition of such measures and thus addresses Sections 44.1(2)(b), 44.1(2)(c) and 44.1(2)(f) of the UCA. This excludes fuel switching and load building initiatives. The Company is not seeking approval of the pro-forma estimated expenditures listed in Section 4.2 (FEI will develop a separate C&EM expenditure schedule and submit this in 2018 for BCUC approval).

Section 4.3 discusses DSM in the broader context of utility activities beyond BC's statutory definition of a demand-side measure. FEI's fuel switching and NGT initiatives and exploration of new, large industrial customer demand are examples of activities that, though they do not meet

[110] http://www.bclaws.ca/civix/document/id/consol24/consol24/00_10022_01.
[111] http://www.bclaws.ca/civix/document/id/complete/statreg/96473_01.

the provincial definition of demand-side measure and are therefore not eligible for C&EM funding, are nevertheless important DSM activities for the Company. The FEI activities discussed in Section 4.3 have been approved by the Commission through other regulatory proceedings and the Company is not seeking approval for any new initiatives or changes to any existing initiatives as part of this LTGRP. The Company believes that these types of initiatives are vital components of FEI's efforts to provide customers with the energy they are seeking while adding cost effective, efficient new load to the system that will help to optimize use of the natural gas infrastructure and put downward pressure on customer rates. The Company is not seeking approval of the activities listed in Section 4.3.

Section 4.4 draws conclusions about FEI's DSM activities and recommends actions to be taken in the near term.

Although there are no specific, government-mandated GHG targets for FEI or the Company's customers to meet, Section 8 presents the emissions reduction estimates for each of the C&EM scenarios outlined in Section 4.2, alongside further discussion of GHG emissions from non-C&EM FEI activities. Section 8 also discusses C&EM rate impacts alongside rate impacts from non-C&EM FEI activities.

4.2 *CONSERVATION AND ENERGY MANAGEMENT (C&EM)*

4.2.1 Background

4.2.1.1 Regulatory Framework

FEI's C&EM initiative is a portfolio of efficiency and conservation programs and activities that meets the province's DSM definition in the CEA and helps customers reduce their natural gas consumption. The Company's C&EM initiative has a range of other customer and societal benefits, such as reducing GHG emissions and water consumption, enhancing human health and comfort, creating jobs, and encouraging a culture of conservation throughout BC. The objectives of the C&EM initiative include, in no particular order, to:

- Provide programs to help customers manage their energy use;
- Educate consumers regarding energy efficiency;
- Improve the overall economic efficiency of buildings and end-use applications;
- Improve the operating characteristics of customers' energy utilization systems;
- Support government energy and emission objectives; and
- Overcome barriers to market transformation for energy efficient technologies.

In BC, the implementation of demand-side measures is governed by the UCA, the

Province's DSM Regulation made pursuant to the UCA, and by the definition of "demand-side measure" found in section 1(1) of the CEA, which provides as follows:

> A rate, measure, action or program undertaken (a) to conserve energy or promote energy efficiency, (b) to reduce the energy demand a public utility must serve, or (c) to shift the use of energy to periods of lower demand . . . but does not include (d) a rate, measure, action or program the main purpose of which is to encourage a switch from the use of one kind of energy to another such that the switch would increase greenhouse gas emissions in British Columbia, or (e) any rate, measure, action or program prescribed.

The DSM Regulation further defines what C&EM measures must be included in a public utility's plan portfolio in order for it to be "adequate" within the meaning of section 44.1(8)(c) of the UCA. Effective March 24, 2017, section 3(1) of the DSM Regulation provides that a public utility's plan portfolio is adequate when it includes all of the following:

Table 4-2: Adequacy Requirements of the DSM Regulation

Section of the DSM Regulation	Adequacy Requirement
3 (a)	A demand-side measure intended specifically (i) To assist residents of low-income households to reduce their energy consumption, or (ii) To reduce energy consumption in housing owned or operated by (A) A housing provider that is a local government, a society as defined in section 1 of the *Societies Act*, other than a member-funded society as defined in section 190 of that Act, or an association as defined in section 1 (1) of the *Cooperative Association Act*, or (B) The governing body of a first nation, If the benefits of the reduction primarily accrue to (C) The low-income households occupying the housing, (D) A housing provider referred to in clause (A), or (E) A governing body referred to in clause (B) if the households in the governing body's housing are primarily low-income households;
3(b)	If the plan portfolio is submitted on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;
3(c)	An education program for students enrolled in schools in the public utility's service area;
3(d)	If the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area;
3(e)	One or more demand-side measures to provide resources as set out in paragraph (e) of the definition of "specified demand-side measure", representing no less than (i) An average of 1% of the public utility's plan portfolio's expenditures per year over the portfolio's period of expenditures, or (ii) An average of $2 million per year over the portfolio's period of expenditures;

Section of the DSM Regulation	Adequacy Requirement
3(f)	One or more demand-side measures intended to result in the adoption by local governments and first nations of a step code or more stringent requirements within a step code.

Section 4 addresses this adequacy requirement by outlining the adequacy initiatives of FEI's current C&EM portfolio (Section 4.2.1.2), confirming that its C&EM analysis includes measures that can be used for adequacy purposes (Section 4.2.1.2), and addressing how its long term plan for implementing C&EM activities will address adequacy in the future (Section 4.2.4)

As discussed in Section 2, FEI's planning environment for C&EM activities has evolved since 2014. The provincial CLP of August 2016 provides direction for FEI to increase its energy efficiency program incentives by at least 100 per cent. The BC Government also amended the DSM Regulation. In addition to any adequacy requirements reflected in Table 4-2 above, these amendments made further changes may impact the ambit of FEI's C&EM activities, such as the following:

- Effective July 10, 2014, BC Reg 141/2014 amended the DSM Regulation to exempt adequacy measures from the Modified Total Resource Cost Test (MTRC) cap and to increase from 0.5 to 1 times BC Hydro's long run marginal cost of electricity the Zero Emissions Energy Alternative (ZEEA) value that the MTRC uses as the avoided cost of gas; and
- Effective March 24, 2017, BC Reg 117/2017 increased from 33 to 40 percent the cap on the ratio of public utility DSM portfolios that may rely on the MTRC for cost effectiveness testing and enables DSM programs to incentivize new construction projects that comply with the BC Energy Step Code in support of municipalities that are implementing steps from the Code.

4.2.1.2 C&EM Portfolio

The Commission approved FEI's existing C&EM portfolio via its decision on FEI's 2014-2019 Performance Based Ratemaking Plan, as the application contained FEI's 2014-2018 DSM Plan.[112],[113],[114] FEI's existing C&EM portfolio meets the adequacy requirements that were in place at the time of approval and certain of the requirements added with the March 24, 2017 revision. The new adequacy requirements that are not met within the existing portfolio will be addressed in the upcoming expenditure schedule application to be filed after the 2017 LTGRP. The 2017 LTGRP C&EM analysis contains measures that are included in FEI's existing portfolio

[112] The 2017 LTGRP refers to FEI's future applications to the BCUC for approval of DSM expenditures simply as C&EM expenditure schedule.
[113] FEI Application for Approval of a Multi-Year Performance Based Ratemaking Plan for 2014 through 2018 ~ Project No.3698715. http://www.bcuc.com/ApplicationView.aspx?ApplicationId=400.
[114] http://www.ordersdecisions.bcuc.com/bcuc/orders/en/item/119195/index.do.

but also adds new measures. In general, many measures are applicable to adequacy situations but their adequacy implications depend on their specific program packaging and delivery (including marketing) which is determined during program design. Sections 4.2.1.2.1 to 4.2.1.2.6 below summarize FEI's current C&EM portfolio. Over the 2017 LTGRP's planning horizon, FEI's specific program offers will likely change to suit the evolving marketplace, legislative provisions (including future adequacy requirements) and FEI customer needs.

4.2.1.2.1 RESIDENTIAL PROGRAM AREA

Residential programs serve over 890,000 FEI customers. These customers predominantly include those living in single-family homes, rowhouses, townhomes or mobile homes.[115] Some in-suite measures, such as low flow fixtures and a small number of fireplaces and water heaters in multi-unit residential buildings are also included in this funding envelope. Residential programs serve retrofit and new home applications. In combination with the Company's education and outreach activities, these programs play an important role in driving the culture of conservation in BC. Residential programs focus on space heating (including fireplaces) and domestic hot water measures as well as insulation upgrades but also include a new construction package and a behavioral program. Typically, residential programs provide incentives towards the incremental capital cost of replacing existing end-use appliances or building envelopes with more efficient options but programs also contain incentives for home evaluations and educational components that encourage customers to optimize their energy use patterns.

4.2.1.2.2 LOW INCOME PROGRAM AREA

FEI's Low Income programs target income-qualified customers specifically via distribution of free energy saving kits and via two home retrofit package programs. The package programs target customers both broadly (via installation of generic energy savings upgrades and basic energy coaching) and also specifically (by conducting deep retrofits of homes that are identified as candidates for such retrofits during broad energy coaching). Low income programs also provide top-ups on rebates for select existing residential and commercial programs. In the residential programs, these top-ups support income-qualified customers. In the commercial programs, these top-ups support qualifying housing operators.

4.2.1.2.3 COMMERCIAL PROGRAM AREA

FEI's commercial C&EM programs focus on space and water heating as well as food service measures in commercial buildings. The Company also offers package programs for commercial new construction and commercial building retrofits. In addition, FEI's commercial program offering includes multiple programs that seek to support energy efficiency by incenting FEI customers to change their operations and maintenance practices. Finally, FEI offers a commercial program that specifically targets rental apartment buildings.

[115] Programs for Multifamily Dwellings served under Rate Schedule 2 or 3 are included in the commercial C&EM program area.

4.2.1.2.4 INNOVATIVE TECHNOLOGIES PROGRAM AREA

FEI's innovative technologies activities identify market-ready technologies that are not yet widely adopted in BC, and which are suitable for the development of or inclusion in the portfolio of ongoing C&EM programs in other program areas. This is accomplished through pilot and demonstration projects, pre-feasibility studies and the use of industry standard evaluation, measurement and verification protocols to validate manufacturers' claims related to equipment and system performance. Results from innovative technologies activities are used in making future C&EM programming decisions.

4.2.1.2.5 INDUSTRIAL PROGRAM AREA

FEI offers two industrial programs. One of these includes measures that allow industrial customers to identify, investigate, and implement natural gas energy efficiency projects in a manner that is customized for their specific facility needs. Participation in the program can span multiple years due to the timescales associated with completing an energy study, procuring and installing an energy conservation measure, and multi-year measurement and verification analysis. The other industrial program provides incentives for customers to install a more prescriptive (i.e. less customized) set of industrial energy efficiency measures.

4.2.1.2.6 CONSERVATION EDUCATION AND OUTREACH AND ENABLING ACTIVITIES

FEI's conservation education and outreach initiatives continue to support C&EM portfolio goals by fostering energy literacy and a culture of conservation among FEI's residential and commercial customers as well as students. In 2016, FEI launched its curriculum-connected online resource program called Energy Leaders for BC elementary and secondary school teachers. FEI also continues to support various training seminars and educational workshops in collaboration with such organizations as the Greater Vancouver Home Builders Association and other industry associations.

C&EM enabling activities focus on trade allies that support FEI's delivery of programming to customers, research, work to advance building codes and appliance standards, maintaining FEI's C&EM tracking system, and funding to support post-secondary energy management programs.

4.2.1.3 BC Conservation Potential Review (BC CPR)

In 2015, FEI, in collaboration with BC Hydro, FBC, and Pacific Northern Gas (PNG), initiated a province-wide BC CPR. This project uses a 2014 base year to determine the technical, economic, and market energy savings potential for natural gas and electricity until 2035. FEI received its BC CPR energy savings market potential results in 2017.

The purpose of a CPR is to examine available energy efficiency technologies, understand the inventory of energy equipment in a utility's service area, and determine the conservation potential that exists. The CPR is a tool that informs current and future C&EM expenditure applications and provides directional input into program development. FEI's 2010 CPR provided the baseline data on which FEI developed the 20-year C&EM energy savings estimates for the 2014 LTRP. Results from the 2010 CPR informed both FEI's previous 2012-2013 and also its current 2014-2018 C&EM expenditure schedule. The BC CPR represents a new study which projects energy savings opportunities between 2015 and 2035 across the service territories of each of the contributing BC utilities. Please refer to Appendix C-1 for the BC CPR report prepared for FEI which describes the study approach and methods alongside a summary of the study results. The BC CPR summary report does not recommend specific programs or targets to be implemented. However, the report does identify technology and market opportunities as well as the scope of market energy savings potential across the study period.

The range of potential C&EM measures from the BC CPR results informs the 2017 LTGRP C&EM forecast. FEI's C&EM forecast includes expenditure estimates and projected cost effectiveness test results. FEI's next C&EM expenditure schedule will be informed by the results of the BC CPR and the 2017 LTGRP's DSM analysis. FEI expects to file the next C&EM expenditure schedule after submission of the 2017 LTGRP. The BC CPR and the 2017 LTGRP represent long term forecasts that do ***not*** request approval from the Commission for specific C&EM expenditures.

Section 4.2.2 below outlines broadly how the 2017 LTGRP processed CPR results in order to apply them to its multi-scenario end-use demand forecast. Section 4.2.3 below details the 2017 LTGRP C&EM forecast analysis results.

4.2.2 Applying C&EM Potential to the Multi-Scenario, End-Use Demand Forecast

The 2017 LTGRP's C&EM analysis displays results for the Reference Case, Upper Bound and Lower Bound scenarios presented in Section 3. The C&EM analysis selected these scenarios to display the impact of forecast C&EM activity on the Reference Case but to also illustrate the potential range of this impact across the Upper Bound and Lower Bound scenarios which resulted in the lowest and highest forecast of annual demand for natural gas. This enables the Company to present the widest range of potential demand for natural gas after energy savings from cost effective demand-side measures. The Reference Case forecast assumes that conditions that are present and legally enshrined in the planning environment when the demand forecasting exercise was undertaken prevail through the planning horizon. For convenience, Table 4-3 below reproduces the descriptions of Scenarios A and E from Section 3:

Table 4-3: Descriptions of Future Scenarios A (Highest Demand) and E (Lowest Demand)

Scenario	Description	Input Settings		Discussion
A (Upper Bound)	The BC economy experiences higher-than-average growth. Infrastructure development in other regions, coupled with extraction	Economic Growth	High	In general, the outcomes of the multiple critical uncertainties can offset each other's impact on annual demand but this scenario combines all

Scenario	Description	Input Settings		Discussion
	infrastructure development in BC, keep regional gas supply abundant. Continued political opposition to carbon pricing and non-price carbon policy action cause governments to focus on issues other than carbon policy but the BC government keeps supporting NGT and RNG as cost effective existing carbon solutions.	Natural Gas Price	Low	outcomes that would increase annual demand. As such, this scenario represents one of two boundary scenarios that frame the scenario analysis. The combination of outcomes on each critical uncertainty is plausible and has occurred in the past.
		Carbon Price	Low	
		Non-Price Carbon Policy Action	Delayed	
E (Lower Bound)	The BC economy experiences lower-than average growth as part of global economic stagnation. This reduces investment in regional gas supply so much that BC's demand balance becomes constricted. Global economic performance contributes to a political climate that is not favourable to carbon pricing and non-price carbon policy action in other jurisdictions but causes a counter-movement in BC. This causes the BC government to focus on carbon policy and electrification without support for NGT and RNG.	Economic Growth	Low	This represents the second of the two boundary scenarios. This combination of outcomes across the critical uncertainties is plausible but has not been prevalent in the past. Governments have typically been reluctant to impose taxes and other restrictions, including carbon pricing and carbon policy actions, during periods of economic stagnation.
		Natural Gas Price	High	
		Carbon Price	High Increase	
		Non-Price Carbon Policy Action	Accelerated	

4.2.2.1 Method

FEI applied the C&EM potential to its multi-scenario end-use forecast via the following steps:

1. In the 2017 LTGRP forecast model, construct a separate Reference Case which matches as closely as possible the BC CPR's Reference Case;
2. Import the CPR measure assumptions into this 2017 LTGRP CPR Reference Case;
3. Produce the technical energy savings potential in the 2017 LTGRP CPR Reference Case and calibrate the measure applicability rates in light of the BC CPR technical energy savings potential results;
4. Produce the economic energy savings potential results in the 2017 LTGRP CPR Reference Case;[116]
5. In the 2017 LTGRP CPR Reference Case, run the market potential energy savings analysis and calibrate individual measure participation rates in light of the BC CPR energy savings market potential results;
6. Import into the 2017 LTGRP CPR Reference Case, the expenditure parameters (i.e. ratio of incentive to non-incentive spending by program area and ratio of incentives to incremental costs by program area) from the BC CPR market potential analysis;
7. Apply the 2017 LTGRP Reference Case and produce the market potential energy savings, benefit-cost, and expenditure results;
8. Calibrate expenditure parameters at the measure level in light of the BC CPR results and existing program experience and re-run step 7; and
9. Run the step 7 analysis for the Upper Bound and Lower Bound scenarios.

4.2.2.2 Sensitivity to the End-Use Scenarios

The availability of potential energy savings will vary from one forecasting scenario to another due to several effects, all of which were incorporated into the demand forecasts for each of the scenarios prior to analyzing the potential savings from C&EM (see scenario explanations contained in Appendix B-1):

- Higher gas pricing, due to commodity prices or a carbon price, will cause more measures to pass the Total Resource Cost (TRC) test, or will cause measures that already pass to pass with a more positive result. Conversely, lower gas pricing will cause more measures to fail the TRC test, or will cause measures that pass to fail in some situations.

[116] The 2017 LTGRP's C&EM analysis requires each measure to meet the cost effectiveness test threshold and does not package measures into programs (where individual non-cost effective measures could be rendered cost effective by other measures). This approach for pursuing all cost effective DSM is consistent with the analysis in the BC CPR. The 2017 LTGRP's C&EM analysis represents a long term directional forecast of addressable C&EM initiatives; FEI's C&EM expenditure schedules bundle measures into specific programs, consider operational program deployment factors, and request BCUC permission for specific DSM expenditures.

- Although customer demand is price inelastic over the short term, higher gas pricing over the long term, while holding all other variables constant, may cause some customers to switch away from natural gas for certain end uses. This will tend to reduce the energy potential for measures that pass the TRC test. Conversely, lower gas pricing may tend to cause some customers to switch from other fuels to gas for certain end uses, increasing the energy potential for those measures that still pass the TRC test.
- Higher economic growth tends to increase the potential for savings due to its impact on the customer forecast; lower economic growth tends to decrease it.
- A policy environment that encourages more existing adoption of energy efficiency (e.g. accelerated appliance standards) will tend to decrease the remaining potential for energy efficiency for utility programs to capture. Conversely, a policy environment that does not encourage existing adoption of energy efficiency will tend to increase the potential for utility programs.
- An environment with increased development of renewable and district energy systems will tend to decrease the remaining natural gas share and therefore the potential for natural gas savings. An environment with little development of renewable and district energy systems will tend to have more potential for natural gas savings.
- Following the BC CPR's approach, the 2017 LTGRP C&EM analysis applies the TRC test to commercial and industrial program areas but the MTRC test to the residential program area to simulate the current DSM landscape. Scenarios that are subject to accelerated non-price carbon policy action apply the MTRC test to all program areas in order to simulate the potential removal of the current MTRC cap as regulators potentially further recognize the economic and social non-energy benefits of C&EM activity.

4.2.3 Long Term C&EM Analysis Results

The 2017 LTGRP's C&EM analysis results are informed by both the BC CPR and existing program experience. The results maintain the BC CPR's segmentation into residential, commercial, and industrial program areas. These do not break out individual adequacy programs specifically (this breakdown will occur in the forthcoming 2018 and future C&EM expenditure schedule submissions). As in the BC CPR, the 2017 LTGRP's C&EM analysis reports apartment buildings in the commercial sector.

The C&EM analysis results indicate the outcome of pursuing all cost effective energy savings potential. Crucially, the BC CPR and the 2017 LTGRP C&EM analysis display a theoretical estimate of energy savings measure uptake in relation to the ratio between incentive levels and measure incremental costs. This estimate takes into account program experience and technology diffusion but does not take into account operational program delivery factors, such as staffing levels or specific program eligibility rules. This represents a critical difference to FEI's C&EM expenditure schedule which requests the Commission to approve expenditures for short or medium term C&EM activities. In contrast the BC CPR and the 2017 LTGRP C&EM analysis provide a long term forecast of estimated C&EM potential and activity.

Section 4.2.3.1 below outlines the estimated long term impact on annual demand of the 2017 LTGRP C&EM analysis. Section 4.2.3.2 details estimated long term C&EM expenditures while Section 4.2.3.3 presents estimated cost effectiveness test results. Section 4.2.3.4 compares top ten energy savings measures across scenarios. Section 4.2.3.5 explains how sensitive the Reference Case C&EM results are to changes in the level of incentive value as a proportion of incremental cost. Section 4.2 concludes with Section 4.2.3.6 referring to the peak demand impact of C&EM activities which will be further discussed in Section 6.

4.2.3.1 Estimated Long Term Impact on Annual Demand

Figure 4-1 below illustrates annual natural gas demand, excluding NGT, before and after estimated C&EM energy savings for all rate schedules. Cumulative Upper Bound energy savings across the planning horizon exceed the Reference Case by 3 percent while cumulative Lower Bound energy savings fall 60 percent below the Reference Case. Forecast 2036 Reference Case energy savings account for 7.89 percent of projected sales. This ratio changes to 6.79 percent and 5.92 percent for the Upper and Lower Bound scenarios, respectively.

Figure 4-1: Natural Gas Demand Before and After Estimated C&EM Savings (Excluding NGT) – All Sectors

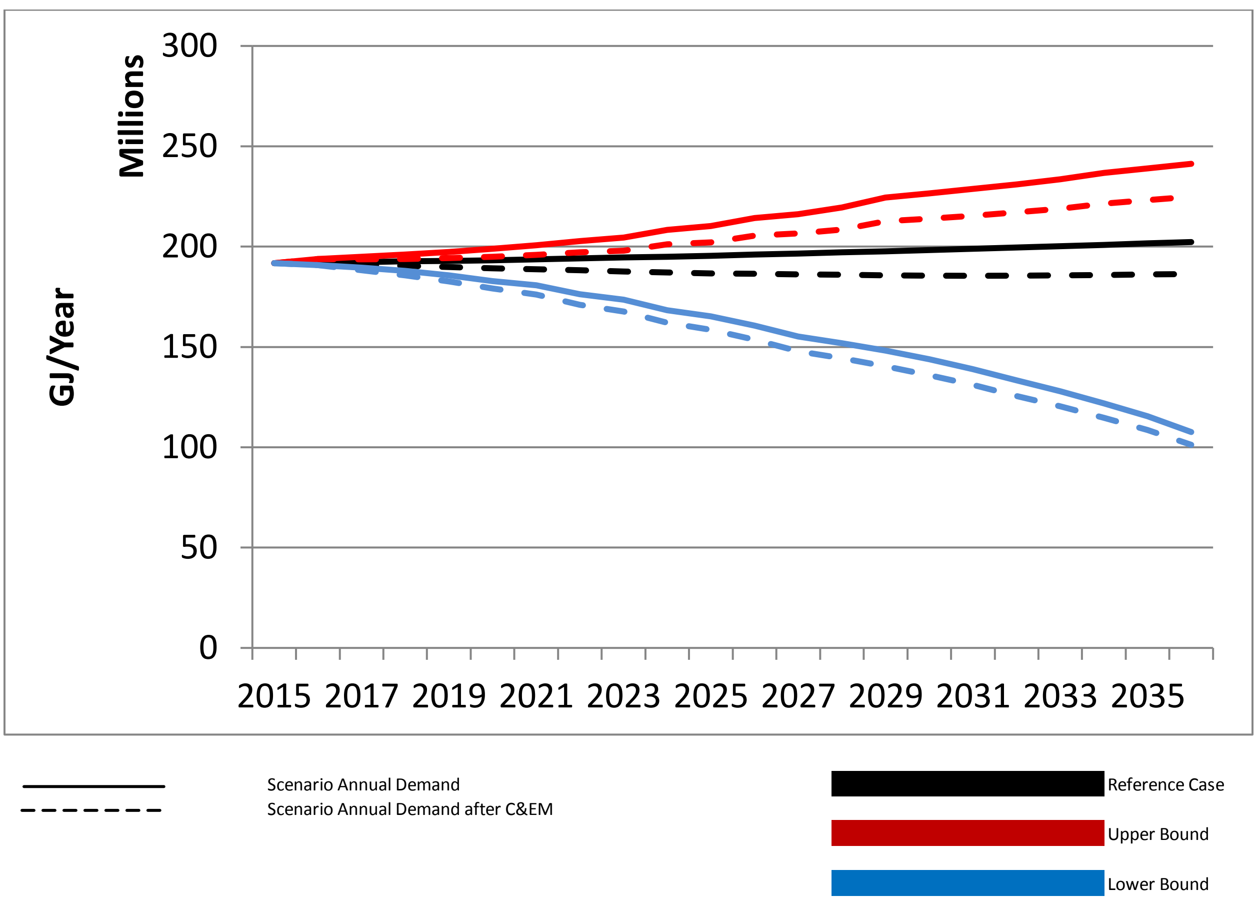


Figure 4-2 below illustrates annual natural gas demand, excluding NGT, before and after estimated C&EM energy savings for the residential rate schedules. Cumulative Upper Bound energy savings across the planning horizon exceed savings in the Reference Case by 9 percent while cumulative Lower Bound energy savings fall 47 percent below those of the Reference Case. Forecast 2036 Reference Case energy savings account for 7.16 percent of projected sales. This ratio changes to 7.19 percent and 6.18 percent for the Upper and Lower Bound scenarios, respectively.

Figure 4-2: Natural Gas Demand Before and After Estimated C&EM Savings (Excluding NGT) – Residential Sector

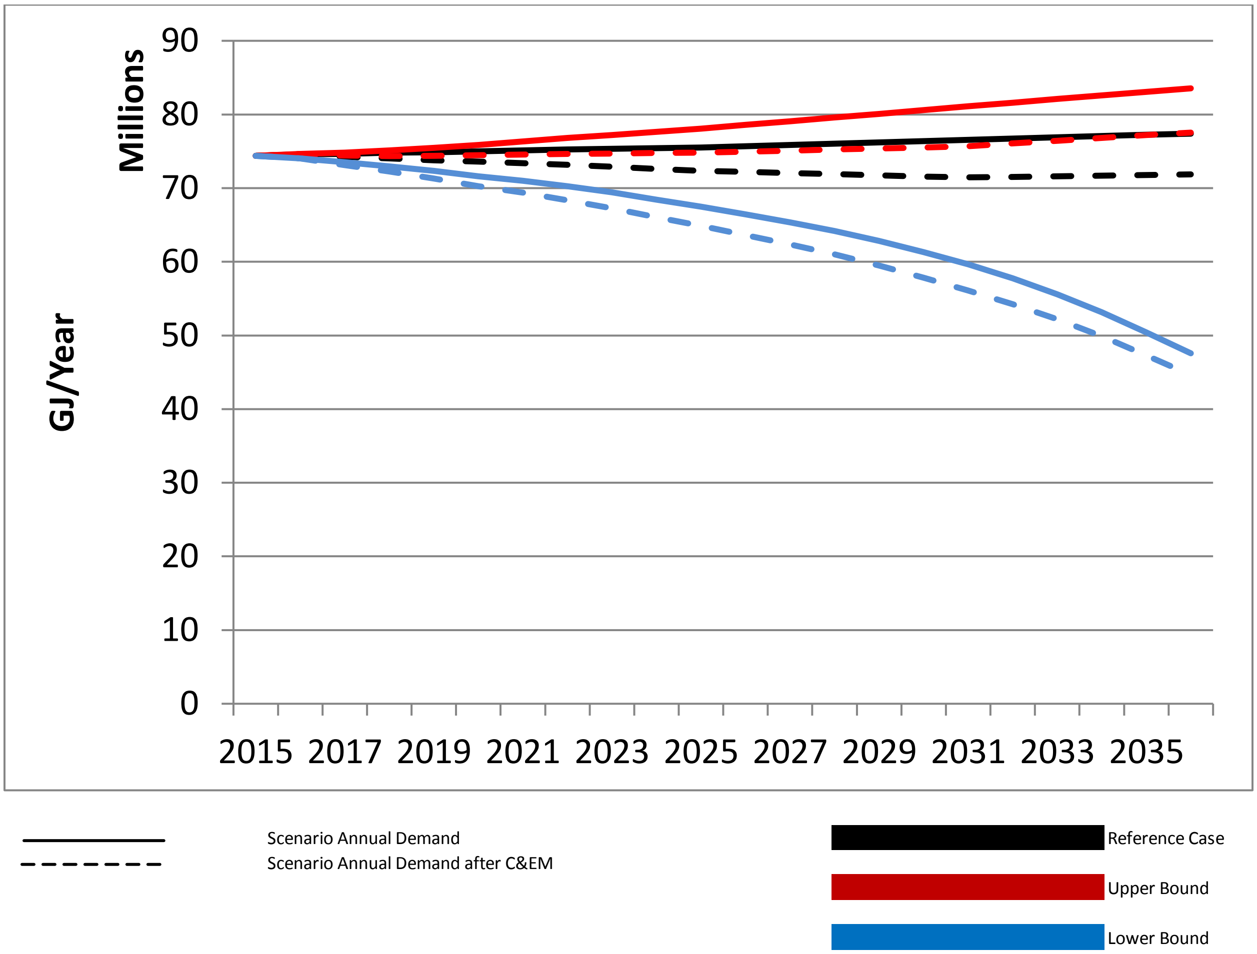

Figure 4-3 below illustrates annual natural gas demand, excluding NGT, before and after estimated C&EM energy savings for the commercial rate schedules. Cumulative Upper Bound energy savings across the planning horizon fall short of the Reference Case savings by 7 percent while cumulative Lower Bound energy savings fall 66 percent below those in the Reference Case. This departs from the pattern of cumulative Upper Bound energy savings exceeding the Reference Case. This appears to be due to low natural gas and carbon price costs in the Upper Bound depressing the avoided cost of gas in this scenario and thus rendering commercial energy efficiency measures uneconomic. This effect appears to outweigh the Upper

Bound having more technical energy savings opportunities than the Reference Case (by virtue of having more natural gas consumption than the Reference Case). Forecast 2036 Reference Case energy savings account for 9.27 percent of projected sales. This ratio changes to 7.34 percent and 6.04 percent for the Upper and Lower Bound scenarios, respectively.

Figure 4-3: Natural Gas Demand Before and After Estimated C&EM Savings (Excluding NGT) – Commercial Sector

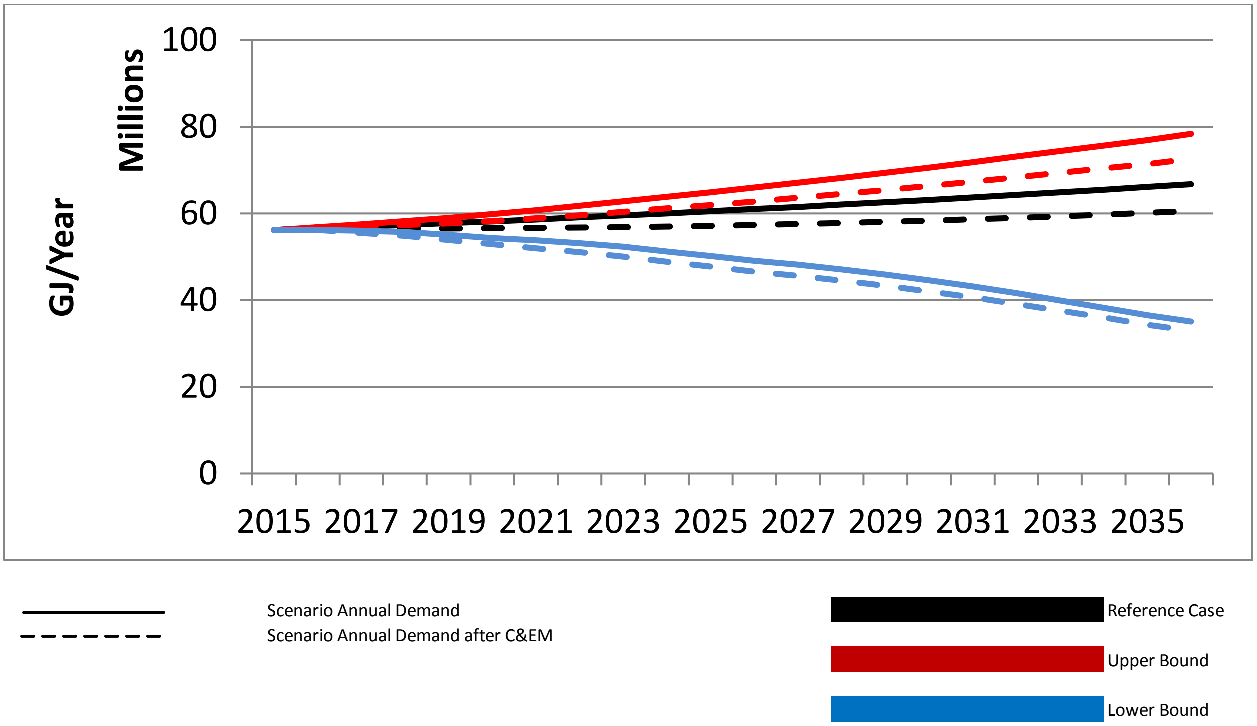

Figure 4-4 below illustrates annual natural gas demand, excluding NGT, before and after estimated C&EM energy savings for the industrial rate schedules. Cumulative Upper Bound energy savings across the planning horizon exceed the Reference Case savings by 10 percent while cumulative Lower Bound energy savings fall 69 percent below the Reference Case. Forecast 2036 Reference Case energy savings account for 7.26 percent of projected sales. This ratio changes to 5.83 percent and 5.25 percent for the Upper and Lower Bound scenarios, respectively.

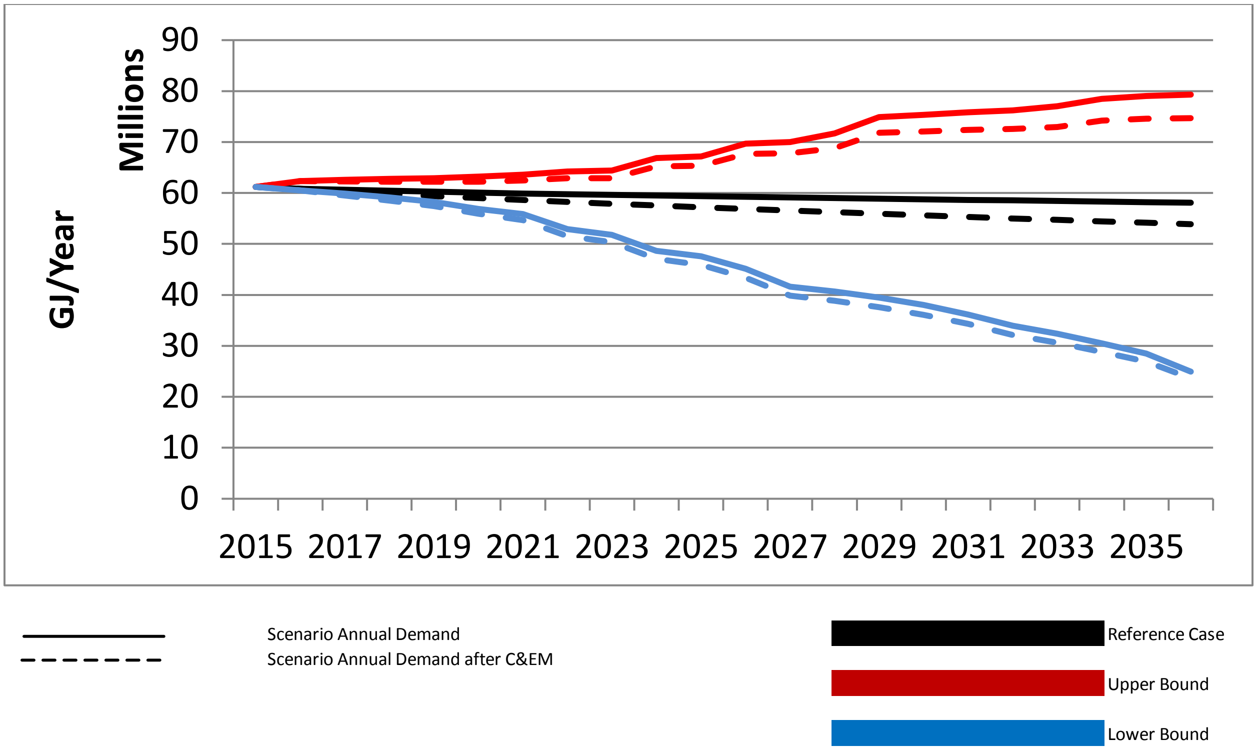
Figure 4-4: Natural Gas Demand Before and After Estimated C&EM Savings (Excluding NGT) – Industrial Sector[117]



4.2.3.2 Estimated C&EM Expenditures

Results presented in this section are long term estimates only and are informed by the results of the BC CPR and program experience. These results do not take into account the following factors which flow into C&EM expenditure schedules and C&EM annual reports to the Commission:[118]

- Non-incentive expenditures that support or enable C&EM programs at the portfolio level, such as Enabling Activities and Conservation Education Outreach expenditures;[119]
- Operational program delivery considerations, such as changes in required C&EM staffing levels or program eligibility requirements; and
- Emergence of new technologies more than five years into the future or technologies which are currently unknown which may increase aggregate energy savings

[117] The 2017 LTGRP commentary for Figure 3-11 in Section 3 explains why projected industrial demand trajectories are jagged.

[118] For this reason, individual C&EM expenditure schedules may contain higher or lower energy savings and expenditures in the short and medium term than indicated in the long term C&EM analysis in the LTGRP.

[119] FEI expects these expenditures to continue but FEI's future C&EM expenditure schedules will determine their specific extent.

opportunities and thus enable greater actual C&EM program expenditures across the planning period.[120]

The base year of the 2017 LTGRP forecast is 2015 but the C&EM analysis does not include data for 2015 and 2016 since these years are in the past already.[121] FEI filed its actual program performance for these years with the Commission in its 2015 and 2016 C&EM Annual Reports.[122,123] FEI does not expect the LTGRP 2017 C&EM expenditure estimates to match its 2017 C&EM Annual Report because both filings are different in nature and methods and use different years of actuals data (2015 versus 2017, respectively).

Table 4-4 below displays estimated annual C&EM expenditures for all program areas. Estimated expenditures are expected to almost double from 2016 levels by 2023 and gradually decline after this year towards the end of the planning horizon as available energy savings opportunities are depleted.

[120] FEI does not project the actual expenditure impact of unforeseen future technologies as these depend on both their per-measure C&EM expenditure and also their total DSM participation rate.

[121] FEI used its 2015 actuals as inputs for the load forecast and C&EM analysis. Based on this 2015 input data, the C&EM analysis starts providing projected results in 2017 since 2015 and 2016 are historical years on the filing date. FEI filed annual reports on its C&EM activity with the BCUC already.

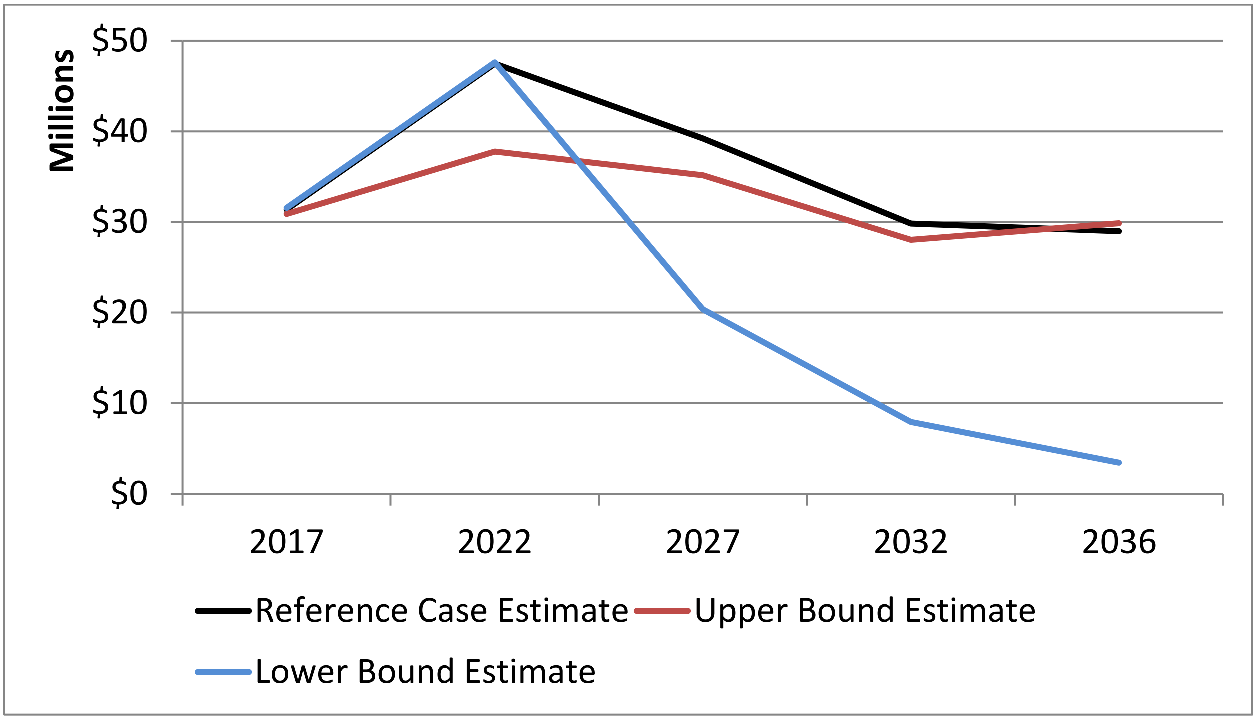
Table 4-4: Estimated Reference Case Annual Expenditures – All Program Areas

	REFERENCE CASE (MILLIONS)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2017	$ 27	$ 5	$ 31
2018	$ 30	$ 5	$ 35
2019	$ 31	$ 5	$ 36
2020	$ 33	$ 5	$ 39
2021	$ 42	$ 7	$ 49
2022	$ 41	$ 6	$ 47
2023	$ 46	$ 7	$ 52
2024	$ 43	$ 7	$ 50
2025	$ 36	$ 6	$ 42
2026	$ 35	$ 6	$ 41
2027	$ 33	$ 6	$ 39
2028	$ 32	$ 6	$ 38
2029	$ 32	$ 6	$ 37
2030	$ 33	$ 6	$ 39
2031	$ 29	$ 5	$ 34
2032	$ 25	$ 5	$ 30
2033	$ 25	$ 4	$ 29
2034	$ 25	$ 4	$ 29
2035	$ 25	$ 4	$ 29
2036	$ 25	$ 4	$ 29

Figure 4-5 below illustrates estimated annual C&EM expenditures across the Reference Case, Upper Bound and Lower Bound scenarios for all program areas. Cumulatively across the planning horizon, Upper Bound estimated expenditures fall 6 percent short of the Reference Case while Lower Bound estimated expenditures are 33 percent below the Reference Case. This departs from the intuitive expectation that cumulative Upper Bound estimated expenditures should exceed the Reference Case. This appears to be due to low natural gas and carbon price costs in the Upper Bound depressing the avoided cost of gas in this scenario and thus rendering energy efficiency measures less economic. Under such conditions, measures with lower incremental cost have a higher chance of being economic than measures with higher incremental cost. Since both the BC CPR and the 2017 LTGRP C&EM analysis conceptualize incentive levels as a proportion of incremental cost, this appears to reduce total expenditures. This effect appears to outweigh the Upper Bound having more technical energy savings opportunities and thus more opportunities for C&EM expenditures than the Reference Case (by virtue of having more natural gas consumption than the Reference Case).

1 **Figure 4-5: Estimated Annual Expenditures by Scenario – All Program Areas**



2

Table 4-5 below displays estimated annual C&EM expenditures for the residential program area. Estimated expenditures are expected to almost double from 2016 levels by 2018, to remain at approximately this level until 2030, and to decline after this year towards the end of the planning horizon as available energy savings opportunities are depleted.

Table 4-5: Estimated Reference Case Annual Expenditures – Residential Program Area

	REFERENCE CASE (MILLIONS)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2017	$ 16	$ 3	$ 19
2018	$ 17	$ 4	$ 21
2019	$ 16	$ 3	$ 19
2020	$ 16	$ 3	$ 19
2021	$ 19	$ 4	$ 23
2022	$ 17	$ 4	$ 21
2023	$ 17	$ 4	$ 21
2024	$ 22	$ 5	$ 27
2025	$ 17	$ 3	$ 20
2026	$ 16	$ 3	$ 19
2027	$ 15	$ 3	$ 19
2028	$ 15	$ 3	$ 18
2029	$ 15	$ 3	$ 18
2030	$ 16	$ 3	$ 20
2031	$ 13	$ 3	$ 15
2032	$ 10	$ 2	$ 12
2033	$ 10	$ 2	$ 12
2034	$ 10	$ 2	$ 12
2035	$ 10	$ 2	$ 12
2036	$ 10	$ 2	$ 13

Figure 4-6 below illustrates estimated annual C&EM expenditures across the Reference Case, Upper Bound and Lower Bound scenarios for the residential program area. Cumulatively across the planning horizon, Upper Bound estimated expenditures exceed the Reference Case by 9 percent while Lower Bound estimated expenditures are 35 percent below the Reference Case. This departs from the portfolio level phenomenon illustrated by Figure 4-5 above. Both the BC CPR as well as the 2017 LTGRP C&EM analysis examine the residential program area under the MTRC in order to mimic the impact of the MTRC cap. The MTRC relies on the ZEEA as the avoided cost of gas. This value, which is informed by the long run marginal cost of BC Hydro electricity, does not fluctuate in response to the 2017 LTGRP scenario parameters.

Figure 4-6: Estimated Annual Expenditures by Scenario – Residential Program Area

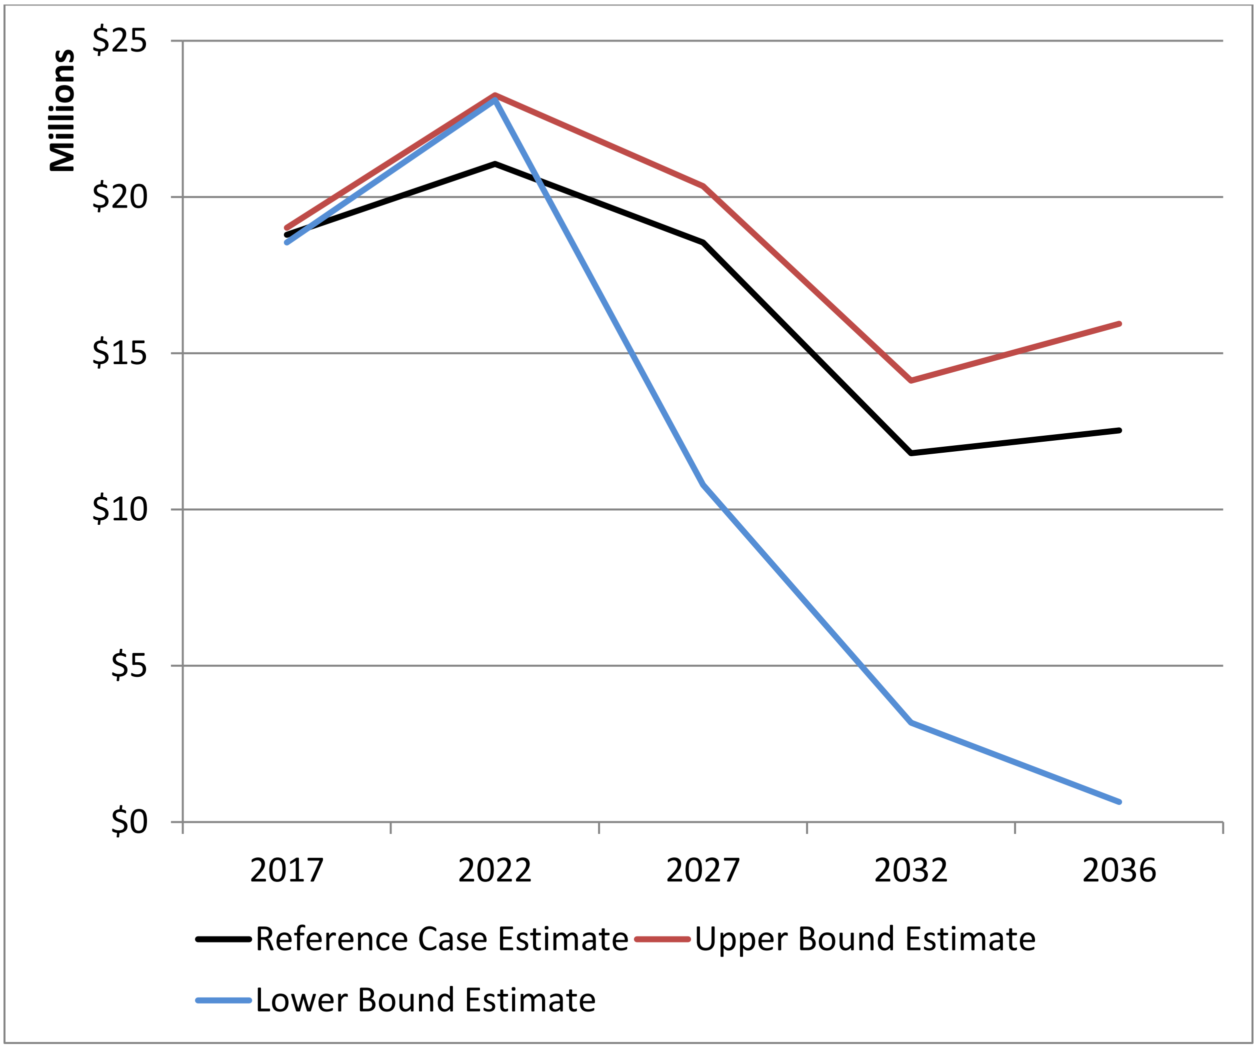


Table 4-6 below displays estimated annual C&EM expenditures for the commercial program area. Estimated expenditures are expected to almost double from 2016 levels by 2021, to increase further until 2023, and to decline after this year towards the end of the planning horizon as available energy savings opportunities are depleted.

Table 4-6: Estimated Reference Case Annual Expenditures – Commercial Program Area

	REFERENCE CASE (MILLIONS)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2017	$ 9	$ 1	$ 10
2018	$ 11	$ 1	$ 12
2019	$ 13	$ 1	$ 14
2020	$ 15	$ 1	$ 16
2021	$ 21	$ 2	$ 22
2022	$ 21	$ 2	$ 23
2023	$ 26	$ 2	$ 28
2024	$ 18	$ 1	$ 19
2025	$ 17	$ 1	$ 18
2026	$ 16	$ 1	$ 17
2027	$ 15	$ 1	$ 16
2028	$ 14	$ 1	$ 15
2029	$ 13	$ 1	$ 14
2030	$ 13	$ 1	$ 14
2031	$ 13	$ 1	$ 14
2032	$ 12	$ 1	$ 13
2033	$ 12	$ 1	$ 13
2034	$ 12	$ 1	$ 13
2035	$ 11	$ 1	$ 12
2036	$ 11	$ 1	$ 12

Figure 4-7 below illustrates estimated annual C&EM expenditures across the Reference Case, Upper Bound and Lower Bound scenarios for the commercial program area. Cumulatively across the planning horizon, Upper Bound estimated expenditures fall 18 percent short of the Reference Case while Lower Bound estimated expenditures are 44 percent below the Reference Case. This appears to be due to the same phenomenon which impacts the aggregate portfolio level results in Figure 4-5 above.

Figure 4-7: Estimated Annual Expenditures by Scenario – Commercial Program Area

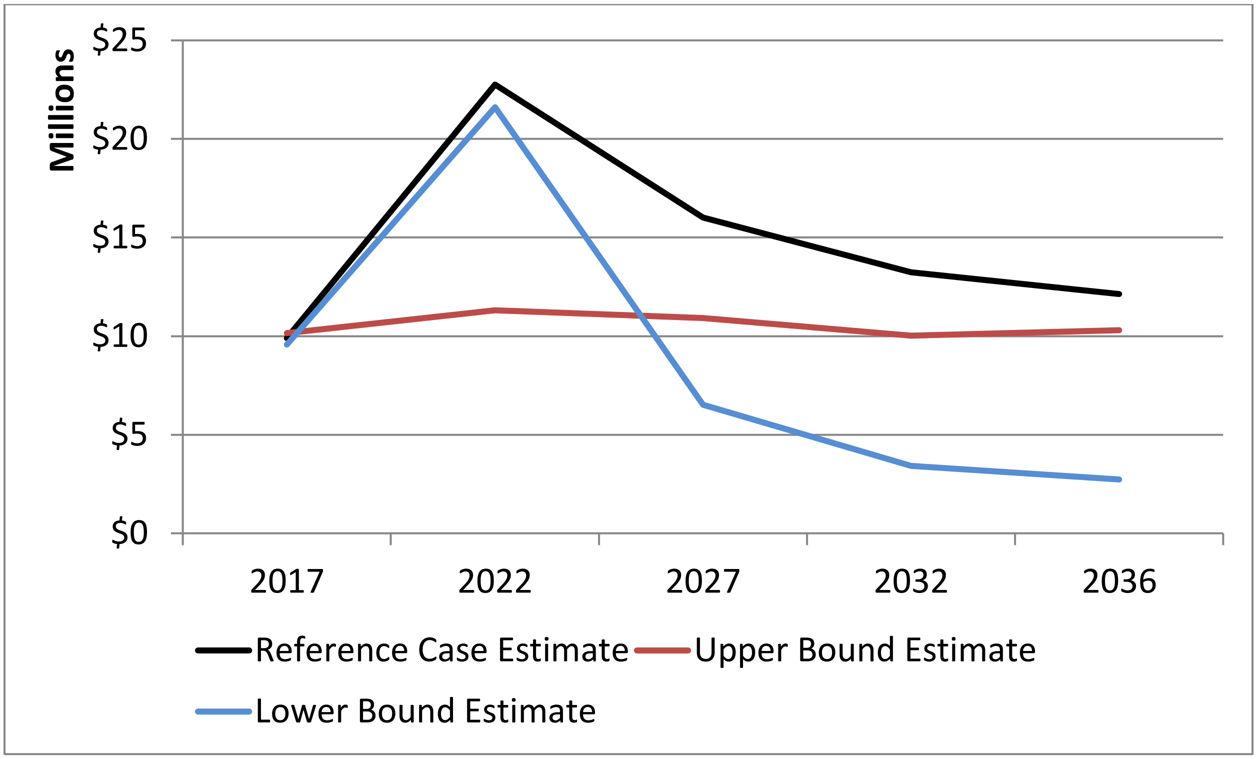

Table 4-7 below displays estimated annual C&EM expenditures for the industrial program area. Estimated expenditures are expected to almost double from 2016 levels by 2017, to increase further until 2026, to remain at approximately this level until 2034, and to decline after this year towards the end of the planning horizon as available energy savings opportunities are depleted.

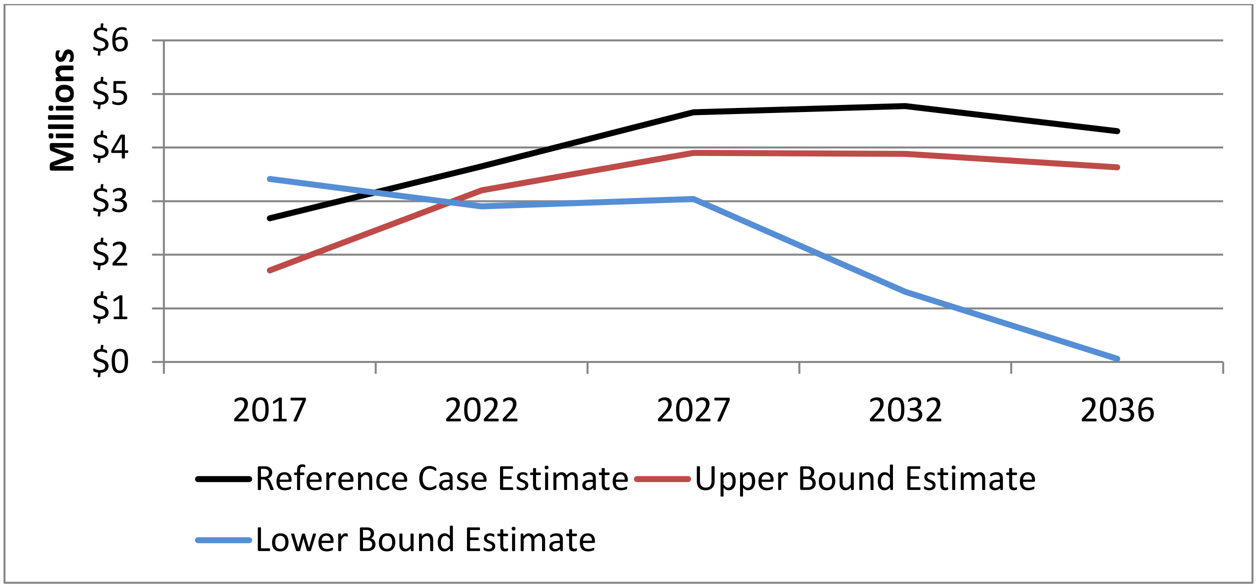
Table 4-7: Estimated Reference Case Annual Expenditures – Industrial Program Area

	REFERENCE CASE (MILLIONS)		
Year	Incentive Estimate	Non-Incentive Estimate	Total Estimate
2017	$ 2	$ 1	$ 3
2018	$ 2	$ 1	$ 3
2019	$ 2	$ 1	$ 3
2020	$ 2	$ 1	$ 3
2021	$ 2	$ 1	$ 3
2022	$ 2	$ 1	$ 4
2023	$ 3	$ 1	$ 4
2024	$ 3	$ 1	$ 4
2025	$ 3	$ 1	$ 4
2026	$ 3	$ 1	$ 5
2027	$ 3	$ 2	$ 5
2028	$ 3	$ 2	$ 5
2029	$ 3	$ 2	$ 5
2030	$ 3	$ 2	$ 5
2031	$ 3	$ 2	$ 5
2032	$ 3	$ 2	$ 5
2033	$ 3	$ 2	$ 5
2034	$ 3	$ 2	$ 5
2035	$ 3	$ 1	$ 4
2036	$ 3	$ 1	$ 4

Figure 4-8 below illustrates estimated annual C&EM expenditures across the Reference Case, Upper Bound and Lower Bound scenarios for the industrial program area. Cumulatively across the planning horizon, Upper Bound estimated expenditures fall 22 percent short of the Reference Case while Lower Bound estimated expenditures are 35 percent below the Reference Case. This appears to be due to the same phenomenon which impacts the aggregate portfolio level results in Figure 4-5 above.

Figure 4-8: Estimated Annual Expenditures by Scenario – Industrial Program Area[124]



4.2.3.3 Estimated Cost Effectiveness Test Results

The base year of the 2017 LTGRP forecast is 2015 but the C&EM analysis does not include data for 2015 and 2016 since these years are in the past already. FEI filed its actual program performance for these years with the Commission in its 2015 and 2016 C&EM Annual Reports.[125,126] FEI does not expect the LTGRP 2017 cost effectiveness test results to match its 2017 C&EM Annual Report because both filings are different in nature and methods and use different years of actuals data (2015 versus 2017, respectively). In particular, the 2017 LTGRP C&EM analysis excludes the items noted in Section 4.2.3.2 above. The C&EM analysis, like the

124 The 2017 estimated expenditure variance across the scenarios appears to be due to the impact of the natural gas and carbon pricing as well as the customer forecast scenario parameters on addressable cost effective industrial energy savings opportunities.

125 Appendix D-27: https://www.fortisbc.com/About/RegulatoryAffairs/GasUtility/NatGasBCUCSubmissions/Documents/160330_FEI_2015_DSM_Annual_Report_FF.PDF.

126 Appendix D-28: https://www.fortisbc.com/About/RegulatoryAffairs/GasUtility/NatGasBCUCSubmissions/Documents/170331_FEI_2016_DSM_Annual_Report_FF.PDF.

BC CPR, also includes numerous energy efficiency measures which are not included in FEI's current C&EM program portfolio.[127]

All cost effectiveness test results reported below exclude data from behavioural and energy management measures (e.g. residential home energy reports or industrial strategic energy management). In alignment with the BC CPR, the 2017 LTGRP C&EM analysis assumes that these measures have negligible incremental costs which cause them to have uncharacteristically high cost effectiveness test results. Excluding data for these measures prevents their results from skewing the aggregate data reported below.

Table 4-8 below summarizes the Reference Case cost effectiveness test results for all program areas while Figures 4-9 to 4-12 illustrate how cost effectiveness test results vary across scenarios. In general, Upper Bound cost effectiveness test ratios are lower than Lower Bound ratios because the low natural gas cost and carbon cost parameters in this scenario depress the avoided cost of gas which reduces the benefits from energy efficiency measures. The MTRC represents an exception to this as this test relies on the ZEEA for its avoided cost of gas. In the 2017 LTGRP, the ZEEA is not impacted by the natural gas and carbon cost critical uncertainties. In general, cost effectiveness test ratios fall over time as the more easily realized energy savings opportunities (i.e. the low-hanging fruit) are depleted. The 2017 LTGRP C&EM cost effectiveness test results also display the Cost of Conserved Energy (CCE) in dollars per GJ. The CCE is an industry standard method for expressing the TRC results in dollars per GJ. Electric utilities use the CCE to express the net cost of saving one unit of utility-supplied energy. The CCE can be used to express Utility Cost Test (UCT) results in dollars per GJ by applying the UCT benefit and cost inputs.[128] CCE results increase over time:

Table 4-8: Estimated Reference Case Cost Effectiveness Test Results – All Program Areas

Year	TRC	MTRC	UCT	CCE ($/GJ)
Aggregate	**2.2**	**11.3**	**2.2**	**4.7**
2017	4.8	25.4	4.4	2.8
2018	4.1	21.3	3.7	3.4
2019	3.5	18.2	3.2	3.7
2020	3.1	16.2	2.9	4.0
2021	2.8	14.5	2.7	4.3
2022	2.6	13.5	2.5	4.5
2023	2.4	12.6	2.4	4.6
2024	2.3	12.0	2.3	4.8

[127] FEI will consider these measures when it prepares its C&EM expenditure schedule for submission to the BCUC in 2018.

[128] In this case, the CCE represents the annualized and, where applicable, discounted UCT net costs (i.e. sum of UCT costs minus sum of UCT benefits, excluding cost savings for utility fuel sales) divided by annual energy savings.

Year	TRC	MTRC	UCT	CCE ($/GJ)
2025	2.3	11.6	2.2	4.8
2026	2.2	11.3	2.2	4.8
2027	2.1	11.1	2.1	4.9
2028	2.1	10.8	2.1	4.9
2029	2.0	10.6	2.1	4.9
2030	2.0	10.5	2.1	4.9
2031	2.0	10.3	2.0	4.8
2032	2.0	10.3	2.0	4.8
2033	2.0	10.3	2.0	4.8
2034	2.0	10.4	2.0	4.7
2035	2.0	10.4	2.0	4.7
2036	2.0	10.4	2.0	4.7

Please see Appendix C-2 for cost effectiveness test results of each of the program areas within the 2017 LTGRP C&EM analysis.

4.2.3.4 Estimated Market Potential Energy Savings from Top Measures

Tables 4-9 to 4-12 below outline projected 2036 cumulative market potential energy savings for the top ten measures in the Reference Case and illustrate how these energy savings change across the scenarios. Overall, projected energy savings in the Upper Bound increase less from the Reference Case than Lower Bound energy savings decrease from the Reference Case. This appears to be due to Lower Bound annual demand (and thus energy savings opportunities) decreasing significantly more over the Reference Case than Upper Bound annual demand increases over the Reference Case. The residential program area top ten measures account for

90 percent of Reference Case program area energy savings. For the commercial and industrial program area this ratio is 65 and 96 percent, respectively. Some measures display zero energy savings in the Upper Bound while other measures display such zero values in the Lower Bound. In the Upper Bound, this appears to be due to the impact of decreased cost effectiveness as a result of the low natural gas and carbon price parameters in this scenario. In the Lower Bound, this appears to be due to reduced energy savings opportunities from accelerated codes and standards and loss of annual demand. FEI's forthcoming 2018 and future C&EM expenditure schedules will be informed by the measure data from the 2017 LTGRP's C&EM analysis and will make program design and delivery decisions in accordance with changing customer needs, regulatory requirements and technology evolution.

Table 4-9: Estimated 2036 Cumulative Savings from Top 10 Measures by Reference Case – All Program Areas

Measures	REFERENCE CASE 2036 Cumulative Savings (GJ)	UPPER BOUND 2036 Cumulative Savings (GJ)	UPPER BOUND % Change from Reference Case	LOWER BOUND 2036 Cumulative Savings (GJ)	LOWER BOUND % Change from Reference Case
Com | NC measure 45 %>code	1,581,337	2,631,732	66%	819,329	-48%
Res | Smart Thermostats	1,364,259	1,433,232	5%	706,260	-48%

4.2.3.5 Reference Case C&EM Results Sensitivity to Incentive Level

In its decision on the 2014 LTRP, the Commission directed FEI to provide in the 2017 LTGRP DSM funding scenarios that reflect the results of the most recent CPR and, at a minimum, should include a reference, a high, and a low DSM funding scenario. FEI provided these scenarios in Section 4.2.3.2 above.

Recently, the Commission and FEI's stakeholders have also shown interest in the sensitivity of FEI's C&EM analysis to changes in the value of FEI's incentives as a proportion of incremental measure cost. FEI instructed the consultant that prepared the BC CPR to use the BC CPR's Bass Diffusion model to explore how different levels of incentive value impact projected energy savings and estimated C&EM expenditures. While the BC CPR model is separate from FEI's 2017 LTGRP forecast model and the 2017 LTGRP Reference Case differs from the BC CPR, the BC CPR's results provide directional insight into this sensitivity.

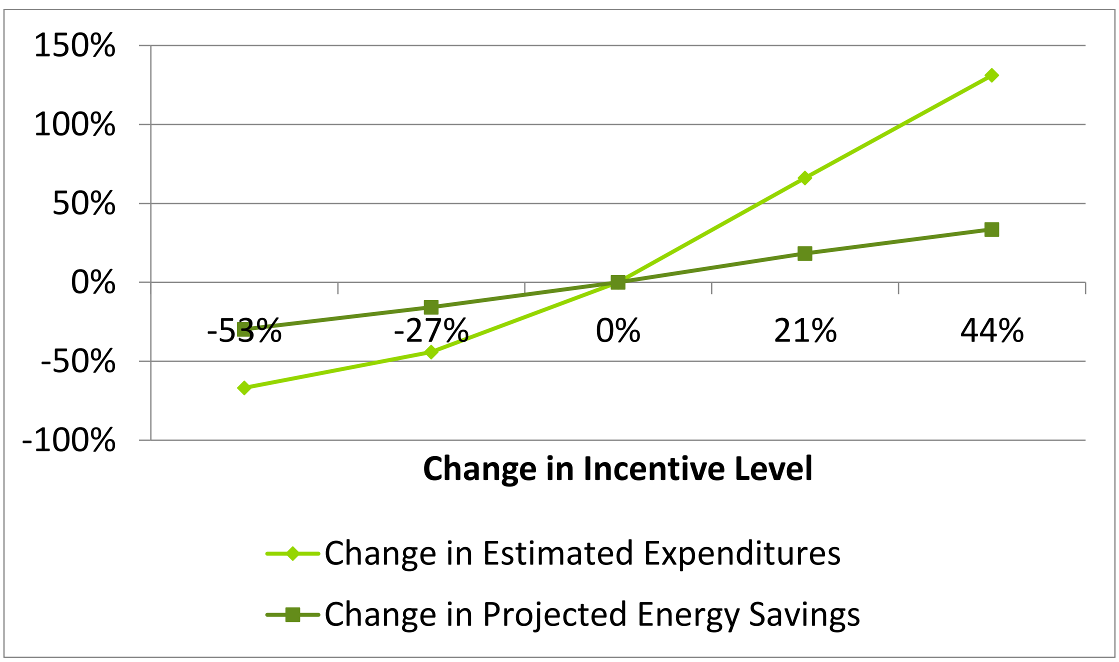
Table 4-13 below summarizes the inputs into the sensitivity analysis. The BC CPR consultant chose the Highest and Lowest input levels to represent the upper and lower bounds on possible incentive strategies. The Lowest input levels represent cases where the incentives are at the low end of industry experience, yet high enough to avoid undue free ridership (i.e. incentives are high enough to promote measure adoption above natural non-incentivized rates). The Highest input levels are intended to represent aggressive incentives, while still requiring participants to cover a small portion of the measure incremental cost. The industrial program area is the exception to this where the Highest input level was elevated to 100 percent because the BC CPR Baseline incentive level was already relatively high. The Low and High incentive levels are set at the approximate midpoints between the Baseline and the respective Lowest and Highest incentive levels.

Table 4-13: Sensitivity Inputs – BC CPR Incentive Levels as Percentage of Incremental Measure Cost

Sensitivity	Commercial	Industrial	Residential
Lowest	30%	30%	30%
Low	45%	60%	40%
Baseline*	61%	89%	52%
High	75%	95%	70%
Highest	90%	100%	90%

Figure 4-13 below illustrates the trend-line results from the sensitivity analysis at the aggregate C&EM portfolio level for the year 2035. Projected energy savings respond linearly to changes in the relative incentive level and have a flat slope. In contrast, estimated expenditures respond on an upward curve with a total slope that is steeper than the slope of the projected energy savings function.[129] Increasing the level of incentives by 44 percent for the aggregate C&EM portfolio yields 34 percent higher projected energy savings at 131 percent higher estimated expenditures:

Figure 4-13: Sensitivity Results Trend-Lines – BC CPR 2035 Incentive Level versus Estimated Expenditures and Energy Savings, All Program Areas



FEI emphasizes that its C&EM program team sets actual incentive levels based on its market research and experience when developing specific programs or preparing C&EM expenditure schedules. In contrast, the BC CPR's Bass Diffusion model represents a theoretical construct

[129] The energy savings trend is driven more by the industrial and commercial than by the residential program area. The estimated expenditure trend is driven more by the residential than by the commercial and industrial program areas.

that is calibrated to FEI's historical program performance and North American industry benchmark data.

4.2.3.6 Estimated Long Term C&EM Impacts on Peak Demand

In its decision on the 2014 LTRP the BCUC requested FEI to make stronger linkages between the peak demand and the annual demand forecasts, to understand how "[…] new insights on evolving customer consumption patterns might affect time-of-day demand as well as annual demand […] and how changes in base load annual demand under different scenarios translate into changes in base load peak demand under the same scenario assumptions."[130]

FEI commissioned Posterity to develop an exploratory process linking peak demand forecasts to the end-use scenarios used in the annual demand forecasts. Section 6.2.1.3 further discusses this process. Overall, Posterity's approach suggests that the 2017 LTGRP's C&EM forecast decreases peak demand. Section 6 discusses in detail how this may impact infrastructure expansion requirements across FEI's regional transmission systems. FEI emphasizes that Posterity's approach currently is theoretical in nature and unsupported by direct measurement. Thus FEI's infrastructure planning continues to rely on FEI's traditional peak demand forecast method (Traditional Peak Method).

4.2.4 Long Term Plan for Implementing C&EM Activities

FEI submits C&EM expenditure schedules to request BCUC approval for its short or medium term C&EM funding envelopes. Based on the results of the BC CPR and the 2017 LTGRP C&EM analysis (and in light of BC provincial energy goals), FEI will develop its next C&EM expenditure schedule for the period beyond 2018. FEI will submit this expenditure schedule to the Commission in 2018 after submission of the 2017 LTGRP.

In the long term, based on the 2017 LTGRP C&EM analysis, FEI projects that it will continue to perform residential, commercial, industrial, low income, innovative technologies, conservation education and outreach as well as enabling C&EM activities. The measures analyzed in the BC CPR and the LTGRP C&EM analysis will inform these activities. In addition, FEI will continue monitoring the cost effectiveness of its C&EM activities and identifying any new measures that can be included in its activities. Over the 2017 LTGRP planning horizon, FEI will operationalize these activities via successive C&EM expenditure schedules. Across these future expenditure schedules, FEI's specific program offers will likely change to suit the evolving marketplace, legislative provisions (including future adequacy requirements), end-use technologies, and FEI customer needs. During the 2017 LTGRP planning horizon, FEI will update its long term C&EM analysis via successive future LTGRPs.

[130] Decision and Order G-189-14, dated December 3, 2014. p. 22.

4.3 *OTHER DSM ACTIVITIES*

While the legislative framework for DSM in BC focuses on energy conservation as the primary means to achieve demand side energy reductions, in the broader context, demand side management encompasses a range of activities in addition to energy conservation. The California Standard Practice Manual, which serves as the general standard of cost effectiveness analysis in the US, identifies the following categories of DSM strategies to distinguish between different types of DSM activity.[131]

- **Conservation:** Programs that reduce natural gas consumption during all or significant portions of the year. This includes all energy efficiency improvements. FEI's C&EM programs fall under this category of load management strategies and are discussed in Section 4.2.
- **Load Management:** Programs that may either reduce peak demand or shift demand from peak to non-peak periods. Since the largest portion of natural gas demand in BC is for space and water heating which are more difficult to shift, and because the natural gas system acts to store energy allowing it to be drawn down over a longer period of time than with electricity, programs that reduce or shift peak demand for natural gas are more challenging in BC. However, increasing the load factor by adding customers who use natural gas in a flat manner helps to manage the system. Transportation customers are an example of this type of customer, as are other manufacturing customers such as those in fertilizer production or LNG for export.
- **Fuel Substitution:** Programs that increase annual consumption of natural gas or electricity by inducing the choice of one fuel over another. Two of FEI's current incentive-based initiatives could be characterized as fuel substitution: the residential fuel switching program and the Company's NGT activities. These two initiatives, discussed later in this section, have the benefit of increasing natural gas consumption and thereby having a downward impact on customer rates, while at the same time reducing customers' GHG emissions as natural gas replaces the combustion of higher carbon fossil fuels.
- **Load Building:** Programs that increase the annual consumption of electricity or natural gas by increasing sales of electricity, natural gas or both. In the broader context of DSM, FEI's fuel switching program and NGT initiatives are also examples of load building demand side activities in that they increase the annual use of natural gas.

The California Standard Practice Manual also notes that recent utility program proposals aimed at "load retention," "sales retention," "market retention," or "customer retention" may be treated as either a fuel substitution or a load building program since in most cases, the effect is identical to such programs.[132] FEI's current activities aimed at building load and retaining customers, for the benefit of FEI customers, are described here in Section 4.3. This discussion is not intended

[131] California Public Utilities Commission and California Energy Commission. 2001. "California Standard Practice Manual: Economic Analysis of Demand-Side Programs and Projects". p. 2.
[132] Ibid. p. 3.

to address any of the requirements of Section 44.1(2) of the UCA —however, the initiatives discussed below help to meet BC Government energy and GHG emission objectives.

Currently, the Company is undertaking two programs that, although they are not demand-side measures as defined in BC's CEA, are demand side activities in the broader sense. These are FEI's fuel switching program and NGT initiatives. Expenditures and cost recovery mechanisms for the fuel switching program and NGT initiatives are separate and distinct from the Company's C&EM activities and have been approved by the Commission at current levels through proceedings separate from the current one. Since the fuel switching program is relatively small and NGT initiatives have been extensively reviewed through other regulatory processes, these initiatives are discussed here only to the extent that they provide examples of the types of fuel substitution and load building activities that FEI should continue to explore, implement and expand where there are benefits to customers and where they create an opportunity for the Company to help meet government energy and emission goals. FEI is also examining the potential for adding new, large industrial load customers and is currently engaging a wide network of builders, developers and other influencers of natural gas use in order to increase awareness of the benefits of natural gas and encourage new load.

The impact of the fuel switching program, NGT activities, annual demand for large new industrial customers, as well as every day sales activities for natural gas demand is already incorporated into the annual energy demand forecasts (Section 3), and therefore, their potential impact on system infrastructure is inherently considered in the system capacity planning and gas supply discussions in Sections 5 and 6, respectively. The main goal, consequently, is to present them here as examples of load management strategies that the Company should continue to explore, implement and expand where they are found to be in the interests of customers by adding throughput to the natural gas system thereby reducing rates while also helping to achieve government energy and emissions reduction objectives. (GHG emission reductions and rate impacts are discussed in Section 8).

4.3.1 Fuel Switching

FEI's fuel switching program (previously known as 'Switch 'n' Shrink') supports customer additions and demand growth, and includes initiatives designed to result in lower overall GHG emissions by using natural gas instead of other fuels such as coal, oil, diesel or propane. This program also promotes energy efficiency through installation of new high efficiency natural gas heating equipment.

Historically, FEI offered this program to its residential customers under the 'Switch 'n' Shrink' moniker. From 2010 until the end of 2016, the Switch 'n' Shrink program had at total of 4,349 participants. A 2012 technical analysis of the program concluded that participants consumed less energy, reduced GHG emissions and lowered their operations costs as a result of the lower cost of gas. [133,134]

[133] Or approximately 11 GJ, based on the energy content of the normalized annual heating oil consumption.

FEI re-launched the program as 'Connect to Gas' in Q3 of 2017. The program changes under this re-launch refine eligibility rules, clarify how FEI's C&EM and Connect to Gas initiatives relate to each other, and encourage the efficient use of energy.

4.3.2 NGT

As discussed in Section 2 FEI is implementing a strategy to stimulate growth in the CNG and LNG market that is focused on return-to-base fleet vehicles, marine vessels, and remote communities. Section 3 provides the annual demand forecast for CNG and LNG. Section 6 discusses the impact of CNG and LNG demand scenarios on FEI's system infrastructure.

4.3.3 New Large Industrial Customers

Additional load from new large industrial customers helps maintain rate competitiveness by increasing throughput on the gas delivery system. With the low natural gas price environment (refer to Section 2.2 for context on natural gas prices), large volume customers have indicated interest to FEI in expanding operations or developing new major industrial facilities that use natural gas as a feedstock.

Within its scenario analysis and contingency planning, FEI is examining its gas delivery systems' and gas supply planning's ability to accommodate transportation service (Firm Transportation) for new, large industrial demand in various locations across its service territories. Sections 6.3.1 and 6.3.2 illustrate an example of a large industrial customer that has requested Firm Transportation and the effect that the increased demand would have on system reinforcement requirements.

Any major required reinforcements to serve potential new industrial loads would be evaluated as part of a formal submission to the BCUC once firm agreements regarding natural gas services have been made.

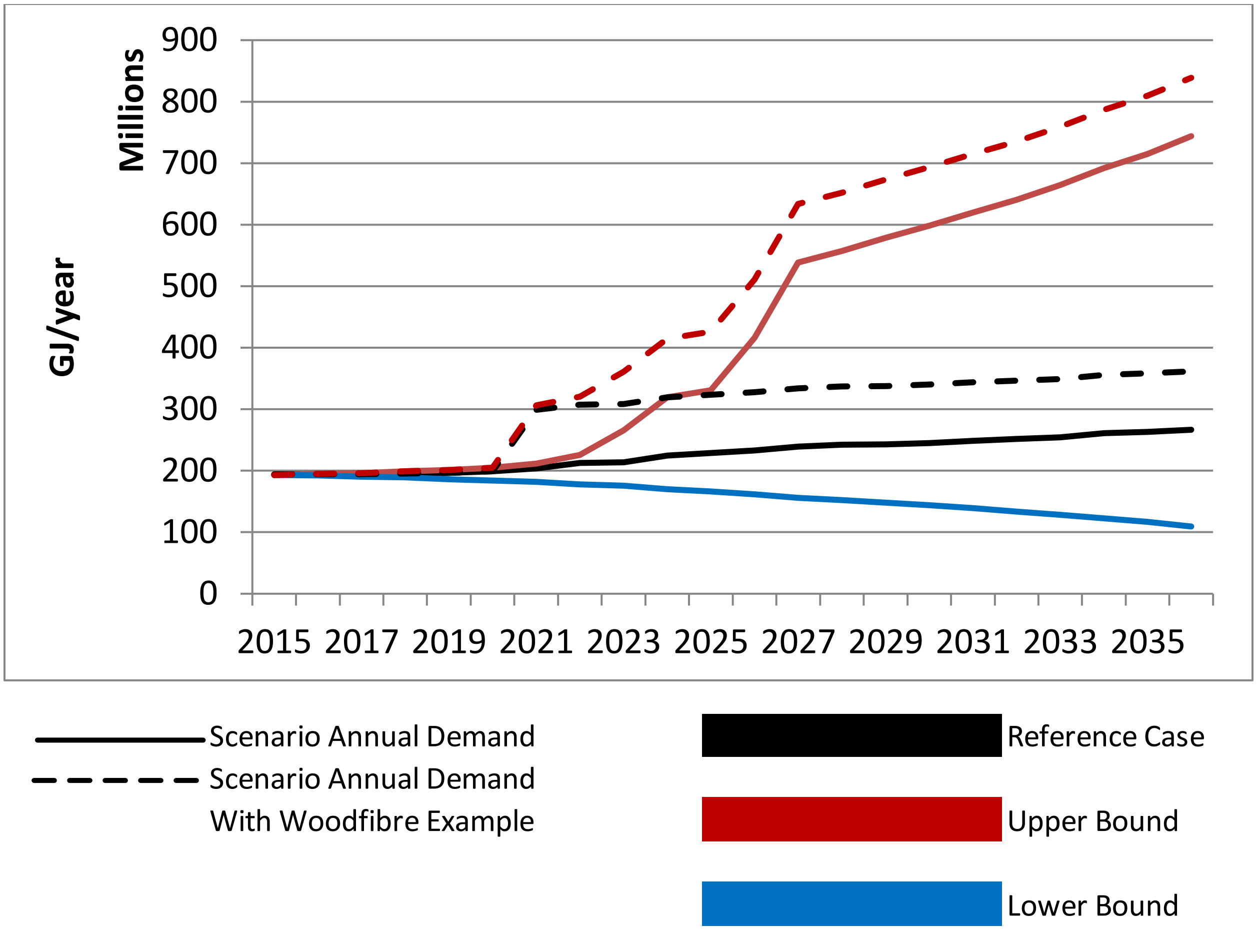
4.4 *TOTAL ANNUAL DEMAND AFTER DSM*

Figure 4-14 below summarizes forecast total annual demand including FEI's base customers, FEI's projected NGT customers, and the effect of projected C&EM activity. As initially outlined in Section 3.4.9, Figure 4-14 also illustrates the hypothetical impact on the Reference Case and Upper Bound scenario of a potential small scale LNG export and processing facility located on the former Woodfibre pulp mill site near Squamish. Without the hypothetical impact of the Woodfibre LNG Project example, total Reference Case annual demand increases by 38 percent across the planning period when taking into account the impact of both forecast NGT and also C&EM activity. This Reference Case total represents the annual demand that FEI plans to in the 2017 LTGRP.

---

[134] InterVistas Consulting (November 21, 2012). "FortisBC Switch 'N Shrink Program Carbon Emissions and Cost Savings Analysis". This report uses a natural gas emission factor of 0.051 tCO_2e.

Figure 4-14: Total Annual Demand After DSM - Including NGT and Woodfibre LNG Project Example



4.5 CONCLUSIONS AND RECOMMENDED ACTIONS

DSM activity continues to be an important part of FEI's resources for meeting customers' energy needs, improving energy efficiency, helping to manage customers' energy costs, optimizing use of the energy infrastructure in BC and reducing GHG emissions. The C&EM analysis shows that significant energy and GHG emissions reductions can be achieved over the planning horizon under the range of future scenarios examined for the LTGRP. The analysis also shows that the C&EM measures implemented through the planning period will shift depending on how the future actually unfolds. Combined with analysis of the impacts of C&EM activities on the capacity requirements of FEI's natural gas transmission system discussed in Section 6, this 2017 LTGRP meets the requirements in Sections 44.1(2)(b) and (f) of the UCA to provide an explanation of how the Utility plans to use C&EM activities to reduce energy consumption and help meet customers' demand for energy over the long term, and to explain the extent to which C&EM activities can defer the need for new infrastructure projects.

FEI should continue to examine opportunities to develop other DSM initiatives that offer similar benefits or to expand existing offerings and where appropriate, seek approval for expenditures related to those offerings. Recommended actions to acquire and implement demand side resources over the planning horizon are to:

- Develop, based on the results of the BC CPR and the 2017 LTGRP C&EM analysis (and in light of BC provincial energy goals), a C&EM expenditure schedule for the period beyond 2018 and submit this request to the Commission after submission of the 2017 LTGRP.
- Implement the near-term C&EM expenditure schedule for the period beyond 2018 in accordance with the BCUC's future decision on FEI's forthcoming expenditure application.
- Continue to examine the potential for all forms of DSM and analyse the potential benefits and risks for FEI and its customers of implementing new and creative programs that help meet customer energy needs, optimize the use of utility infrastructure, keep energy rates down and/or reduce customers' GHG emissions.
- Continue to work with federal, provincial and municipal governments and other potential partners to explore and identify ways in which FEI's DSM activities can continue to help meet government objectives while ensuring benefits for FEI and its customers.

5. GAS SUPPLY PORTFOLIO PLANNING AND PRICE RISK MANAGEMENT

Section 2 of this 2017 LTGRP discussed FEI's planning environment as a basis for Section 3 to provide a long term annual demand forecast and Section 4 to consider the impact on forecast annual demand of FEI's projected C&EM activities. On this basis, Section 5 addresses how FEI plans to meet such demand in the long term via its gas supply arrangements. These arrangements encompass FEI's activities and means to contract for both natural gas as well as the resources to bring this gas to the FEI pipeline system. Subsequently, Section 6 will analyze long term requirements for FEI's own infrastructure and options for meeting these requirements over the planning horizon.

This section is organized as follows:

- Section 5.1 provides background information on FEI's gas supply portfolio planning instruments and regulatory requirements for gas supply planning in the LTGRP;
- Sections 5.2 to 5.4 discuss relevant regional developments, FEI's supply portfolio planning, and long term planning strategies; and
- Section 5.5 outlines FEI's long term approach to Price Risk Management.

It is important to note that gas supply portfolio planning considers a subset of the total system throughput that FEI considers for system capacity planning in Section 6. FEI's gas supply planning is responsible for ensuring that the forecast normal and peak day demand of core market (Core) customers is appropriately planned for[135]. The gas supply requirements for the remaining portion of the total system throughput are the responsibility of customers who have elected to take Firm Transportation. These Firm Transportation customers arrange for their own supply that is then transported by FEI to their premises. In contrast, system capacity planning needs to consider total system throughput to ensure that sufficient capacity exists on FEI's system to reliably move gas supply to meet the demand of all customers. Table 5-1 below illustrates the differences between FEI's customer service types for gas supply portfolio and system capacity planning in the LTGRP.

[135] As outlined in Table 5-1, this also applies throughout Section 5 to any applicable delivery component of Interruptible customers.

Table 5-1: Summary of LTGRP Customer Service Types

LTGRP Customer Service Type	Rate Schedules	FEI Gas Supply Portfolio Planning	FEI System Capacity Planning
Core	1, 2, 3, 4, 5, 6	Included	• Rate Schedules 1, 2, 3, 5, 6 included; and • Rate Schedule 4 (seasonal) excluded.
Firm Transportation	• 23, 25; and • Contracted firm delivery component of 22 (including 22A and 22B) and other special Rate Schedules.	Excluded (these customers may secure their commodity supply on their own or through a shipper agent)	Included
Interruptible	• 7, 27; and • Interruptible component of 22 (including 22 A and 22B) and other special Rate Schedules.	• For Rate Schedule 7 and any non-transportation component of special Rate Schedules: ○ Included: contracted firm delivery component; ○ Excluded: interruptible delivery component; and • Excluded for all other Interruptible service customers.	Interruptible components excluded (FEI can reduce natural gas flow to these customers during peak conditions to any firm contract amount)

This section and the Annual Contracting Plan (ACP) rely on FEI's traditional method for deriving system-wide demand for each day throughout the entire year as well as for the peak design day (i.e. the coldest day of the design year estimated via extreme value analysis within a return period of 20 years). In contrast, Section 6, which discusses FEI's resource needs and alternatives, relies on location-specific (not system-wide) peak demand. Section 6 outlines FEI's Traditional Peak Method for deriving peak demand and also explains FEI's test in this 2017 LTGRP for arithmetically linking the annual end-use demand forecast to peak demand.

Key factors in FEI's gas portfolio planning include resource cost and availability, which are determined in the competitive natural gas marketplace. Consequently, gas supply portfolio planning activities must also consider regional marketplace developments that will affect traditional regional gas flows, supply and demand in the region, as well as the cost and availability of regional market resources for FEI (briefly highlighted in Section 5.2 and further discussed in Appendix A). At this point, these gas market developments include understanding the shale gas supply potential in northern BC, initiatives by TransCanada in capturing this BC gas for its Alberta markets, and the potential for additional industrial demand in the region (e.g. methanol or LNG exports).

Currently, FEI contracts for all of the gas supply resources required over the short to medium term. However, as infrastructure in the region is fully utilized and now very constrained, new regional demand will require the construction of new infrastructure. The timing of when the new demand materializes and when new infrastructure is completed will likely present significant uncertainty for the natural gas marketplace. While FEI is likely to avoid facing issues over the short to medium term given its planning approach, these challenges may have significant impact on regional participants who have historically relied on interruptible transportation capacity. Currently, these participants are able to serve the demand of their customers by accessing some transportation capacity in the secondary market and by purchasing more costly gas supply at the Huntingdon-Sumas market hub. In the long term, however, as new regional demand materializes, much of this capacity may be taken back to serve this new demand. For FEI this may cause some Firm Transportation[136] customers to seek to return to Core service.

In this section, the term ‘region’ broadly refers to the PNW which includes BC. However, US-specific gas supply considerations are different from BC-specific considerations within the PNW region. For orientation, Figure 5-1 below provides an overview of FEI’s operating region, the supply basins that service markets in the PNW, the transportation pipelines and storage facilities required by these markets, and the location of the market supply hubs where commodity purchases are transacted.

[136] Throughout Section 5, this also applies to any applicable delivery component of Interruptible customers.

1 **Figure 5-1: Regional Supply Resources – Pipelines, Storage and Trading Hubs**

2

For managing market price risk, physical tools such as commodity purchases using different index and supply hubs, and the use of storage, as well as financial tools, such as hedges, help FEI maintain cost effective supply of natural gas and reduce adverse market price movements on rates. As previously mentioned in Section 2, while natural gas prices have continued to remain low in recent years because of the growth in shale gas supply, market price volatility remains because of frequent supply and demand imbalances. Furthermore, natural gas prices are not expected to remain at their current low levels over the long term. While the focus of price risk management in the past has been primarily on short term planning, FEI believes the current market price environment creates opportunities for longer-term strategies. Going forward, these could include consideration of longer term instruments or tools that could improve long term cost certainty. These strategies could then help to provide improved rate stability and ensure better security of supply for customers.

5.1 BACKGROUND

5.1.1 Relationship Between FEI's Gas Supply Planning Instruments

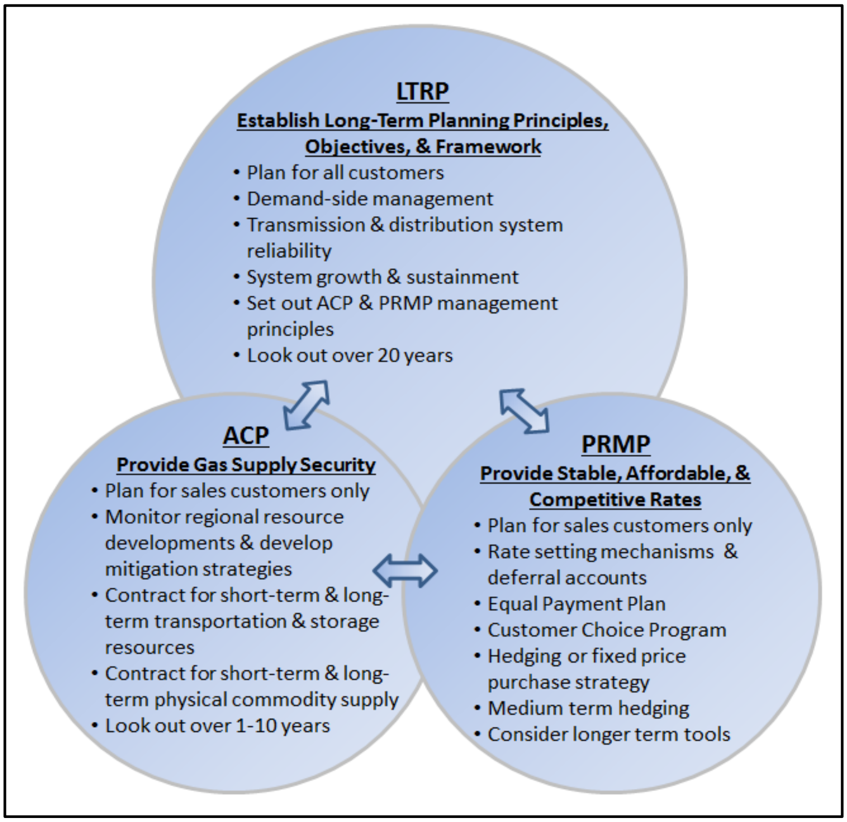
FEI uses multiple tools for planning its gas supply and price risk management activities. These tools are the LTGRP, ACPs and PRMPs. An important difference between the LTGRP and the ACP and PRMP is the type of demand forecast on which the various plans are prepared. The LTGRP is based on a broad range of long term demand forecast scenarios based on the total system throughput of all customers. In contrast, the ACP and PRMP are based on short term and medium term forecasts derived from trends observed in recent years (or on customer reported expectations in the case of industrial customers) and only consider the demand of Core customers, a subset of total system throughput.

The LTGRP establishes long term planning principles, objectives, and a framework that is used to help ensure the long term provision of safe, reliable, and cost effective service to all customers. In doing so, the LTGRP also sets out gas supply contracting and price risk management principles within the context of a 20-year outlook. The ACP and the PRMP each describe more detailed strategies and tactics for managing either the physical availability of natural gas supply or the impact of gas costs on rates.

The ACP is an annual plan that focuses on the next gas year's resource requirements but also looks out beyond the next gas year at any market conditions that may impact future supply procurement strategies. Although the ACP is primarily concerned with ensuring the physical availability of natural gas supply, it also enables several price risk management benefits. These include diversity and purchasing term supply from different market hubs, purchasing term supply on a daily and monthly indexed basis, and using storage resources to take advantage of any summer-winter price differentials.

The PRMP provides strategies and tools to enhance existing price risk management in managing the impacts of market price volatility on commodity rates and in capturing market price opportunities to help provide customers with affordable rates. The PRMP is, to a large degree, informed by the ACP since the ACP determines the physical resources required and degree of portfolio exposure to market prices. Figure 5-2 below illustrates the general components included in each instrument and the relationship between them:

Figure 5-2: Components Of And Relationship Between FEI Gas Supply Planning Processes



FEI is not seeking approval of its gas supply portfolio or price risk management activities as part of the LTGRP, as these approvals are sought through separate applications to the Commission. Discussion of the Company's ACPs and PRMPs is included in the LTGRP in order to provide context for resource planning considerations.

5.1.2 Regulatory Requirements for Gas Supply Planning in the LTGRP

Section 44.1(2) of the UCA outlines multiple requirements for long term resource plans. In relation to energy supply, the UCA requires long term resource plans to provide:

> e) Information regarding the energy purchases from other persons that the public utility intends to make in order to serve the estimated demand referred to in paragraph (c); and

f) An explanation of why the demand for energy to be served by the facilities referred to in paragraph (d) and the purchases referred to in paragraph (e) are not planned to be replaced by demand-side measures.[137]

FEI submits that Section 5 of this LTGRP meets the above UCA requirements by outlining the long term considerations that apply to FEI's energy purchases and the impact of demand drivers, such as DSM, on such considerations. FEI's ACP and PRMP operationalize these considerations in the short and medium term and, in doing so, will consider specific purchase requirements and demand driver impacts that affect FEI at their time.[138]

5.1.3 Factors Impacting FEI's Long Term Gas Supply

At a high level, the major market factors that may affect FEI's gas supply planning over the long term include:

- Large scale industrial projects (such as the large industrial point loads discussed in Section 3.4.9 that would not rely on their own pipeline connections to gas supply resources) potentially in-service by 2020 have already secured firm transportation capacity on existing regional pipelines for a portion, if not all, of their supply requirements. Once these projects come online, the regional flow dynamics and price for all customers may be impacted.
- Changes in the demand forecast within FEI's natural gas service areas[139] and regional local distribution utilities in the PNW.
- Risk of FEI's shorter duration market storage assets, specifically Mist, being recalled by approximately 2021/22.[140]
- Any major pipeline expansion in the region will require planning and lead time for approvals and implementation, given a greater amount of uncertainties now tied to large scale pipeline expansions (i.e. new customer contributions to underwriting the expansion and environmental/regulatory challenges).
- The significant supply potential in NEBC, specifically in the Montney region, has prompted the development of competing infrastructure initiatives to provide greater access to existing and new markets. These developments could impact FEI's future access to secure reliable natural gas supply at a fair market price in BC.

[137] http://www.bclaws.ca/Recon/document/ID/freeside/00_96473_01#section44.1

[138] The impact of demand-side measures to date is inherently considered in the ACP since the short term demand forecast, on which the ACP is based, captures these recent efficiency trends. Future ACPs will likewise consider future demand-side measures.

[139] Service areas include Mainland, Fort Nelson, Whistler and Vancouver Island.

[140] NW Natural's 2016 Integrated Resource Plan indicates future load growth within its service region (Oregon and Washington). https://www.nwnatural.com/aboutnwnatural/ratesandregulations/regulatoryactivities/integratedresourceplanning.

The following sections explain FEI's approach to handling these long term uncertainties. Section 5.2 commences this explanation by summarizing regional market developments. Section 5.3 outlines FEI's gas supply planning process and describes the sources as well as the need for diversification of regional gas supply resources. On this basis, Section 5.4 details the elements of FEI's long term supply planning and contracting strategy and Section 5.5 discusses price risk management.

5.2 REGIONAL MARKET DEVELOPMENTS

Significant changes continue to occur in the region that will affect FEI's long term gas supply resource contracting. Regional resources that are currently available are fully utilized to meet existing customer demand during colder than normal winters, as evident from three of the past ten winters. However, demand for natural gas is expected to increase in the future within both FEI's natural gas service areas and more broadly in the PNW region, which could have a significant impact on supply and demand dynamics in the region. For instance, the addition of new load will require the construction of new transportation capacity so that demand in the Lower Mainland and the US I-5 corridor can be served reliably. The potential new regional load is discussed in Appendix A. However, providing new transportation capacity will require advance planning, given that a limited regional pipeline expansion is unlikely to be completed before November 2020 and a further more significant regional pipeline expansion is unlikely to occur before 2023. The timetable for a more significant regional pipeline expansion may be subject to considerable changes, as it will only be undertaken after shippers commit to contribute to underwriting an expansion and may face environmental and regulatory challenges.

Another major development in the region is the significant supply potential in NEBC has prompted the development of infrastructure initiatives to provide greater access to existing and new markets. With increasing demand from industrial, power generation and oil sands demand within Alberta, and a push by producers to access this economic supply source, TransCanada has brought forward plans to expand into NEBC to access the significant resource that is located there. TransCanada's proposed projects will compete for the same supply currently accessed by Westcoast Energy Inc. (Westcoast) and on which FEI is reliant on for its customers. These regional pipeline initiatives are discussed in greater detail in Appendix A.

Finally, over the past few years, prices at the AECO/NIT market have dropped significantly, and are forecasted to remain lower than other gas market hub prices in the US and Canada, as the western gas market faces challenges to clear the substantial supply producers seek to bring to it. At the same time, less natural gas supply from the WCSB has been required by traditional eastern US and Canadian markets due to the growth in gas supply and pipeline connections from the Marcellus and Utica shale regions located in the north eastern US. This trend will likely continue as more pipeline expansions connecting this supply to eastern markets are expected to come into service in the near future. Western Canadian producers had hoped that the decline in its eastern market share would be offset by the emerging LNG export market in the PNW. However, this market has been slow to develop in the region and now faces an uncertain future given the delays and cancellations of many of these potential projects. As a result, the increase in supply combined with stagnating demand from the WCSB has caused AECO/NIT prices to plummet. It remains to be seen if and when gas producers will cut back on gas production in reaction to these low prices. These current low market prices provide an opportunity for FEI to capture and maintain low gas costs under its price risk management activities for customers.

5.3 SUPPLY PORTFOLIO PLANNING

5.3.1 Background and Overview of the Gas Supply Planning Process

Key factors in FEI's portfolio planning include resource cost and availability, which are determined in the natural gas marketplace where FEI competes with other parties. Basic elements of the gas supply portfolio include the purchasing of gas commodity volumes, contracting on third party transportation pipelines that connect supply to market, and contracting for storage resources, which allows the movement of gas to and from storage facilities as required. Gas supply is also provided via FEI's own on-system LNG storage facilities.[141]

Competition among market participants for supply and for transportation capacity on the regional transportation infrastructure means that utilities must remain vigilant in identifying regional developments that could negatively impact customers or, conversely, identifying opportunities that could provide benefits. FEI is involved in several regulatory proceedings and works with regional associations to help manage regional issues. These issues include ensuring the availability of regional gas supply as well as the appropriate development and tolling of new infrastructure that facilitates the reliable movement of supply to market.

FEI files an ACP with the Commission in the spring of each year, in which FEI assesses the overall North American market and evaluates the regional market with respect to supply and infrastructure. Key objectives of the ACP are:

1. To contract for resources that appropriately balance cost minimization, security, diversity and reliability of gas supply in order to meet the Core customer forecast design peak day and annual requirements; and
2. To develop a gas supply portfolio mix, which incorporates flexibility in the contracting of resources based on short term and long term planning and evolving market dynamics.

FEI's portfolio is designed to provide secure and reliable daily gas supply to Core customers so that system-wide forecasted normal, design and peak design day demand is met. FEI also evaluates the impact of the RNG initiatives; however, given the small relative volume of this

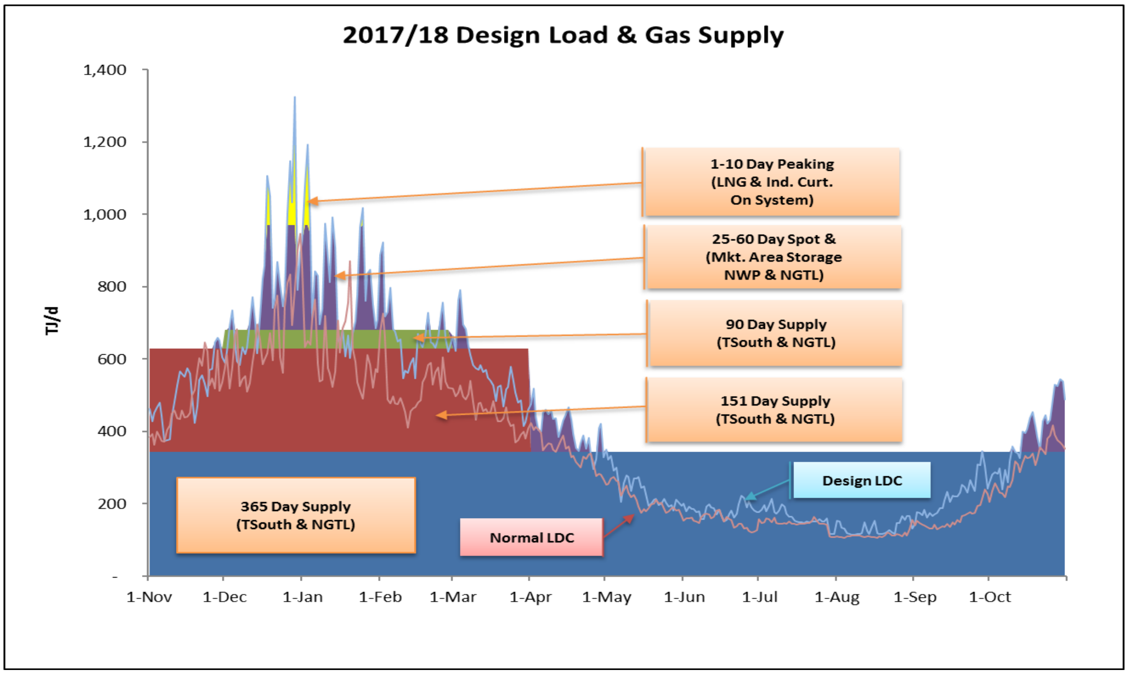
[141] The FEI-owned Tilbury LNG storage facility in Delta, BC currently has a capacity of approximately 0.6 million GJ. The Mt. Hayes LNG storage facility near Ladysmith, BC has a capacity of approximately 1.6 million GJ. The current 1.1 million GJ expansion at Tilbury will serve the transportation fleet market.

supply (current and forecasted) to the FEI system, it has not yet warranted an adjustment to the portfolio.

Supply resources include contracted term and spot supply, gas injected and withdrawn from various leased storage facilities, and use of company owned on-system LNG facilities. Many of these resources are contracted for the long term if they are cost effective and reliable, which is prudent given how limited these resources are in the region. Over the short term, the portfolio does not generally change significantly from year-to-year. However, the portfolio can and may need to rebalance over the long run as market changes occur and new infrastructure is developed.

Figure 5-3 illustrates the gas supply resources that are planned to be used in the 2017/18 gas contract year and how their durations fit the forecast annual normal and design load for Core customers.

Figure 5-3: 2017/18 FEI Forecasted Peak and Normal Loads vs. Resources[142]



This figure also illustrates that the colder weather in the winter period is highly variable, which requires resources that are flexible so that they can be deployed on relatively short notice to meet changes in load requirements.

5.3.2 Sources of Regional Natural Gas Supply Resources

FEI, on an ongoing basis, evaluates its portfolio of resources, which includes a mix of transportation pipeline capacity, storage and supply options in order to balance security and diversity of gas supply, while attempting to minimize the cost of the total portfolio. FEI currently

[142] This forecast is for Core requirements and does not represent total system throughput.

purchases its supply from two market hubs - Station 2 in NEBC, and AECO/NIT in Alberta. Alternative market hubs for consideration when contracting for supply are on the international border at Huntingdon-Sumas and Kingsgate.

FEI also contracts seasonal and shorter duration storage resources in order to meet seasonal and peaking demand requirements during the winter season, while balancing the overall pipeline system of FEI on a daily basis. Contracting considerations for storage facilities are generally planned to cover a longer time horizon, due to the limited availability of such resources in the region.

FEI contracts for seasonal storage at Aitken Creek Storage in NEBC and currently with Rockpoint Gas Storage in Alberta. These seasonal storage assets are available to be utilized throughout the winter season (November-March).

FEI also contracts for shorter duration market area storage resources, which are needed when colder than normal winter loads are greater than the supply available from seasonal storage and termed gas supply. FEI contracts these shorter duration assets at Jackson Prairie Storage in Washington and Mist Storage in Oregon. FEI also contracts with third parties such as Westcoast, TransCanada, and Northwest Pipeline (NWP) for transportation capacity in order to move supply purchased at the different market hubs, and to manage withdrawals and injections from storage facilities for delivery to FEI's transmission system.

Contracting for transportation capacity on Westcoast's T-North and T-South system provides FEI with access to gas supply from NEBC. Westcoast's T-North system allows FEI to access gas supply north of the Station 2 market hub, and to inject or withdraw from the Aitken Creek storage facility. Westcoast's T-South system allows gas supply to be delivered from Station 2 to FEI's Lower Mainland and Interior delivery system.

Contracting for capacity on TransCanada's NGTL and FoothillsBC systems and utilizing FEI's own Southern Crossing Pipeline (SCP) allows FEI to access gas supply from the AECO/NIT and Kingsgate markets and Alberta located storage facilities.

Finally, transportation capacity on NWP provides access to supply from storage facilities south of the border in Washington and Oregon states. Additionally, FEI uses its own on-system LNG storage facilities at Tilbury LNG and Mt. Hayes LNG to provide gas supply during periods of cold and extreme winter weather or during emergency situations.

5.3.3 Importance of Diversification of Gas Supply Resources

It is critical that FEI's supply and resource portfolio incorporate a flexible variety of resources ranging from purchased term and spot gas supply, seasonal and short duration third party storage contracts, and high volume on-system resources. Each resource within the portfolio has different characteristics and functions to meet the load requirements of FEI's customers. For example, while seasonal winter supply is used to meet average winter loads during each day of the winter, peaking resources such as Tilbury LNG storage are designed to be used on only the coldest days of the winter. The resources are selected based on how they meet the load profile, its cost, and their availability in the marketplace. Accessing gas supply from a variety of locations and sources provides FEI with a diverse pool of resources that is essential to help mitigate locational supply disruptions and price risk.

FEI and other utilities in the PNW rely heavily in the winter months on gas supply originating from NEBC that is transported on Westcoast's T-North and T-South pipelines. To manage the risk of supply interruptions associated with well freeze-offs, upsets in processing plants, and potential transmission force majeure events, FEI sources gas from producers that have supplies flowing out of Westcoast's Fort Nelson, McMahon, and Pine River gas plants, as well as from several smaller facilities for delivery to Station 2. Historically, two-thirds of gas supply in BC flowed from Pine River located east of Station 2, McMahon located south of Fort St John, and Fort Nelson located south of the town of Fort Nelson. However, over the past few years, the supply from these plants has declined significantly. The drop in production levels from these three plants is due to the sustained low commodity prices making them uneconomic. New production is now focused primarily on the Montney basin, where the cost of supply is significantly lower. This has led to increasing production in a number of smaller plants that are tied to Westcoast's T-North system. Production growth at these smaller plants is important because it has helped to diversify from the dependency on the three major gas plants. However, reliance on these smaller plants may come with additional risk over time. The risk exists that producers in the Montney basin may not be able to maintain their production levels given the significant drop in regional prices, as discussed briefly in Section 5.2. Moreover, with TransCanada's expansions in BC (discussed in Appendix A), the portion of NEBC gas production could change between Station 2, Alliance, and NGTL.

5.4 *FEI'S LONG TERM SUPPLY PLANNING AND CONTRACTING STRATEGY*

FEI's existing portfolio of resources will be able to meet forecast demand in the coming gas contracting years for the Core customers. However, certain market conditions that have been discussed throughout this section may unfold that could impact future resources available to FEI. This 2017 LTGRP presents FEI's contingency planning considerations, which illustrate how FEI may be able to respond to market conditions that differ from the Reference Case assumptions.

A reduction in FEI's demand forecast will not create a major risk to FEI's long term planning strategy because of the contracting flexibility of FEI's portfolio:

1. Commodity Purchases – Although FEI has entered into some long term supply commitments with counterparties, a majority of the gas supply purchased for the Core customers is negotiated on an annual basis and priced off a market index. Therefore, FEI could easily reduce or resell the amount of commodity purchases, if Core demand declines.
2. Transportation Capacity – FEI's transportation portfolio has been designed so that portions of capacity on third-party pipelines are up for renewal each year. This would allow FEI to de-contract most of its transportation capacity over a five-year period if it

encounters a future with significantly lower demand than expected in the Reference Case.

3. Storage Portfolio – FEI's approach to storage contracts is similar to the transportation portfolio; however, the contract terms may not necessarily expire on an annual basis but on a two or three-year period. Storage contracts are harder to manage because there are no renewal rights embedded in the contract terms so FEI must balance term length versus the risk of losing access to storage supply. In any case, if the load duration curve changes over time such that less storage supply is needed, FEI will still have the ability to determine, as a long term solution, an approach to de-contracting storage resources.

As such, the severity of the risk to FEI customers (in terms of access to sufficient and cost effective gas supply) of demand outperforming Reference Case expectations is higher than the severity of demand underperforming in relation to Reference Case expectations. This is due to the limited transportation and storage resources currently available in the region, and FEI must often compete with other regional utilities, such as those in Washington and Oregon, for these resources. Moreover, any potential infrastructure development could face significant delays, as discussed in Section 5.2. Therefore, if demand greatly increases compared to the Reference Case, caused by a large industrial project or demand from NGT, there may be a mismatch in available new infrastructure to serve that demand.[143] It is for this reason that FEI must continue to be proactive in securing reliable and diversified gas supply cost effectively over the long term. In order to meet these objectives, FEI continues to use the following broad strategies to secure future resources:

- FEI continues to actively participate in pipeline infrastructure developments, tolling proceedings and other initiatives to help ensure that the market hubs at which FEI contracts for gas supply continue to improve their market liquidity. This will help ensure that FEI's gas supply remains cost effective.
- FEI continues to establish key relationships with major producers that plan to develop gas supply in NEBC, including the Montney and other producing regions, over the long term. Efforts include seeking long term supply arrangements with producers who are evaluating or actively involved in developing their production sources in order to commit them to supply the Station 2 marketplace; and
- FEI continues to evaluate opportunities within its own operating region to improve infrastructure that will provide greater access to regional markets, leading to better diversity and reliability within the gas portfolio over the long term. These potential infrastructure developments are discussed at a high level in Appendix A.

[143] FEI's long term planning strategy will not be impacted by any large scale LNG projects that, by virtue of their natural gas demand, will require new pipeline infrastructure before they can begin service. The LNG projects that could impact FEI are the smaller scale projects that may have already contracted firm transportation on existing pipelines.

In addition to these strategies, FEI has also started to contract for some resources in excess of what Core customers are forecast to require in the short term. This approach is reasonable because the costs and ability to manage contract renewals within the portfolio of resources help to reduce the risk to Core customers. The alternative is to attempt to contract for additional resources in the future when they are forecast to be needed. However, in the future regional market factors may make it more difficult or even impossible to contract for critical additional resources on a firm basis. If, during this period, FEI's Core load requirements decline year-over-year and/or market developments proceed at a pace that do not result in any incremental demand, FEI's contract portfolio offers the flexibility to either allow contracts to roll off or decrease contracted amounts when they are up for renewal.

5.5 *PRICE RISK MANAGEMENT*

FEI operates in a marketplace characterized by volatile market prices and competing sources of energy for customers. Ensuring that natural gas rates remain competitive with other energy sources, maintaining affordable and reasonable rates for customers and reducing market price volatility are fundamental to retaining existing load, adding economic new load, and providing rate stability for customers. FEI has developed diversified procurement strategies and utilized PRMPs to manage commodity price risk and facilitate competitive and affordable natural gas rates. While the cost of natural gas relative to other energy sources can be a factor that is considered by energy users, FEI recognizes that other factors are also important, such as the impact of public policy and level of GHG emissions.

5.5.1 Price Risk Management Vision, Guiding Principles and Objectives

In the Commission's decision regarding the 2014 LTRP FEI was directed to include in the next long term resource plan a description of its long term vision for price risk management and provide broad principles, which can be used to inform future price risk management plans. FEI's long term vision for price risk management is to effectively reduce the impacts of market price volatility on commodity rates for FEI's customers. This vision is consistent with the 20-year vision of this 2017 LTGRP. As discussed in Section 8, FEI's 20-year vision is to be BC's trusted energy provider for safe, reliable and cost effective natural gas delivery services to its customers and to be a healthy, growing contributor to BC's economy and to the well-being of BC's communities. By effectively managing the impacts of market price risks, FEI enables customers and communities to consider natural gas as a competitive and affordable source of energy. For example, while natural gas market price volatility, causing fluctuations in natural gas commodity rates and bills, may not prompt natural gas customers to switch to another source of energy for home heating immediately or in the near term, it may cause them to consider switching fuel sources when it comes time to upgrade or retrofit their heating appliances. This may unnecessarily increase costs for customers over the long run. Effective price risk management can help mitigate such market price volatility.

FEI's guiding principles for its long term price risk management include the following:

- Reduction of market price risk: adverse market price movements and their subsequent impacts to customers through commodity rates should be reduced;
- Capture market opportunities: where possible, FEI should capture low-priced market opportunities in the interests of keeping rates low for customers; and
- Cost effective: price risk management tools and strategies should be cost effective so as to not significantly increase costs for customers.

FEI's price risk management objectives include mitigating market price volatility to support rate stability and capturing favourable prices to provide customers with more affordable rates. These objectives should be met in a cost effective manner in order to provide value for customers. FEI considers these objectives applicable for the medium (up to 5 years) and long term (beyond 5 years). As discussed in Section 5.3.2, FEI's supply contracts, whether for the upcoming gas contracting year or longer terms, are based on market index prices, which means that the purchase cost for this supply is unknown until gas delivery occurs. As there is uncertainty in terms of gas market supply, demand and pricing in the future, FEI believes it prudent to cost effectively reduce some of this price risk for customers. FEI's contracting strategies include securing commodity supply, transportation and storage contracts out several years and beyond. Nevertheless, the cost of the natural gas commodity supply fluctuates with market prices and can cause volatility in commodity rates for customers.

Although natural gas prices are currently low relative to price levels before the shale gas era (as discussed in Section 2), they continue to remain volatile and may increase in the future as demand for natural gas helps to balance the over-supply situation. The focus of FEI's price risk management in the past has been primarily on medium term planning; however, FEI believes the current market price environment provides opportunities for longer term strategies in the interests of meeting the objectives. The objectives for the medium and longer term are the same, but the tools for managing price risk management are different. For example, the use of gas storage helps to manage gas price volatility for the next winter period but does not mitigate potential price volatility five years from now. Longer term instruments or tools could include fixed price purchases or making a capital investment in natural gas supply from a producer (such as in a Volumetric Production Payment (VPP) arrangement). Not only do these provide longer term cost certainty and help provide stability in rates, but they also ensure security of supply for customers. FEI's current 2017 PRMP includes requests for approval relating to five-year fixed price hedges but does not seek approval for longer term fixed price purchases or investment in reserves. FEI plans to continue to investigate longer term strategies such as VPPs and, if warranted, will bring forward any requests to the Commission for approval in the future.

In this current low market price environment, FEI's hedging strategy has been an opportunistic one, capturing low market prices based on predefined hedging price targets founded on consideration of gas producers' break-even costs. It has also included capturing the currently favourable discount, or basis, between Station 2 and AECO/NIT prices, through fixed-price purchases, per the ACP to lower costs for customers. However, if, for example, market conditions were to change such that market gas prices were higher and more volatile, FEI would consider adjusting its hedging tools and strategy to a more defensive approach, potentially using call options or costless collars to mitigate upside price risk while still providing the benefit of achieving lower costs if market prices were to fall.

It is essential that FEI periodically review its price risk management tools and strategies to determine if they are effectively meeting the objectives. Currently, FEI prepares and submits a Price Risk Management Annual Report to the Commission, which summarizes the performance and effectiveness of price risk management plans and includes any recommendations for adjusting or refining strategies. FEI also hosts workshops on a periodic basis, for stakeholders and Commission staff, to discuss the price risk management initiative performance. These workshops assist FEI in gaining feedback in order to make recommendations going forward. While the goal of FEI's price risk management is not to "beat the market", it must be cost effective over time to provide value for customers. FEI considers the development of its price risk management an iterative process, which evolves over time, depending on market conditions and customers' preferences.

More discussion of FEI's price risk management tools and strategies is provided in the next section.

5.5.2 Physical Resources

The FEI gas supply portfolio includes diversified commodity, storage and transportation resources to maintain supply reliability and moderate commodity price uncertainty. As outlined in Section 5.1, the LTGRP sets out gas supply contracting principles within the context of a 20-year outlook. In accordance with these long term principles, ACPs (which cover a shorter time horizon than the LTGRP and are submitted separately to the Commission for review) outline FEI's approach to physical resources. While the ACPs include the portfolio of resources for each upcoming gas year, they also include resources and contracts that extend for ten years and longer. This is because the natural gas marketplace is competitive and many resources cannot be acquired, or contracted for, just prior to each gas contract year but instead must be planned for and arranged ahead of time.

Volatility in natural gas prices is partially managed by maintaining access to liquid trading hubs, utilizing a variety of storage and transportation resources, and using different pricing structures and contract terms. FEI considers access to appropriate natural gas infrastructure and minimizing reliance on any one price point a critical element of price risk management. FEI diversifies the gas supply portfolio to manage price risk, including taking into consideration the following measures:

- Diversifying gas pricing by purchasing at various market hubs, including Station 2, AECO/NIT, and Kingsgate;
- Purchasing physical supply at daily and monthly prices;

- Procuring seasonal and market area storage capacity and deliverability from third parties. Storage provides a natural physical winter hedge by locking in the value between summer and winter gas prices for gas that will be used during the heating season. Storage also increases security of supply and reliability by significantly reducing the risk of gas well or plant upsets and by providing greater operational flexibility (day-to-day and intra-day nominations) for load balancing to meet unexpected changes in supply or demand;
- Contracting for base load supply based on the average daily load over the contract year. In the summer, any base load supply that is not needed to meet load is injected into storage so that it will be available to help meet higher demand in the winter months;
- Contracting for long term supply contracts, up to ten years in length, with BC gas producers and other counterparties to support supply security at Station 2;
- Contracting for term purchases outside the gas year (up to three years out) if the Station 2 monthly discount to AECO/NIT is wider than a target level laid out in the ACP. This allows FEI to layer in term supply, by reducing the buying exposure at Station 2 during a given contract year;
- Diversifying storage resources with different facilities and staggered contract expiry dates. Storage contract terms and expiry dates are staggered to provide optionality for portfolio shaping, reduce negotiation failure risks, and alleviate the need to contract for large volumes of storage capacity, particularly during periods of high storage prices.
- Contracting for transportation capacity with staggered expiry dates. FEI has pipeline contracts with terms ranging between one to twenty years, however, the majority of its contracts are negotiated for terms of five years or less. Staggering expiry dates reduces the risk of having to re-contract for all or most of the required transportation capacity at once, and provides the flexibility to adjust capacity-based changes to supply and storage resources. With limited exceptions, transportation agreements currently have full or limited renewal rights upon notification as specified under the respective contracts;
- Contracting for transportation capacity to access different market hubs. FEI has firm transportation contracts with Westcoast, TransCanada (in BC and Alberta), NWP and SCP to diversify sourcing of supply from numerous supply hubs; and
- The Tilbury LNG and Mt. Hayes LNG facilities are utilized to balance the load in cold or extreme weather conditions, or to provide gas supply during emergency conditions. The high level of deliverability from these facilities will greatly assist in managing price volatility at the Huntingdon-Sumas marketplace while providing a secure source of on-system gas supply.

Other potential instruments or tools for managing longer-term market price volatility could include investment in natural gas reserves or long term fixed price contracts. Investment in natural gas reserves would provide even longer-term price protection. This could involve entering into a joint venture arrangement with a natural gas producer, wherein the right to a portion of the gas production is earned by paying a share of the costs to develop the gas plays. Managing the risks associated with investing in reserves would be of paramount importance to FEI. These risks could include those relating to drilling, completing, and operating wells and would differ from typical regulated utility assets. This type of transaction would not provide the same degree of price certainty as a hedging or fixed price purchase strategy but would provide cost-based supply for a longer period. FEI suggests that long term fixed price hedges better suit FEI's risk profile and field of expertise. However, at this point, FEI plans to investigate investing in reserves as a longer term strategy for helping to ensure security of supply and to provide cost stability.

Long term fixed price contracts would involve FEI purchasing physical supply from a natural gas producer at a fixed price for a term of up to ten years. Fixed-price physical purchases provide long term security of supply as well as provide a hedge against market price volatility. The significant decline in forward market AECO/NIT gas prices to levels near gas producer break-even costs (as discussed in Section 2) suggests that the value of this type of instrument may not be much higher than one involving investing in reserves, but without the production risk and additional work and time relating to due diligence. In addition, long term fixed price purchases up to ten years out provide more flexibility in terms of adjusting to FEI's future customer load requirements than investing in gas reserves, which is a commitment of up to thirty years. While FEI has traditionally experienced increasing gas load requirements in the past, there is no guarantee that this will continue indefinitely into the future (as discussed in Sections 3 and 6).

5.5.3 Locational Basis Risk

Locational basis risk results when the pricing at one market hub disconnects from that of other regional market hubs. The Huntingdon-Sumas market hub, with its Sumas pricing, is considered to have relatively high locational basis risk, due to regional market forces that can severely disconnect prices from other market hub prices, such as AECO/NIT and Station 2, and cause high volatility in prices. Such periods of pricing disconnects occur when increased demand in the PNW region exceeds the delivery capacity at Huntingdon and causes Sumas prices to increase significantly above other prices.

FEI is somewhat limited in its ability to reduce this basis risk due to the limited regional resources available to the PNW utilities. Key ways to manage this locational basis risk include contracting for market area storage, relying on on-system LNG resources, and reducing Huntingdon supply in the portfolio when possible. The use of storage and on-system LNG resources also provides the Company with much needed intraday flexibility, overnight withdrawals, and security of supply in the portfolio. The Mt. Hayes LNG facility has also recently reduced the need for peaking supply at Huntingdon during extreme weather, thereby reducing portfolio exposure to Huntingdon-Sumas prices.

This Huntingdon-Sumas price disconnection risk is not expected to diminish in the short term given the current transportation infrastructure, winter demand in the region, and the potential for greater power generation and industrial demand. New infrastructure in the region that brings more gas supply to the Huntingdon and PNW I-5 demand corridor[144] could help reduce some of this basis risk over the long term. FEI will continue to monitor developments in this regard, and respond appropriately, to provide the Company's customers with continued protection.

5.5.4 Financial Hedging

Financial hedging strategies are another way of managing price volatility. Hedging involves the use of financial derivative instruments wherein the market index-based price for gas supply purchases is converted to a fixed price or capped price (i.e. financial swap) via a transaction with a counterparty, such as a bank. The benefits of this approach include greater gas supply price and cost certainty and protection against rising market prices. It is important to note that hedging directly impacts the cost of gas supply for the medium or longer term while other rate smoothing mechanisms, such as the use of deferral accounts, do not directly affect gas costs but rather defer costs or surpluses for refunding over the shorter term.

Under its current 2017 PRMP (submitted June 13, 2017 and pending approval by the Commission), FEI's medium-term hedging strategy will enable FEI to capture low AECO/NIT market prices near gas producer break-even cost levels. This is an opportunistic strategy wherein hedges are only implemented if certain pre-defined market price targets are reached. However, the current low market gas price environment further out in time creates an opportunity for longer-term hedges, providing greater cost certainty and stability in the portfolio. Therefore, FEI's 2017 PRMP also includes the request to implement hedges with terms of up to five years, given that FEI's price risk management objectives are long term in nature. These hedges can include financial swaps or fixed price physical purchases – the overall effect in terms of mitigating price volatility is the same. However, fixed price physical purchases do offer the additional benefit of security of supply.

5.6 *CONCLUSION*

Effective gas portfolio planning and price risk management on both a short and long term basis enables FEI to secure cost effective, reliable gas supply and reduce rate volatility for customers. Given the significant marketplace developments in terms of North American gas supply, demand and pricing as well as regional infrastructure changes, FEI must continue to monitor changes and be proactive in assessing challenges and identifying opportunities.

Regional market developments (discussed in Appendix A) such as infrastructure initiatives to facilitate the movement of natural gas from BC to the Alberta market and west to supply LNG export projects may change traditional regional gas flows, along with supply and demand balances and pricing. In addition, industrial developments such as methanol and LNG projects in the Lower Mainland and the US PNW could also have an impact on gas pricing and flow factors from approximately 2020 and beyond. By monitoring these developments and responding to changes through portfolio planning, FEI can help ensure continued access to cost

[144] The I–5 demand corridor includes BC's Lower Mainland and Vancouver Island, Western Washington and Western Oregon.

effective supply for Core customers. FEI will continue to examine these regional developments and participate in regional project approval processes wherever it sees a need to act to protect customers' interests in maintaining secure, cost effective supply sources and infrastructure over the long term. This includes continuing to examine potential opportunities on FEI's own transmission and storage systems.

As discussed in Section 2, natural gas prices are near their lowest levels in a decade. However, market price volatility continues to be present and recent price forecasts suggest that future market prices will likely be higher as supply and demand come into a more sustainable balance. Effective price risk management can help reduce this market price volatility and is fundamental to retaining existing load and adding new load. FEI will continue to explore a range of price risk management activities to mitigate the impact of commodity price increases and volatility on customers' rates in both the near and long term. FEI will also continue to make separate applications to the Commission for approval of the price risk management activities that the Company believes are in the best interests of its customers.

6. SYSTEM RESOURCE NEEDS AND ALTERNATIVES

6.1 *INTRODUCTION*

A key aspect of ensuring safe, reliable and secure supply of natural gas to customers is identifying when and where any capacity constraints may appear and planning for the facilities, or system resources, that FEI needs to construct over the planning horizon to enable unrestrained delivery of natural gas to consumers. This section discusses FEI's examination of the Utility's natural gas delivery infrastructure and identifies any system resource needs in consideration of regional peak capacity to ensure that FEI's systems continue to serve the energy needs of customers across the province. This section is intended to address the requirements in Sections 44.1(2)(d) and (f) of the UCA.

Growth in peak demand is among the most significant challenges for FEI's long term planning. System expansion needs are driven by annual increases in forecast peak demand. A low gas commodity price environment and the use of cleaner natural gas over traditional fossil fuels are stimulating increased interest from the industrial sector in using natural gas for new or expanded applications, although this interest can change quickly as energy prices change. Growth in natural gas demand as a transportation fuel is also increasing as a result of these market conditions. At the same time, FEI's system sustainment planning process identifies important near-term and longer term system renewal requirements; most recently projects of this nature are underway in the Lower Mainland area of FEI's system. FEI takes a broad outlook that considers long term system capacity and sustainment plans, potential new, large increases in industrial load, and growing CNG and LNG demand, enabling an integrated approach to determining the most effective system improvements.

Section 6.2 discusses FEI's approach to system capacity planning, describing the method for determining peak demand forecasts and infrastructure project alternatives to address forecasted capacity constraints. Peak demand forecasts for system capacity (infrastructure) planning include considerations of demand at the local and regional level. This is a bottom up and more granular approach than the approach used when considering system wide peak demand use in gas supply planning (see Section 5). Traditionally, FEI has built regional peak demand forecasts based on the current peak hour use per customer (UPC_{peak}) that is held constant over the planning horizon. Recently, FEI has worked with a consultant, Posterity, in studying a potential means of applying knowledge gained from the end-use method of forecasting annual demand to forecast how UPC_{peak} might vary for each end-use future scenario presented in Section 3.4.4.

Section 6.3 discusses the capacity of FEI's natural gas transmission infrastructure to meet current and forecast peak demand for each of FEI's major transmission service regions – Vancouver Island, Coastal and Interior. Forecasts resulting from FEI's Traditional Peak Method forecast as well as the unique regional peak demand forecasts for each end-use scenario are presented and discussed. Consideration is also given to potential future new LNG and CNG and industrial loads that are not captured in the Core and Firm Transportation demand forecast.

Forecast capacity constraints and significant projects impacting FEI's transmission laterals and Distribution System networks are described in Sections 6.3.4 and 6.3.5, respectively.

Section 6.4 provides a description of other major system projects, not driven by system capacity considerations that FEI currently anticipates may result in CPCN applications in the next several years.

6.2 SYSTEM CAPACITY PLANNING

Ensuring adequate capacity within the transmission and distribution systems to meet existing and forecast load is critical to ensuring the safety and reliability of natural gas delivery. This section outlines the natural gas system infrastructure and the system capacity needs to continue delivering energy safely, reliably and at the lowest reasonable cost to the Company's customers. After determining forecast growth in natural gas demand and the expected impact of demand-side measures across FEI's service areas, FEI's system capacity planners examine the capacity of gas transmission systems to meet the anticipated demand. When forecast demand exceeds available capacity, a gas system expansion is required. Different system expansion alternatives are then identified in order to examine how to most effectively address specific capacity constraints.

Supply-side (gas supply) system resources must be designed to meet peak demand requirements of the Core and any applicable firm component for Interruptible customers on the system. Gas supply considers a system wide peak in assessing supply side resources. On a system wide basis an increase in peak demand in one location can be offset by a decrease in demand in other regions and still meet the supply requirements of the system as a whole. As system demand changes year over year supply resources can generally be adjusted in a timely and responsive manner to meet the peak requirement (see Section 5).

Infrastructure projects on transmission systems to address system capacity constraints are often large and take many years to plan and execute. As a result, securing infrastructure resources is not as responsive as securing gas supply resources. In addition, the location of customer demand on the system is a significant factor in determining the ability (capacity) of the system to deliver. Increasing peak demand in one region cannot necessarily be offset by a system expansion or decrease in peak demand in another region. To address the specific local and regional requirements, regional peak demand forecasts are built from the bottom up, assembling the peak demand from the recent consumption and regional weather history of each customer within the system. For commercial or industrial loads that are not temperature dependent, their contract firm or maximum consumption values are used. Planning for transmission system expansion is based on this regional peak forecast of demand for Core customers but also includes Firm Transportation not included in gas supply resource planning.

6.2.1 On-System Infrastructure Planning

Gas system infrastructure planning must ensure that gas system assets are of sufficient capacity (in terms of size, compression requirements and volume, for example) to meet the demand on a given system. To ensure constraints are identified and considered with sufficient lead time to plan and construct the necessary infrastructure, peak demand forecasts over a 20-year planning horizon are used.

In general, system demand growth is determined by region and applied to hydraulic models which determine resulting pressures at different locations for existing pipe, compression and LNG facilities. Eventually, demand exceeds capacity and a system expansion is required. In addition to load growth, other factors can also affect system capacity. For example, increased urban density close to existing pipeline assets can lead to a class location designation change and may result in a subsequent reduction in allowable operating pressure for that pipeline. Class location designations are defined in CSA standard Z662-15 and used as a protective measure in pipeline design to address population density and other criteria in the vicinity of a pipeline. A reduction in operating pressure will lead to a decrease in available pipeline capacity. These additional factors must be taken into account and are briefly discussed in this section.

6.2.1.1 System Expansion Planning Considerations

Pipeline capacity is determined by the quantity of gas that can be transported from a supply point at a given supply pressure to delivery points at or above required minimum delivery pressures. The key objective of any new capacity expansion options is to maintain, under peak conditions, pressures at all delivery points sufficient for the system to deliver to the consumer the contracted quantities of natural gas. Physically, pipeline capacity depends on the diameter and length of the pipeline, internal roughness of the pipeline, maximum operating pressure (MOP), required minimum delivery pressures and the distribution of customer demand along the system. Pipeline pressures are constrained by the MOP. The MOP is established in accordance with provincial regulations and good engineering practice in consideration of original construction specifications. To overcome friction and allow gas to flow through the pipeline, a pressure differential between the supply and delivery points is required. Compressors are used to increase this pressure differential and move large volumes of natural gas at high pressures through the transmission pipelines to major delivery points. The end pressures, which vary inversely with flow, are then controlled by pressure-regulating stations before natural gas enters the intermediate or distribution pressure systems for delivery to customers.

There are three resource options to evaluate when planning system expansions: pipelines, compression and storage. To solve capacity constraints, each alternative is analysed with respect to overall cost, difficulty of implementation, operational flexibility, implementation time, and other factors within the overall philosophy of system sustainment and reliability. Often, some combination of the three resource options leads to an optimal solution:

Pipelines

To increase throughput capacity, an existing pipeline can be replaced by a larger diameter pipeline (increasing the flow area and decreasing the gas velocity) or it can be "looped" with a parallel pipeline.

Compression

Adding compression helps to increase the average pipeline pressure, thereby providing a higher supply (or driving) pressure to move the gas. This higher pressure also increases the gas density leading to a reduction in gas pipeline velocity and correspondingly lower rate of pressure drop along the pipeline. Compressors can be added to existing compressor sites to provide additional station throughput capacity or new compressors can be added at intermediate locations on the pipeline.

On-System Storage

Storage facilities located within a service region are considered "on-system" supply-side resources. FEI considers LNG storage to be an on-system storage facility. During low demand periods, natural gas is liquefied and pumped into the storage facility. Conversely, during high demand periods, stored gas is vaporized and compressed back into the pipeline system in order to maintain pipeline operating pressure and increase system capacity without having to install throughput capacity from pipelines or compressors. Since FEI can call upon these resources when necessary, system security and reliability increases through the use of these on-system storage facilities. Another benefit of FEI's LNG facilities is the ability to provide customers with the potential to buy LNG for fuel use.

6.2.1.2 System Capacity Planning Considerations

Options to improve the capacity of a system to deliver to consumers are identified through hydraulic analysis using computer models of the pipeline systems. Computer simulations allow various "what if" scenarios to be evaluated and compared against one another. In determining the need for transmission system expansions, FEI considers the following:

- Optimizing resource capacity additions to meet demand requirements over a 20-year planning period.
- Correlating actual billed consumption information against temperature to determine the expected demand under design temperature conditions.
- Planning capacity additions to meet Core and Firm Transportation peak demand. Interruptible demand is not considered when identifying system improvements to sustain this peak demand. System improvements identified for peak demand provide opportunities for interruptible customers during off peak conditions.
- Designing transmission systems to meet peak demand. Core demand varies on an hourly basis and typically exhibits a morning peaking period between six and ten a.m.

and an evening period between five and nine p.m. The peak hour demand for these customers can be more than 40 percent above the hourly average (daily demand/24 hours). Transmission systems are designed to meet this peak demand condition.

- The amount of line pack within a transmission system determines whether it should be designed to meet peak day or peak hour conditions. A pipeline system with a large relative line pack can temporarily support increased demand out of the system that exceeds the supply into the system. As demand exceeds supply the amount of gas "packed" in the pipeline (i.e. line pack) is reduced and pressure in the pipeline is drawn down , until such time that the demand drops below the supply into the system, at which point pressure (and line pack) can recover. Pipeline length and operating pressure determine the amount of line pack available in the system. Typically, longer, larger diameter systems operating at higher pressures with high line pack are designed to peak day conditions; conversely, systems with lower amounts of line pack (due to factors such as lower pressures and smaller volumes) are designed to meet peak hour loads.
- Long lead times are needed for large infrastructure projects. This is due to regulatory reviews, public consultation, conceptual design, and detailed engineering, procurement, construction and commissioning schedules.

6.2.1.3 Regional Peak Demand Forecasting

Traditional Peak Method

FEI has long established methods for creating regional peak demand forecasts that have worked well in identifying system constraints and developing projects to address constraints in a timely fashion. FEI's Traditional Peak Method forecast is built from a "load gather" process that determines unique daily and hourly UPC_{peak} values for each customer. Values for most customers are based on regression analysis of average consumption against local temperature using the most recent 24 months of consumption information extracted from monthly meter read data. Measured values are then extrapolated to the regional design temperature where the customer is located, a temperature representing a 1 in 20 year extreme value determined for each region. For customers where hourly consumption data is available (typically large commercial and industrial customers) UPC_{peak} is determined directly from that data. These unique hourly UPC_{peak} values for each customer are then grouped by rate and region to determine average hourly UPC_{peak} for each region and rate schedule that can then be applied to an account forecast to determine a peak demand forecast. A unique UPC_{peak} for residential, small commercial and large commercial rate schedules in 66 separate regions across the province is developed in FEI's Traditional Peak Method. For large industrial demand the Traditional Peak Method forecast has not applied any forecasted growth or decline in the number of these customers. This is because the ability to forecast both the future load and location of these customers is subject to a great deal of speculation. UPC_{peak} for large industrial customers varies widely and can significantly impact local system capacity. Speculating on infrastructure requirements for loads of unknown magnitude and location has little value in long term planning of facilities whose design can be greatly influenced by their location within the transmission or distribution system. However, to explore impacts to peak demand as a result of potential changes in industrial account forecasts, FEI has produced both high and low account forecasts that show increasing or decreasing account numbers, respectively. These forecasts have been applied to the regional peak demand forecasts using the average peak demand for existing industrial customers in that region as an estimate of the peak demand for any new account additions or subtractions. As the location of new industrial demand is not specifically known, this increase or decrease in industrial peak demand was applied proportionally across the relevant transmission system.

UPC_{peak} values used in the Traditional Peak Method forecast are determined based on current measured consumption for customers. When applied to the 20-year account forecast to determine the peak demand forecast, these values are assumed to remain unchanged over the planning horizon. As such, there is no explicit allowance for evolving customer utilization in this approach. The estimates of UPC_{peak} are, however, refreshed annually so that assessments of future capacity constraints are always determined against current customer consumption patterns and end uses that reflect the presently measured impacts of energy economics, housing renewal, and DSM programs.[145]

The Traditional Peak Method forecast currently remains FEI's base forecast for determining infrastructure requirements and timing for addressing capacity constraints. For system capacity contingency planning in the 2017 LTGRP, FEI creates High and Low Traditional Peak Method forecast scenarios by applying high and low variations of its LTGRP customer forecast to the Traditional Peak Method's UPC_{peak} values. The method for developing the High and Low customer forecast perturbations is comparable to the method used for the annual demand forecast in Section 3.

Deriving Regional Peak Demand Forecasts from End-Use Scenarios

In its decision regarding the 2014 LTRP the BCUC asked FEI to make stronger linkages between the peak demand and the annual demand forecasts, to understand how "[…] new insights on evolving customer consumption patterns might affect time-of-day demand as well as annual demand […] and how changes in base load annual demand under different scenarios translate into changes in base load peak demand under the same scenario assumptions."

FEI has since commissioned Posterity, a consultant, to develop an exploratory process linking peak demand forecasts to the end-use scenarios used in the annual demand forecasts. At this point, the exercise is theoretical in nature and unsupported by direct measurement. As such, FEI's infrastructure planning continues to rely on the Traditional Peak Method. The exploratory end-use method does, however, provide a means of assessing a range of peak demand forecast possibilities and the impact on system capacity upgrade project scope and timing.

Posterity's approach relies on applying a series of appliance load shape profiles, developed from industry studies on appliance use, to sequentially break down annual consumption into

[145] In the Section 6 analyses, the term DSM refers to FEI's forecast C&EM activity from Section 4.2 only.

peak monthly consumption, monthly to peak daily consumption and finally daily to peak hourly consumption. Using the base year LTGRP inputs developed for the annual demand forecast Posterity then derived a base year hourly UPC_{peak} for each rate schedule and region. The results were corrected to peak design temperatures for each region. Posterity then determined calibration factors to match the derived UPC_{peak} values for the base year to FEI's current values of UPC_{peak} (determined from FEI's established load gather process and used in FEI's Traditional Peak Method regional peak demand forecasts). The process, using the derived calibration factors, can then be applied similarly to any year in any scenario to derive UPC_{peak} forecasts and subsequently peak demand forecasts in a format that can be easily applied to FEI's established capacity modelling methods.

The results are interesting in providing a means for relating annual demand more directly to peak demand. Future effects of DSM programs and the impact on peak demand and infrastructure requirements can be reviewed using this approach. This exercise also provides some indication of how various end-use scenarios might influence the peak hour factor (PHF), the ratio of peak hour consumption to peak day consumption. The results of this exploratory, end-use approach are represented below in the sections discussing each regional transmission system.

Since the exploratory end-use method is not based on metered FEI customer data, the Traditional Peak Method forecast which intrinsically reflects the current effects of DSM programs remains FEI's base forecast for determining infrastructure requirements and timing for addressing capacity constraints. By relying on the Traditional Peak Method, Section 6.3 thus addresses the requirements of section 44.1(2)(f) of the UCA. FEI will continue monitoring potential metering solutions that may allow FEI to field-validate the projections of the exploratory end-use peak demand forecast method and to better serve its customers.

6.3 *REGIONAL TRANSMISSION SYSTEM CAPACITY PLANS*

For capacity planning purposes, FEI is split into three main transmission systems and a number of smaller transmission laterals. The three main transmission systems are:

- Vancouver Island Transmission System (VITS or VI Transmission System): encompassing customers served on Vancouver Island, the Sunshine Coast, Squamish and Whistler;
- Coastal Transmission System (CTS): encompassing the Fraser Valley and surrounding cities, Metro Vancouver and North Vancouver; and
- Interior Transmission System (ITS): encompassing Southern Interior communities in the Kootenays, the Okanagan Valley and the South Thompson Valley.

Each of the three main transmission systems is discussed in further detail below. For each system, FEI will discuss:

- Existing major system infrastructure;
- Demand and capacity balance, which determines approximately when demand in the region will reach the ability of the system to deliver natural gas during peak conditions, thus identifying when system constraints will occur;
- Peak demand forecast sensitivity using the range of peak demand forecasts;
- System expansion alternatives. These are the infrastructure options that exist for solving identified system constraints. The options for constraints that occur in the near term are presented in more detail than those that are further out in the planning period;
- The impact of new demand for natural gas as a transportation fuel (CNG and LNG) on the expected timing of system constraints and consideration of alternative solutions; and
- The impact of potential large, new industrial loads on the expected timing of system constraints and consideration of alternative solutions.

In forecasting peak demand associated with future CNG, for the VITS, CTS and ITS, FEI projected that incremental annual CNG demand of 200 TJ/year would trigger a new fuelling station somewhere in the system. A typical fuelling station designed to deliver up to 200 TJ/year is estimated to exert a peak hour demand of 2,200 standard m^3/hour. These peak demands are based on fast fill stations currently installed or being designed throughout the FEI system. The projected CNG facility demand is then distributed proportionally across the region and is included in each forecast. To illustrate the relative impact of CNG, forecasts with and without the CNG forecast included are shown in most demand forecast graphs in the following sections.

FEI examines these factors to identify the expected timing of system constraints and the action plan needed to develop formal solutions that may require further expenditure applications to the Commission. Year after year, changes in the planning environment and new information may emerge that could impact the timing of the constraints or the alternative solutions being considered. Such changes will be presented in future LTGRPs or in any required applications to the Commission.

6.3.1 Vancouver Island (VI) Transmission System

The Vancouver Island Transmission System serves Vancouver Island, the Sunshine Coast and feeds the communities of Squamish and Whistler. It consists of 626 km of high pressure pipelines including three twinned marine crossings of the Georgia and Malaspina Straits, three compressor stations, and the Mt. Hayes LNG storage facility in Ladysmith. Natural gas for VI customers is delivered from upstream sources on the Westcoast pipeline system to the Huntingdon-Sumas trading point. From Huntingdon, the VI Transmission System demand transits through the CTS to the start of the VI system at Eagle Mountain in Coquitlam. The Mt. Hayes LNG storage facility has improved system reliability and enabled significant operational flexibility of the combined CTS and VITS.

Figure 6-1 shows the layout of the VI Transmission System including the location of the Mt. Hayes LNG storage facility, compressor stations, major industrial customers and locations of distribution networks.

Figure 6-1: Layout of the VI Transmission System

VI Demand and Capacity Balance

The VI Transmission System needs to serve the natural gas capacity requirements for the following customers:

- VI Core residential and small commercial customers located on Vancouver Island and the Sunshine Coast, in Squamish and in Whistler;
- Pulp and paper mills represented by the Vancouver Island Gas Joint Venture (VIGJV);

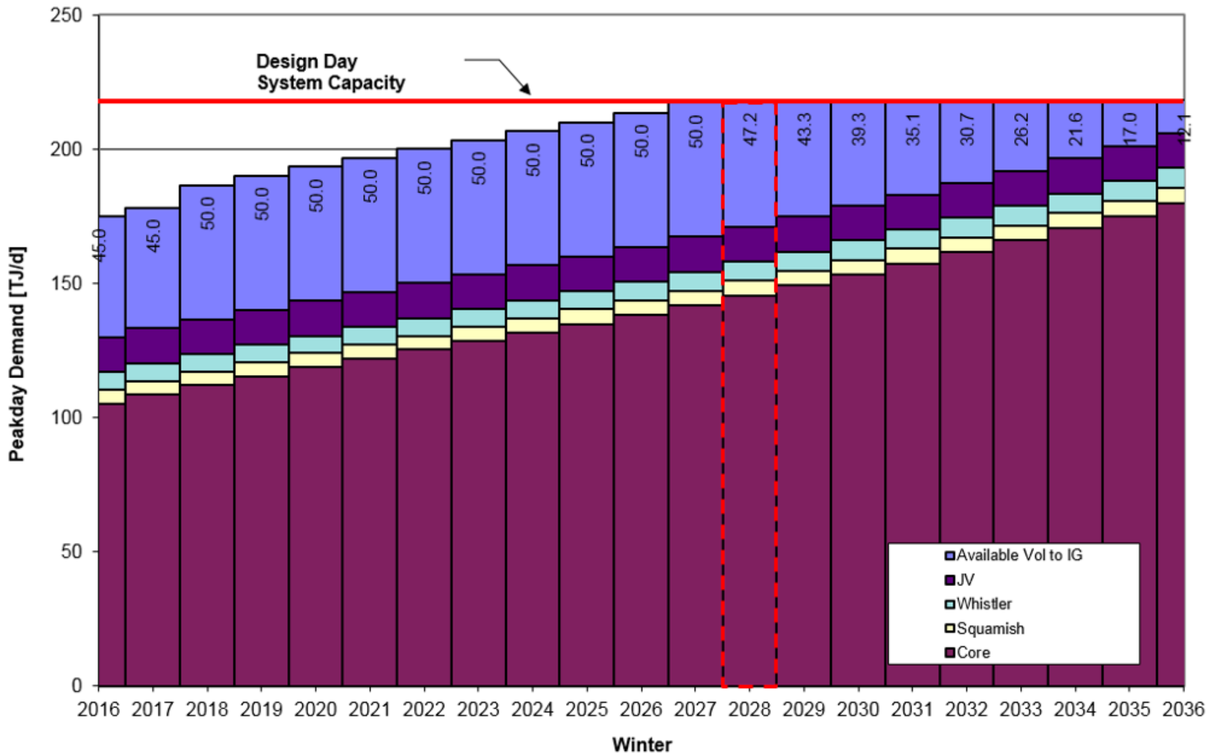
- BC Hydro for its Island Generation (IG) Plant, pursuant to a long term Transportation Service Agreement; and
- Forecasted expectations for demand from customers using natural gas as a transportation fuel.

Peak demand for VI's Core and Firm Transportation customers follows. As of November 2016, the current contract demand requirement for BC Hydro Island Generation is 45 TJ/d. For the 2017-18 winter, BC Hydro has requested and been granted a contract demand of 45 TJ/d. Since this contract demand can be amended for the following year (i.e. for 2018-19) to a maximum value of 50 TJ/d, FEI has analysed transmission requirements for the VI Transmission System based on the BC Hydro Island Generation contract demand increasing to and remaining at 50 TJ/d from 2018 onwards. The Vancouver Island Gas Joint Venture has recently increased its contract demand from 12 to 13 TJ/d starting in the 2015-16 winter season. For demand and capacity modelling, it is assumed that Vancouver Island Gas Joint Venture demand is fixed at 13 TJ/d from 2015 onwards. From the CNG forecast provided in Section 3.4.7.1 it was approximated that 10 percent of the total annual forecast demand would appear in the VI system.

Prior to installation of the Mt. Hayes LNG storage facility, the VITS was fully subscribed and relied upon a right to call back capacity from BC Hydro Island Generation during design weather events in order to serve its Core and Firm Transportation market design day (i.e. peak demand) requirements. Construction of the Mt. Hayes LNG storage facility was completed in 2011 and the facility entered service for the 2011-12 winter season. This on-system storage facility optimizes the existing system infrastructure by providing significant operational flexibility, regional storage resource benefits for FEI's customers, and improved system reliability.

The Mt. Hayes facility has a storage capacity of 1.5 Bcf (approximately 1,614 TJ), a liquefaction capacity of 7.5 million standard cubic feet per day (MMscfd), and a send-out deliverability of 150 MMscfd (161 TJ/d). Traditionally, the capacity of the VITS is represented by allocating one third of the Mt. Hayes sendout capacity to the VITS, with the balance remaining available for the rest of the FEI system. The peak day capacity on the following figures reflects this arrangement. Further capacity constraints on the VITS are not expected until 2028, at which time additional Mt. Hayes send-out capacity above the one third allocation is required. Figure 6-2 shows the peak demand and capacity balance for the VITS with 2015 Traditional Peak Method long range forecast, Core design day demand, and daily transportation requirements for Vancouver Island Gas Joint Venture mills (13 TJ/d, 2015 onwards) and BC Hydro Island Generation (50 TJ/d, 2018 onwards). The CNG demand relative to the Core and Firm Transportation customer peak demand is small in the base forecast and is barely noticeable in the demand plot for the VI Transmission System. This graph shows a capacity constraint on the VI Transmission System by 2028.

Figure 6-2: VI Demand-Capacity Balance with the Mt. Hayes Facility (Traditional Case)

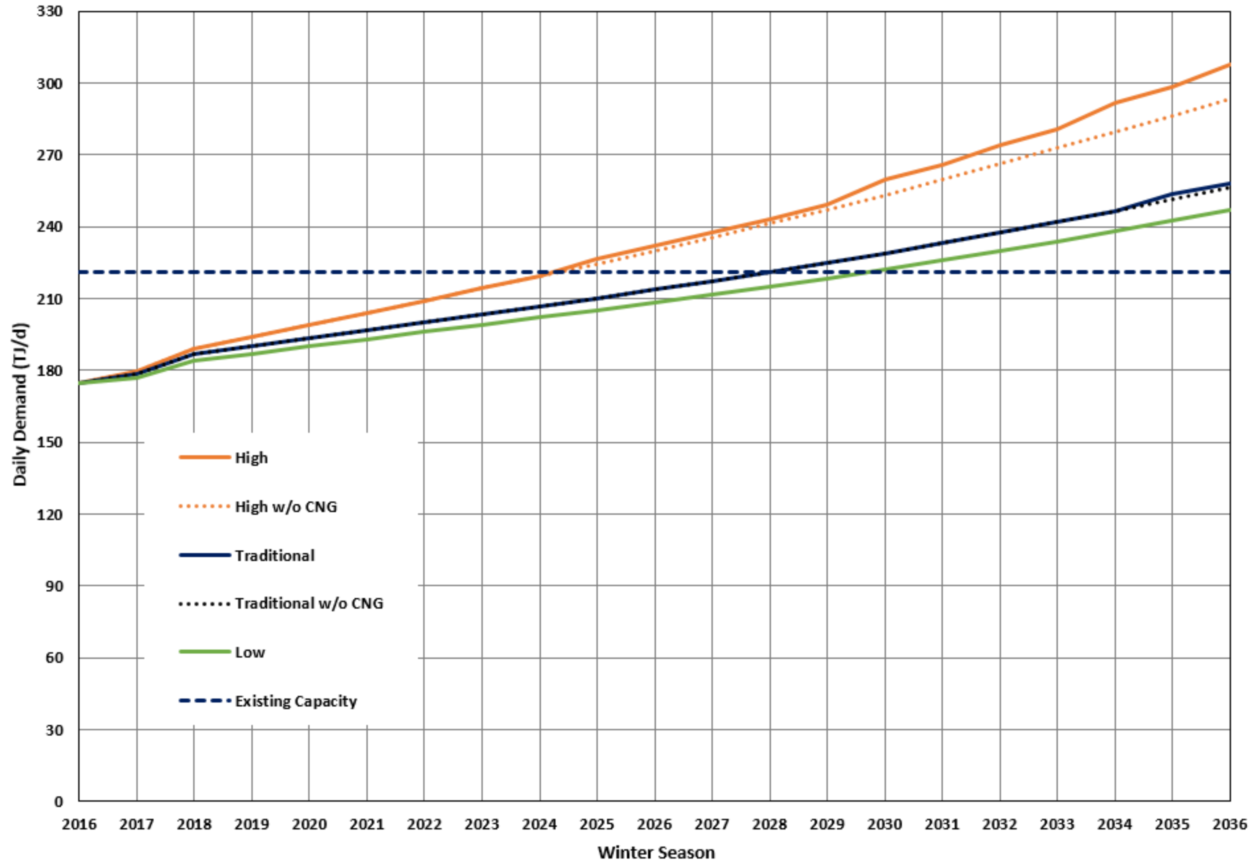


VI Peak Demand Forecast (Traditional with Low and High Forecast Scenarios)

The VI regional peak demand forecast shown in Figure 6-3 below was analysed against Low and High demand scenarios. The Low and High demand scenarios were determined by applying high and low variations of the account forecast to the UPC_{peak} values derived in the Traditional Peak Method.[146] With respect to large industrial account additions, which traditionally have not been forecast because of the widely varied and unique demands of these customer classes, the high and low load forecasts represent an increase and reduction in industrial class customers, respectively. In order to approximate the UPC_{peak} for these customers, an average of existing customer UPCs in the region was used. In addition, the CNG forecast is included in the each forecast. Figure 6-3 shows that the Low and High scenarios move the VI capacity constraint back by two years to 2030, or advance it by three years to 2025. For comparison, the dotted lines show the peak demand forecast after removing the impact of CNG. In the case of the Low forecast the influence of CNG demand is negligible. Note that in Figure 6-3 there is a 5 TJ/d increase in demand in 2018. This represents BC Hydro Island Generation's contractual right to request a firm capacity of 50 TJ for 2018.

[146] The method for developing the Low and High account forecast perturbations is comparable to the method used for the annual demand forecast in Section 3.

Figure 6-3: VI Demand-Capacity Balance Using Traditional, Low and High Peak Demand Scenarios



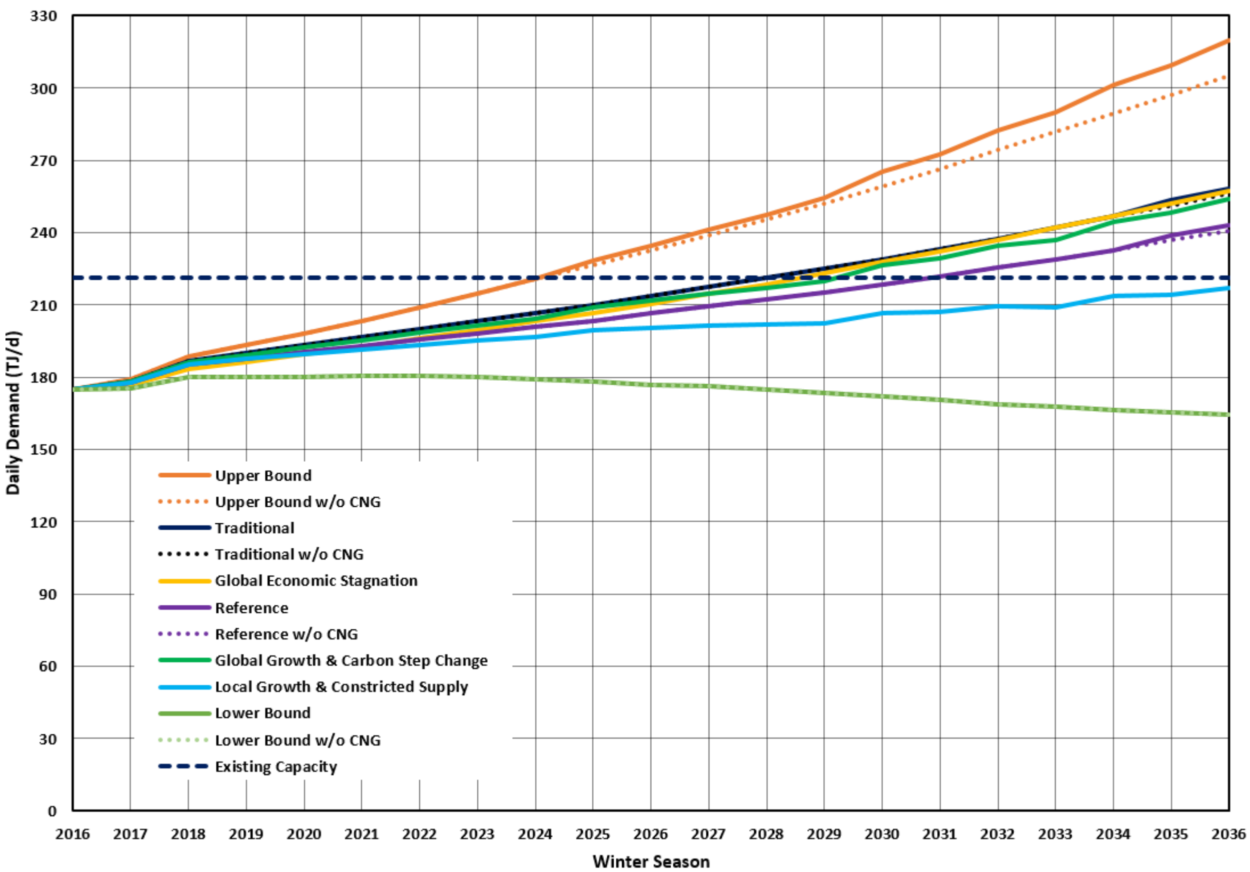
Sensitivity of VI Peak Demand to Alternative CNG and LNG demand forecasts

NGT growth on the VITS is largely in CNG, with growth in LNG demand being addressed through expansion at Tilbury in the Lower Mainland. In 2036 CNG base case peak demand will amount to 2 TJ/d across the system and as high as 14 TJ/d in the high forecast. This forecasted range of peak demand is not sufficient to influence the timing of system expansion requirements in any of the forecasted scenarios.

VI Peak Demand Forecast with End-Use Peak Demand Scenarios

A comparison of the peak demand forecasts using the Traditional Peak Method as well as the end-use scenarios is shown in Figure 6-4 below. The end-use method shows a wide variation in peak demand forecasts showing both increasing and decreasing demand over time. The forecasts are bounded on the upper end by the Upper Bound scenario with high economic growth and low commodity and carbon pricing and on the lower end by the Lower Bound scenario with low economic growth and high commodity and carbon pricing. The Reference Case illustrates the possible impact of declining UPC_{peak} on the “business as usual” forecast scenario and shows lower demand growth than the Traditional Peak Method forecast which assumes no variation over the planning horizon in the average UPC_{peak} values. Figure 6-4 shows that the Reference Case scenario defers the capacity constraint by 3 years to 2031. The Upper Bound scenario advances the timing of the capacity constraint by 3 years to 2025. The Global Growth and Carbon Step Change and Global Economic Stagnation scenarios show increasing peak demand in the planning horizon, very similar to the Traditional Peak Method forecast predicting a capacity constraint by 2029. The Local Growth and Constricted Supply scenario predicts moderate growth within the existing system capacity and the Lower Bound scenario shows a slow decline in peak demand over time with no capacity constraint projected within the planning horizon.

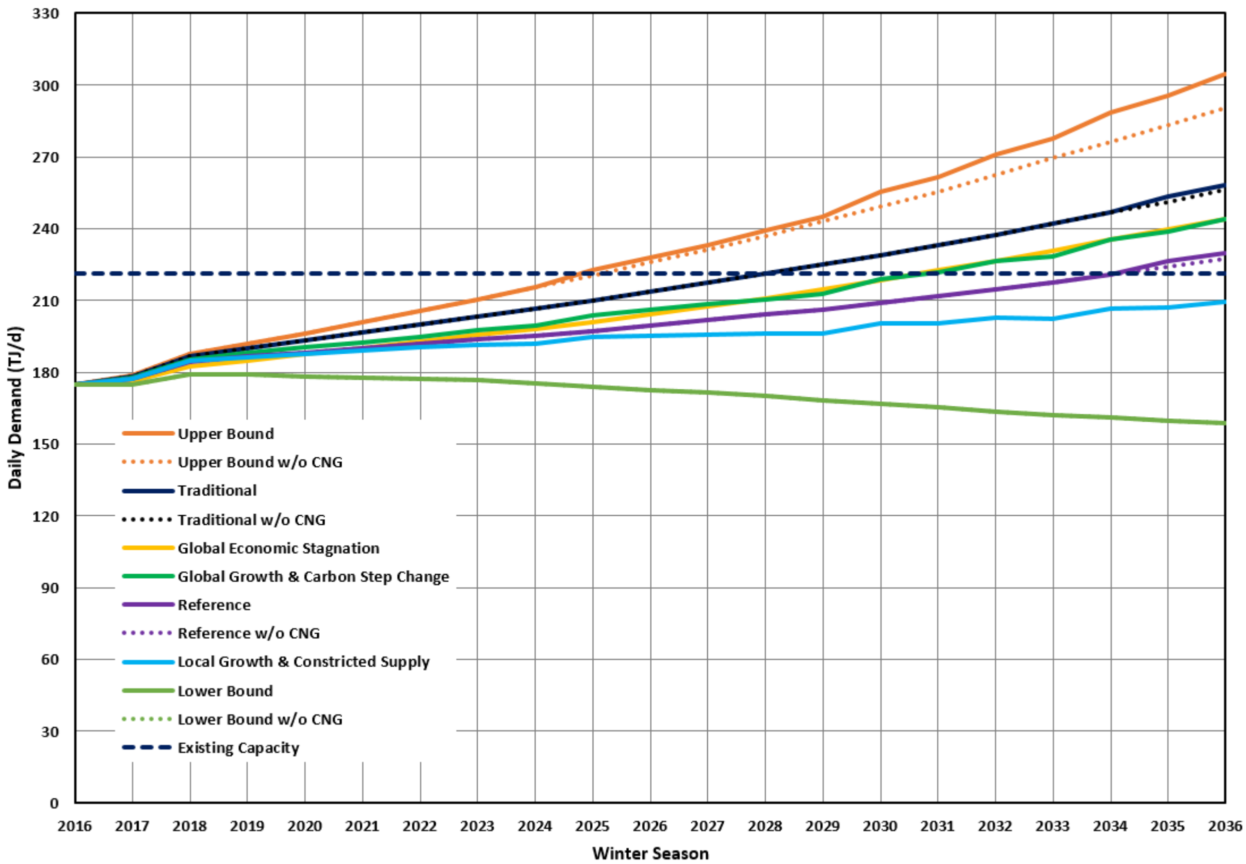
Figure 6-4: VI Demand-Capacity Balance Using Traditional and End-Use Peak Demand Scenarios



VI Peak Demand Forecast with End-Use Peak Demand Scenarios with DSM

A comparison of the peak demand forecasts using the Traditional Peak Method as well as the end-use scenarios with DSM impacts is shown in Figure 6-5 below. The addition of DSM has the impact of moving all the end-use peak demand scenario forecasts downward. The Upper Bound scenario continues to show a capacity constraint in 2025. The Global Growth and Carbon Step Change and Global Economic Stagnation scenarios defer the constraint to 2031. The capacity constraint in the Reference Case forecast is deferred to 2035, compared to 2031 when using the Reference Case forecast without DSM. The Local Growth and Constricted Supply scenario again predicts low but increasing growth within the existing system capacity, and the Lower Bound scenario shows a decline in peak demand over time with no capacity constraint projected within the planning horizon.

Figure 6-5: VI Demand-Capacity Balance Using Traditional and End-Use Peak Demand Scenarios with DSM



VI System Expansion Alternatives

The identified capacity constraint in 2028 occurs six years after expiry of the FEI-BC Hydro Transportation Service Agreement (TSA) for service to BC Hydro's Island Generation facility. If FEI and BC Hydro extend the TSA beyond 2022, based on current Traditional forecast numbers, the VITS would have the following resource options to manage forecast demand for the Core and Firm Transportation customers (including the transportation requirements for the Vancouver Island Gas Joint Venture and BC Hydro Island Generation) and to thus address the capacity constraint that occurs in 2028:

OPTION 1: COMPRESSION NEAR SQUAMISH

Maintain the traditional VI send-out and storage allotment from Mt. Hayes and install a new single compressor station (V2) near Squamish in 2028. In order to meet the projected demand of the High and end-use Upper Bound forecasts, V2 is required by 2024 and pipeline looping on the south of Vancouver Island, south of Mt. Hayes, along with additional compression and looping on Texada Island may be required by 2030.

OPTION 2: INCREASE MT. HAYES SEND-OUT ALLOTMENT WITH COMPRESSION NEAR SQUAMISH

Increase the VI send-out and storage allotment from Mt. Hayes to provide more on-system supply for the VITS during peak demand periods. This option defers requirements for additional compression near Squamish by 2 to 4 years to 2029 in the High forecasts and 2030 in the Traditional forecast. The High and end-use Upper Bound forecasts may also require additional compression upgrades and south Vancouver Island and Texada Island pipeline loops in 2030. This option involves accommodating an adjustment of gas supply strategy between FEI's Vancouver Island and Mainland regions for storage and send-out services from Mt. Hayes.

KEY INPUT: RENEGOTIATE BC HYDRO CONTRACT WITH IG

Renegotiating the existing peaking agreement with BC Hydro in 2022 may allow curtailment of flows to IG to meet Core and Firm Transportation market requirements. Depending on the peaking agreement reached with IG, reduction of the peak day firm quantity has the potential to defer the capacity constraint within the planning horizon or move it beyond the 20-year forecast horizon altogether. The final agreement will be a key factor in determining the requirement and timing of the preferred option for capacity expansion.

Table 6-1 presents analysis results for the VI Transmission System expansion portfolio assuming the BC Hydro Island Generation contract continues with a firm amount of 50 TJ/d. The earliest date that a system expansion would be required is in 2024 for the High demand scenario. Given that an operational solution (Option 2) is available to defer a V2 compressor installation to later in the planning horizon, this is the preferred and most cost effective solution.

Table 6-1: Summary of VI Transmission System Expansion Portfolio and Timing

Demand Scenario	Option 1: Install Compressor near Squamish (V2)		Option 2: Increase Mt. Hayes Send-Out Allotment and Defer Squamish V2 installation	
High and Upper Bound	Install V2	2024	Increase Send Out	2024
			Install V2	2025
	Additional Compression and Install South Vancouver Island and Texada Island Pipeline Loops	2030	Additional Compression and Install South Vancouver Island and Texada Island Pipeline Loops	2030
Traditional	Install V2	2028	Increase Send Out	2028
			Install V2	2031
Reference	Install V2	2031	Increase Send Out	2031
			Install V2	2034
Low	Install V2	2030	Increase Send Out	2030
			Install V2	2034

In addition to capacity expansion on the VITS, there are two pressure control station additions served from new pipeline taps from the VITS that are identified for installation in the next few years to improve capacity in the growing distribution systems of Campbell River (Deerfield Road area) and Nanaimo (Extension Road area).

Potential Large New Industrial Loads

The High forecasts discussed previously address some additions of large industrial loads generally across the system. Additions of large single customers on the VITS are evaluated on a case-by-case basis to ensure they are in the interests of customers and align with FEI's objectives of delivering cost effective, safe and reliable energy. Low natural gas prices and possibly other market dynamics in BC have spurred interest from a range of industries in locating or expanding facilities that would use large volumes of natural gas within the province. Any required major reinforcements to serve potential new industrial loads would be evaluated as part of a formal submission to the BCUC once firm agreements regarding natural gas services have been made.

As a result of inquiries received, FEI is exploring developing the Utility's systems to accommodate transportation service for new, large industrial demand in various locations in its service territories. One such example in the VI service territory is a small scale LNG export and processing facility (Woodfibre LNG Project) located on the VITS at the former Woodfibre pulp mill site near Squamish. Woodfibre LNG Limited, a subsidiary of Pacific Oil & Gas, and FEI entered into a Development Agreement and, for a number of years, FEI has been carrying out development work, including a feasibility study, engineering, and exploring the regulatory and other approvals required to expand the VITS to provide a firm natural gas transportation service to the Woodfibre LNG Project. Woodfibre LNG Limited has presently indicated that it expects to require Firm Transportation service from FEI of up to 236 MMscfd on the VITS.[147] Should a final investment decision be made, the estimated in-service date of this facility is currently projected no earlier than 2021.

To accommodate this load addition, there is a need to reinforce the existing VITS with pipeline looping and added compression near Squamish. This infrastructure expansion would match the Firm Transportation capacity contracted by Woodfibre LNG Limited under peak demand, preserving available capacity for existing customers, but would allow large volumes of interruptible capacity to be available for much of the year. FEI expects the Woodfibre LNG Project to help reduce costs for firm service on FEI systems and thus provide benefits to FEI's existing customers through lower rates.

The Woodfibre LNG Project is an example of large industrial load being considered in detail on an FEI system and the challenges of forecasting and planning around such a load addition. These projects take many years of advance planning and design, and are significant in scope and impact on the pre-existing system. The projects are managed and are designed to preserve existing capacity and service to customers and eventually, if approved, are constructed to meet

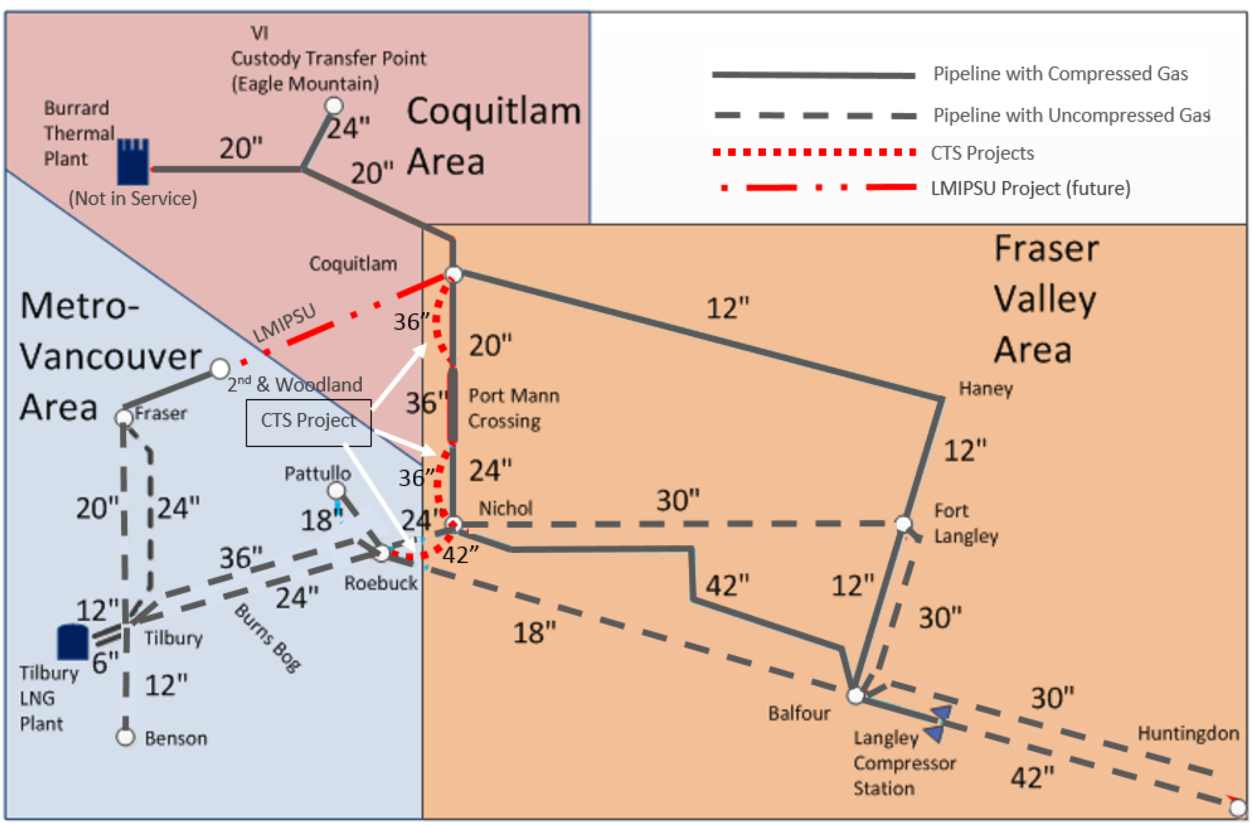
[147] As a transportation service customer, the Woodfibre LNG Project would not impact FEI's Vancouver Island gas supply planning as the customer would independently acquire its gas supply.

FEI system requirements and the very specific process and economic needs of the industrial customer. The solution for the Woodfibre LNG Project and required system changes would look significantly different if the location of the project were at a different point on the FEI system. However, the process of managing the timing of large load additions and associated system expansion requirements without eroding service reliability to existing customers would not change.

6.3.2 FEI Coastal Transmission System

The CTS consists of a 276 km network of pipelines providing gas transportation from the Huntingdon-Sumas trading point to various metering and regulating stations in the Fraser Valley, Metro Vancouver and Coquitlam areas. There are two primary capacity related facilities on the CTS: the Langley Compressor Station, which is used to boost pressures on the CTS during periods of high demand, and the Tilbury LNG storage facility, which is used to provide peaking gas supply during colder weather. The CTS delivers gas to the distribution networks in the Lower Mainland and to the VI Transmission System at Eagle Mountain in Coquitlam. The schematic diagram in Figure 6-6 shows the general layout of the CTS.

Figure 6-6: Schematic of the Coastal Transmission System Including the Langley Compressor Station and Tilbury LNG Storage Facility



CTS Peak Demand and Capacity Balance

There have recently been several changes that have impacted the CTS capacity balance. The CTS capacity to support growth has been enhanced by the construction of three transmission pipeline loops (these enter service in late 2017 and were described in Section 5.2 of the 2014 LTRP):

- A 1.5 km NPS 42 pipeline loop of an existing NPS 24 pipeline between Nichol and Roebuck Valve Stations in Surrey;
- A 4.9 km NPS 36 pipeline loop of an existing NPS 24 pipeline between Nichol and Port Mann Valve Stations in Surrey; and
- A 4.5 km NPS 36 pipeline loop of an existing NPS 20 pipeline between Cape Horn Valve Station and Coquitlam Gate Station in Coquitlam.

Approval for the construction of these loops, collectively identified as the CTS project, was granted through BC Government Direction No. 5 under OIC 557 in 2013 (please see Section 2.3.3.5 for details). The project loops existing pipelines that were single points of failure on the CTS and additionally addresses the existing capacity constraints on the CTS that were identified in Section 5 of the 2014 LTRP.

In addition to the CTS project, the LMIPSU projects (Coquitlam Gate IP Project and Fraser Gate Project) are currently in progress. The Coquitlam Gate IP Project will replace an existing NPS 20 pipeline nearing the end of its service life, between Coquitlam Gate Station and 2nd Avenue and Woodland Drive Station in Vancouver with a new high capacity NPS 30 pipeline. The Fraser Gate Project will replace approximately 300 meters of NPS 30 pipe with new NPS 30 pipe to upgrade the Fraser Gate IP Pipeline to current seismic design standards. The LMIPSU projects impact the CTS by shifting peak load within the transmission system from Fraser Gate to Coquitlam Gate.

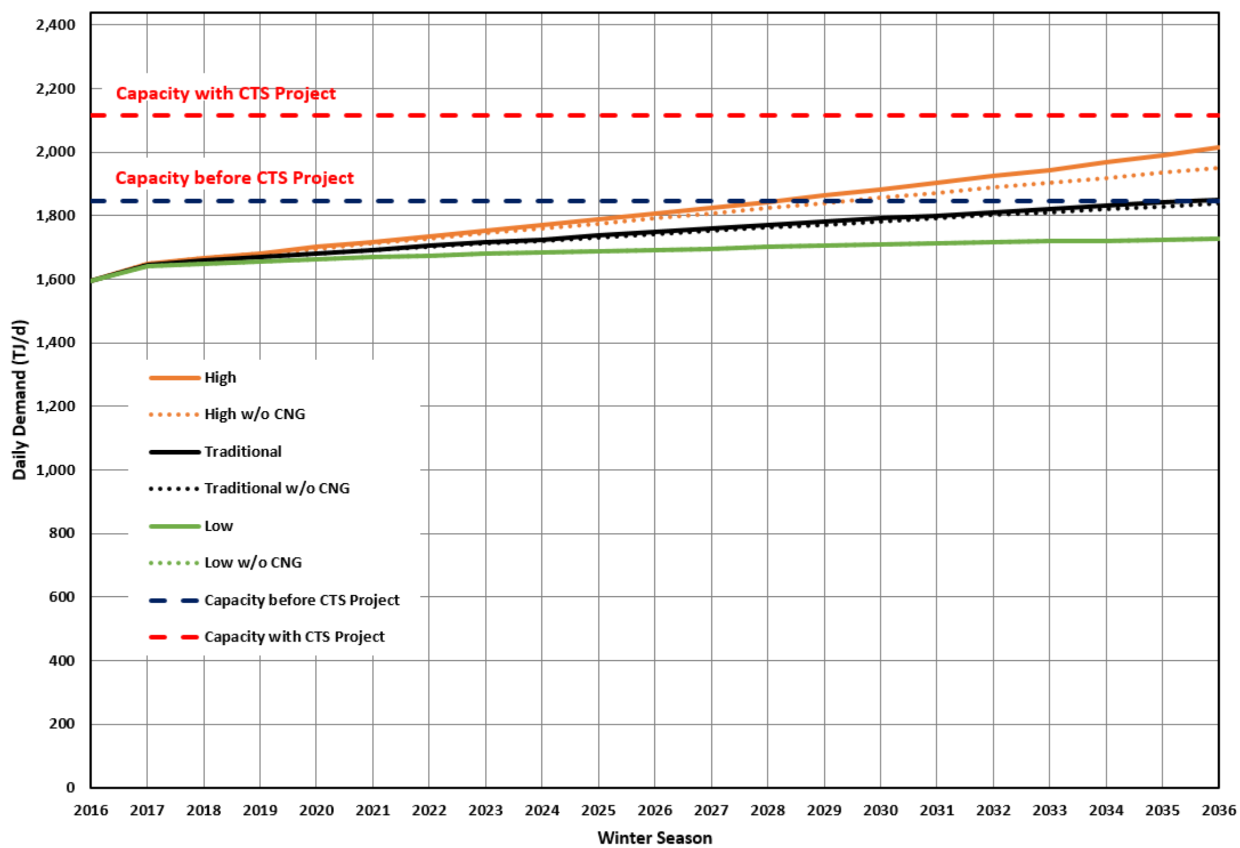
Finally, as anticipated, BC Hydro phased out the Burrard Thermal power generation plant effective November 1, 2016. The retirement of Burrard Thermal reduced the firm peak demand on the CTS by 215 MMscfd.

CTS Peak Demand Forecast Sensitivity (Traditional with Low and High Forecast Scenarios)

Currently, with the CTS project in place and Burrard Thermal decommissioned, the CTS has sufficient capacity to support Traditional, High or Low peak demand throughout the 20-year planning horizon with additional capacity to support increased LNG capacity at locations like Tilbury LNG in Delta and the Woodfibre LNG Project site in Howe Sound. For the foreseeable future, additional expansion requirements for the CTS will be driven by similar LNG additions or other large industrial demand in the Lower Mainland or VITS rather than Core customer growth.

The regional Traditional, Low and High peak demand forecasts are shown in Figure 6-7 and compare forecast peak demand to system capacity in order to illustrate when system constraints may occur. Peak demand for CNG as a transportation fuel is included in the forecast. For comparison, the forecast without CNG is shown as the dotted lines. The system capacity as it existed before the CTS project is also shown in comparison to the expanded capacity with it installed. With installation of the CTS project, FEI does not expect any capacity constraints to occur within the 2017 LTGRP planning horizon under these forecasts.

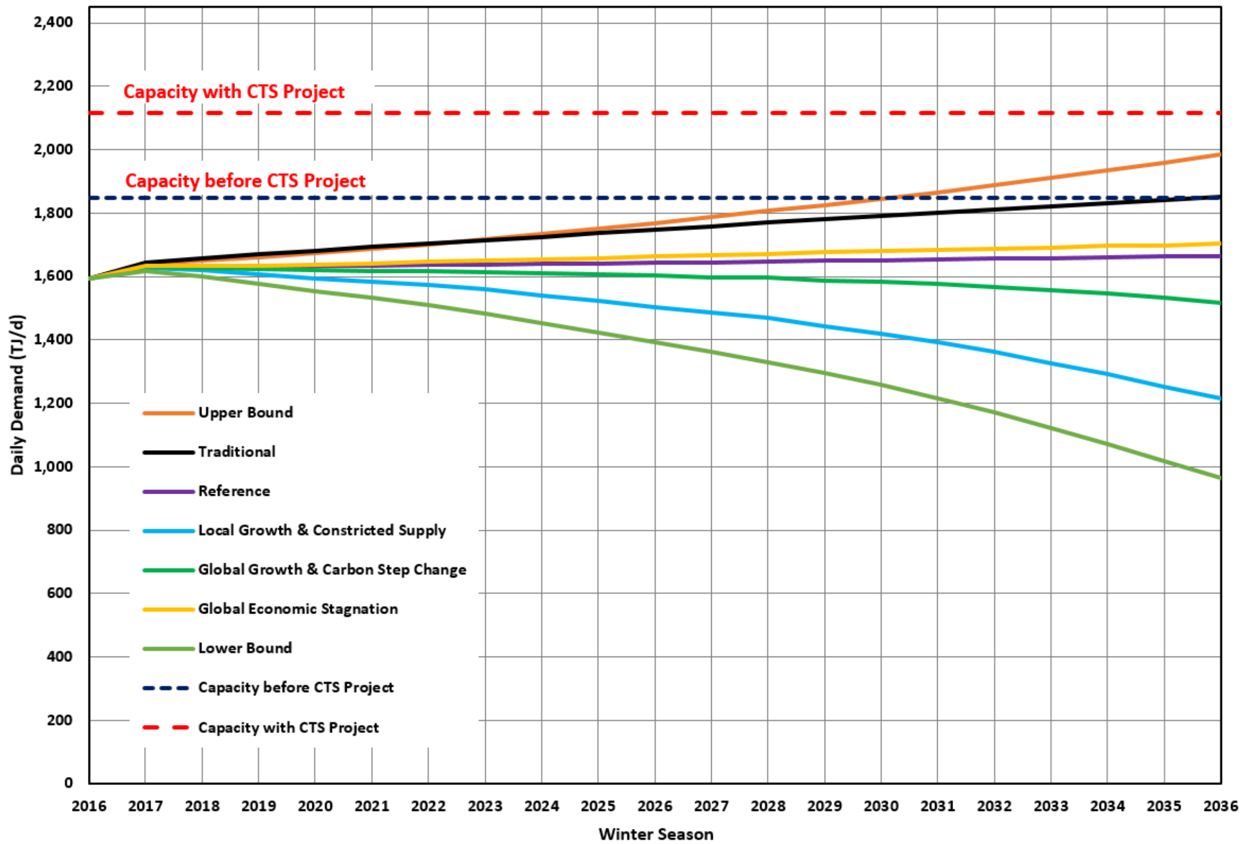
Figure 6-7: CTS Demand-Capacity Balance Using Traditional, Low and High Peak Demand Scenarios



CTS Peak Demand Forecast with End-Use Peak Demand Scenarios

Figure 6-8 provides a look at peak demand derived via the exploratory peak demand forecast method from the end-use scenarios. As in Figure 6-7 above, these forecasts also include the peak demand of CNG as a transportation fuel. For comparison, the Traditional forecast is also included. The forecasts show a wide range of peak demand, with the Upper Bound scenario showing greater growth in the forecast period than the Traditional forecast. The Reference Case and the Global Economic Stagnation scenarios show very slight increases in peak demand over the forecast, while the remaining scenarios show modest to more significant peak demand decline with the Lower Bound scenario showing the greatest peak demand decline.

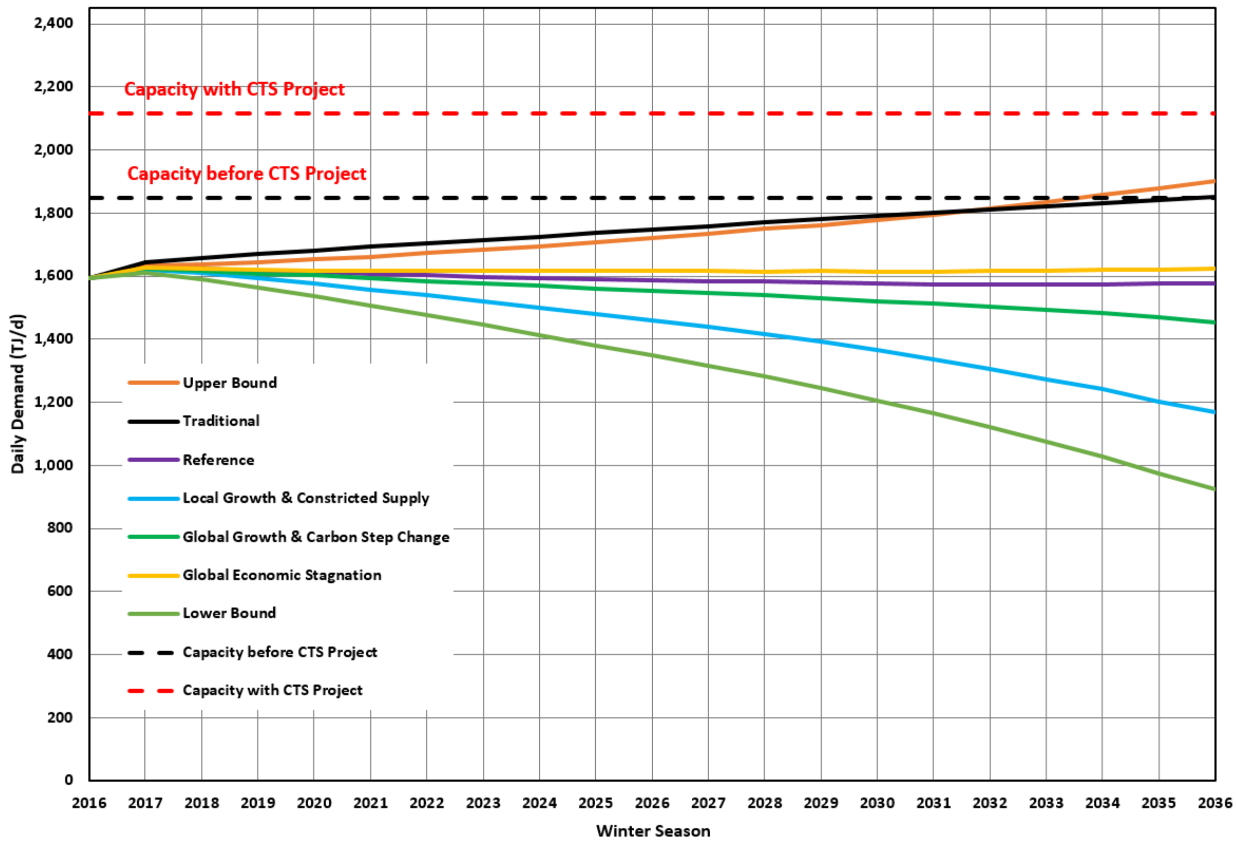
Figure 6-8: CTS Demand-Capacity Balance Using End-Use Peak Demand Forecasts



CTS Peak Demand Forecast with End-Use Peak Demand Scenarios with DSM

Figure 6-9 shows the end-use scenarios with DSM program impacts added. Applying the impacts of DSM using the end-use peak demand method moves all end-use scenario forecasts lower. The Upper Bound shows growth to be very comparable to the Traditional forecast, exceeding it slightly in the last years of the planning horizon. The Global Economic Stagnation scenario shows flat to very slight positive growth through the forecast and the Reference Case scenario shows very slight decline in peak demand through the forecast horizon. The remaining scenarios show moderate to more significant decline in peak demand through the forecast.

Figure 6-9: CTS Demand-Capacity Balance Using End-Use Peak Demand Forecasts with DSM



Impact of Potential Future Demand for LNG Transportation Fuel

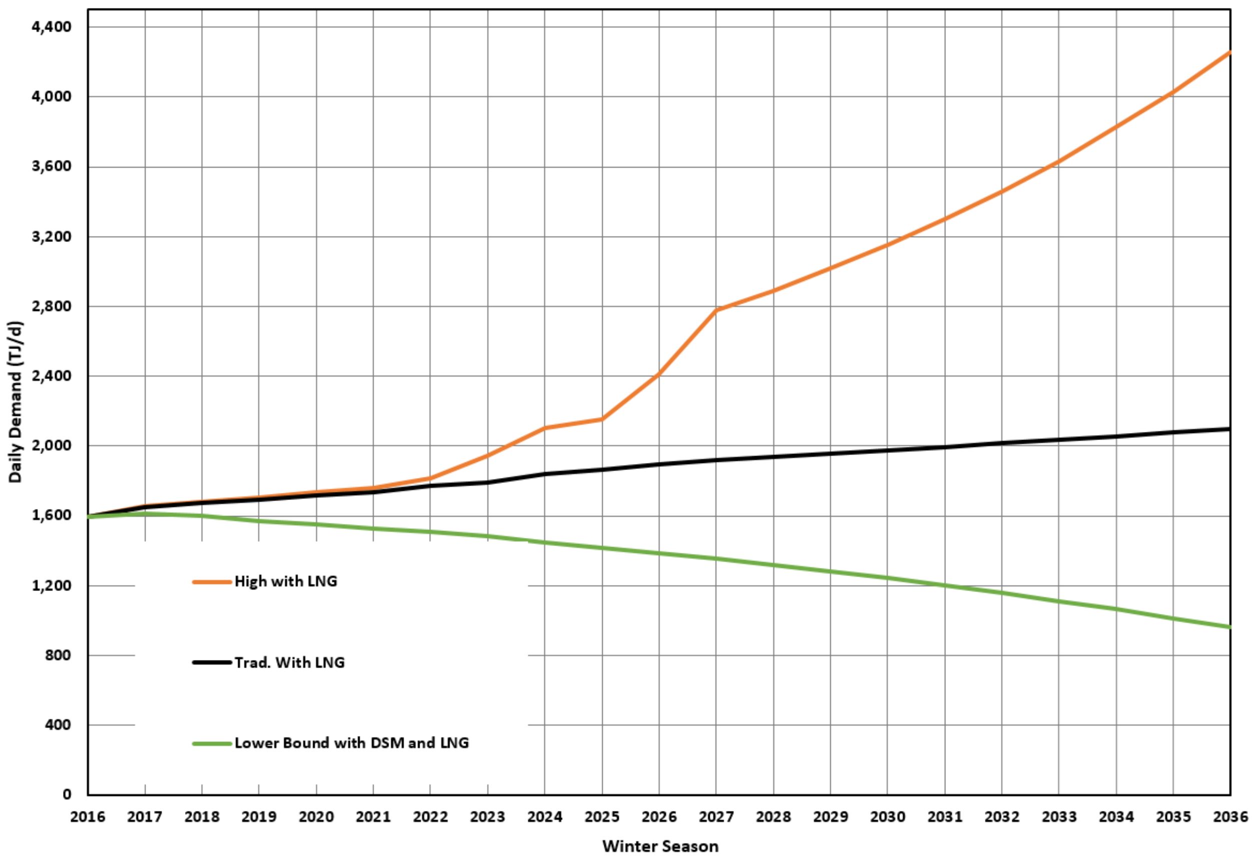
Natural gas demand for transportation consists of both the markets for CNG and LNG as vehicle fuel. Additional CNG load for transportation would be added in relatively small increments at various points on the system and has been included in the previous forecasts presented. In contrast, the greater potential demand and the point source nature of additional LNG production at Tilbury may create broader system impacts and could trigger the need for suitable system reinforcements of the CTS. The demand for natural gas from transportation sector fuel customers is forecast to continue growing over the next 20 years (see Section 3.4.7); the Lower Mainland area will likely drive LNG and CNG demand growth due to increasing road and coastal marine transport demand.

Based on FEI's natural gas demand forecasts for LNG, future phases of Tilbury LNG expansion beyond the current Phase 1A will need to be constructed. FEI's long term outlook must consider the system requirements for such an expansion.

For LNG, the demand on the transmission system originates from a point source – the location of the LNG liquefaction and storage facility used to serve that demand. FEI expects demand by LNG customers across the FEI service territories to be primarily served by the Tilbury LNG liquefaction and storage facility in Delta, BC, or from the Tilbury, South Delta or Richmond areas.

Figure 6-10 shows the impact of the Traditional, High and Lower Bound (with DSM) peak demand forecasts including LNG and CNG demand on the CTS over the next 20 years. These three forecasts define the widest range of peak demand (the highest highs and the lowest lows) for all the forecasts explored.[148]

Figure 6-10: Impact of Traditional, High and Lower Bound (with DSM) on CTS Peak Demand Including LNG and CNG



The peak demand forecasts shown have a very similar profile to the annual demand with LNG forecasts shown in Figure 3-18. The production of LNG is consistent throughout any day of the year and has no seasonal or daily peak. In practice, the actual peak demand that may occur on the CTS in any given period would be dependent on the liquefaction capacity installed at the LNG plant to meet the forecast. LNG liquefaction trains generally operate at a fixed production rate and, for reasons of efficiency, do not vary production rates substantially when in operation.

[148] High with LNG and Traditional with LNG rely on FEI's Traditional Peak Method. These forecasts also use the High or Base NGT market development assumptions, respectively (see Section 3.4.7 for further details about the assumptions). Lower Bound with DSM and LNG relies on the exploratory end-use peak demand forecast method. This forecast also uses the Low NGT market development assumptions from Section 3.4.7 and the Lower Bound DSM results from Section 4.2.

The peak demand profile on the CTS would therefore occur in a more defined stepwise fashion with each step corresponding to a phase of expansion at the LNG facility.

To illustrate the potential impact of the LNG forecasts on the CTS, the expansion of the CTS through the CTS and LMIPSU projects followed by a series of additional hypothetical CTS expansion phases are described in Table 6-2, with the corresponding capacity for liquefaction that could be delivered to the Tilbury area.

Table 6-2: CTS Expansion Scenarios for LNG

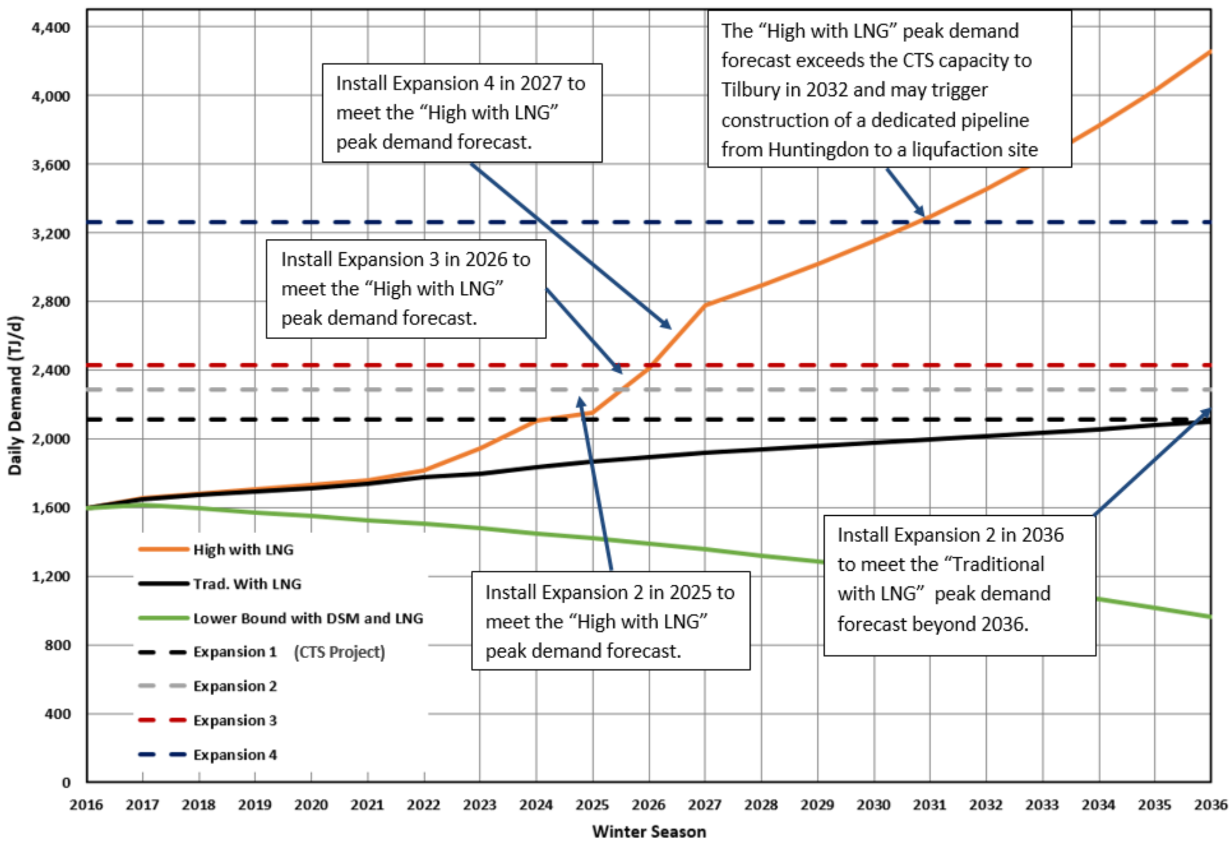
Expansion Scenario	CTS Expansion Description	Max CTS Delivery to Tilbury Island, Delta
1	After CTS and LMIPSU projects	264 TJ/d
2	a) Add Replacement of 1.9 km NPS 6 feed to Tilbury Plant b) Add 15,000 HP to existing facility at Langley Compressor Stn.	436 TJ/d
3	a) Add 14.8 km NPS 42 Loop from Langley Compressor to Clayton Valve Stn. b) Add 15,000 HP to existing facility at Langley Compressor Stn.	577 TJ/d
4	a) Add 28.1 km NPS 42 Loop from Clayton Valve Stn. To Tilbury Area. b) Add 25 km NPS 42 Loop from Huntingdon to Langley Compressor Stn. c) Add 15,000 HP to existing facility at Langley Compressor Stn.	1,414 TJ/d

The recent expansion project at the Tilbury LNG site will draw a peak demand of approximately 37.7 TJ/day. The additional peak capacity afforded by the CTS project (up to 264 TJ/d) will easily accommodate this LNG expansion phase. Figure 6-11 illustrates that the CTS would meet the expected Traditional peak demand forecast with LNG and CNG until 2036 at which point an expansion to meet future demand may be required.

Expanding capacity to deliver to the Tilbury site beyond 264 TJ/d may be required within the planning horizon to meet a High LNG forecast and can be accomplished in large part by expansion projects as described in Table 6-2. Expansion Scenario 2, replacing approximately 1.9 kilometers of NPS 6 pipe and adding 15,000 horsepower (HP) in additional compression at

FEI's existing Langley Compressor site would enable a total of 436 TJ/d to be delivered to the Tilbury site. Adding additional pipeline looping of the CTS and incremental expansion of compression at Langley Compressor Station as described in Expansion Scenarios 3 and 4 would show an intermediate, and then, the ultimate phased expansion within the CTS, enabling up to 577 TJ/d and 1,414 TJ/d, respectively, to be delivered to Tilbury while also meeting the peak demand requirements of the CTS. Figure 6-11 shows how these potential expansion scenarios might be phased relative to the LNG Peak Demand Forecasts.

Figure 6-11: Phased Expansion of the CTS to meet LNG forecasts



Potential Large New Industrial Loads

The High forecast with high LNG demand includes forecasted industrial account additions distributed proportionally throughout the CTS. This captures generic typical industrial demand increases. However, a single large industrial customer can be large enough to disrupt this forecast and have an impact on any potential expansion plans. The specific requirements for system facility expansion are very dependent on the magnitude and location of any proposed large industrial consumer on the system. As discussed previously, the Woodfibre LNG Project facility, should it proceed, will be served from the VI Transmission System. This facility would impact the CTS as the CTS delivers the VITS requirements to the Eagle Mountain compressor facility in Coquitlam. Table 6-3 shows examples of how deliverability to the Tilbury, or other adjacent South Delta or Richmond locations might change should the Woodfibre LNG Project facility proceed with a requirement to deliver approximately 260 TJ/d. With the CTS project in service, the requirement to deliver 260 TJ/d at Eagle Mountain would reduce the deliverability to the Tilbury area from 264 TJ/d to 98 TJ/d, a reduction of 166 TJ/d at Tilbury. The deliverability reduction at Tilbury is not equal to the full 260 TJ/d added to the VI Transmission System as the CTS has a lesser constraint to deliver gas north through Coquitlam to Eagle Mountain than to deliver gas west to the Tilbury area. If the CTS expands as described in Expansion Scenario 4, this variance in deliverability reduces from 166 TJ/d to 108 TJ/d (adding 260 TJ/d at Eagle Mountain reduces the deliverability to the Tilbury area by only 108 TJ/d). This is a consequence of the CTS expansions inherently improving the deliverability in both regions of the CTS. However, due to the existing configuration of the CTS, each region has capacity constraints that respond to the compression additions and pipeline loops to different degrees. If a large industrial load of the same magnitude as the Woodfibre LNG Project was added in the Tilbury, South Delta, Richmond region of the CTS instead of at Eagle Mountain there would be a more direct 1:1 impact on deliverability to the Tilbury region. This is representative of the challenges inherent in analysing the system capacity and infrastructure requirements to support large industrial demand additions to complex pipeline systems when both the specific demand and location are uncertain.

Figure 6-12 identifies the locations within the CTS of the Expansion Scenarios discussed.

Figure 6-12: CTS Expansion Scenarios to Meet Potential LNG or Large Industrial Load Growth

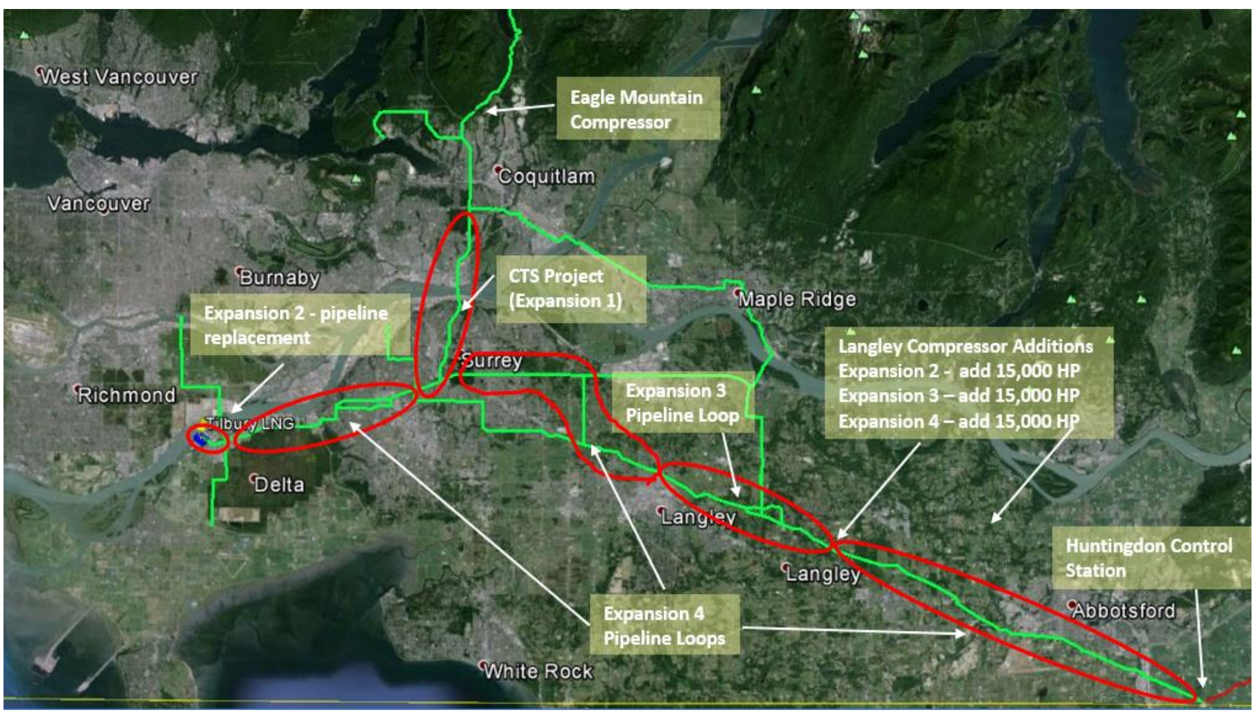


Table 6-3: CTS Expansion Scenarios for LNG

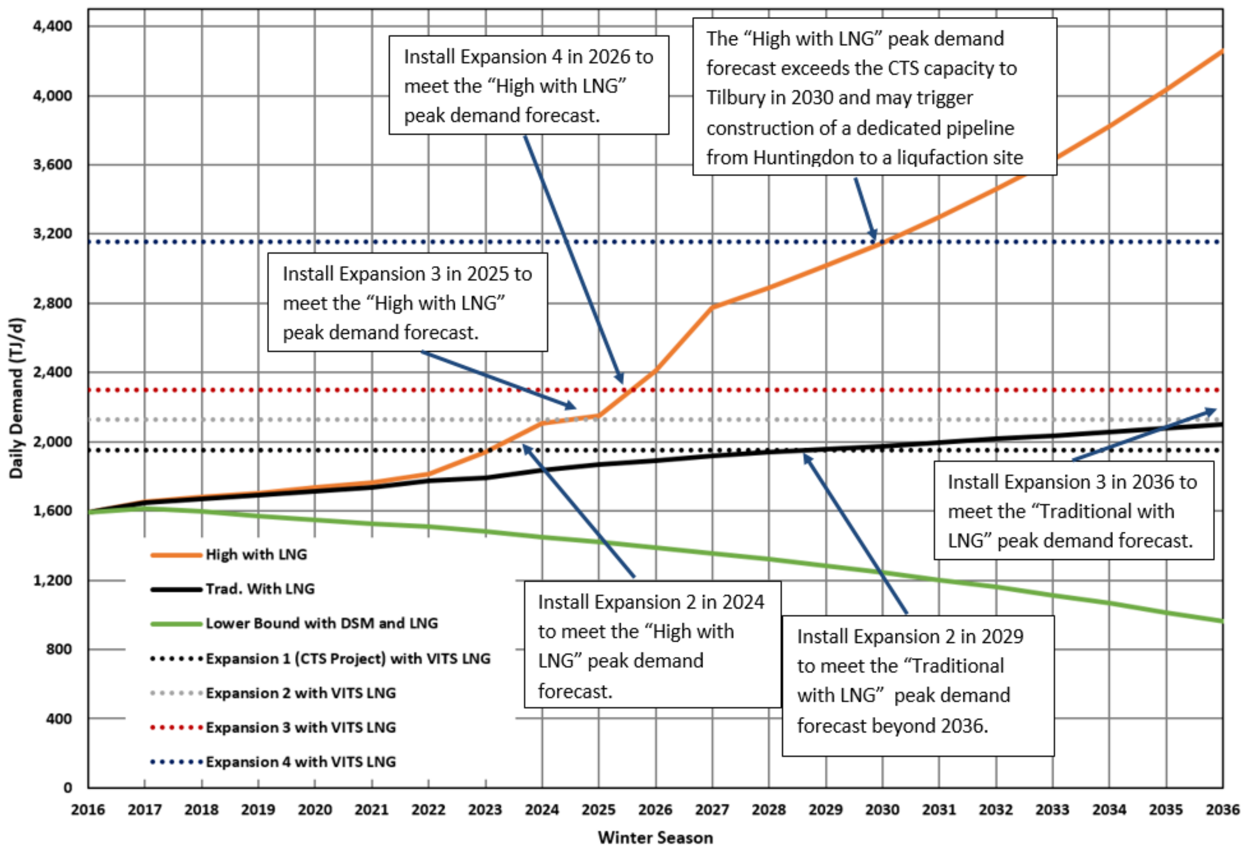
Expansion Scenario	CTS Expansion Description	Max CTS Delivery to South Delta/Richmond	
		With Export LNG on VI System (260 TJ/d)	Without Export LNG on VI System
1	CTS project	98 TJ/d	264 TJ/d
2	a) Add Replacement of 1.9 km NPS 6 feed to Tilbury Plant b) Add 15,000 HP to existing facility at Langley Compressor Stn.	276 TJ/d	436 TJ/d
3	a) Add 14.8 km NPS 42 Loop from Langley Compressor to Clayton Valve Stn. b) Add 15,000 HP to existing facility at Langley Compressor Stn.	448 TJ/d	577 TJ/d
4	a) Add 28.1 km NPS 42 Loop from Clayton Valve Stn. to Tilbury Area. b) Add 25 km NPS 42 Loop from Huntingdon to Langley Compressor Stn. c) Add 15,000 HP to existing facility at Langley Compressor Stn.	1,306 TJ/d	1,414 TJ/d

Figure 6-13 compares how adding 260 TJ/d to the VI system might shift the timing of hypothetical expansion phases of the CTS. The reduced delivery capacity in the Tilbury, South Delta or Richmond area is shown as the dotted lines. For the Traditional forecast with LNG the change would advance the need for Expansion 2 from 2036 to 2029 and trigger the requirement for Expansion 3 by 2036. For the High forecast with LNG the change would advance the timing for each proposed phase of expansion by one to two years.

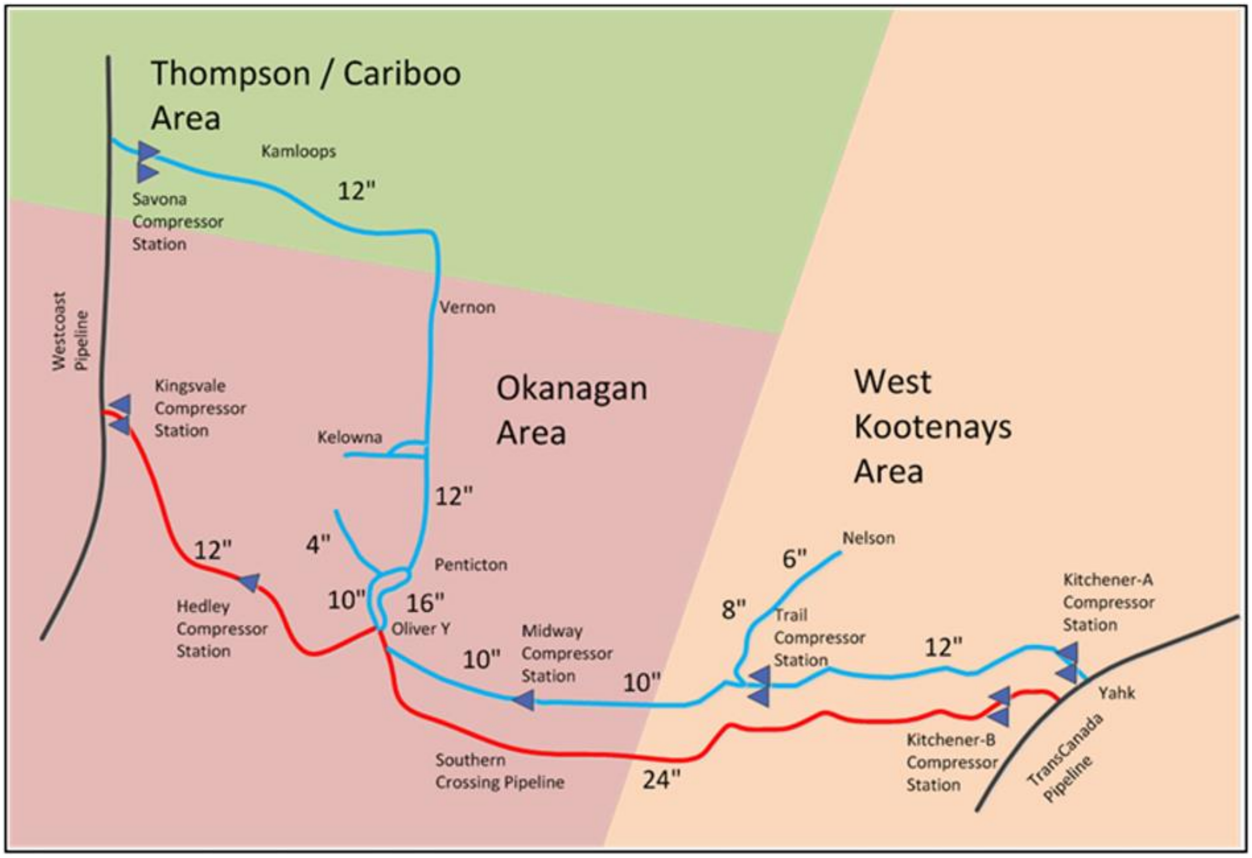
Figure 6-13: Expansion Phases of the CTS for LNG with 260 TJ/d VI System Expansion



6.3.3 FEI Interior Transmission System

The ITS consists of 1,515 km of transmission pipelines operating at maximum operating pressures between 4,600 Kilopascals gauge pressure (kPag) and 9,928 kPag. The ITS system interconnects supply from Westcoast pipelines in the west and TransCanada pipelines in the east. Gas received from the Westcoast pipeline at Savona typically supplies customers in the Thompson and North Okanagan regions, while gas received from the TransCanada Pipeline at Yahk supplies customers in the West Kootenay region via pipelines to Trail and Oliver. The FEI-owned SCP is a bi-directional transportation pipeline between Yahk and Oliver. From the Oliver hub, referred to as the Oliver-Y, pipelines transport gas to serve customers in the South and Central Okanagan. In winter periods, the Kingsvale-Oliver pipeline transports gas from the SCP via the Oliver-Y hub to Kingsvale for redelivery to the Lower Mainland via the Westcoast Pipeline. Figure 6-14 shows the layout of the ITS system.

Figure 6-14: FEI Interior Transmission System



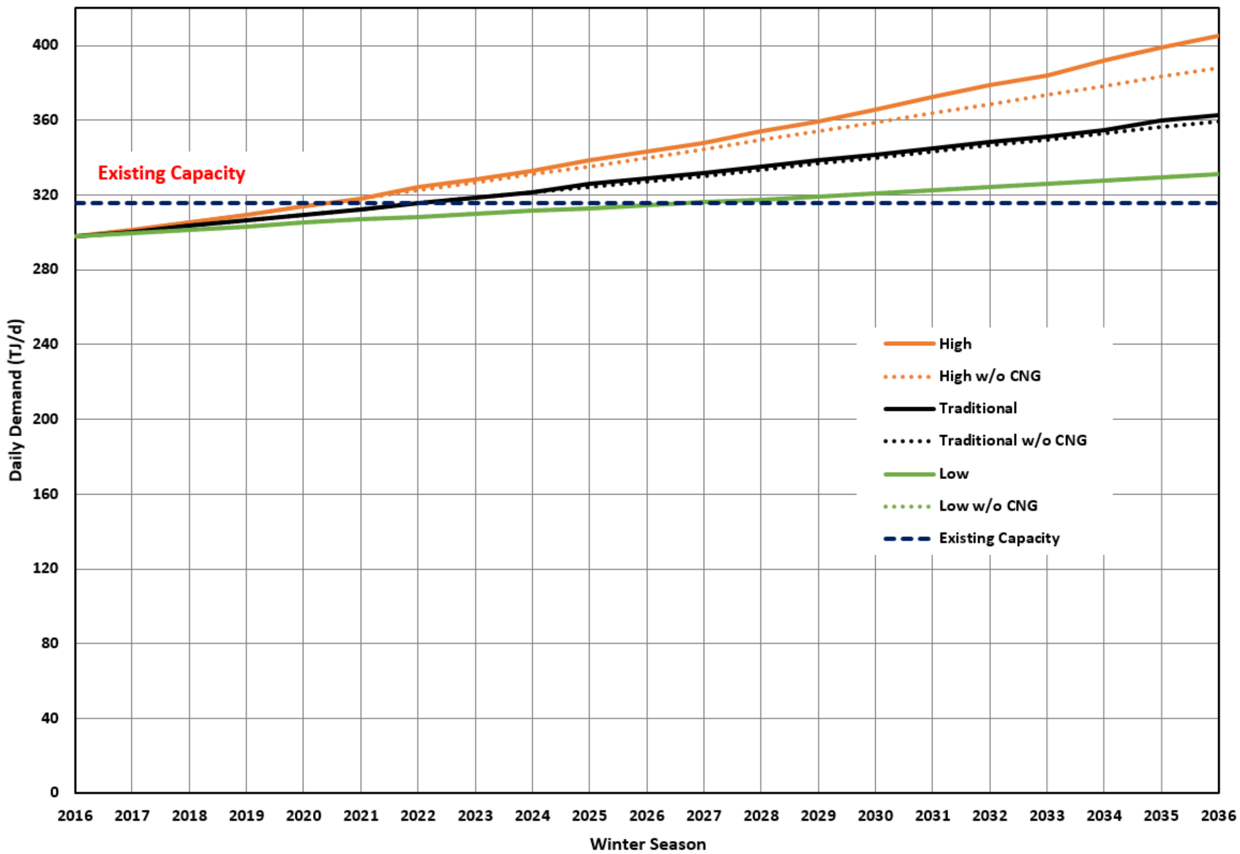
ITS Demand and Capacity Balance

Approximately 60 percent of the current ITS Core and Firm Transportation customer demand is concentrated in the South, Central and North Okanagan regions. Growth in the Okanagan region is one of the main factors driving the location of future incremental capacity additions to the ITS. Because the ITS is characterized by long pipeline lengths through a number of less densely populated areas, the system benefits from line pack effects – the "storage" of usable pressurized gas up to the pipeline MOP that can be drawn on to support short term peak demand. The ability to draw down the gas that is stored in the ITS allows FEI to plan the ITS on a peak day, rather than a peak hour, maximum flow. The current peak day system capacity for the ITS is approximately 315 TJ/d.

As previously described, natural gas is delivered to the ITS from two upstream pipelines—the Westcoast pipeline at Savona in the west and the TransCanada Pipeline at Yahk in the east. The ITS peak demand will reach pipeline capacity when the system cannot maintain minimum system pressures near the high load centres in the Central Okanagan region.

The Traditional case peak demand forecast for this region is shown in Figure 6-15, indicating this capacity constraint occurs in 2022. The High and Low peak demand forecasts show the capacity constraint could appear as early as 2021 or as late as 2027. For comparison the forecasts without CNG are shown as the dotted lines.

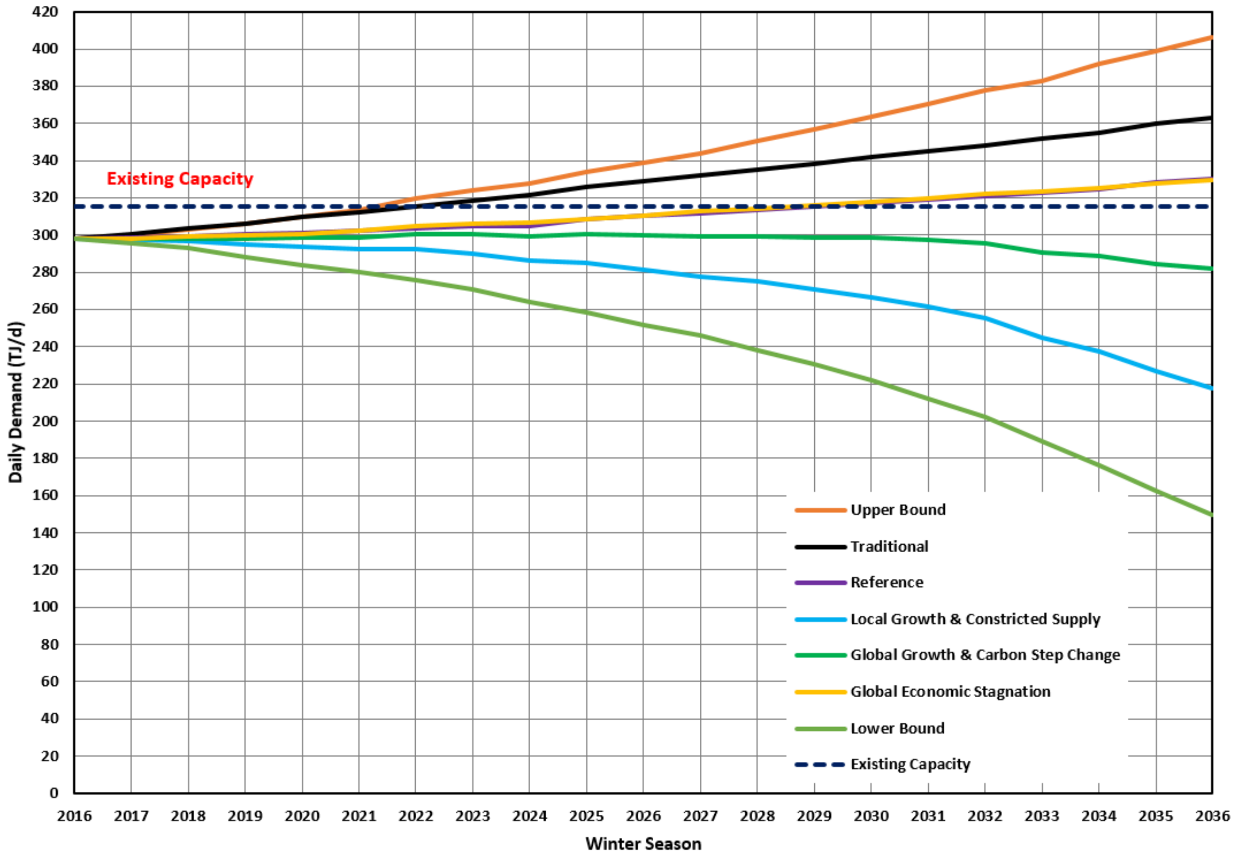
Figure 6-15: ITS Forecast Demand and Capacity Curves - Traditional, High and Low Scenarios



ITS Peak Demand Forecast with End-Use Peak Demand Scenarios

Figure 6-16 provides a look at the peak demand forecast derived from the end-use scenarios for the area served by the ITS. These forecasts include the CNG forecast as well. For comparison the Traditional forecast is also included. The forecasts show a wide range of peak demand, with the Upper Bound scenario showing greater growth in the forecast period than the Traditional Peak Method, with a capacity constraint appearing in 2022. The Reference Case and the Global Economic Stagnation scenarios show lesser increases in peak demand over the forecast, indicating that the capacity constraint might appear in 2030. The remaining scenarios show modest to more significant peak demand decline, remaining within the bounds of the current ITS capacity, with the Lower Bound scenario showing the greatest peak demand decline.

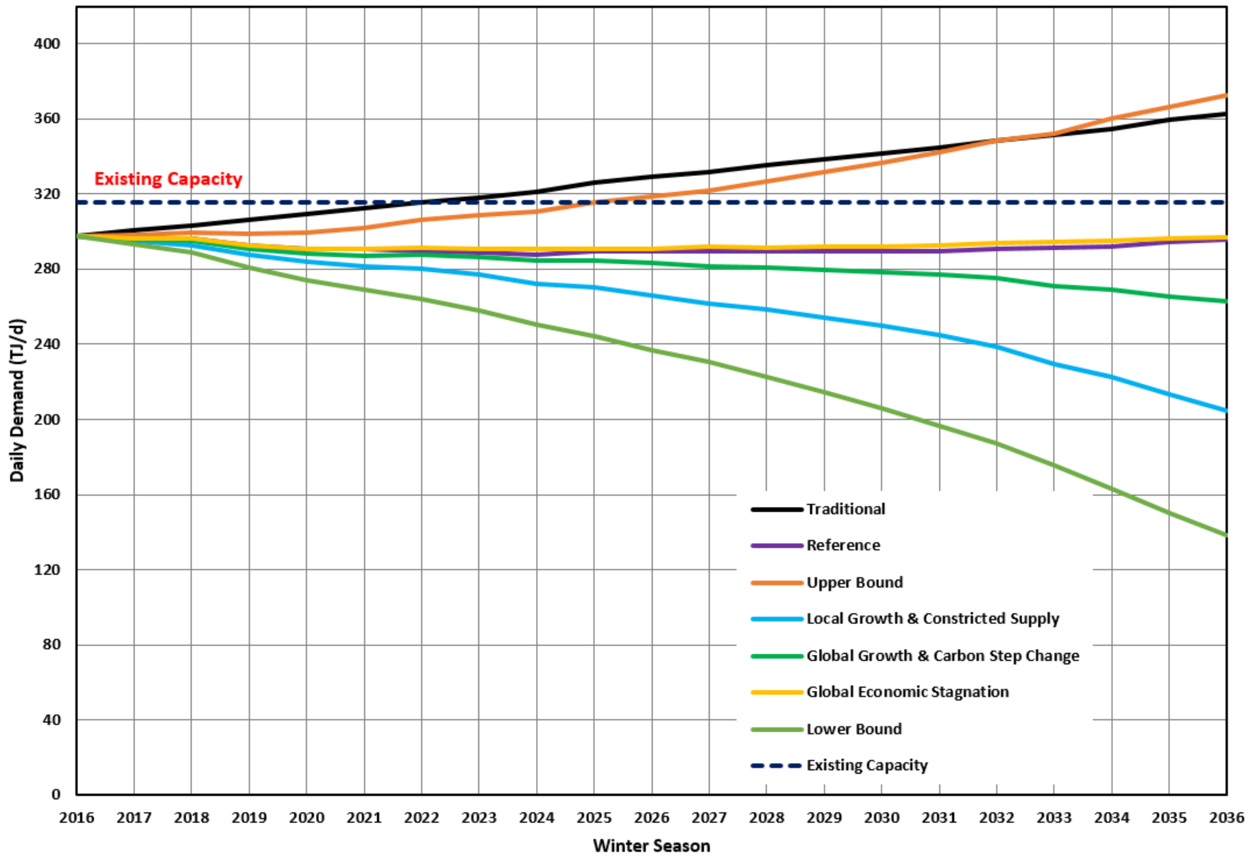
Figure 6-16: ITS Demand-Capacity Balance Using End-Use Peak Demand Forecasts



ITS Peak Demand Forecast with End-Use Peak Demand Scenarios with DSM

Figure 6-17 shows the end-use scenarios with DSM program impacts added. Applying the impacts of DSM using the end-use peak demand method moves all end-use scenario forecasts lower. The Upper Bound shows peak demand initially growing slower than the Traditional forecast, then increasing and exceeding the Traditional forecast slightly in the last years of the planning horizon. The Reference Case and the Global Economic Stagnation scenario shows flat to very slight positive growth through the forecast and no longer exceeds the existing capacity of the ITS within the planning horizon. The remaining scenarios show moderate to more significant decline in peak demand through the forecast horizon.

Figure 6-17: ITS Demand-Capacity Balance Using End-Use Peak Demand Forecasts with DSM



ITS System Expansion Alternatives

Four reinforcement alternatives have been identified to meet the Traditional case demand forecast:

OPTION 1 – OKANAGAN REINFORCEMENT SOUTH LOOP FROM ELLIS CREEK WITH ADDITIONAL COMPRESSION

The first alternative solution to address the capacity constraint in 2022 is installation of a NPS 20, or 508 mm, diameter pipeline loop that follows the existing pipeline right of way, running from Ellis Creek (Penticton) to north of Naramata, a distance of approximately 28 kilometres. This pipeline looping would be accompanied by an additional compressor unit at Kitchener-B compressor station and would increase gas supply delivered from the TransCanada Pipeline at Yahk via the SCP. In 2035, the Kelowna #1 lateral (consisting of both 4 and 8 NPS pipelines on the lateral) would have to be upgraded to dual NPS 8 pipeline (i.e. remove existing NPS 4 and replace with NPS 8).

OPTION 2 – PIPELINE REPLACEMENT AND PRESSURE UPGRADES WITH ADDITIONAL COMPRESSION

This alternative is currently being explored to defer the south loop reinforcements by replacing up to 9 km of NPS 12 pipe that currently has an MOP below the rest of the ITS pipeline between Penticton and Kelowna. This will enable an increase in the MOP north of the existing Ellis Creek control valve in Penticton which is currently limiting pipeline pressures in this region of the ITS to 5,171 kPag. The pipeline upgrades would eventually allow an MOP of 6,584 kPag at Ellis Creek and defer any further NPS 20 looping to beyond 2036. The same compressor upgrades at the Kitchener B compressor station as required for Option 1 would still be required.

OPTION 3 – OKANAGAN REINFORCEMENT NORTH LOOP FROM SAVONA

The third alternative is installation of a NPS 20 (508 mm) loop running from Savona to Valve SN 3-2 (East of Kamloops) a distance of approximately 52 kilometres. This pipeline looping would increase gas supply delivered via the Westcoast pipeline at Savona. In 2028, the Kelowna #1 lateral (consisting of both 4 and 8 NPS pipelines on the lateral) would have to be upgraded to dual NPS 8. In 2033, an additional extension to the NPS 20 pipeline loop of just over 9 km would be required, followed by an upgrade in 2035 to the 4.1 km NPS 4 Coldstream lateral in Vernon.

OPTION 4 - LNG STORAGE FACILITY

The third alternative is an LNG storage facility located between Westwold and Grandview Flats close to Vernon in addition to upgrading the Kelowna #1 Lateral. An LNG facility located closer to the load centre allows natural gas to be moved into storage in times of low gas demand when excess pipeline capacity is available, and provides on-system delivery to the region during periods of high demand.

Figure 6-18 below shows the potential locations of the three system resource expansion options on the ITS.

Figure 6-18: Location of Possible ITS Reinforcement Options

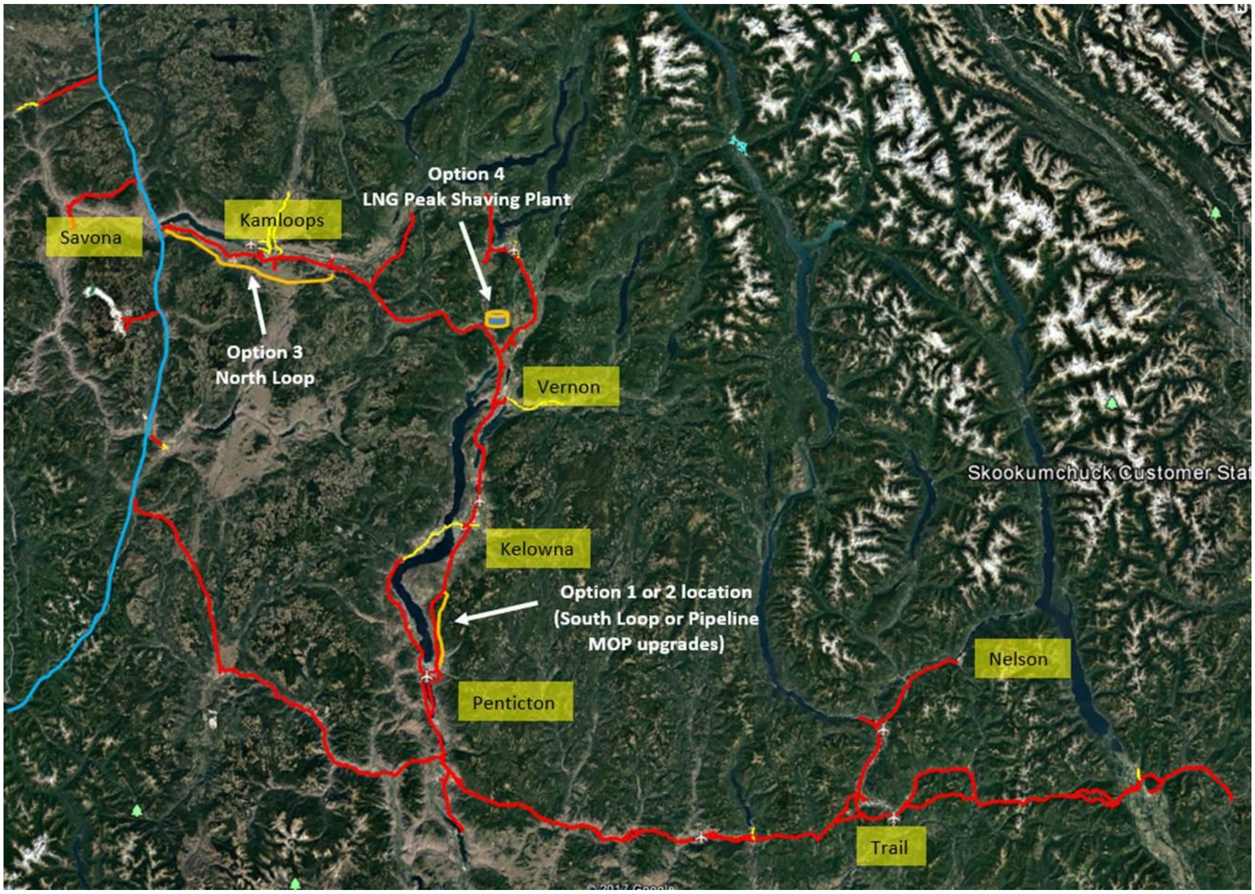


Table 6-4 summarizes the scope and required timing for the ITS facility additions for each resource option with timing variances for the various forecasts. In general, the High and Upper Bound forecasts advance and the Reference and Low forecasts delay required system infrastructure additions in relation to the Traditional forecast.

Table 6-4: ITS Resource Requirements

Option 1: Okanagan Reinforcement - South Loop	28 km x NPS 20 pipeline Ellis Creek to North of Naramata 3rd Compressor Unit at Kitchener B Station	Upgrade Kelowna #1 Lateral 2.1 km x NPS 8 Pipeline	South Loop Extension 8 km NPS 20 Pipeline
High and Upper Bound	2021	2031	2032
Traditional	2022	2035	-
Reference	2030	-	-
Low	2027	-	-

Option 2 – Pipeline MOP upgrades	Replace 3.3 km NPS 12 pipeline and increase Ellis Creek to 5,791 kPag and 3rd Compressor unit at Kitchener B Station	Replace 5.5 km NPS 12 pipeline and increase Ellis creek to 6,584 kPag	Upgrade Kelowna #1 Lateral 2.1 km x NPS 8 Pipeline
High and Upper Bound	2021	2027	2027[1]
Traditional	2022	2028	2036
Reference	2030		
Low	2027		

[1] High forecast also requires NPS 20 south loop and Coldstream lateral upgrade in 2033

Option 3: Okanagan Reinforcement - North Loop	52 km x NPS 20 pipeline Savona to West of Kamloops	Upgrade Kelowna #1 Lateral 2.1 km x NPS 8 Pipeline	North Loop Extension 9.3 km NPS 20 Pipeline and Coldstream Lateral upgrade 4.1 km NPS 6
High and Upper Bound	2021	2023	2029[2]
Traditional	2022	2028	2033
Reference	2030	-	-
Low	2027	-	-

[2] High forecast also requires that the North Loop Extension be 39.5 km longer than Traditional forecast

Option 4: LNG Storage and Peak Shaving	LNG Plant	Upgrade Kelowna #1 Lateral 2.1 km x NPS 8 Pipeline
High and Upper Bound	2021	2021
Traditional	2022	2022
Reference	2030	2030
Low	2027	2027

Potential New Industrial Load

Based on the FBC 2016 LTERP filed with the BCUC in November 2016, a simple cycle gas-fired turbine (SCGT) power generating station was identified as one of the preferred long term options in the Okanagan area between 2026 and 2035, possibly 2033, to meet growing peak electricity demand. Adding this load in 2033 would impact the ITS expansion options. In the case of Option 1, for example, the Okanagan Reinforcement South Loop extension would be required for the Traditional forecast just before the generating station in-service date.

6.3.4 Transmission Laterals

FEI operates transmission laterals that connect to the Westcoast and TransCanada pipelines to serve communities and industrial users in north-central and southeastern BC. The Cache Creek/Ashcroft Lateral has been identified as the only lateral to have insufficient capacity to meet the forecast demand throughout the 20-year planning horizon.

The Cache Creek/Ashcroft Lateral is served from the Westcoast pipeline in the Thompson region. The lateral delivers gas to Cache Creek and Ashcroft, which are located approximately 70 km west of Kamloops. The lateral consists of a combination of two pipelines and is at its capacity to meet peak demand. Reductions in available supply pressure from the Westcoast pipeline are increasing the possibility of curtailment to an industrial customer on the lateral. Addition of a 19-22 km pipeline loop is required to meet current Firm Transportation service to the industrial customer. FEI continues to work cooperatively with this customer to manage demand under peak conditions to avoid the need for the pipeline loop.

6.3.5 Distribution System Capacity

By convention, FEI considers infrastructure operating at or below 2,069 kPag as distribution assets, which are further divided into:

- IP systems operating above 700 kPag up to 2,069 kPag; and
- Distribution pressure systems operating at or below 700 kPag.

For ease of operation and maintenance, safety to the public and reliable service, distribution networks operate at a relatively low pressure. In general, FEI operates its distribution networks at a MOP of 420 kPag; on Vancouver Island and the Sunshine Coast, FEI typically operates its distribution networks at a MOP of 550 kPag. Supply resources for distribution systems include:

- *Pressure regulating stations* – capacity reinforcement to a distribution network could be obtained by the addition of a new regulating station as an additional supply source; and
- *Distribution pipelines* – similar to a pipeline except at a lower operating pressure, capacity reinforcement in a distribution network can be accomplished by increasing the effective cross-sectional area of a distribution pipe section. This can be achieved by replacing an existing pipe with a larger diameter pipe, adding a parallel pipe (a loop) or by introducing gas into the network from an alternate source (a back feed).

Since distribution systems operate at a low pressure through relatively small diameter pipes, there is little line-pack capability for managing hourly demand fluctuations. Therefore, capacity requirements for distribution systems are based on peak hourly demand rather than peak daily demand.

Distribution system improvement projects generally occur more frequently and are smaller in scale than transmission system projects. Distribution system improvement projects are routinely identified as part of the capital planning process and are not discussed in any detail here. The 2014 LTRP identified two systems where more significant changes were being assessed. The following is a brief update on the status of these systems as well as a description of work underway on the Whistler distribution system.

6.3.5.1 Metro Vancouver IP System

Construction on the LMIPSU projects referred to previously in Section 6.2 will begin in 2018. The LMIPSU projects will replace an existing, end of life, 20 km NPS 20 pipeline between Coquitlam Gate Station and 2nd Avenue and Woodland Drive Station in Vancouver with a new high capacity NPS 30 pipeline. This new pipeline will significantly improve the capacity and security of supply to more than a quarter of a million natural gas customers in the region. In addition, the LMIPSU pipeline will also address capacity constraints identified for the Metro Vancouver IP System in previous LTRP submissions that were to be addressed with two NPS 30 pipeline looping projects in South Vancouver (totalling 4.8 kilometres in length).

6.3.5.2 Revelstoke Propane System

FEI operates a satellite, off-grid propane distribution system that serves residential and commercial customers in the Revelstoke area. Due to its geographic location, Revelstoke is located too far away to economically connect to the natural gas grid. Consequently, propane is transported by railcar and tanker truck to Revelstoke where it is then off-loaded into storage tanks, vaporized as needed and distributed to customers through an underground pipeline system. Core demand growth in Revelstoke is forecast to be minimal and serviceable by the pipe, storage and send-out capacity of the current system. However, plans for a large scale ski hill and resort development could potentially double the area's load requirements in 20 years and would require FEI to expand the propane system with pipeline extensions, main looping, additional storage tanks and loading facilities. The development has been delayed though, and this delay has resulted in FEI delaying the planned expansion indefinitely, pending status of the development. As part of FEI's commitment to provide safe and reliable service to its customers, current plans are to increase the capacity of Revelstoke's second vapourizer in order to provide full redundancy.

FEI has identified Revelstoke's satellite propane system as a potential opportunity to convert the community from propane to natural gas. FEI has conducted an internal pre-feasibility study on using LNG from Tilbury for a possible conversion from propane to natural gas using a satellite LNG station at Revelstoke. Converting the town of Revelstoke from propane to natural gas could provide GHG emission reduction benefits. Based on current propane consumption levels of FEI's Revelstoke customers, the community's GHG emissions would fall by 2,019 metric tonnes of carbon dioxide equivalent (CO_2e) per year.[149] At this point, economics do not support this conversion but FEI will keep monitoring this potential opportunity.

[149] This estimate is made using a current normalized annual propane energy consumption of 212,500 GJ/year, a propane emission factor of 61 $kgCO_2e$/GJ and a natural gas emission factor of 51.5 $kgCO_2e$/GJ.

6.3.5.3 Whistler Distribution System

The Whistler distribution system is supplied by the VI Transmission System at Squamish. From Squamish, an NPS 8 pipeline operating at 2069 kPag follows the Highway 99 corridor north to Whistler. The pipeline was commissioned in 2009 and the Whistler distribution system was converted from propane to natural gas that summer, prior to the 2010 Winter Olympics. Since that time, there has been sustained growth in the community. In late 2014, a series of phased system improvements were proposed to be installed between 2015 and 2020 that would ultimately result in extending the NPS 8 2069 kPag pipeline approximately 5 km further north into the community along with another Gate Station facility to address growth. In 2016, BC Transit announced its intention to convert the Whistler transit fleet to CNG and construct a CNG fuelling facility at its existing transit site on the north side Whistler. The facility will begin operation late 2017 or early 2018. As a result of this substantial load near the northern extremities of the system, the need arose to advance the future system improvement phases from future years to the present.

The limited alignment options for the extended pipeline have been challenging and delays have resulted as FEI continues to work with the Ministry of Highways, the Resort Municipality of Whistler, BC Hydro and others to secure approval for the proposed alignment. As an interim measure, pending completion of the system upgrades, FEI and BC Transit have worked cooperatively. BC Transit has allowed the installation and operation of a portable small scale LNG peak shaving unit at the transit site to provide for peak demand requirements for the surrounding Whistler natural gas consumers as well as the initial needs of the BC Transit CNG fuelling compressors when they are commissioned in the winter of 2017-2018. FEI expects to complete the required pipeline and station facilities in 2018.

6.4 *OTHER MAJOR SYSTEM PROJECTS*

Of the capacity driven transmission system projects outlined in Section 6.2 the Okanagan Reinforcement Project is currently the only project anticipated to occur before 2022 and FEI is currently initiating Front End Engineering Design studies in anticipation of a future CPCN application. Several other significant projects that address needs other than system capacity are also under consideration for CPCN applications in the near term. While these projects are not driven by capacity, FEI strives to ensure any projects integrate effectively with system capacity requirements of each system. A brief description of each project under consideration follows:

Transmission System Laterals In-Line Inspection (ILI) Capability

FEI operates transmission pressure laterals across the province served from either FEI operated transmission systems, the Westcoast pipeline or TransCanada and ranging from several hundred meters to several tens of kilometres in length. A total of more than 400 km of these pipeline laterals are between NPS 6 and NPS 10 and currently are not configured to allow ILI tools to be used as part FEI’s pipeline integrity management programs. ILI technology is an effective tool for detecting and subsequently repairing pipeline corrosion and defects prior to leaking or rupture. FEI is currently investigating the cost and justification to install tool launching and receiving facilities and remove existing pipeline obstructions on up to thirty-one lateral pipeline segments.

Pattullo Bridge Crossing Replacement

The Pattullo Bridge currently supports a major FEI NPS 20 distribution system crossing of the Fraser River. This crossing provides nearly 15 percent of the peak hour supply to the Metro Vancouver region. It is integral to the resiliency provided by the major regional supplies at Fraser Gate in Vancouver, Coquitlam Gate in Coquitlam and the LMIPSU that will be under construction in 2018. TransLink has indicated the existing bridge will be replaced by the end of 2021 and has directed FEI to decommission the existing distribution line by the end of 2021. FEI is currently conducting the Front End Engineering Design study necessary to examine the feasibility and cost of establishing a replacement crossing or equivalent prior to decommissioning the current bridge crossing.

Southern Crossing Pipeline Class Location Project

Urban development around existing pipelines can drive changes in pipeline class location as defined in CSA Z662(15) and necessitate changes to increase pipeline safety factors. Pipeline safety factors can be increased by either:

- Decreasing pipeline operating pressures at existing or new pressure control stations; or alternatively
- Replacing the identified pipeline segment in populated areas with higher grade and/or thicker walled pipe.

Installing additional mainline valves may also be necessary in either case. Decreasing pipeline operating pressure to increase the safety factor will reduce the capacity of the pipeline. Replacing the pipeline segments with higher grade and/or thicker walled pipe can maintain operating pressures (and capacity) or allow increases. The SCP is an NPS 24 pipeline operating between Yahk and Oliver in the BC Southern Interior. The Class Location Project will address the installation of several kilometres of pipe replacement and seven new mainline valves between 2019 and 2022 to sustain established pipeline operating pressure and pipeline safety factors.

Advanced ILI on Pipelines Currently Inspected with ILI

Advanced ILI technology for pipelines that are already ILI capable is being considered by FEI, but is in the early stages of development. One advanced technology considered is Electro-Magnetic Acoustic Transducer (EMAT) ILI. EMAT technology can detect Stress Corrosion Cracking (SCC) and cracks in alignments currently not detected by traditional ILI tools. The implementation of this technology may necessitate:

- Alterations of the sending and receiving barrels to accept the newer tools;

- Alterations to the transmission pipelines so that the new tools can traverse them without hindrance or interruption to ensure successful data collection; and
- The installation of flow control equipment and/or transmission loops to facilitate the control (i.e. reduction) of the gas flow velocity in order to ensure successful data collection.

The initial scope of this activity would focus on older pipeline systems in the CTS and the ITS that currently are ILI capable already.

Bridge Crossing Seismic Upgrade Assessment – Lower Mainland

FEI Integrity Management is expanding on seismic assessment of below ground assets in the Lower Mainland region to assess system risks that include security of supply associated with pipeline crossing on third-party infrastructure. Specifically, FEI is evaluating the NPS 24 IP pipeline located on the Ironworkers Memorial Bridge, with the objective to determine if upgrades should be considered to improve the resiliency of the piping during a seismic event or whether a new underwater crossing would be more appropriate.

Reliability Upgrade to Langley Compressor Facility

The Langley compressor facility consists of two 7,400 HP units. If additional phases of Tilbury LNG expansion occur or large industrial load additions like the Woodfibre LNG Project proceed, Langley compressor units would be needed to run for periods of several days to weeks in winter periods. The current units, although they have the required horsepower, are no longer produced and supported by the manufacturer and the current units are not considered reliable for the type of sustained operation that may be required in the event that such large loads materialize on the CTS or VITS. These units would likely require replacement when such demand appears to ensure reliable performance in sustained operation.

6.5 RECOMMENDATIONS FOR SYSTEM REQUIREMENTS TO MEET GROWTH NEEDS

Sustaining FEI's existing natural gas system infrastructure and planning to meet future demand growth are undertaken to ensure that planned improvements optimize operation of the system as a whole. With annual increases in forecast peak demand and potential new sources of demand from NGT and industrial sources, the VI, CTS and ITS transmission systems could all face capacity constraints within the 20-year planning period. FEI's plans to address system capacity are to:

- Continue monitoring and studying the system capacity constraints identified to occur in 2028 on the VI Transmission System and complete the analysis of system reinforcement and load or supply reallocation alternatives;

- Identify system reinforcements that would be required to maintain system reliability and resilience for Core customers as LNG expansion or other large industrial loads are added on the CTS system;
- Continue to monitor and study the system capacity constraints identified to occur in 2022 in the Okanagan region of the ITS and complete the analysis of system reinforcement alternatives in anticipation of a CPCN application to the BCUC in the next two to three years; and
- Continue evaluating other major system projects outlined in Section 6.4 and submit CPCN applications for these projects if required.

7. STAKEHOLDER ENGAGEMENT

Connecting with customers, communities and other stakeholders on long range planning issues is of critical importance to FEI. Effective stakeholder engagement provides valuable insight that can impact the energy planning process, demand forecasting and C&EM program development, through to the development of an action plan for implementing the Company's preferred resource solutions.

When soliciting stakeholder input during the resource planning process, the BCUC's Resource Planning Guidelines encourage utilities to "focus such efforts on areas of the planning process where it will prove most useful and to choose methods that best fit their needs."[150] FEI undertook a number of initiatives to offer stakeholders the opportunity to participate in discussions to inform the 2017 LTGRP. These activities continued until the third quarter of 2017 and included:

- Workshops with the dedicated RPAG;
- Community Engagement workshops in communities served by FEI; and
- Other activities that indirectly inform the resource planning process, including dialogue with First Nations, advisory groups, industry associations and other stakeholders.

FEI considers stakeholder engagement for resource planning to be an on-going process and one element of the many stakeholder activities that the Company undertakes for a range of purposes. This section summarizes the range of stakeholder engagement initiatives leading up to the 2017 LTGRP.

7.1 *RESOURCE PLANNING ADVISORY GROUP*

The RPAG engages strategic representatives of municipalities, government, First Nations, customers, associations and organizations in the development of the LTGRP. The group consists of members with interest and experience in the resource planning process and significant industry knowledge who provide key insight and feedback to FEI. The RPAG membership includes representatives of the following entities:

- First Nations Energy and Mining Council
- BC Ministry of Energy and Mines
- Community Energy Association
- Commercial Energy Consumers Association of BC
- BC Business Council
- BCUC (as an information provider)

[150] http://www.bcuc.com/Documents/Guidelines/RPGuidelines_12-2003.pdf. p.5.

- City of Kamloops
- City of Prince George
- Greater Vancouver Board of Trade
- Union of BC Municipalities
- BC Public Interest Advocacy Centre
- City of Victoria
- BC Sustainable Energy Association
- Pembina Institute
- NWGA
- Multiple third-party utilities in the PNW

RPAG workshops provide a forum for discussing many broad themes, including but not limited to the following:

- LTGRP process, inputs and analytical results;
- Forecasting methods and results;
- FEI initiatives and expectations;
- The energy and emissions planning environment; and
- Energy and emissions policy and regulation.

FEI held three RPAG workshops between 2016 and 2017 to review key steps in the LTGRP process and to discuss inputs into and results from the 2017 LTGRP analysis. Engagement from attendees was in the form of questions and discussion throughout each presentation, as well as interactive sessions allowing for more in-depth discussion and feedback. Table 7-1 below outlines meeting dates and major topics discussed. After the first RPAG meeting on November 30, 2016, FEI fielded an online survey to the RPAG membership in order to gauge the RPAG's attitudes towards FEI's proposed forecast and scenario analysis methods. The online survey revealed RPAG support for FEI's approach.

Table 7-1: RPAG Meetings and Major Topics Covered

Meeting Date	Topics Discussed
November 30, 2016	• Annual demand forecast approach • Policy environment review • Regional gas market update • Scenario analysis process and methods • Qualitative scenario inputs and proposed scenario plotlines
April 11, 2017	• Annual demand Reference Case • Quantitative scenario inputs and preliminary annual demand results • System capacity planning methods
August 9, 2017	• NGT annual demand scenarios • DSM analysis • System requirements and options analysis • Projected portfolio natural gas delivery rate and GHG impacts

The feedback submitted by the RPAG to FEI has been useful in helping FEI to develop the 2017 LTGRP. Through the RPAG workshop sessions, stakeholders have been able to provide FEI with input on areas, such as demand forecasting and scenario analysis methods as well as annual demand drivers and scenarios. More specifically, some of the feedback and areas of stakeholder interest in the workshops included the following items:

- Distinguishing aspirational goals from specific targets in energy and emissions policy;
- Framing and clearly delimiting the annual demand scenario analysis;
- Validating the annual demand scenario analysis method and inputs;
- Considering First Nations perspectives in the 2017 LTGRP report; and
- Considering emerging information on innovative natural gas technologies, such as cellulosic biogas.

Examples of FEI's ability to benefit from and implement such feedback in the 2017 LTGRP include items, such as the following:

- Explicitly addressing innovative natural gas technologies that will help FEI to meet its customers' preferences for natural gas while also addressing societal plans for GHG emissions reductions (see Sections 2.4.2, 2.4.3, 8.2.4 and 9);
- Applying the MTRC test to forecast commercial and industrial C&EM activities in scenarios that are subject to the Accelerated outcome on the Non-Price Carbon Policy Action critical uncertainty in order to account for potential future regulatory easements

that further recognize the non-energy benefits of C&EM programs (see Section 4.2.2.2); and

- Clarifying more explicitly how FEI's Traditional Peak Method versus its exploratory peak demand forecast method relate to the scenarios established by the end-use annual demand forecast (see Section 6.2.1).

FEI also received feedback, which it considered but was unable to implement in the 2017 LTGRP. Examples of such feedback include the following items:

- Including a Resource Planning Objective in Section 1 of the 2017 LTGRP that specifically addresses cost effective GHG emissions reductions. FEI considered this item and concluded that this objective is implicit in its existing objective *Ensure consistency with provincial energy objectives* (see Section 1.3.3).
- Showing up to ten years of historical data in all charts to provide more context to the forecast data. FEI considered this item and concluded that including such additional data would render charts too dense in the printed version of the 2017 LTGRP.

As resource planning is an iterative and on-going process, some of the feedback and recommendations received from the RPAG during this planning period will also be considered by FEI in the next iteration of the resource planning process.

7.2 COMMUNITY ENGAGEMENT WORKSHOPS

FEI recognizes the importance of considering diverse community perspectives when planning for the future, and has established resource planning Community Engagement workshops to gather feedback from stakeholders throughout FEI's service territories. Individuals involved in a variety of roles are invited to attend these ongoing events, including:

- Community planners/developers;
- Energy and sustainability managers and professionals;
- First Nations representatives;
- Municipal community leaders;
- Energy and sustainability non-profit organizations;
- Real estate builders and developers;
- Large businesses/manufacturers;
- Local businesses and business associations; and
- Other interested parties.

FEI hosted nine Community Engagement workshops until the end of May 2017 in communities across BC, with over 50 registrants.[151] These workshops sought input on a variety of topics related to resource planning, including distribution and safety, demand forecasting, the impact of evolving energy technologies and uncertain energy and emissions policy. FEI presented plans to meet the future needs of customers and communities, and discussed issues affecting energy supply and demand, along with other initiatives to help meet future energy needs such as DSM, RNG, and NGT.

Themes consistently identified by stakeholders included:

- Programs to help customers and communities manage energy costs and emissions, such as C&EM, RNG and NGT;
- Energy affordability considerations;
- Natural gas and carbon pricing trends;
- Finding solutions to reduce GHG emissions.
- Emerging natural gas technologies, such as cellulosic biogas;
- New FortisBC Alternative Energy Services offerings such as district energy systems;
- Advanced metering and billing options; and
- Coordinating activities between utilities and municipalities.

Overall, the 2017 LTGRP Community Engagement workshops facilitated the sharing of valuable long term planning information between stakeholders and FEI. In particular, the workshops assisted FEI in identifying energy issues or planning opportunities in municipalities throughout BC. Stakeholders appreciated the opportunity to learn about FEI's initiatives and energy issues in BC, speak directly with FEI staff in an open and consultative format, and offer feedback on how the Company is addressing the challenges that impact its customers. Attendees gave positive feedback on the workshop evaluation forms and stated that they found the workshops both valuable and informative. The workshop discussions were robust and customer-focused, and they demonstrated that FEI's long term planning considerations align well with stakeholder expectations.

7.3 OTHER ENGAGEMENT ACTIVITIES

7.3.1 Dialogue and Engagement with First Nations

FEI is a leader in developing and building mutually beneficial working relationships with First Nations communities. Understanding, respect, open communication and trust continue to be FEI's aim when working with First Nations groups throughout the province.

[151] Penticton, Rossland, Cranbrook, Kamloops, Prince George, Abbotsford, New Westminster, Colwood, Courtenay.

FEI works to ensure that First Nations' interests are represented in the Company's various advisory groups. The RPAG and Energy Efficiency and Conservation Advisory Group (EECAG) both include members that represent BC First Nations, which ensures that First Nations play an active role in the ongoing resource planning process. In addition, First Nations have participated in Community Engagement workshops throughout the preparation of this 2017 LTGRP.

FEI's Statement of Aboriginal Principles[152] ensures the Company's business operations are conducted with respect for social, economic and cultural interests. One of these principles declares FEI's commitment to dialogue through clear and open communication with Aboriginal communities on an ongoing and timely basis for the mutual interest and benefit of both parties. To meet this objective, FEI aims to establish an open dialogue with First Nations at the earliest planning stages to ensure that First Nations engagement and accommodation requirements are met. For example, FEI, when entering into talks regarding its EGP Project, was made aware that the Squamish Nation had developed its own project assessment process that would be independent of the existing government environmental assessment process. The objective of that assessment process was to provide the Squamish Nation with the ability to make an informed decision on a proposed project based on information the Squamish Nation had gathered and an opportunity to have government to government discussions to make a shared decision with the Crown on a proposed project. FEI sought to work with the Squamish Nation and provided necessary funding and support for what is now called the Squamish Process. As a result of the process, FEI proposed a number of changes to the project, including a new location for a compressor station, re-routing around culturally sensitive sites, and a construction methodology which would avoid surface disturbance in the Skwelwil'em Squamish Estuary Wildlife Management Area. The Squamish Nation Chiefs and Council voted to approve the project, with a set of conditions, in June 2016 and the BC Government issued an Environmental Assessment Certificate for the project in August 2016.

The importance of engaging First Nations "early and often" has been reiterated by First Nations representatives throughout FEI's 2017 LTGRP engagement activities. FEI strives to engage First Nations in its projects early and often. As part of its long term resource planning Community Engagement activities, FEI was invited by a First Nation in the BC Interior to present on its integrated resource planning process and activities. FEI conducted a half-day workshop which included an outlook on potential FEI projects in the region. During the workshop, the First Nation voiced feedback on two issues: (1) a concern about the cost and affordability of space heating in regions that do not have access to natural gas, combined with support for making available natural gas service to First Nations, and (2) support for C&EM programs that facilitate First Nations to upgrade the energy performance of existing buildings or to construct energy efficient new buildings.

[152] Appendix D-29: https://www.fortisbc.com/About/OurCommitments/AboriginalRelations/Pages/Statement-of-Principles.aspx.

7.3.2 BC CPR Technical Advisory Committee (TAC)

The BC CPR informed the 2017 LTGRP's C&EM analysis. FEI, in collaboration with the other BC utilities that co-founded the CPR (please see Section 4.2.1 for details), established a Technical Advisory Committee (TAC) for the BC CPR. The BC CPR TAC is a group of knowledgeable members of the public with significant interest, stake, and experience in determining energy conservation potential in BC and provided technical advice and feedback during the development of the BC CPR.

7.3.3 Industry and Market Involvement

FEI meets regularly with industry associations and other organizations such as the Canadian Home Builders' Association (CHBA), Quality Urban Energy Systems of Tomorrow (QUEST), the Urban Development Institute (UDI) and the Union of British Columbia Municipalities (UBCM) in order to share information and insight. This dialogue is mutually beneficial as it allows FEI to stay abreast of industry trends and developments while facilitating the distribution of important information to stakeholders.

FEI's involvement with such organizations allows the Company to develop a more comprehensive picture of how the energy market is evolving. Participating in conferences, workshops and other engagement opportunities with these organizations has helped to position FEI as a leader in the marketplace, strengthen the Company's credibility, and generate a number of business opportunities.

7.4 *CONCLUSION AND RECOMMENDATIONS*

FEI has a strong record of conducting effective stakeholder engagement activities. Continuing its practice from the 2014 LTRP, FEI has consulted a dedicated RPAG and hosted a number of Community Engagement workshops to engage diverse perspectives on FEI's planning activities across the communities that the Company servers.

These initiatives adhere to the stakeholder engagement considerations contained in the BCUC's Resource Planning Guidelines and continue to be beneficial to the development of FEI's LTGRPs. The information gained through these activities inform FEI's market research and analysis, identifying long term planning issues of concern to a number of stakeholder groups, and identifying interested stakeholders who may become more engaged in the LTGRP process.

FEI recommends continuing with the RPAG and community engagement activities in order to build on the successful interest and input obtained through these initiatives. FEI will also continue to assess the success of these activities and make enhancements as needed based on the feedback received.

8. 20-YEAR VISION FOR FEI

The BCUC's decision regarding the 2010 LTRP included a requirement for the 2014 LTRP to describe a vision of FEI in 20 years:

> …pursuant to section 44.1(2)(g) of the UCA the Panel directs the following be included in the next LTRP: 1. [FEU] – A 20 Year Vision. This vision could describe what [the FEU] may look like in the future: its business lines, its customers, the expectations for supply and demand and the major issues it will deal with over the 20 year resource plan timeframe.[153]

The directive lists a number of areas appropriate to be covered in the 20-year vision. Following the approach of the 2014 LTRP, this section of the 2017 LTGRP presents a brief description of FEI's long term vision along with the following:

- The contextual background that in part defines FEI's 20-year vision for the LTGRP in response to this directive;
- The challenges inherent in defining a 20-year vision and the limitations thereof; and
- Those components of a 20-year vision as listed by the BCUC within their directive and for which information is available for FEI to include.

FEI's long term vision is to be BC's trusted energy provider for safe, reliable and cost effective natural gas delivery services to its customers, and to be a healthy, growing contributor to the BC economy and to the well-being of communities in BC. FEI has examined a broad range of future potential conditions under which it must realize this vision. Since the likelihood of correctly predicting the future is low, FEI's approach has been to identify a set of resources to acquire that will meet the range of analyzed potential futures rather than to attempt to predict a most likely future and plan only to that future. Sustainability represents a key component of this vision and FEI considers all three pillars of this concept: social, environmental, and economic sustainability. As such, Section 8 addresses how new technologies and market transformation may impact FEI's operating environment (Sections 8.2, 8.4, and 8.7), how FEI's forecast natural gas demand and activities may impact customer rates and average bills (Section 8.6) and how FEI's activities will impact GHG emissions and BC's energy objectives (Section 8.3).

8.1 *CONTEXT AND LIMITATIONS FOR FEI'S LONG TERM VISION*

The BCUC's directive to include a 20-year vision in the 2010 LTRP was issued at a time when FEI was developing service initiatives to provide low carbon thermal energy solutions complimentary to the Company's natural gas services. Since that time, the Commission has undertaken a review of the regulation of low carbon thermal energy solutions and determined that thermal energy projects not exempt from regulation are "most appropriately undertaken

[153] Terasen Utilities 2010 Long Term Resource Plan, BCUC Decision, February 1, 2011.

through an Affiliated Regulated Business".[154] As a result, some items that the Commission contemplated for the 20-year vision are no longer appropriate for FEI's 2017 LTGRP. For example, FEI's consideration of low carbon thermal energy services is limited to the potential impact that such services provided by other parties may have on demand for natural gas, rather than being included as a new initiative undertaken by FEI.

Another important limitation to describing FEI's long term vision is the degree of detail that can be included. The Commission's directive was made at a time when the outlook for natural gas supply resources and long term gas price forecasts was different than it is today. The 20-year vision directive does not appear to have contemplated the government's shift in emphasis to the development of natural gas resources and a provincial LNG strategy, for exports, economic development, job creation and global emission reductions. As outlined in Section 2, FEI has developed the current 2017 LTGRP within a planning environment that is characterized by continued high policy uncertainty. A long term vision thus cannot be made so specific that it does not allow for changes in the planning environment.

Like the 2014 LTRP, the 2017 LTGRP has attempted to address the items outlined by the Commission for inclusion in its 20-year vision without being so specific that it quickly becomes outdated as changes in the planning environment occur. The remainder of this section discusses how the 2017 LTGRP has addressed the following items:

- Market transformation;
- The relationship between GHG reductions and demand and FEI's forecasted contribution to BC's GHG reduction targets;
- The potential impact of new technologies and market conditions on demand for natural gas;
- FEI's new initiatives;
- BC's energy objectives;
- The impact of long term demand variations on customer rates; and
- Key drivers impacting the need for resources.

8.2 *MARKET TRANSFORMATION*

The 2017 LTGRP incorporates analysis of four areas which FEI will discuss in this section: (1) transformation of the market for natural gas as a transportation fuel, (2) market transformation of C&EM technology that is inherent in the DSM analysis (please see Section 4), (3) a range of assumptions about how much low carbon thermal energy demand might replace natural gas demand in the alternate future scenarios, and (4) a range of assumptions about how FEI may use RNG and other innovative technologies to help meet market preferences while also supporting BC energy objectives.

[154] BCUC AES Inquiry Report. December 2012.

8.2.1 NGT

Section 3.4.7 discusses the impact of varying levels of NGT market transformation on customer demand for natural gas over the 20-year planning period. This section splits the analysis into CNG and LNG demand. FEI assumes a range from one to 15 percent CNG market capture in the relevant transportation market sectors by 2036. While capturing 15 percent of the applicable CNG market is reasonably possible, FEI's Reference Case demand forecast uses a more modest 4 percent market capture rate by 2036. FEI's LNG demand forecast ranges between adding a low amount of 13 million GJ only to adding a high amount of more than 500 million GJ over the planning period. While adding more than 500 million GJ over 20 years is reasonably plausible by transforming energy use in the marine market, FEI's Reference Case uses a more moderate LNG demand forecast, which assumes only 5 percent additional annual growth beyond 2028 and adds approximately 78 million GJ of annual demand by the end of the planning horizon.

Section 6.3 analyses and discusses the impact on FEI's infrastructure needs of these alternate NGT adoption scenarios.

8.2.2 C&EM Technologies

Section 4 of this 2017 LTGRP addresses the annual demand impact of C&EM technology (Figure 4-1 summarizes this impact). Sections 6.2 and 6.3 discuss the impact on system resources of such technologies.

Although FEI has not identified the extent of market transformation that will occur for each measure or technology via specific C&EM programs, the analysis results do represent an estimate of the amount of energy efficiency that can be achieved by the Company over the planning horizon.

8.2.3 Low Carbon Thermal Energy

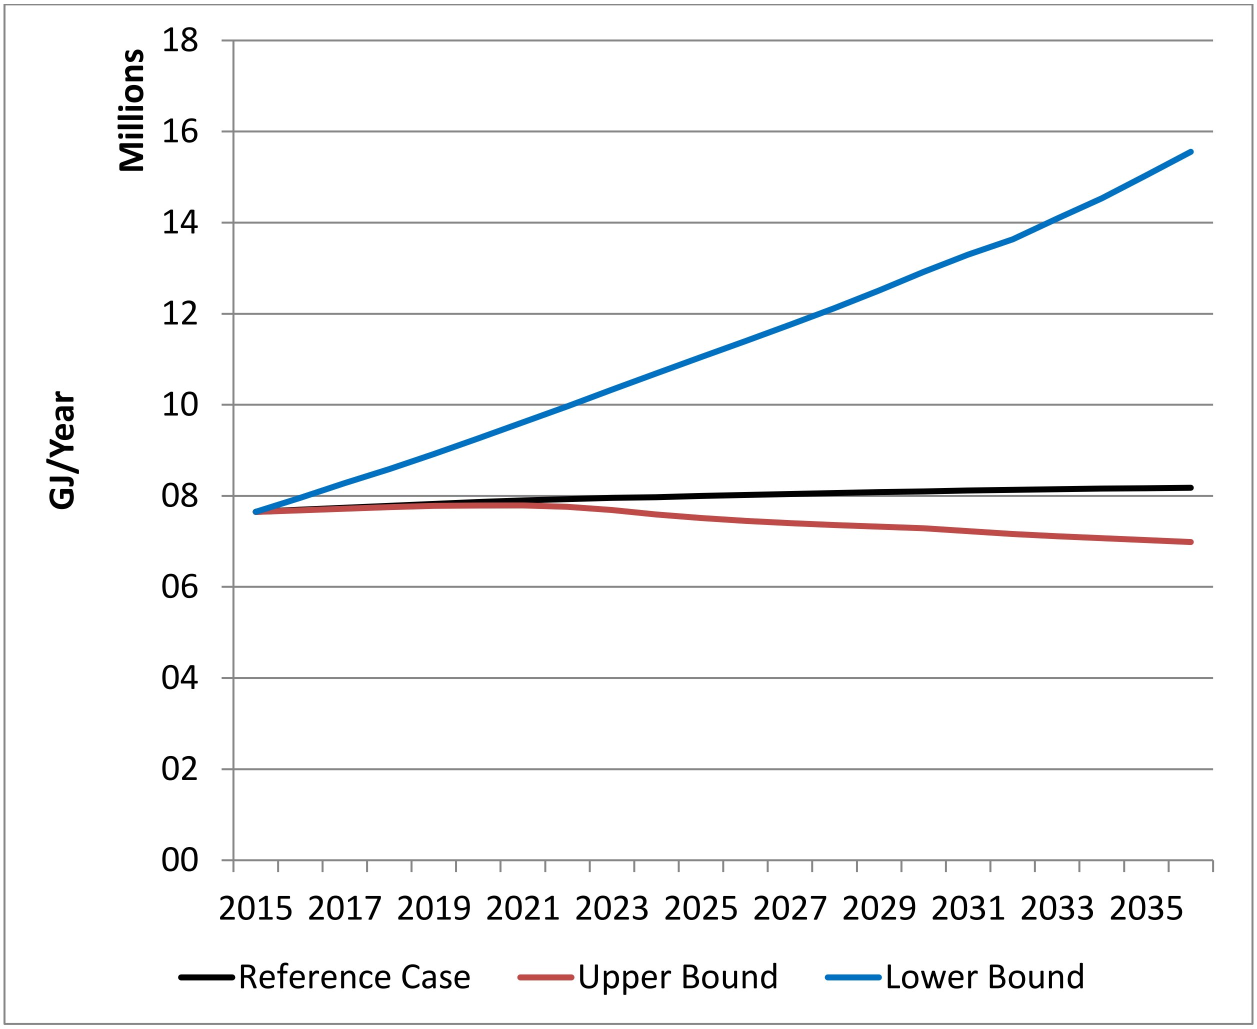
Low carbon thermal energy solutions such as geo-exchange systems, waste heat recovery systems and solar thermal systems can displace both existing and future expected demand for natural gas. While FEI does not offer these services to its customers, the potential for other third party service providers to do so creates a risk to FEI's annual demand profile and thus to the Company's revenue expectations. The 2017 LTGRP has addressed this risk by including varying levels of displacement of natural gas demand by low carbon thermal technologies in its alternate future scenarios (presented in Section 3 and Appendix B-1). The highest level of displacement is included in the lowest natural gas demand scenario (Lower Bound) while the lowest level of displacement is included in the highest natural gas demand scenario (Upper Bound).

Figure 8-1 below illustrates the low carbon thermal energy demand profile for the Reference Case as well as the Upper and Lower Bound scenarios over the next 20 years. In the Reference Case, low carbon thermal energy demand grows by seven percent over the planning period. In the Upper Bound scenario, this growth switches to a decline of nine percent. In the Lower

Bound scenario, low carbon thermal energy demand grows significantly and displaces eight percent of 2015 base year natural gas demand by 2036. The 2017 LTGRP annual demand forecast assumes that any fuel switching away from natural gas that is not absorbed by RNG or low carbon thermal energy will result in increased electricity demand. A complete analysis of the impacts of this potential increased demand for electricity is an important consideration, but is outside the scope of this LTGRP. While this shift may not appear significant in terms of market transformation, it is an important trend for FEI to monitor and address as it represents a risk to the demand and revenues from the Company's customers. Please see Appendix B-1 for the scenario analysis input assumptions that inform this forecast behavior.

This highlights the need for FEI to invest in other load building initiatives such as NGT and to support development of its RNG program and other technologies that enable FEI to meet market preferences while also helping to meet BC energy objectives. With today's limited but growing market penetration of low carbon thermal energy systems, FEI will continue to monitor thermal energy demand in order to gauge its impact over time on the Company's natural gas load and system capacity.

Figure 8-1: Low Carbon Thermal Annual Demand



8.2.4 RNG and other Innovative Natural Gas Technologies

Section 3.4.6 discusses the annual demand impact of RNG across the 2017 LTGRP's alternate future scenarios. Even FEI's high assumption of RNG demand results in RNG accounting for a small proportion of FEI's total annual demand (less than three million GJ, compared to a maximum allowance of approximately 8.9 million GJ under the GGRR, as discussed in Section 2.3.3.4) by the end of the planning horizon. However, this analysis assumes current RNG supply technologies. If cellulosic biogas technologies become commercially scalable at reasonable cost, RNG demand may account for a significant share of FEI's demand within 20 years.

Similarly, other technologies exist that may decarbonize the natural gas stream and enable the natural gas infrastructure to store electric energy (indirectly by injecting into the pipeline system hydrogen derived via electrolysis), decarbonize natural gas end-use appliances or increase beyond 100 percent the efficiency of natural gas appliances. Section 2.4.3 outlines how FEI is monitoring and, where applicable, supporting the evolution of such technologies. If such technologies become commercially scalable at reasonable cost, they may mitigate policy-driven risks of downward pressure on natural gas demand (identified in Section 2) and create an investment opportunity for the Company. As such, FEI, its customers, and the public would benefit from FEI having access to a funding envelope that FEI can use to monitor, and where applicable, support such innovative natural gas technologies. FEI's 2017 LTGRP stakeholder engagement activities suggest that stakeholders support FEI monitoring and, where appropriate, supporting such technologies.

8.3 *GHG EMISSIONS FORECASTS*

The BCUC has requested FEI to discuss the relationship between demand and GHG emissions within its 20-year vision. The BCUC also identified as part of a 20-year vision a discussion of FEI's contribution to BC's GHG targets. Outlined in Part 1(2) of the province's CEA, BC's energy objectives include taking demand side measures to conserve energy, encouraging efficient energy use, fostering the development in BC of innovative technologies that support energy conservation and efficiency, encouraging switching from one kind of energy to another that decreases provincial GHG emissions, and reducing BC's GHG emissions. FEI's C&EM activities, NGT initiative, RNG offering and Connect to Gas Program are all important activities that help to meet these goals. FEI notes that BC's current energy objectives apply to the province as a whole and do not identify any sector-specific allocations.

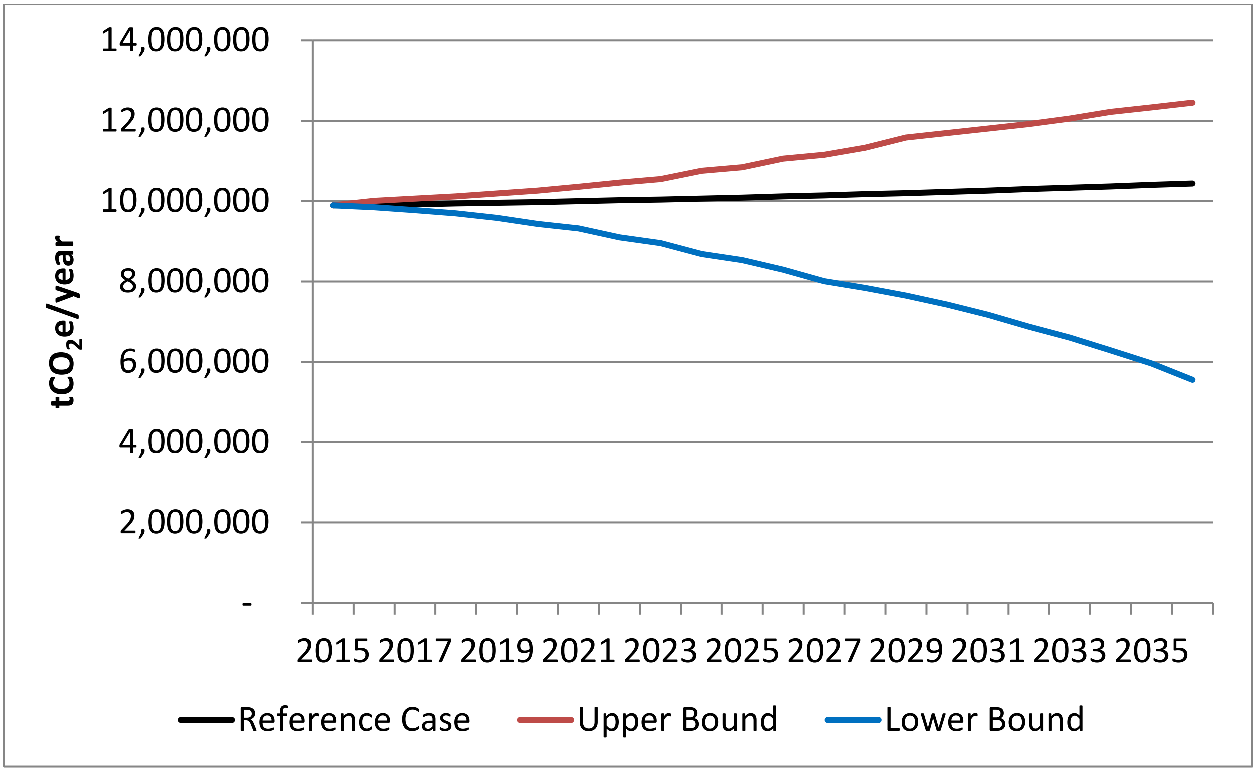
Section 8.3.1 below discusses the relationship between GHG emissions and annual demand while Section 8.3.2 outlines FEI's forecast contributions to BC's GHG emissions targets.

8.3.1 Relationship between GHG Emissions and Annual Demand

Natural gas is the cleanest, lowest GHG-emitting fossil fuel. The 2017 LTGRP's GHG emissions analysis simply details the CO_2 equivalent emissions in metric tonnes of FEI's customers combusting natural gas. As such, the 2017 LTGRP's GHG emissions reduction analysis does not quantify impacts of GHG-reducing upstream initiatives, such as electrifying natural gas extraction and processing facilities or implementing methane leakage controls in extraction, processing, and storage facilities. Potential implementation of a renewable portfolio standard would likely also cause downward pressure on GHG emissions from natural gas while presenting a risk of upward pressure on natural gas commodity costs. As outlined in Appendix B-1, the 2017 LTGRP scenario analysis uses a range of natural gas and carbon prices to encapsulate possible price fluctuations.

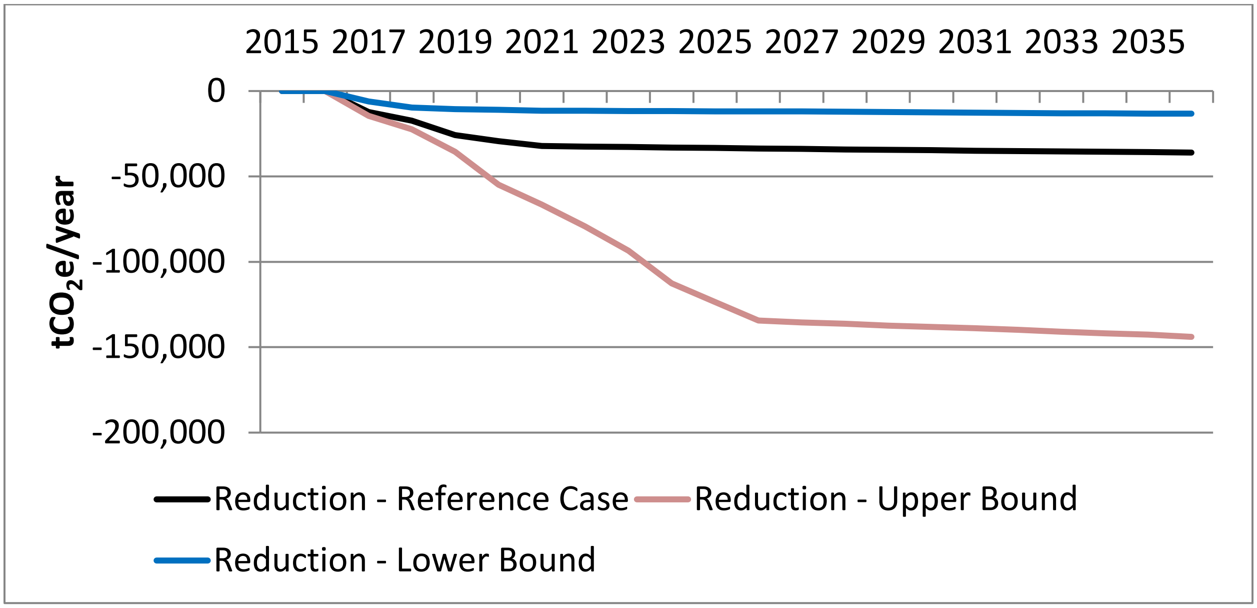
Figure 8-2 below illustrates the emissions of FEI's residential, commercial, and industrial customers without considering the emissions impacts of FEI's NGT, RNG, and C&EM initiatives. In the Reference Case, emissions grow by five percent across the forecast horizon. In the Upper Bound scenario emissions grow by 26 percent, whereas Lower Bound emissions decrease by 44 percent across the planning horizon.

Figure 8-2: Annual GHG Emissions of Residential, Commercial, Industrial Customers (metric tonnes) – Excluding NGT, RNG, and C&EM



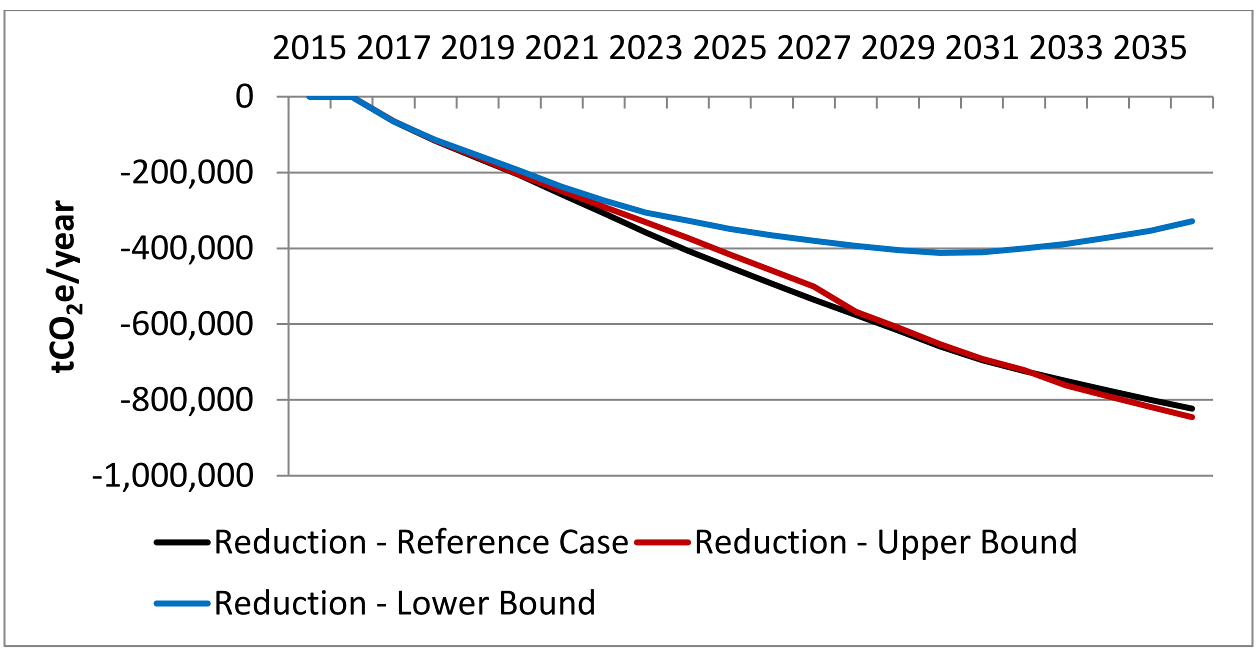
FEI's RNG initiative reduces GHG emissions because the initiative displaces the combustion of fossil natural gas with the combustion of RNG sourced from biomass (biomass decomposition emissions are considered part of the natural carbon cycle). Figure 8-3 below illustrates these forecast emissions reductions. FEI's method for determining emissions reductions from its RNG initiative is conservative because it does not account for avoided landfill methane emissions that are diverted as a result of the initiative. For example, a portion of organic waste that would normally be placed in landfills is being diverted to digesters. The methane that would have been created in the landfill would not normally be fully captured because landfills typically only capture between approximately 50 and 75 percent of their methane production. In contrast, an RNG digester captures approximately 100 percent. Based on using a calculated capture of 50 to 75 percent of methane at landfills versus approximately 100 percent at a digester, this could result in approximately 6 to 12 times additional avoided GHG emissions that FEI does not use in its calculated emission reductions. In the Reference Case, the 2036 RNG forecast result accounts for an emissions reduction of 0.4 percent over the 2036 emissions presented in Figure 8-2 (above). This value changes to 1.5 percent and 0.1 percent for the Upper and Lower Bound scenarios, respectively.

Figure 8-3: Annual GHG Emissions Reductions of RNG Customers Only (metric tonnes)



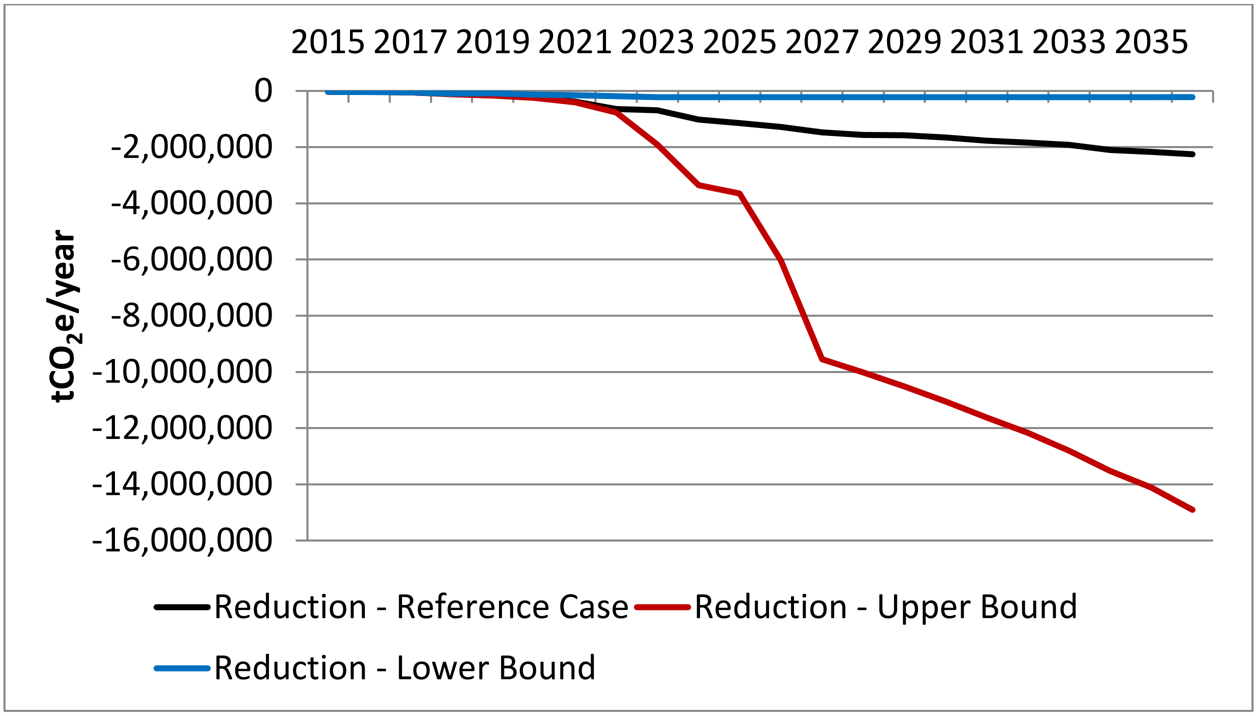
C&EM program participants generate emissions reductions because they effectively eliminate a portion of their pre-participation natural gas demand. Figure 8-4 below illustrates these forecast emissions reductions. In the Reference Case, FEI's 2036 C&EM forecast result accounts for an emissions reduction of 8.3 percent over the 2036 emissions presented in Figure 8-2 (above). This value changes to 8.5 percent and 3.3 percent for the Upper and Lower Bound scenarios, respectively.

Figure 8-4: Annual GHG Emissions Reductions of C&EM Program Participants Only (metric tonnes)



FEI's NGT customers generate emissions reductions because they use natural gas to displace consumption of higher-emitting fossil fuels. As such, NGT emissions reductions are a function of the NGT annual demand forecast presented in Figure 3-16 and the difference in emissions intensity between the incumbent fuels and natural gas. Figure 8-5 below illustrates these forecast emissions reductions. In the Reference Case, FEI's 2036 NGT forecast result accounts for an emissions reduction of 22.5 percent over the 2036 emissions in Figure 8-2 (above). This value changes to 150.7 percent and 2.0 percent for the Upper and Lower Bound scenarios, respectively.[155]

Figure 8-5: Annual GHG Emissions Reductions of NGT Customers Only (metric tonnes)

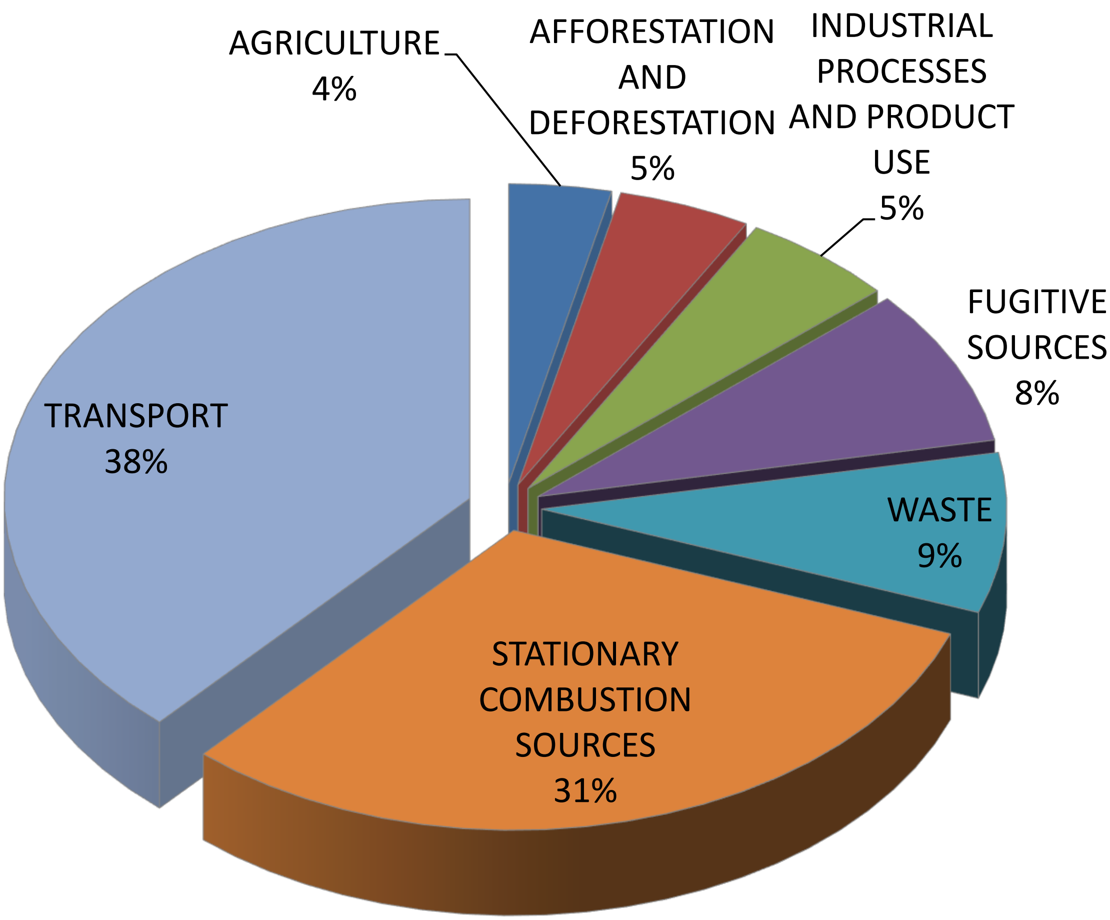


8.3.2 FEI's Contributions to BC's GHG Emissions Targets

To provide context, Figure 8-6 below illustrates BC's 2014 GHG emissions (64.5 million metric tonnes of CO_2 equivalent) by category. Transport accounts for more than one third of 2014 emissions.

155 NGT emissions reduction factors are sourced from GHGenius. RNG and C&EM emissions factors are sourced from the BC Ministry of Environment & Climate Change Strategy.

Figure 8-6: 2014 BC GHG Emissions[156]



The combined impact of FEI's forecast RNG and C&EM emissions reductions (illustrated individually in Figures 8-3 and 8-4 above) results in 2036 Reference Case emissions declining by three percent in relation to the 2015 base year. The Upper Bound scenario changes this figure to 16 percent growth. The Lower Bound scenario displays a 47 percent decline. In the Reference Case, forecast 2036 NGT emissions reductions (illustrated in Figure 8-5 above) amount to 2.3 million metric tonnes. This figure changes to 14.9 million metric tonnes in the Upper Bound and 0.2 million metric tonnes in the Lower Bound scenarios, respectively. Overall, these GHG emissions reductions occur in the Transport, Stationary Combustion Sources, and Industrial Processes and Product Use categories of Figure 8-6.

156 FEI from 2014 BC GHG Inventory Report. Climate Action Secretariat.

Some forecast NGT emissions reductions are realized outside the current boundaries of the BC emissions inventory. This most impacts the Upper Bound which includes internationally travelling vessels whose energy demand accounts for the majority of NGT annual demand in the Upper Bound scenario. Since climate change represents a global challenge, all emissions reductions outlined in Section 8.3.1 above contribute to addressing this challenge no matter where such reductions occur.

In order to show how forecast emissions reductions from FEI activities compare to BC's GHG emissions reduction goals, FEI used a linear regression to calculate targeted province-wide 2036 emissions levels from BC's 2014 reported province-wide emissions, the percentage emissions reductions target from the Government of Canada's 2017 Nationally Determined Contribution under the Paris Agreement (reducing GHG emissions by 30 percent from 2005 until 2030), and BC's legislated sector-agnostic 2050 emissions reduction target. FEI received stakeholder support for using the Government of Canada's 2030 percentage reduction target as a reasonable alternative to the GGRA's 2020 target as an interim step towards the GGRA's ultimate 2050 target. Based on this calculation, BC would have to reduce its 64.4 million metric tons of 2014 CO_2 equivalent emissions by 29.3 million metric tons by 2036 (a reduction of approximately 45 percent). Applying the same calculation to the BC CLP suggests that the Plan accounts for 25 million metric tons of emissions reductions by 2036 (a reduction of approximately 35 percent).

Table 8-1 below compares 2036 emissions reductions of FEI's initiatives with the calculated 2036 emissions reductions target.[157]

Table 8-1: Comparison of FEI's Emissions Reduction Activities with the Calculated Emissions Reduction Target

GHG Reductions Required to Meet the Calculated 2036 Target ($MtCO_2e$, 2014 Base)	Forecast Emissions Reductions in 2036 ($MtCO_2e$, 2015 Base)		
29.3	**Reference Case**	**Upper Bound**	**Lower Bound**
RNG	0.04	0.14	0.01
C&EM	0.8	0.8	0.3
NGT	2.3	14.9	0.2

Notes:
Some forecast NGT emissions reductions are realized outside the current boundaries of the BC emissions inventory.

[157] FEI's RNG, C&EM and NGT initiatives each have their own merits and run under separate regulatory approval processes.

As part of developing its long term vision and given current trends in the discourse on energy use and emissions policy (see Section 2.3), FEI examined potential pathways through which emerging initiatives and technologies could help FEI lead efforts to pursue long term GHG emissions abatement in each of the economic categories that FEI's activities can address. Please see Appendix E for this examination. Stakeholders have supported including this examination in order to better illustrate that pathways to a lower carbon future do exist that include, and may be better enabled by, the use of natural gas and natural gas infrastructure.

8.4 POTENTIAL IMPACT OF NEW TECHNOLOGIES AND MARKET CONDITIONS ON DEMAND

FEI has incorporated a range of annual demand end-use forecast scenarios for commercial, residential and industrial demand discussed in Section 3.4.4. FEI does not attempt to specify what technology innovations or market changes occurred in each scenario, as the purpose of the end-use forecasting method is to model a range of directional impacts on demand that could be caused by changing market trends, policies or technologies. The Company further examines the impact of market and technology trends favorable for natural gas use by modelling the impact of NGT demand on total annual demand in Section 3.4.8 and the impact of potential large new industrial demand in Section 3.4.9. Section 3.4.6 discusses the impact on annual demand of FEI's RNG initiative.

The impact of new technologies on peak demand is discussed in Section 6.2.

The end-use forecasting method has also provided the opportunity for FEI to examine technology and market trends that result in declining annual demand (see Figure 3-8 for the full range of annual demand forecasts). The Company believes that this range of forecasts from declining demand to demand growth—largely from transportation and industrial customers—represents a reasonable range of potential future demand scenarios for which to plan over the next 20 years.

8.5 BC'S ENERGY OBJECTIVES

Section 2 of BC's CEA outlines 16 energy objectives for the Province. Of those, three are directed specifically at BC Hydro and a number of others are related specifically to electricity resources and are not applicable to the natural gas services offered by FEI. The discussion below outlines how the 2017 LTGRP has addressed the remaining BC energy objectives.

ENERGY OBJECTIVE (B) TO TAKE DEMAND-SIDE MEASURES AND TO CONSERVE ENERGY:

Section 4.2 of the 2017 LTGRP discusses the analysis of potential C&EM measures and Section 4.2.4 sets out a plan for implementing C&EM activity that will reduce demand for natural gas during the planning period.

ENERGY OBJECTIVE (D) TO USE AND FOSTER THE DEVELOPMENT IN BRITISH COLUMBIA OF INNOVATIVE TECHNOLOGIES THAT SUPPORT ENERGY CONSERVATION AND EFFICIENCY AND THE USE OF CLEAN OR RENEWABLE RESOURCES:

FEI's existing C&EM programs contain an innovative technologies component. Technology evaluation results from this component have informed the BC CPR and thus the 2017 LTGRP DSM analysis. As such, the 2017 LTGRP DSM analysis contains some innovative technologies, such as smart learning thermostats. Section 4.2 of the 2017 LTGRP discusses the analysis of potential C&EM measures and Section 4.2.4 sets out a plan for implementing C&EM activity that will reduce demand for natural gas during the planning period.

The 2017 LTGRP discusses FEI's NGT initiative (Section 2.4.1) which fosters technology adoption to meet the needs of FEI customers while increasing annual and peak demand (Section 3.4.7 and 6.3) but putting downward pressure on the Company's customers' GHG emissions (Section 8.3) and FEI's long term rate projections (Section 8.6).

ENERGY OBJECTIVE (G) TO REDUCE GREENHOUSE GAS EMISSIONS:

Section 8.3 quantifies the extent to which FEI's RNG, C&EM, and NGT activities can reduce GHG emissions under alternate future scenarios. FEI notes that BC's current legislated GHG emissions reductions targets are not sector-specific.

ENERGY OBJECTIVE (H) TO ENCOURAGE SWITCHING FROM ONE KIND OF ENERGY SOURCE OR USE TO ANOTHER THAT DECREASES GREENHOUSE GAS EMISSIONS IN BRITISH COLUMBIA:

FEI's Connect to Gas and NGT initiatives are each an example of fuel switching initiatives that move customers from higher to lower GHG-emitting fuels and are discussed as ongoing initiatives that have been considered in the development of the 2017 LTGRP. Of these, the NGT initiative has the highest potential for GHG emission reductions as shown in Section 8.3.

ENERGY OBJECTIVE (I) TO ENCOURAGE COMMUNITIES TO REDUCE GREENHOUSE GAS EMISSIONS AND USE ENERGY EFFICIENTLY:

The 2017 LTGRP DSM analysis contains activities that encourage communities to reduce GHG emissions and use energy efficiently. Section 4 of the 2017 LTGRP discusses the analysis of potential DSM activities and Section 4.2.4 sets out a plan for implementing C&EM activity that will reduce demand for natural gas during the planning period. The analysis projects FEI's C&EM programs to increase by two thirds near the middle of the planning horizon.

ENERGY OBJECTIVE (J) TO REDUCE WASTE BY ENCOURAGING THE USE OF WASTE HEAT, BIOGAS AND BIOMASS:

FEI's RNG offering is designed to encourage the collection of biogas from organic waste sources in BC. The RNG offering is discussed in Section 2.4.2 with the annual demand outlook presented in Section 3.4.6.

ENERGY OBJECTIVE (K) TO ENCOURAGE ECONOMIC DEVELOPMENT AND THE CREATION AND RETENTION OF JOBS:

FEI has an important role to play in this objective by remaining a healthy, growing contributor to BC's economy and to the well-being of BC communities as described in the long term vision presented in the introduction to Section 8. Capital investments from projects identified in Section 6 as solutions to capacity constraints or system sustainment requirements will contribute to BC's economy and the communities in which FEI operates. Further, FEI's C&EM activities have been shown to have economic and job creation benefits in addition to energy and emission reduction benefits.[158]

ENERGY OBJECTIVE (N) TO BE A NET EXPORTER OF ELECTRICITY FROM CLEAN OR RENEWABLE RESOURCES WITH THE INTENTION OF BENEFITING ALL BRITISH COLUMBIANS AND REDUCING GREENHOUSE GAS EMISSIONS IN REGIONS IN WHICH BRITISH COLUMBIA TRADES ELECTRICITY WHILE PROTECTING THE INTERESTS OF PERSONS WHO RECEIVE OR MAY RECEIVE SERVICE IN BRITISH COLUMBIA):

By continuing to serve BC's thermal energy needs with natural gas, FEI will help to curb increases in electricity demand that would otherwise be caused by gas-to-electric fuel switching in either new or existing buildings. While this electric load avoidance would not eliminate emissions in BC, it would preserve more of BC's clean electricity for potential export to other jurisdictions within the electricity trading region. Such electricity exports could economically benefit British Columbians and may result in greater emissions reductions by displacing coal or natural gas fired electricity generation currently in use in those jurisdictions.[159] At the same time and as discussed in Section 8.2.4, progress is being made on technologies and initiatives that will help to decarbonize the natural gas that does directly serve thermal energy end uses in BC. Continuing to serve BC's thermal energy needs with natural gas helps to maintain BC's natural gas infrastructure which may enable BC to capitalize on future low carbon energy opportunities, such as cellulosic biogas or power-to-gas (see Sections 2.4.2 and 2.4.3).

8.6 *IMPACT OF LONG TERM DEMAND ON PROJECTED CUSTOMER DELIVERY RATES*

One of FEI's central objectives is to provide customers with cost effective delivery service.

Customer demand can have a significant effect on delivery rates as increasing natural gas demand has a downward impact on delivery rates for all customers, all else being equal. As such, the Company aims to increase system efficiency and optimize infrastructure use by maintaining sufficient throughput on FEI's distribution system.

---

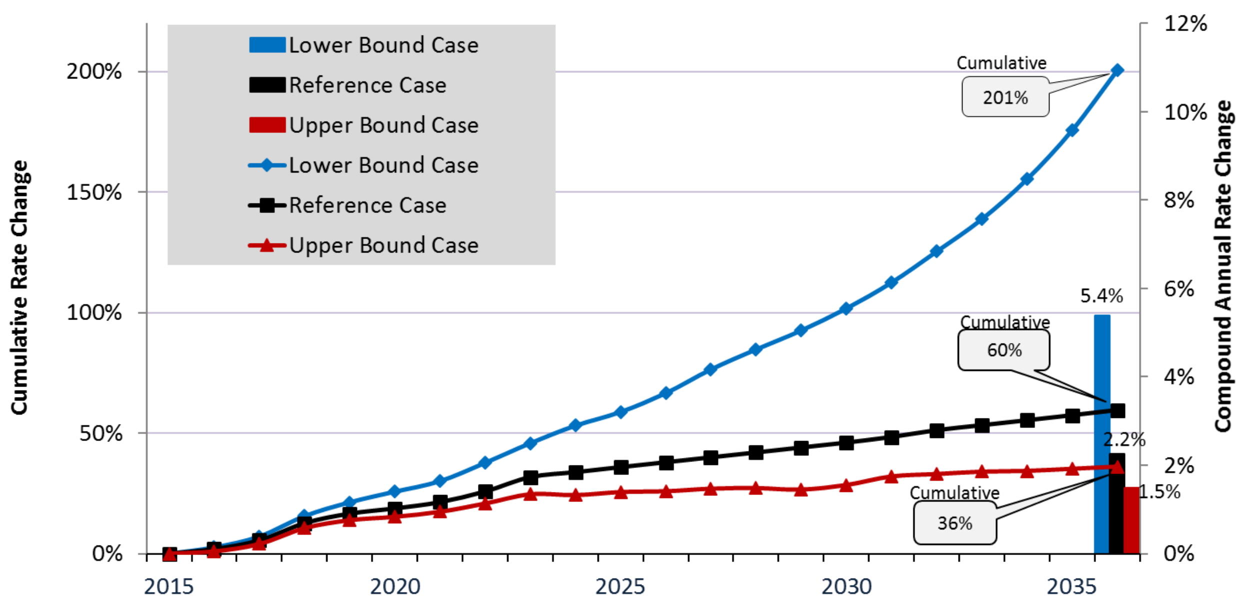
158 ICF Marbek (May 2011). Conservation Potential Review 2010 FortisBC. "Impact of CPR-2010 Natural Gas Savings on the BC Economy (2010-2030)".

159 Using natural gas directly to meet thermal energy demand is more efficient than using fossil fuels to generate electricity (see Section 2.3.2.4). While the majority of BC's electricity is supplied by hydroelectric resources, other jurisdictions in BC's electricity trading region do rely on fossil fuels for power generation.

To provide context for FEI's long term volume forecasts as they relate to delivery rates, Figures 8-7 through 8-9 provide a directional look at the potential impact of long term demand on customer rates. Using approved rates and actual volumes from 2015[160], the following figures include the cost of service for major capital items and forecast C&EM activity plus an escalation of the cost of service by a growth factor of two percent per year, divided by delivery volumes in each scenario. The figures do not consider future rate design changes and are not indicative of a detailed rate forecast—they simply provide a directional, 20-year view of FEI's delivery rates over time.

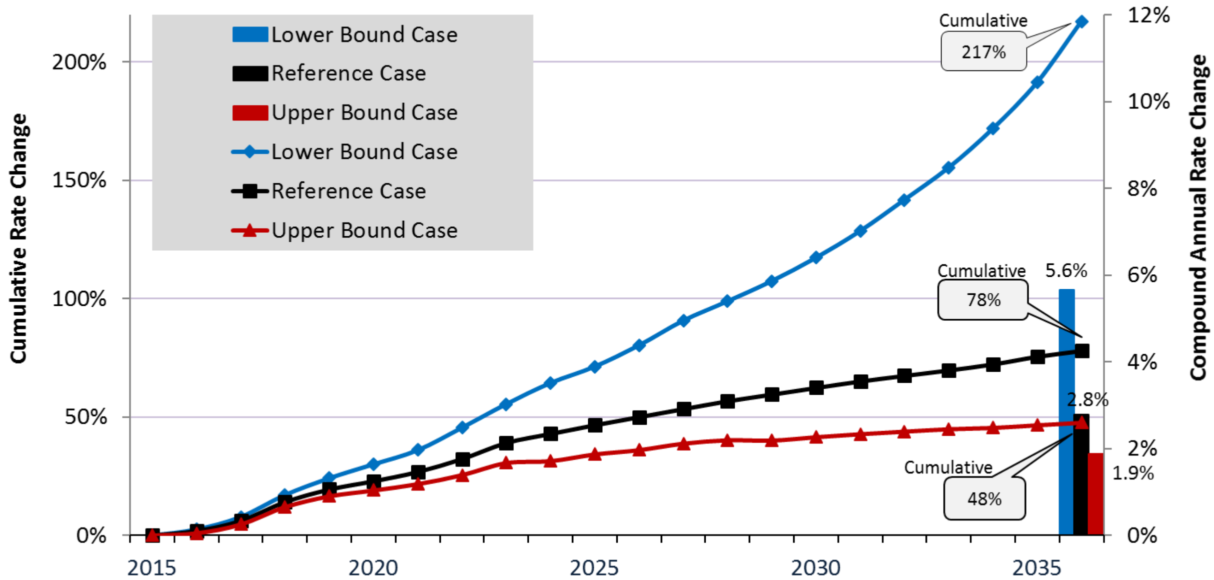
Figure 8-7 illustrates the delivery rate direction for the Reference Case, the Upper and the Lower Bound scenarios, respectively. In the Reference Case, the compound annual delivery rate change is 2.2 percent, which amounts to a 60 percent cumulative delivery rate change over the 20-year planning horizon. Below, Figures 8-8 and 8-9 illustrate the expected influence on delivery rates of FEI's C&EM and NGT initiatives. In general, as the volume of delivered gas decreases, delivery rates increase because less throughput on the system results in higher delivery costs per customer. C&EM programs incent customers to use less gas, causing demand for gas on the system to fall, thereby putting upward pressure on delivery rates. FEI also recovers the cost for its C&EM programs from its customer base which reinforces this upward pressure effect. As such, the compound annual delivery rate change in the Reference Case of Figure 8-8 grows to 2.8 percent which amounts to a 78 percent cumulative delivery rate change over the planning horizon in this simplified model.

Figure 8-7: Delivery Rate Direction – All Rate Schedules (without C&EM, NGT)



160 The projected delivery rate analysis uses 2015 actuals to remain consistent with the 2015 base year of the annual energy demand forecast from Section 3.

Figure 8-8: Delivery Rate Direction – All Rate Schedules with C&EM (without NGT)



Conversely, adding NGT demand (shown in Figure 8-9 below) increases total demand on the system and thus puts downward pressure on delivery rates. When adding the effect of NGT demand to the previous two projections, the Reference Case compound annual delivery rate change falls to 2.3 percent and the cumulative delivery rate change over the 20-year planning horizon also falls to 62 percent. In sum, holding all else constant, increasing delivery volumes has a positive effect for rates. Expanding the NGT market is an important opportunity for growth on the delivery system and underscores the importance for the Company to explore other opportunities for growth that will assist in mitigating upward pressure on delivery rates.

Figure 8-9: Delivery Rate Direction – All Rate Schedules with C&EM and NGT

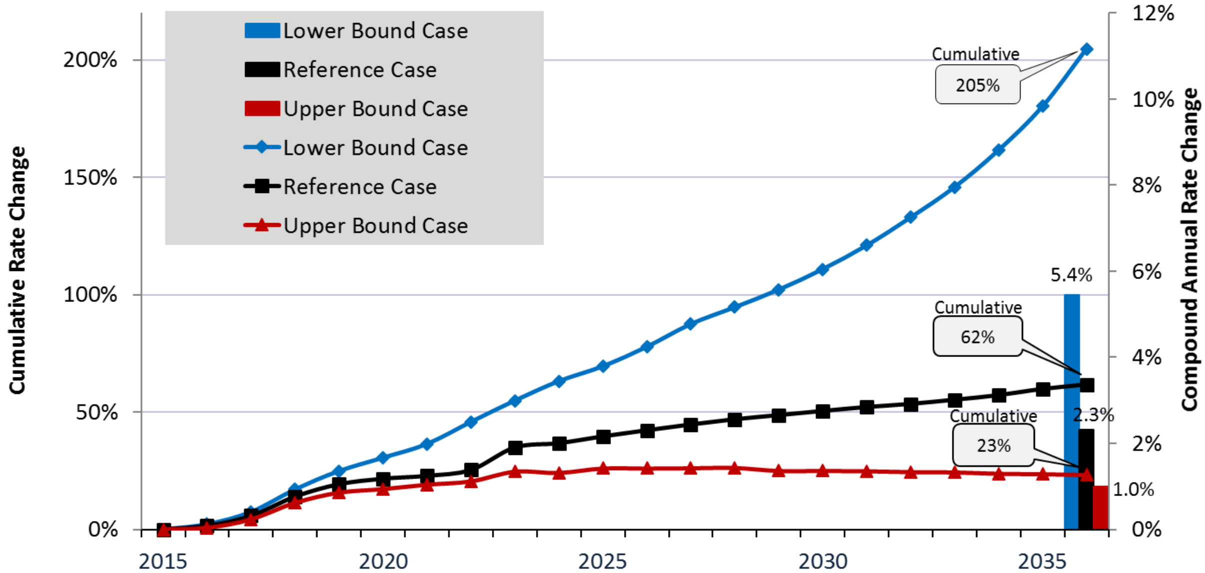


Table 8-2 below summarizes the aforementioned delivery rate impact projections.

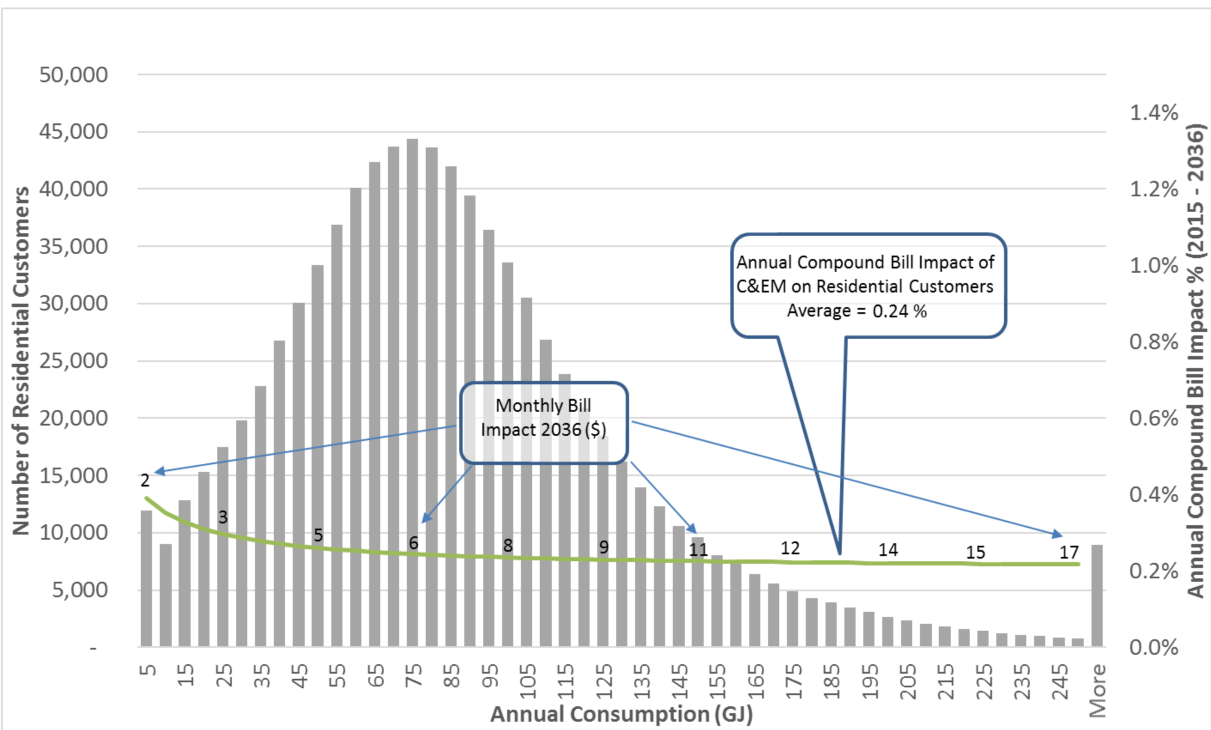
Table 8-2: Summary and Comparison of Average Projected Delivery Rate Changes

	Rate Change (2015-36, %)					
	Base		Base + C&EM		Base + C&EM + NGT	
	Cumulative	Compound Annual	Cumulative	Compound Annual	Cumulative	Compound Annual
Reference Case	60	2.2	78	2.8	62	2.3
Upper Bound	36	1.5	48	1.9	23	1.0
Lower Bound	201	5.4	217	5.6	205	5.4

To provide further context on the customer impact of FEI's projected C&EM activity, Figures 8-10 to 8-12 below provide a directional look at the potential total bill impact (including commodity and delivery) of such C&EM activity. The figures do not consider future rate design changes and are not indicative of a detailed bill forecast - they simply provide a directional view of estimated

2036 total C&EM bill impacts.[161] Annualized percentage compound 2015-2036 bill impacts are higher for low consumption customers than for high consumption customers. In contrast, monthly absolute 2036 impacts are higher for high consumption customers than for low consumption customers. In the Reference Case, average annualized percentage compound 2015-2036 bill impacts are 0.24 percent. This average value is increased to 0.25 percent for the Upper Bound scenario but decreases to 0.13 percent for the Lower Bound scenario. This appears to be due to the combination of two primary factors: (1) projected C&EM energy savings and expenditures increase from the Lower Bound scenario across the Reference Case to the Upper Bound scenario (which creates upward pressure on projected rates), but (2) the carbon price and natural gas commodity cost decrease from the Lower Bound scenario across the Reference Case to the Upper Bound scenario (which places downward pressure on estimated bills but also reduces the base values upon which percentage bill impacts are calculated). These dynamics also apply to Table 8-3 which displays estimated total bill impacts for average customers in select commercial and industrial Rate Schedules. Overall, estimated bill impacts of C&EM are forecast to be small.

Figure 8-10: Estimated Total Bill Impact of Projected C&EM Activity on Residential Customers – Reference Case



---

[161] This analysis indicates estimated bill impacts from the perspective of a customer that does not participate in C&EM programs. C&EM program participants are likely to experience cost savings on their bills.

Figure 8-11: Estimated Total Bill Impact of Projected C&EM Activity on Residential Customers – Upper Bound

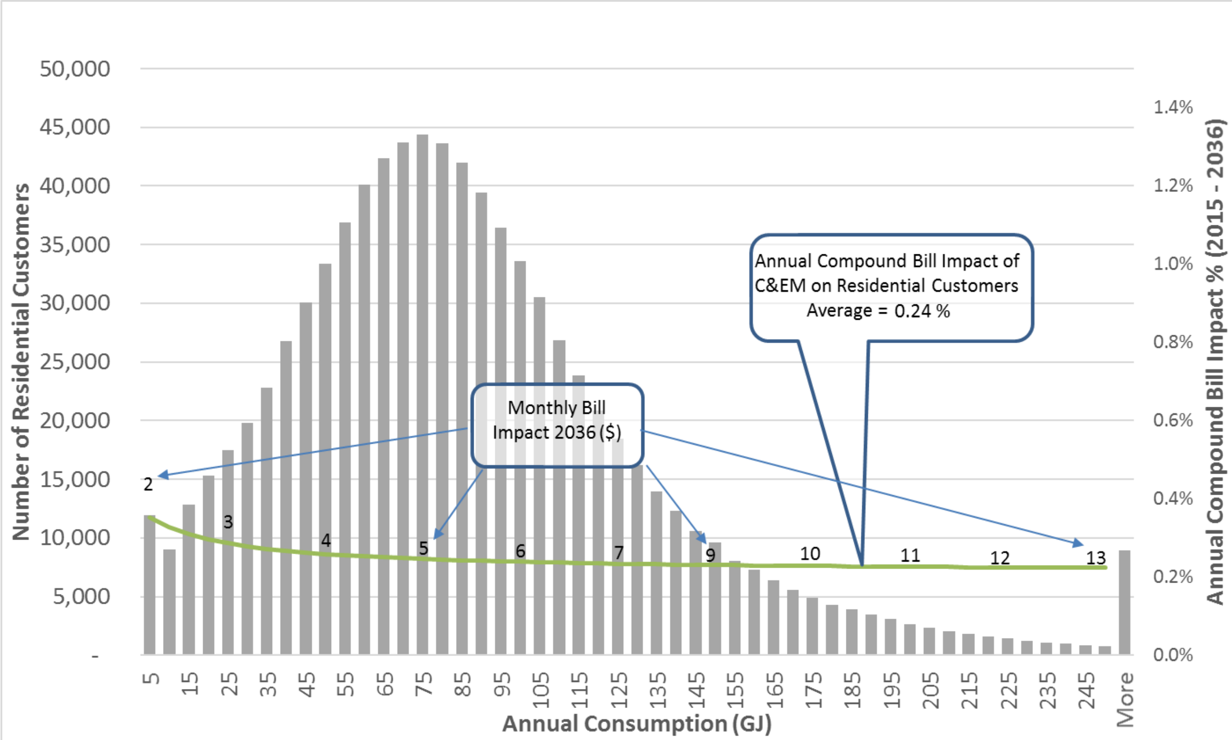


Figure 8-12: Estimated Total Bill Impact of Projected C&EM Activity on Residential Customers – Lower Bound

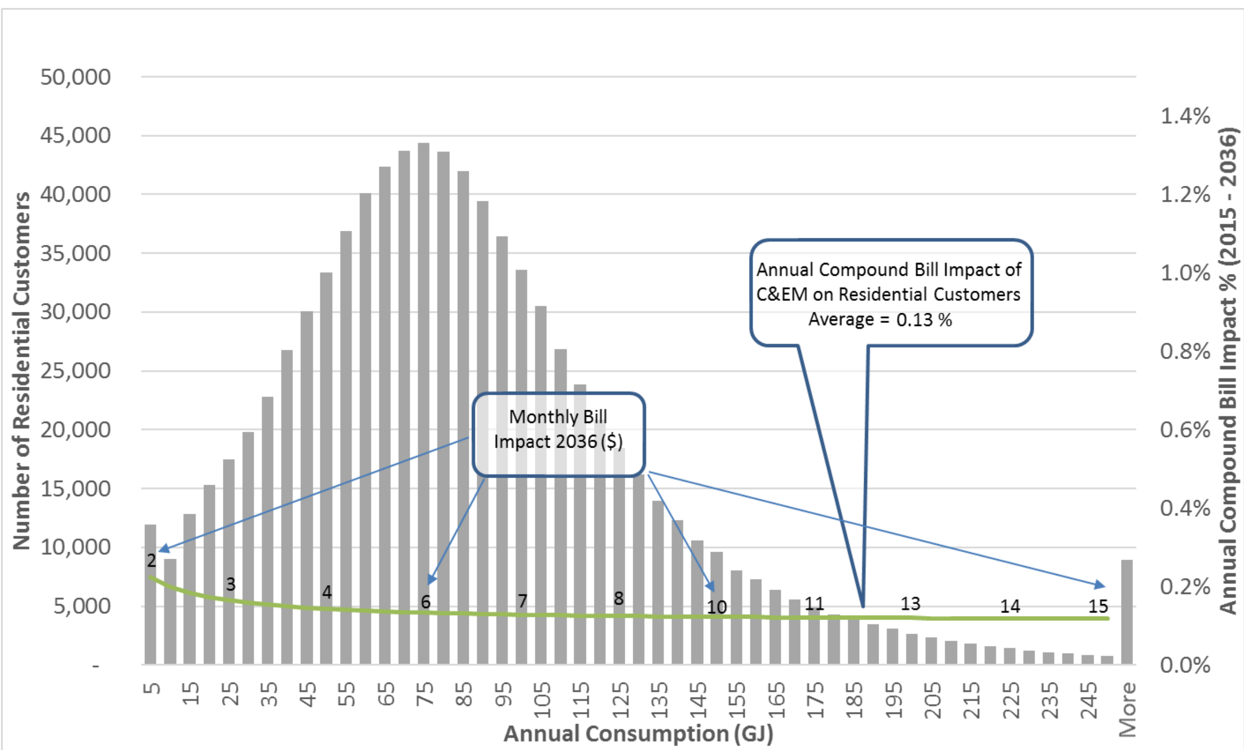

Table 8-3: Estimated Total Bill Impact of Projected C&EM Activity on Commercial and Industrial Customers[162]

Rate Schedule	Result	Reference Case	Upper Bound	Lower Bound
2	2015-2036 Annualized Compound Bill Impact	0.28%	0.24%	0.14%
	2036 Monthly Bill Impact ($)	24	17	13
3	2015-2036 Annualized Compound Bill Impact	0.25%	0.20%	0.10%
	2036 Monthly Bill Impact ($)	213	140	90
6	2015-2036 Annualized Compound Bill Impact	0.35%	0.19%	0.30%
	2036 Monthly Bill Impact ($)	467	183	415
7	2015-2036 Annualized Compound Bill Impact	0.23%	0.15%	0.20%
	2036 Monthly Bill Impact ($)	1,354	701	979
22	2015-2036 Annualized Compound Bill Impact	0.08%	0.05%	0.05%
	2036 Monthly Bill Impact ($)	12,352	5,199	8,082

8.7 KEY DRIVERS IMPACTING THE NEED FOR RESOURCES

The key drivers impacting the need for resources are the amount of natural gas demand over the forecast horizon, the impact that demand will have on available system capacity, system sustainment requirements for continued delivery of safe, secure and cost effective gas supply, and the amount and nature of demand side activities that FEI expects to undertake over the planning period. The demand forecast is presented in Section 3 and the amount of energy savings from C&EM activities is presented in Section 4. Section 6.3 presents the analysis of system capacity requirements and the expected timing of capacity expansions. Other major system projects identified in Section 6.4 may be needed regardless of the extent to which demand grows. The system capacity requirements identified in Section 6.3 may shift in terms of timing depending on how quickly demand grows, but they may also be easily integrated into system sustainment projects to satisfy both needs under all of the future scenarios examined.

The final driver impacting the need for resources is the extent to which the planning environment may change over the planning period and the nature of those changes. FEI believes that the demand scenarios analyzed in this 2017 LTGRP adequately capture the range of planning environment changes that may begin to unfold by the time the next LTGRP is prepared.

Section 8.6 shows the importance of adding natural gas demand in new markets to help offset increases in customer rates caused by declining UPC in other sectors, and the risk of further declines represented in the lower demand forecast scenarios (presented in Section 3).Therefore, resources to conduct customer and market research, and to identify and acquire customers in new and traditional markets are among the resources that FEI must continue to maintain over the planning horizon.

[162] The total bill impact analysis for Rate Schedule 22 assumes the same commodity cost values and midstream as well as distribution adders as the analysis for the other commercial and industrial rate schedules.

8.8 CONCLUSION

The context in which to provide a 20-year vision for FEI is significantly different today than it was six years ago when the Commission issued the applicable directive in the 2010 LTRP Decision. Notably, FEI was developing service initiatives to provide low carbon thermal energy solutions, the outlook for natural gas supply and long term gas price forecasts was significantly different, and since that time, the Government of BC has placed increasing emphasis on developing natural gas resources for transportation use and export. Uncertainty remains about the further evolution of this policy direction due to recent changes in government in BC and the US.

In Section 8, FEI has explained how and where the 2017 LTGRP addresses a number of items related to a 20-year vision. This section also highlights the need to monitor a small but important trend of growing low carbon thermal energy demand, the extent to which FEI initiatives contribute to BC's overall GHG reductions, and how variations in demand over the planning period can influence customer delivery rates. Since decreases in demand (whether through market trends or C&EM activities) place upward pressure on delivery rates while increases in demand lead to the reverse effect, the Company will continue to explore opportunities for demand growth on the distribution system. This includes FEI monitoring and, where applicable, participating in efforts to test and implement innovative natural gas energy technologies that help meet FEI's customers' needs while also supporting BC energy objectives.

9. ACTION PLAN

The following Action Plan describes the activities that FEI intends to pursue over the next four years based on the information and recommendations provided in this 2017 LTGRP. Pursuant to Order G-189-14, dated December 3, 2014, FEI confirms that it has built this Action Plan based on its Reference Case end-use annual demand forecast and its Traditional Peak Method forecast.

1. Continue monitoring and analyzing the energy planning environment.

Being aware of and understanding the many factors that influence FEI's long term analysis is critical to providing appropriate context for the analysis, results and recommendations that are made throughout the LTGRP. FEI will continue to monitor market and policy developments that may impact regional gas flows, supply, demand and pricing. FEI's research and investigations will seek to uncover any potential challenges as well as identify opportunities to improve on the secure, reliable and cost effective energy services that the Company provides to its customers.

2. Continue exploring the application of projected changes across end-use patterns to peak demand forecasting.

In the 2017 LTGRP, FEI outlined an exploratory method for examining peak demand under projected changes across end-use patterns. This method is theoretical and not based on metered FEI customer energy consumption. As such, FEI continues using its well-established Traditional Peak Method for analyzing peak demand for system capacity planning. This Traditional Peak Method is based on metered data and serves as FEI's basis for developing action plans and contingencies around such plans. FEI will continue monitoring potential metering solutions that may allow FEI to field-validate the projections of the exploratory end-use peak demand forecast method and to better serve its customers.

3. Protect and promote the interests of the Utility's customers by securing a reliable, cost effective long term gas supply.

Fundamental objectives for FEI are to procure a stable, secure gas supply over the long term while minimizing the cost of the annual portfolio. In order to meet these objectives, FEI will use the following broad strategies to secure future resources:

- Manage volatility in natural gas prices by maintaining access to liquid trading hubs, utilizing a variety of storage and transportation resources, and using different pricing structures and contract terms.
- Continue to actively participate in pipeline infrastructure developments, tolling proceedings and other initiatives to ensure that the marketplace in BC offers supply liquidity and competitive pricing compared to neighbouring regional markets.

- Continue to establish key relationships with major producers that plan to develop gas supply in the Horn River, Montney and other producing regions of BC over the long term, including those actively involved in attempting to develop LNG exports to Asian markets.
- Evaluate opportunities within FEI's own operating region to improve infrastructure that will provide greater access to markets, leading to better diversity and reliability within the gas portfolio over the long term.
- Continue using financial hedging strategies as approved by the Commission in FEI's PRMPs and, where applicable, request Commission approval for an expansion of financial hedging strategies via future PRMPs.

FEI also plans to investigate VPP or similar arrangements with gas producers as a longer term strategy for helping ensure security of supply and provide cost stability for customers.

4. Continue monitoring and evaluating system expansion needs in the Okanagan and Vancouver Island areas to maintain reliable and cost effective gas delivery to FEI's customers.

FEI's Traditional peak demand forecast method has identified a capacity constraint in the Okanagan region of the ITS in 2022. Under the High Traditional scenario this constraint is projected to occur as early as 2021. Under the Low Traditional scenario this constraint is projected to be delayed to 2027. The Company will continue to evaluate the four proposed reinforcement options presented in Section 6.3.3 as part of FEI's contingency planning. In addition, the Company will continue to monitor developments in FBC's long term planning and the potential need for natural gas generation as a back-up to renewable electricity production during peak electric demand periods. Should FBC proceed with a gas-fired peaking generating station, this or any other large additional industrial load will result in a need to submit a CPCN for facility expansion.

FEI's Traditional Peak Method forecast has identified a capacity constraint in the VI Transmission System in 2028. Under the High Traditional scenario this constraint is projected to occur as early as 2024. Under the Low Traditional scenario this constraint is projected to be delayed to 2030. The Company will continue monitoring VI Transmission System capacity and evaluation the two reinforcement options presented in Section 6.3.1 as part of the FEI's contingency planning. FEI will submit a CPCN for system expansion if required.

5. Plan for and prepare CPCN applications for near-term system requirements identified in Section 6 to support safe, reliable and cost effective gas delivery to FEI's customers.

The high priority projects on the CTS and FEI's regional infrastructure for which the Utility intends to submit CPCN applications and will be examining in the near term are:

- Upgrades to lateral pipeline segments in the interior region to enable and implement In Line Inspection programs (referenced in Section 6.4 as Transmission System Laterals ILI Capability);
- The Southern Crossing Pipeline Class Location Project;
- The Patullo Bridge Crossing Replacement;
- The evaluation of major bridge crossings on the CTS to determine if upgrades should be considered to improve the resiliency of piping during a seismic event (referenced in Section 6.4 as Bridge Crossing Seismic Upgrade Assessment – Lower Mainland);
- Implementation of advanced technology In Line Inspection programs (e.g. EMAT) for the transmission pipelines that are already inspected using current technology; and
- A potential reliability upgrade to the Langley compressor facility.

As FEI's planning efforts are undertaken to ensure that planned improvements optimize operation of the system as a whole, these system upgrade requirements have been integrated with the reinforcement options that are under consideration to meet FEI's capacity needs.

6. Continue implementing the Company's NGT initiatives to meet market needs while capturing an important opportunity for load growth and GHG emissions reductions.

FEI will continue implementing the Company's NGT initiatives to provide an important source of load growth on FEI's natural gas system while also capturing a significant opportunity for GHG emissions reductions. This includes implementing any required expansions to the Tilbury LNG facility and FEI's CTS for meeting NGT and non-NGT LNG demand as discussed in Sections 6.3.1 and 6.3.2 and pursuant to the BC Government's Direction No. 5.

7. Pursue approval of C&EM funding for the period beyond 2018 by submitting for BCUC approval a C&EM expenditure schedule in 2018.

Pursuant to Order G-189-14, FEI will develop a C&EM expenditure schedule and seek approval for this from the BCUC in 2018. This expenditure schedule will be informed by the results from the BC CPR and the 2017 LTGRP C&EM analysis.

FEI will continue to examine the potential for all forms of DSM activity to optimize the use of BC's energy infrastructure by implementing programs that help meet customer energy needs while working toward BC energy objectives.

8. Pursue approvals as necessary of a funding envelope dedicated to enabling FEI to further monitor and, where applicable, support innovative natural gas technologies which may help FEI meet market preferences while also supporting solutions for BC's emissions policy objectives.

As described in Sections 2.4.2, 2.4.3, and 8.2.4 such technologies, including but not limited to power-to-gas, cellulosic biogas, natural gas heat pumps, end-use appliance combined heat and power, and end-use appliance carbon capture, may have a significant impact on energy use patterns and GHG emissions. During FEI's 2017 LTGRP RPAG and Community Engagement workshops, stakeholders considered and supported FEI monitoring and, where appropriate, supporting such technologies.

Appendix A

REGIONAL MARKET OVERVIEW

APPENDIX A: REGIONAL MARKET OVERVIEW

1.1 INTRODUCTION

Regional resources in the Pacific Northwest that are currently available are fully utilized to meet existing customer demand in the region during normal and colder than normal winters. However, demand for natural gas is expected to increase in the near future within both FEI's natural gas service areas and the PNW, which could impact supply and demand dynamics. For instance, the addition of new load will require further transportation capacity to be constructed so that demand in the Lower Mainland and the US I-5 corridor can be served reliably. Additionally, the significant supply potential in Northeast BC (NEBC) has prompted the development of infrastructure initiatives to provide greater access to existing and new markets. With increasing demand from industrial, power generation and oil sands demand, and the need to replace supply declines elsewhere within Alberta, TransCanada PipeLines Limited (TransCanada) continues to bring forward plans to expand into NEBC to access the significant resource that is located there.

FEI is actively involved in National Energy Board (NEB) proceedings that potentially affect FEI's access to supply and is involved in developing solutions with regional stakeholders to help ensure issues related to third party pipeline infrastructure are resolved fairly. These activities are important because they help to ensure that customers in BC will continue to have reliable access to gas supply at fair market prices.

As a basis for the discussion in this appendix, Figure A-1 provides an overview map of existing pipeline systems in BC, Alberta and the US PNW.

Figure A-1: Overview map of the Western Canadian and US PNW region

1.2 THE IMPORTANCE OF NEBC SUPPLY

Improvements in production technologies that have unlocked the potential of shale and tight gas resources have transformed the North American natural gas supply picture. In BC, the natural gas potential is second only to the Marcellus shale gas play that is being developed in the northeast region of United States. A recent joint study conducted by the NEB, Yukon Geological Survey, the Northwest Territories Geological Survey and the British Columbia Ministry of Natural Gas Development reported the estimated total potential of marketable gas in the Western Canadian Sedimentary Basin (WCSB) (discovered and undiscovered) is now 1,051 Tcf.[1] The 1,051 Tcf estimation is 230 Tcf higher than the NEB's previous estimate in 2013 of 821 Tcf.[2] Taking into consideration that annual natural gas demand in Canada is approximately 3.5 Tcf, the WCSB resource represents the equivalent of approximately 300 years of supply at the current consumption level.[3] The Montney formation in BC alone represents 271 Tcf of potential marketable natural gas.[4]

As a result of the size of this resource and its attractive production economics, production of natural gas from basins located in NEBC has the potential to grow significantly in the coming years. This supply will be able to support existing markets in BC, as well as support potentially new markets (LNG and methanol exports) and meet growing industrial demand in Alberta, specifically from continued oil sands growth. However, the impact of these developments for FEI customers remains difficult to foresee with any accuracy because the quantity and timing of additional market demand and new matching transportation capacity remains uncertain.

The prospect of new markets for production has not developed as quickly as many producers active in the WSCB had hoped. Environmental and regulatory review and approval requirements have slowed the development of new markets for this gas. Also, the crash in commodity prices in 2014 has eroded the economic attractiveness of much of the LNG export development considered for NEBC. Producers have been able to manage through this period by focusing on further production efficiencies. However, continued production efficiency improvement is increasingly difficult to realize.

Compounding this challenge over the past few years has been the steady displacement of traditional eastern Canadian and US markets for natural gas produced in the WCSB by production in other more competitive basins. This decline is driven primarily by the development of shale gas basins, in particular the Marcellus shale gas play, that are located

4 Appendix D-3: https://www.neb-one.gc.ca/nrg/sttstc/ntrlgs/rprt/ltmtptntlmntnyfrmtn2013/ltmtptntlmntnyfrmtn2013-eng.pdf. Note: the Montney formation geographically straddles the border between BC and Alberta. The total ultimate potential for the full Montney formation is 449 Tcf.

much closer to key consuming markets in eastern North America. These developments, combined with a producer push to develop new supply in anticipation of new markets, have reduced commodity prices over the past few years; prices are forecast to remain at the current low level in the near future.

Gas producers in Western Canada who need reasonable certainty that new markets will materialize in order to continue to develop new supply given current commodity pricing levels, now face an uncertain market environment. While increased industrial, power generation, and oil sands demand will help to offset reduced demand from traditional markets, significant new markets are required in order to fully develop the potential of the WCSB, including the new supply basins located in NEBC.

1.2.1 The Configuration of Regional Infrastructure

FEI is required to serve several major regional demand centres in BC that are largely isolated from each other by considerable distances and spread across a large, varied geographical footprint. Serving customers across this diverse geography and balancing daily system loads requires interconnection with third party pipelines and access to a flexible mix of supply, storage, and transportation resources.

As a matter of additional complexity, BC's geography, its location relative to supply basins, and its winter seasonal market, has limited transportation infrastructure available that connects the BC marketplace to sources of supply. As a consequence, the BC market is extremely reliant on supply originating in production basins located in NEBC. Approximately 75 percent of FEI's current supply is sourced in BC and transported to FEI's service area via Westcoast Energy Inc.'s (Westcoast) T-North and T-South pipeline systems. This reliance on NEBC supply is unlikely to change significantly in the short to medium term given that only limited pipeline capacity exists to connect supply from Alberta and for redelivery from market area storage located in the US PNW.

In response to the potential increase in demand in Alberta and the slower than expected development of LNG exports off the BC coast, attention has increasingly turned to expanding pipeline connectivity from supply basins located in NEBC to Alberta. The majority of recent pipeline expansions to the AECO/NIT market, such as the Groundbirch Mainline and Towerbirch lateral pipelines by TransCanada's Nova Gas Transmission Ltd. (NGTL) system, now provide BC producers with the option to flow increased supply directly to the AECO/NIT marketplace, bypassing the Westcoast T-North system. Future facilities additions in NEBC contemplated by TransCanada for its NGTL system will accelerate this trend. Gas production from smaller plants in the Montney region has displaced traditional supply from the Fort Nelson and Pine River Plants. A number of the future NGTL system expansions are planned in the Montney region, and could shift the proportion of gas flowing through Station 2, given the attractiveness to producers of direct access to the AECO/NIT marketplace. This development would have a significant impact on markets reliant on the Westcoast systems, such as those served by FEI.

Notwithstanding this development, it is possible for gas produced in BC to flow onto the NGTL system into Alberta and then flow back into BC. The infrastructure connections with Westcoast's T-North system at Groundbirch and Gordondale could permit flow from NGTL onto Westcoast's system. However, this requires the addition of facilities on the NGTL system. Such additions would result in increased costs to access this gas since shippers would have to pay the AECO/NIT price plus both the NGTL system delivery toll and the Westcoast T-North toll to deliver gas to Station 2. T-North tolls would also increase as a result of facilities additions that would be required to increase capacity in order to accommodate any significant increase in flows on T-North to Station 2 from the Groundbirch/Gordondale area on the NGTL system.

1.2.2 US Production Impact on The Regional Market

The significant shale gas potential in North America and the improvements in drilling technology have provided North America with an abundant supply of low cost natural gas. This ability to maintain production even with a relatively low commodity price has resulted in supply outpacing demand across most regions in North America.

The WCSB faces a particular challenge in this environment because US shale production is taking place very close to the WCSB's traditional markets in eastern North America, which has caused a significant portion of these markets to contract with this new supply source. Unless additional demand develops to match the growth in supply, prices will likely remain low for the near future and the ability of producers to survive in this environment becomes more uncertain.

1.2.3 Implications for FEI

The ability to maintain production in an environment facing sustained low commodity prices, and where considerable uncertainty exists about the timing of when new demand may materialize and new infrastructure is constructed, are the primary reasons for FEI to believe that it is critical to monitor and actively participate in developments affecting the BC and regional gas marketplace. This activity includes monitoring the development of major regional infrastructure and pipeline systems, the emergence of new markets and sources of gas supply, the emergence of new regional regulatory issues, and the evaluation of major new infrastructure requirements within FEI's own systems.

FEI's involvement in these developments allows it to identify when the gas supply portfolio strategy needs to be altered by, for example, adjusting the use and mix of counterparties, pricing strategies or fundamentally altering transportation and storage arrangements. These activities are critical to helping ensure that FEI remains effective in providing reliable gas supply to customers so that it is able to continue to meet the security of supply, diversity, and cost minimization objectives of the gas supply portfolio.

1.3 NEBC DEVELOPMENTS

Developing new supply in the Montney basin has increasingly been the primary focus of producers active in the WCSB since new production technology made shale gas development economically attractive over the past decade. Within the WCSB, sub-plays in the Montney formation in BC have among the most attractive production economics in North America. As a result, development interest is concentrated in a small geographical area with market access provided primarily by Westcoast's T-North system and to a lesser extent by Alliance Pipeline and by the NGTL system.

Over the past decade, NGTL proposed to construct a number of extensions of its system into the North Montney region in BC, offering direct access to the large and very liquid AECO/NIT market. These facilities extensions by NGTL have been contentious, with interveners, including FEI, taking the position that the proposed tolling of these facilities places too little cost accountability on the shippers requesting the facilities and that this tolling creates incentives for shippers to bypass Westcoast's T-North system entirely. Any bypass of the Westcoast system raises a concern about the future liquidity of the Station 2 market and the ability of participants in that market to bid on the physical gas molecule.

1.3.1 BC LNG Export Projects

Since 2010, over twenty different LNG export projects have been announced, proposing liquefaction terminals located on the coast of BC, as well as large diameter pipelines to transport natural gas from production basins in NEBC. The main driver of these projects had been the desire to take advantage of the historically lower North American natural gas prices compared to Asian natural gas prices. Asian markets were also attracted by the desire to diversify their sources of supply and by the political stability and mature market structure for accessing natural gas that Canada offers.

With the collapse in oil prices in 2014, global oil-indexed LNG prices declined, undermining the economic viability of these projects. Environmental and regulatory hurdles have also contributed to hampering the development of many of the proposed major projects. A number of smaller projects, and one major project by PETRONAS of Malaysia, have been cancelled. As a result, the remaining projects face an uncertain future. A potential need, however, to build new liquefaction capacity by 2023 offers hope that some of these projects may be sanctioned to proceed in the next year or two.

Although the economic, regulatory and environmental hurdles are significant, smaller scale projects, such as the Woodfibre LNG Project, continue to be active with their development plans and could emerge as frontrunners to become one of the first terminals to export LNG from BC.

The prospect of several major LNG export terminals located on the coast of BC prompted considerable producer activity in the liquids-rich North Montney basin. This activity was undertaken to prove the existence of sufficient supply to serve several major potential projects. When it became more likely that the LNG export projects faced delay following the 2014 price collapse, producers were forced to consider other markets, such as Station 2, served by Westcoast, and AECO/NIT, served by NGTL. Both pipelines proposed and received approval to construct new pipeline infrastructure to move considerable additional supply to market.

1.3.2 The Westcoast System

Westcoast is regulated by the NEB and is an affiliate of Enbridge Inc. The Westcoast T-North system transports natural gas produced in BC through its system to the interconnect with the Westcoast T-South system at Station 2 for transportation to markets located in BC and the PNW. It also transports supply east to the NGTL system at the Groundbirch and Gordondale interconnects to access the AECO/NIT marketplace and via a number of other pipelines to various markets in North America. FEI relies on the Westcoast systems to transport Station 2 supply to and from Aitken Creek Storage located in NEBC and to transport supply from Station 2 to the FEI system in the BC Interior, the Lower Mainland, and on Vancouver Island.

Prompted by producers seeking market access for significant additional supply, Westcoast received NEB approval over the last several years to construct the Jackfish Lake, High Pine, and Wyndwood expansion projects on the T-North system. These projects will provide additional capacity for deliveries to Station 2 and to the interconnect with the NGTL system at Groundbirch. These projects will be placed into service in 2017 and 2018. FEI supported these projects because of the additional supply that will be brought to or move through Station 2 even though they impact the T-North toll significantly.

Westcoast is planning to apply for NEB approval of a further project, Spruce Ridge that will also bring additional new supply to or through Station 2 for delivery to the NGTL system. If approved, this project is planned to be placed into service in 2019.

These Westcoast projects are important because they will help to ensure that the liquidity at Station 2 will be maintained, which is critical given FEI's reliance on this market hub for reliable, cost effective supply. FEI will continue to monitor developments relating to additional projects proposed by Westcoast in order to assess the potential impact they may create.

1.3.3 The NGTL System

The NGTL system is regulated by the NEB and is an affiliate of TransCanada Pipelines Limited. The NGTL system transports natural gas produced in British Columbia and Alberta through its system to the AECO/NIT marketplace and via a number of other pipelines to various markets in North America. FEI relies on TransCanada's NGTL and FoothillsBC systems to transport AECO/NIT gas supply to and from storage locations in Alberta and to transport gas supply from Alberta to the FEI system where they interconnect in the southeast of BC.

The favourable production economics and size of the resource located in the Montney basin, but limited infrastructure in NEBC to bring it to market, prompted producers to seek direct access to the NGTL system. In response, NGTL has proposed a number of extensions of its system into NEBC since 2009. Three extensions were approved by the NEB and constructed:

the Groundbirch Mainline, the Horn River Mainline, and most recently, the Towerbirch lateral. Other significant extensions that were required to support the development of LNG export projects were given conditional approval but are unlikely to be constructed as planned following the recent cancellation of the Northwest LNG project by PETRONAS.

TransCanada is directly involved in the proposed development of BC regulated pipelines that are planned to transport natural gas to a number of LNG export facilities which are proposed to be located on the northwest coast of BC. Gas supply is planned to be transported from NEBC and from the AECO/NIT market via extensions of the NGTL system. Much or all of this additional supply will be produced in plants that will not be connected to the Westcoast T-North system and bypass it entirely. These developments are important for FEI because they could impact FEI's access to secure and reliable natural gas supplies in the future at fair market prices in BC.

NGTL is expected to continue to initiate plans to provide additional transportation capacity to move production from NEBC into Alberta. FEI will continue to monitor developments relating to such projects in order to assess the potential impact they may create.

FEI's need to monitor such facilities developments is also important because past facilities proposed by NGTL in NEBC have been contentious. Interveners, including FEI, took the position that the proposed tolling of these facilities places too little cost accountability on the shippers requesting the facilities and that this tolling creates incentives for shippers to bypass Westcoast's T-North system entirely.

NGTL's recent filing of its North Montney Variance Application is another example of a project that is likely to be contested on the same grounds as other NGTL projects proposed for NEBC. This project proposes to alter the North Montney Project, for which NGTL received conditional approval, by changing its intended purpose and changing the facilities to be built. Instead of using the facilities to support a major LNG export project, they are now planned to be used to bring additional supply to the AECO/NIT market. NGTL however, proposes to retain the tolling conditions the NEB ordered when it provided the original approval for the North Montney Project. Those conditions require NGTL to seek approval of a new tolling methodology for the facilities. If NGTL does not receive such approval, standalone tolling will apply. FEI has an interest in ensuring that the original tolling conditions ordered by the NEB are maintained and addressed.

Given the contentiousness of these NGTL facilities applications, the NEB is separately considering a potential inquiry into the appropriate tolling treatment for facilities proposed by federally regulated pipelines in NEBC and matters relating to competition for the development of gas infrastructure in the area. These issues are too broad in scope to be addressed in individual facilities applications. FEI is expected to be a participant in the process if the NEB orders an inquiry.

1.4 FEI SYSTEM DEVELOPMENTS

FEI continues to explore further developing parts of its own system to accommodate the potential for increased demand from large industrial loads, such as LNG projects. Successfully serving such new loads would increase system throughput significantly on a daily basis and potentially have a net positive rate impact for existing customers. Current projects include the Woodfibre LNG Project located near Squamish and the expansion of the Tilbury LNG facility.

1.4.1 Woodfibre LNG Project

Woodfibre LNG Ltd. (WLNG), a subsidiary of Pacific Oil and Gas Limited of Singapore, is proposing to construct and operate an LNG export facility (estimated to cost about $1.6 billion) at the former Woodfibre Pulp Mill site located near Squamish. As part of its plans, WLNG has requested natural gas transportation (NGT) service from FEI so that it can access gas supply for its plant.

Figure A-2: Woodfibre LNG Project Location on FEI's Transmission System

To meet WLNG's NGT service requirement for the Woodfibre LNG Project, FEI will need to expand its existing system, which includes adding new pipeline looping and compression. In order to support WLNG's timeline, FEI must have the pipeline expansion completed and in-service before WLNG's LNG plant becomes commercially operational. WLNG will need to formally authorize FEI to commence work on the pipeline before any construction can begin.

1.4.2 Tilbury LNG Expansion

FEI is currently expanding the Tilbury LNG facility to include a 1 Bcf/d LNG storage tank with 32 MMcf/d (35 TJ/day) of liquefaction. This expansion will provide LNG primarily for the transportation market sector and is expected to enter service at the end of 2017.

An evolving market for LNG from Tilbury could come from the shipping industry, which will be required to reduce sulfur and nitrous oxide particle emissions from the use of heavy fuel oils globally starting in 2020. This requirement could result in more companies moving to cleaner fuels such as LNG or methanol for new vessels and converting some existing ships to these fuels.

The port location of the Tilbury facility, combined with the availability of existing pipeline infrastructure to transport gas supply for liquefaction, provides customers with a significant benefit and long term access to LNG. In addition, the Tilbury location has the potential to further expand over time to meet the needs of projects that are suitably sized for development in the Lower Mainland. Pipeline capacity expansions on both FEI's system and upstream will be required so that gas can be sourced from market hubs to support such projects in the Lower Mainland. Such pipeline infrastructure growth options are discussed in this appendix in Section 1.5 below.

1.5 BC PIPELINE EXPANSION OPTIONS

The construction of any of the infrastructure projects discussed above will impact the amount of gas flow into the BC and PNW region. Although it is unlikely that all announced projects will proceed, it is very likely some will come to full development over the course of the next few years. Even this level of development will have a significant impact on the region with respect to the volume of gas supply flowing, pipeline capacity utilization and possibly gas pricing. The volume of daily baseload gas required for each of the projects is significant when compared to the amount of gas that currently flows into the region and the design capacity of existing regional pipeline systems. The existing regional pipeline capacity is constrained already during key periods in the winter months in order to meet the current requirements of customers in the Lower Mainland and the US I-5 corridor.

The PNW region, including British Columbia, has historically been a winter seasonal market and the regional resources consisting of pipeline capacity and storage have been developed to meet this seasonal demand rather than high load factor baseload demand. Regional pipeline capacity is used to meet loads in the summer while, in the winter, both pipeline capacity and storage resources are generally required to fully serve demand. Regional pipeline capacity is utilized at a high level or near capacity for a large proportion of the winter. Even two or three of the above named projects in full or partial scope will require significant incremental regional pipeline capacity in order to serve the combined needs of existing and new customers.

The greatest impact of any future capacity constraints will affect existing industrial-type customers who are responsible for purchasing their own supply directly or through a marketer.

Today, these customers purchase gas at the Station 2 market for delivery to the Huntingdon-Sumas area using available excess pipeline capacity on the T-South system. This approach has been followed over the course of the last decade as the firm capacity on the T-South system from Station 2 to the Huntingdon-Sumas marketplace had not been fully contracted, which led to the availability of large gas volumes to flow on interruptible capacity. Continuing with this approach for purchasing gas is likely to become less certain when new demand comes online since all available capacity on T-South has now been fully contracted by shippers. This lack of available firm transportation capacity in the region is driving the evaluation of regional solutions that would bring incremental gas supply to the Lower Mainland and Huntingdon-Sumas marketplace.

1.5.1 Westcoast System

Since the vast majority of FEI's supply is transported on Westcoast's T-North and T-South systems, it is important for these systems to remain competitive and provide supply for the existing marketplace, while evaluating opportunities for growth. Proponents of new regional projects will require access to large volumes of baseload gas supply. The supply for these potential projects is expected to flow largely on Westcoast's T-North and T-South systems, especially if the projects are located in southern BC or even parts of the US PNW.

Therefore, the Westcoast T-South system will require staged expansions over the next several years to accommodate new industrial demand. From a capital expenditure point of view, capacity expansions of any type would require long term commitments from creditworthy shippers. Project proponents that request system expansions will be required to provide security and backstop the capital costs during the development stages of new capital intensive expansions.

Westcoast announced an open season on April 25, 2017 for a relatively minor expansion to increase capacity on T-South between Station 2 and Huntingdon to gauge shipper interest for firm commitments. This resulted in shippers signing very long term contracts for the entire 190 MMcf/d of volume that was offered in the open season. The incremental capacity is expected to be in service in late 2020. It is FEI's understanding that any new Westcoast expansions in addition to the 2020 in-service capacity may only be viable if the nature of the expansions results in a major increase in capacity on the T-South system. Such expansions may only be economically viable if they are supported by major new loads in the Lower Mainland and PNW region. A major expansion on Westcoast's T-South system is estimated to require a minimum of five years to complete after an open season is successfully concluded.

1.5.2 Kingsvale-Oliver Reinforcement Project (KORP)

FEI continues to look at KORP as a regional solution that could be developed as an alternative to a major expansion on Westcoast's T-South system in order to provide the PNW with pipeline diversity and improved security of gas supply. This bi-directional pipeline can also provide BC producers with access to markets, by connecting northern BC supply basins to markets in PNW, California and Nevada via deliveries to Kingsgate for flow on TransCanada's Gas Transmission Northwest (GTN) pipeline system.

KORP consists primarily of a 161 km, 24-inch or greater diameter pipeline expansion from Oliver to Kingsvale, BC on FEI's existing interior system. KORP would be able to deliver additional gas supply to meet the needs of projects that are suited for the Lower Mainland region. A collaborative tolling structure could provide shippers with a viable solution when regional pipeline infrastructure developments are being assessed.

Recently, there has been renewed interest from producers and large end-use shippers to contract for pipeline capacity in order to move gas to markets such as Huntingdon-Sumas on a firm basis. This phenomenon has not been seen since the early 2000s when producers started to decontract their firm pipeline capacity on the T-South system and avoid demand charges while focussing their attention to move gas to the more liquid AECO/NIT marketplace. However, the oversupply of gas around North America has prompted producers to compete for market share that was readily available to them prior to the emergence of large scale prolific shale gas basins.

The construction of the KORP system would help to strengthen regional pipeline infrastructure and also provide pricing diversity and improve the security of supply for projects needing baseload gas supply. This project provides the region with a viable alternative and add 300-400 MMcf/d of new pipeline capacity for projects that could be situated in the Lower Mainland. FEI will continue to monitor developments in the region and work with parties to help develop infrastructure solutions that will effectively meet the needs of the region.

1.6 US PACIFIC NORTHWEST INFRASTRUCTURE UPDATE

In response to potential new industrial demand, several potential major pipeline and infrastructure projects are being considered for construction in the US PNW. These projects could impact gas flows and pricing dynamics within the region if some or all projects are constructed over time.

1.6.1 Northwest Innovation Works Methanol Projects

Northwest Innovation Works (NWIW) is proposing to construct a methanol production plant in Kalama, Washington hat will use natural gas to produce methanol. NWIW is in the final stages of garnering full permitting needed to declare a positive final investment decision for a USD$ 1.8 billion plant south of Tacoma, in the Port of Kalama.

The multiple trains planned for each methanol plant would require anywhere from 125 MMcf/d to 150 MMcf/d of gas supply per train depending upon the size of the production trains and whether or not there is a requirement for gas to be used for electricity generation. Based on the current regional pipeline infrastructure, it is expected that a significant portion of gas supply for the Kalama plant will primarily be met via the Westcoast T-South system in addition to sourcing gas from other regional hubs via the Northwest Pipeline (NWP) system.

If the Kalama plant becomes operational and if NWIW evaluates the potential of building other plants in the vicinity of the Kalama plant, the regional pipeline infrastructure will need to be expanded. Depending upon the location of additional plants, pipeline expansion options include routes that access gas from BC, Alberta and the Rockies supply basins or some combination thereof (discussed in Section 1.1.6.2 in this appendix).

Figure A-3: NWIW's Port of Kalama Project Location

1.6.2 Potential Regional US Pipeline Expansion Options

Other pipeline expansion projects that have been assessed in the past and have the potential to be developed in the US PNW region if large scale industrial demand materializes include:

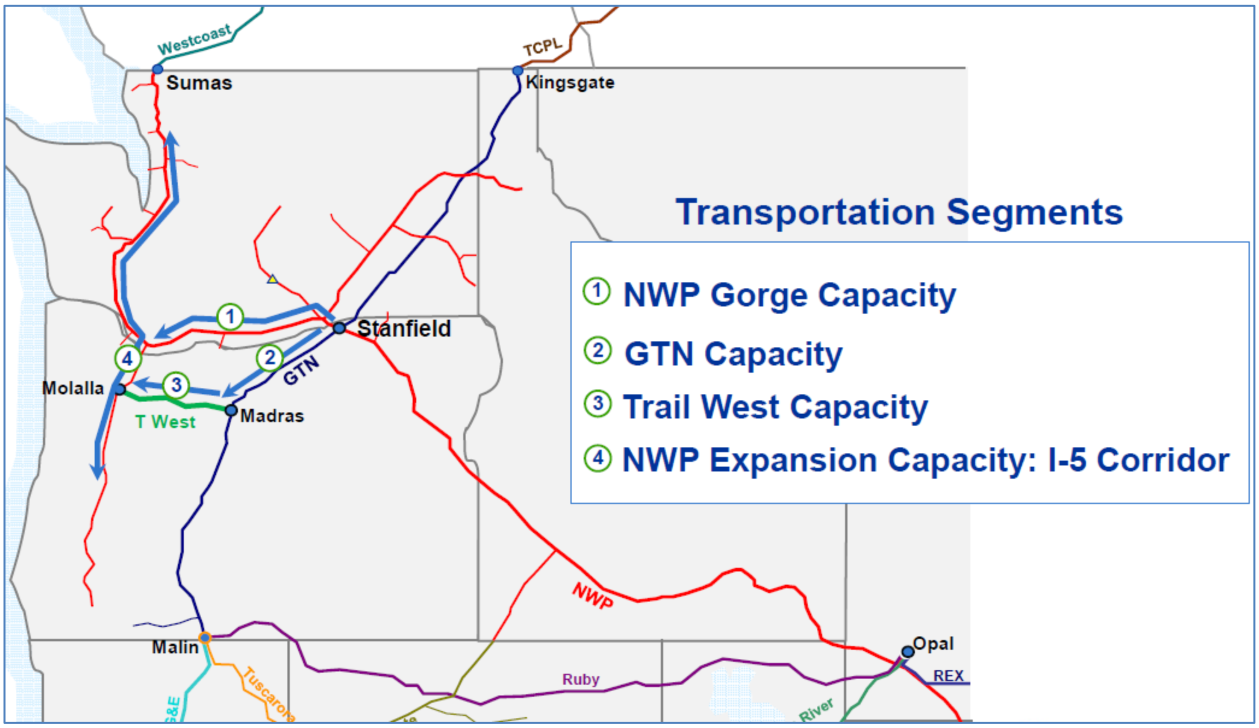
i) The Trail West expansion proposed by Northwest Natural Gas Company would receive gas from TransCanada's GTN system for delivery to the Molalla area on the NWP system. This expansion could enable NWP to expand its system from the Molalla area to flow gas northbound.

ii) Expand the NWP Gorge capacity on the NWP system that will expand the system westbound from Stanfield. This would allow gas to flow north into the Seattle and Tacoma region.

iii) Expand the NWP system from Sumas south on the I-5 corridor to Woodland, Washington. The project plan included 140 miles of 36-inch diameter pipe to be constructed in ten different segments around NWP's existing right-of-way along the I-5 corridor in Washington State between Sumas and Woodland. This project would access gas from the Sumas marketplace.

Figure A-4 below illustrates the potential pipeline expansions that could occur in the US PNW.

Figure A-4: Potential US PNW Pipeline Projects[5]



1.7 KEY CONCLUSIONS ON REGIONAL INFRASTRUCTURE

The pipeline capacity in BC and the PNW region is projected to be constrained over time if industrial projects that require additional gas supply are approved for construction. Meeting the needs of such projects that require daily baseload gas volume can only be fulfilled by adding new pipeline capacity rather than via other resources, such as storage. The development of new pipeline systems will only proceed if industrial project proponents are prepared to financially underpin any new pipeline expansion.

The system or systems that ultimately expand will depend on the locations of the potential future industrial projects. For example, projects that are developed in the Lower Mainland, such as a

[5] TransCanada Presentation (December 11 & 12, 2014). "GTN Collaboration Meeting, Phoenix, AZ".

staging of expansions at FEI's Tilbury location, will require gas supply to be accessed from the WCSB for delivery from Station 2 and/or the AECO/NIT market hub. This large scale increase of incremental gas supply will need to be complemented with expanding pipeline capacity either on Westcoast's T-South system or via a combination of both T-South pipeline and KORP expansion. A development of methanol plants or other large scale loads in the US PNW around the southern part of Washington or northern Oregon vicinity will require a solution such as a Trail West pipeline expansion. All these projects will require some level of expansions on adjoining pipeline systems that feed into each other. This is mainly due to the vast distances between the gas production regions and the location of the proposed industrial projects.

All parties will need to work collaboratively in order to develop solutions that serve the interest of everyone concerned at large, ranging from project developers, pipeline companies, gas producers, First Nations and local stakeholders, in order to ensure the successful advancement of large scale projects in BC and PNW marketplace.

Appendix B

ANNUAL ENERGY DEMAND FORECASTING

Appendix B-1

END-USE DEMAND FORECAST SCENARIO PARAMETERS

APPENDIX B-1: END-USE DEMAND FORECAST SCENARIO PARAMETERS

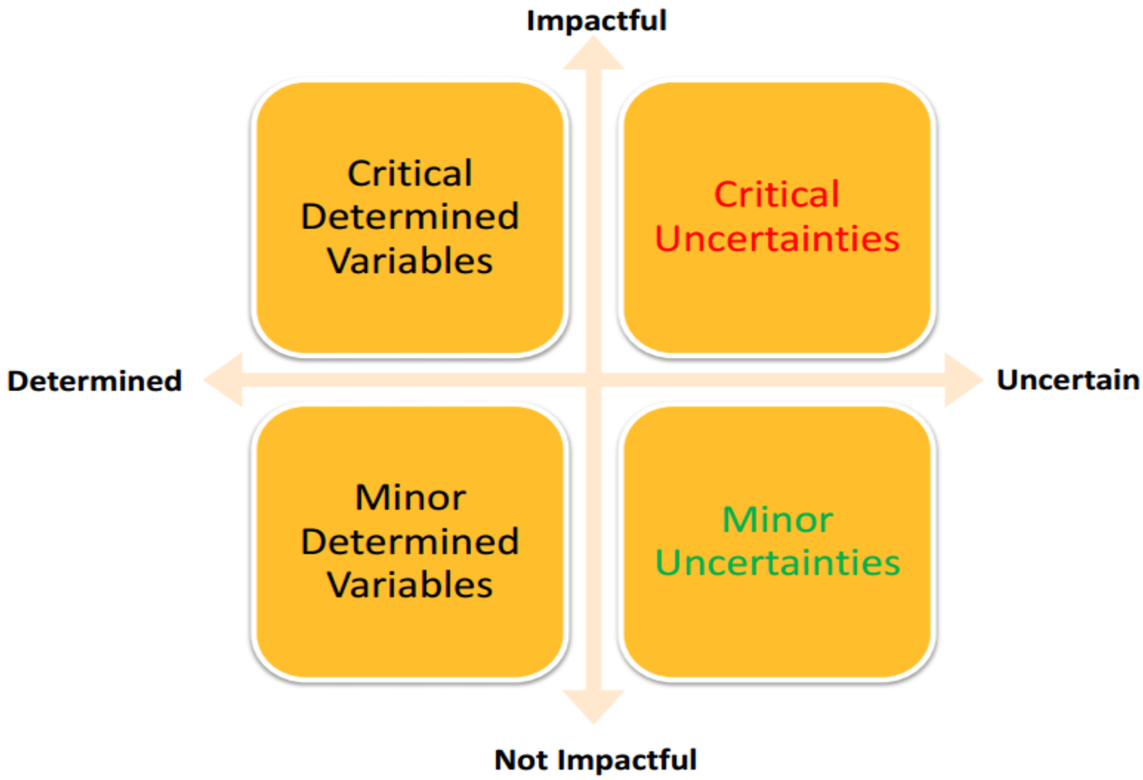
The Reference Case provides a baseline against which forecast demand under five different alternate future scenarios is examined. Since FEI's planning environment for energy services continues to change and present uncertainty, the five future scenarios are intended to provide insight into the impact on demand of a broader range of potential future conditions than has been examined in previous LTRPs. These five scenarios were developed based on critical uncertainties identified with input from the scenario analysis work for the 2014 LTRP, both internal FEI stakeholders and members of the external Resource Planning Advisory Group (RPAG), as well as themes that emerged from the 2017 LTGRP's community engagement workshops. The critical uncertainties represent those future conditions that stakeholders felt could have the biggest impact on FEI's business.

Following a standard scenario planning approach, FEI's scenario analysis proceeds in four steps:

1. Evaluating planning environment variables and identifying critical uncertainties;
2. Determining the number of outcomes and their broad qualitative boundaries for each selected critical uncertainty;
3. Determining plausible combinations of outcomes for each critical uncertainty and creating reasonable scenario plotlines; and
4. Populating quantitative data into the outcomes for each critical uncertainty and iterating with internal and external stakeholder feedback.

The first step in the above list intends to focus the scenario analysis by determining which of the manifold variables in the planning environment should be used to alter the Reference Case into various alternate future scenarios. This involves selecting the most impactful and most uncertain variables. Figure B1-1 below illustrates how FEI classified planning environment variables for this first step:

Figure B1-1: Classification of Planning Environment Variables



FEI intentionally held each step separate from the other steps. Selecting critical uncertainties first and then determining their qualitative boundaries before generating the plotlines and populating quantitative data guards against inadvertently favoring certain visions of the future over others by presupposing scenario results rather than focusing on inputs.

The following sections outline the qualitative boundaries of the outcomes of each critical uncertainty, illustrate the actual quantitative trajectories for these outcomes, and discuss how these trajectories impact the end-use forecast model.

1.1 Qualitative Details on Scenario Critical Uncertainties

Table B1-1 below summarizes the outcomes that FEI modelled for each critical uncertainty and briefly discusses any specific attributes that apply to individual critical uncertainties:

Table B1-1: Summary of Modelled Critical Uncertainty Trajectories

Critical Uncertainty	Modelled Trajectories	Comments
Economic Variables		
Economic Growth	- High - **Reference** - Low	Please see Section 1.2.1.1 in this appendix for an explanation of how FEI modelled economic growth assumptions.
Natural Gas Price	- High - **Reference** - Low	Multiple factors, such as regional demand patterns, natural gas extraction costs and policies that regulate natural gas extraction, influence natural gas prices. This critical uncertainty and its modelled trajectories intend to encompass the effect of such factors.
Policy Variables		
Carbon Price	- High increase - Medium increase - **Reference** - Low	N/A
Non-Price Carbon Policy Action	- Accelerated - **Reference** - Delayed	This critical uncertainty accounts for building codes (for newly constructed dwellings), appliance standards, and other effects and policy actions that may results in customers switching from natural gas to other end-use fuel types.

Critical Uncertainty	Modelled Trajectories	Comments
Extraneous Variables		
RNG Demand	- High - **Reference** - Low	The links between the core end-use forecast and the RNG annual demand forecast are qualitative only because RNG represents an emerging market. FEI provided the core end-use forecast scenario parameters to its RNG program team and requested this team to prepare three forecast trajectories (Reference Case, Low, High) based on these scenario parameters. FEI's RNG program team prepared the three forecast trajectories by modulating expectations about committed projects, projects under negotiation, and assumptions about plausible future capture rates. FEI's RNG program team also shaped the resulting RNG annual demand forecast trajectories to align with expectations about RNG supply availability at reasonable prices. FEI's forecast trajectories assume current RNG supply technologies.
CNG and LNG Demand for Vehicles	- High - **Base** - Low	Similar to the RNG forecast, the links between the core end-use forecast and the NGT annual demand forecast are qualitative only because NGT represents an emerging market. FEI provided the core end-use forecast scenario parameters to its NGT programs department and requested this department to prepare three forecast trajectories (Base, High, Low) based on these scenario parameters.

Critical Uncertainty	Modelled Trajectories	Comments
Large Industrial Point Loads	- **Reference** - Woodfibre example	Please see Section 3.4.9 in the Application for FEI's discussion of this critical uncertainty.

The following section discusses the detailed quantitative inputs of each critical uncertainty.

1.2 Quantitative Details of Scenario Critical Uncertainties

1.2.1 CRITICAL UNCERTAINTY INPUTS

1.2.1.1 Economic Growth

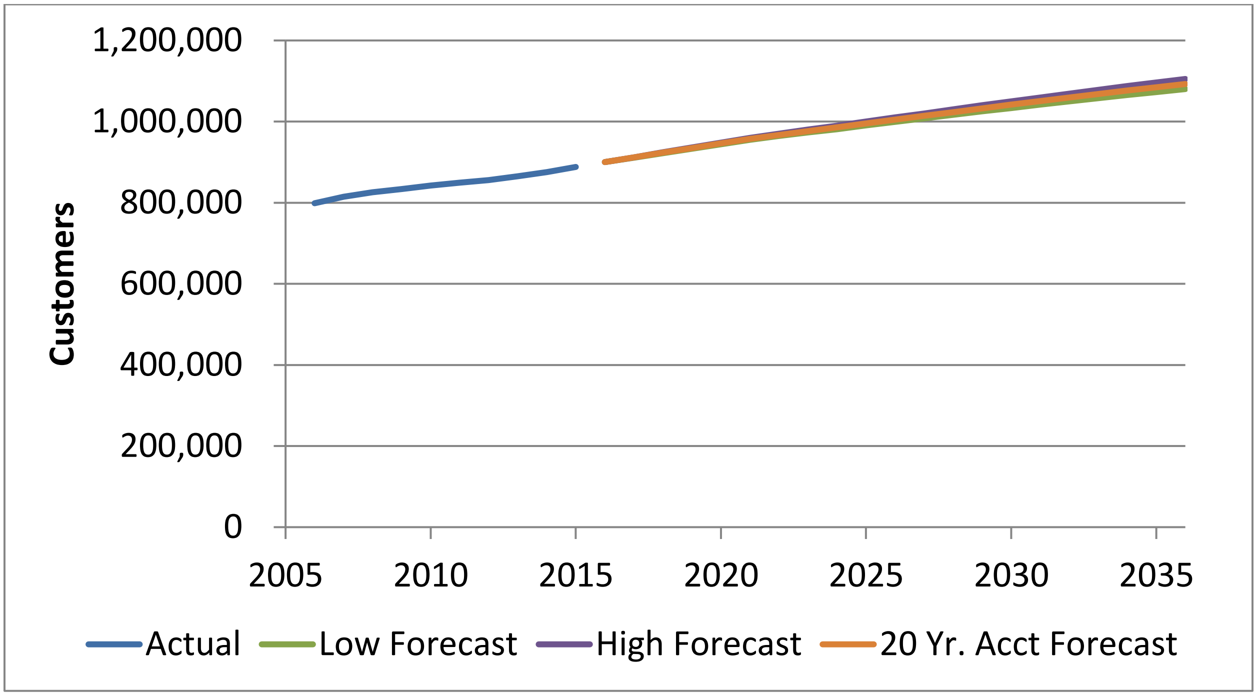
The 2017 LTGRP provides further analysis to simulate the impact of economic growth on customer counts. FEI relies on simulation because its research does not suggest sufficient correlation between Gross Domestic Product (GDP) and natural gas consumption or customer counts. Moreover, relying on third party GDP growth forecast ranges introduces an additional source of potential forecast errors.

As an alternative to any strong direct correlation between GDP growth and customer numbers/natural gas consumption, the 2017 LTGRP relies on a statistical approach using Prediction Intervals (PI). This approach applies FEI's historical variance in customers by rate schedule to FEI's Reference Case customer forecast. The 2017 LTGRP uses these PI to perturb the Reference Case customer forecast into respective High and Low customer forecast outcomes.

This statistical method serves as a proxy to model the potential impact of economic growth on customer numbers but may also account for other intrinsic factors, such as FEI marketing and promotional campaigns. Note that rate schedules with fewer customers experience a greater range between their High and Low outcomes than larger rate schedules.

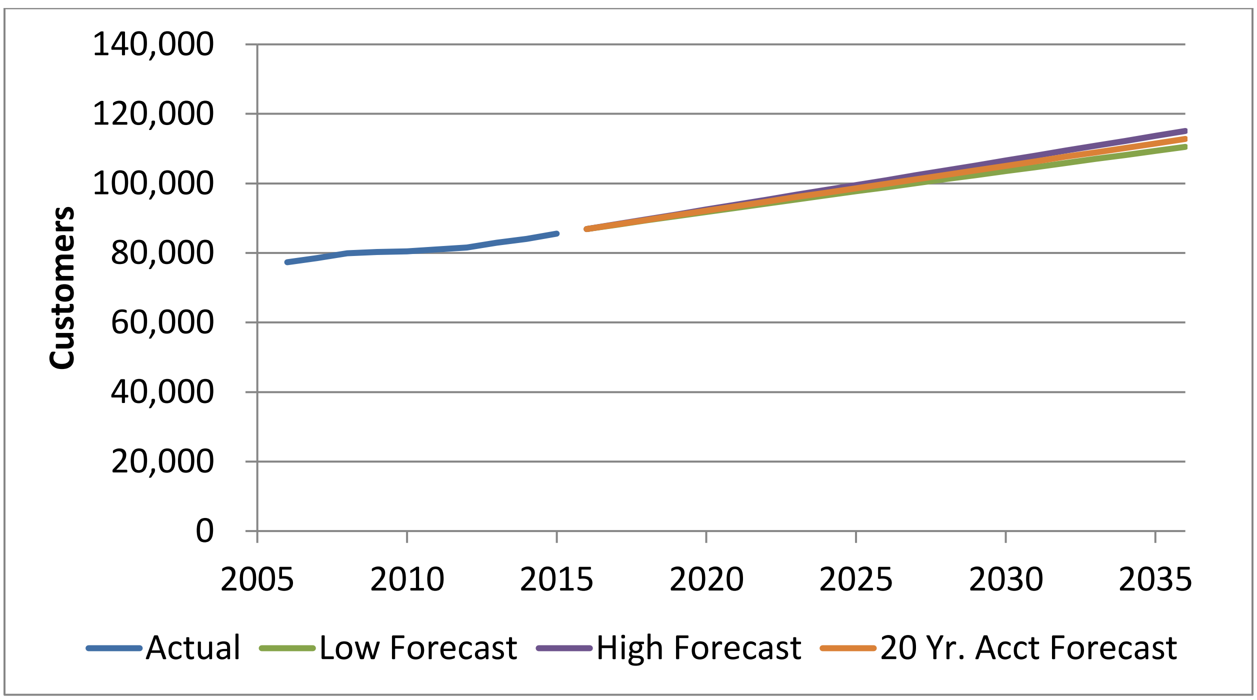
Figures B1-2 to B1-6 illustrate the customer number trajectories for key rate schedules.

1 **Figure B1-2: Customer Forecast Parameters – Rate Schedule 1**



2

3 **Figure B1-3: Customer Forecast Parameters – Rate Schedule 2**



4

Figure B1-4: Customer Forecast Parameters – Rate Schedule 3

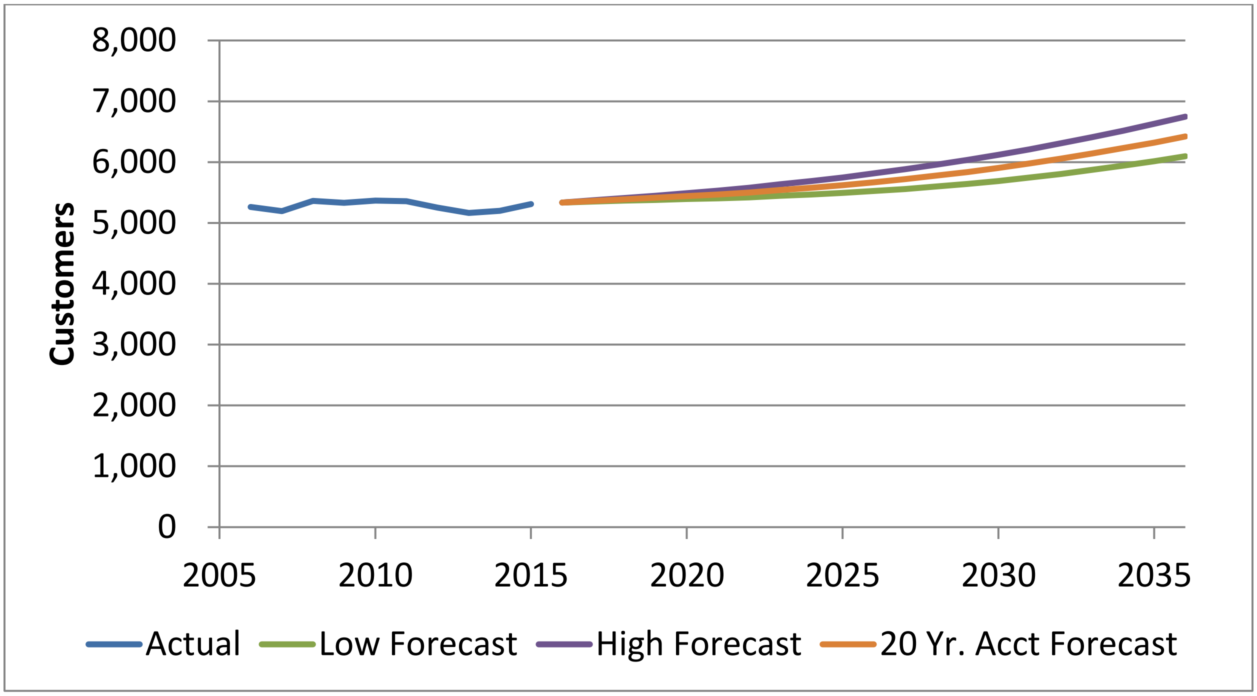


Figure B1-5: Customer Forecast Parameters – Rate Schedule 23

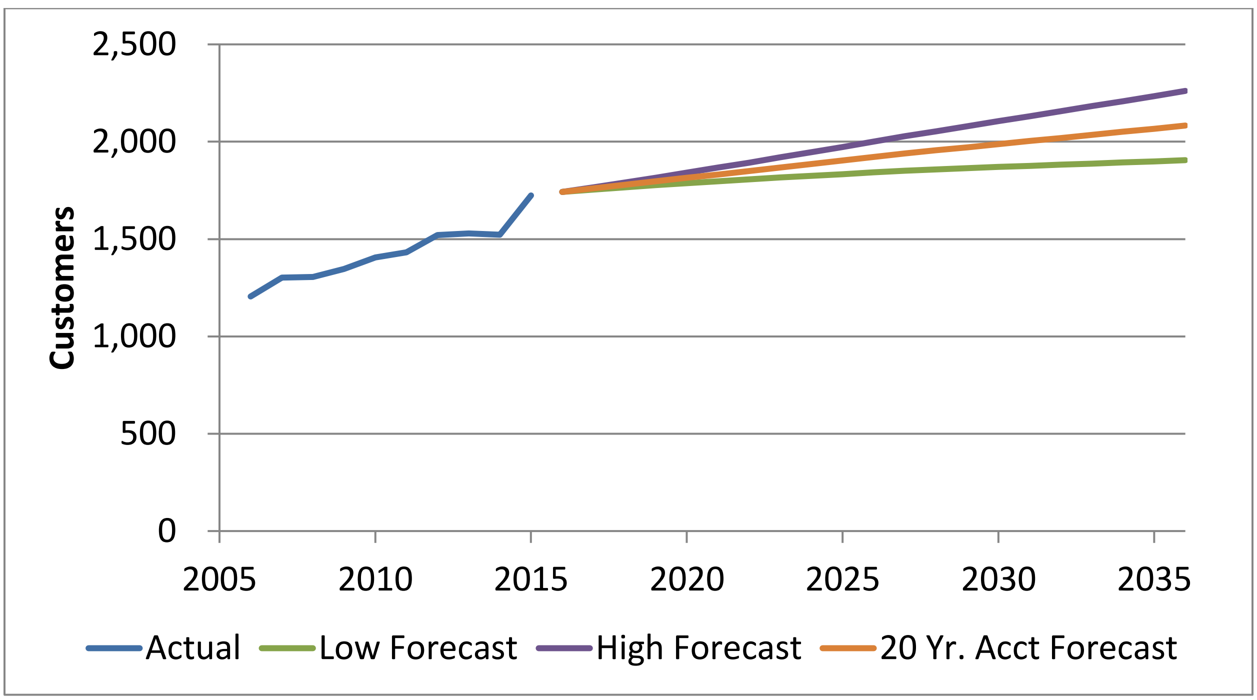

Figure B1-6: Customer Forecast Parameters – Industrial Rate Schedules

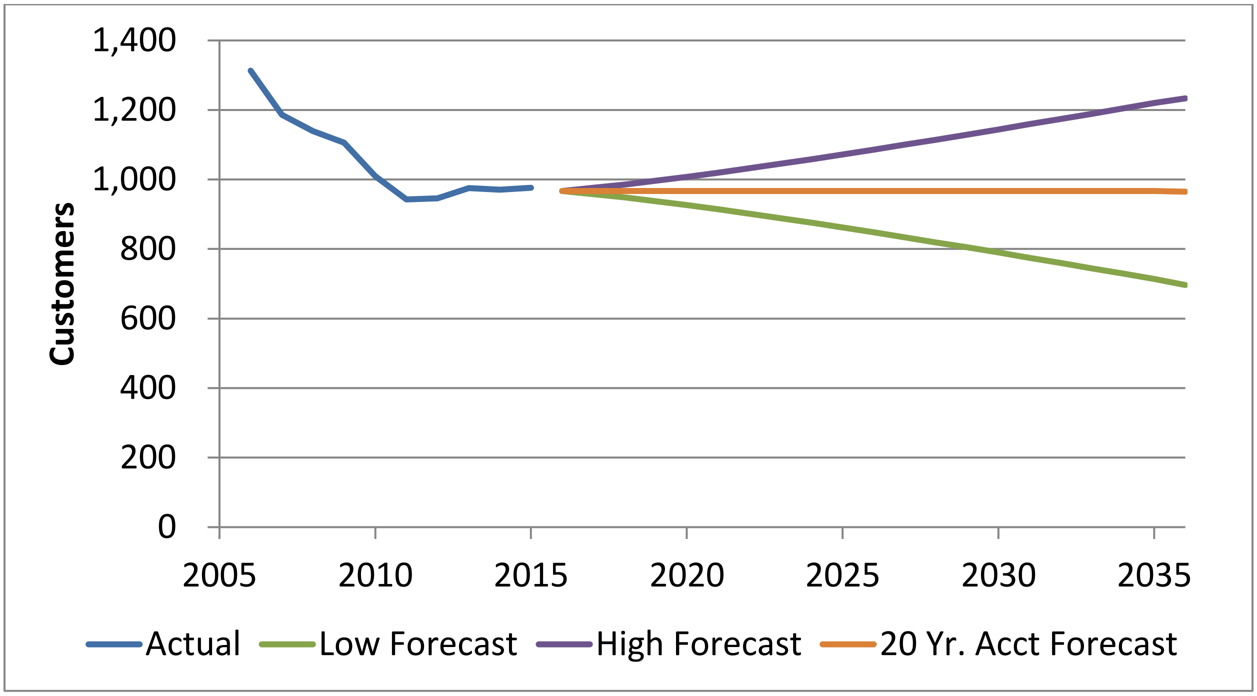


1.2.1.2 Natural Gas Price

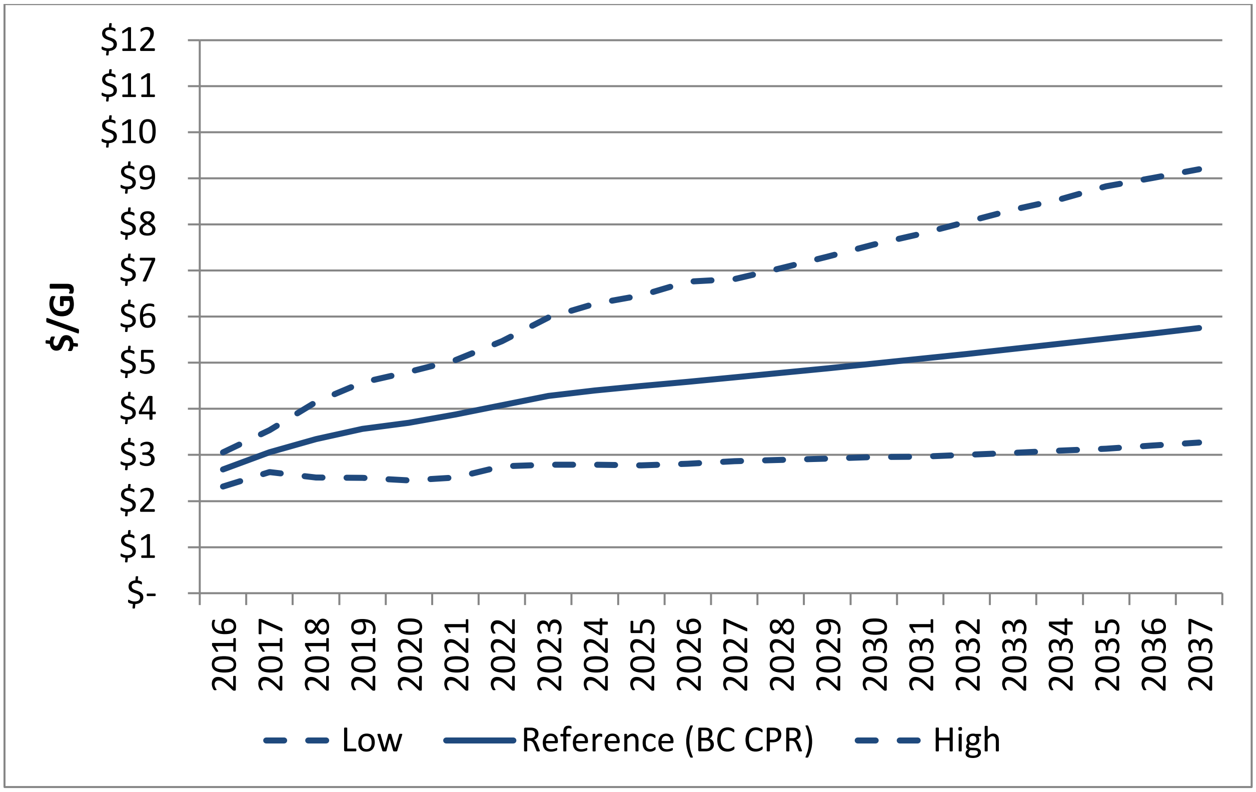
FEI relied on forecasts from multiple third party expert entities to prepare the 2017 LTGRP natural gas price forecast trajectories. The Reference Case natural gas price trajectory represents the same trajectory that FEI used for the BC CPR. FEI selected this trajectory for the 2017 LTRGP in order to facilitate the BC CPR results informing FEI's calibration of the 2017 LTGRP DSM analysis.

In its 2015 natural gas price forecast, Northwest Power and Conservation Council (NPCC) generates its own base, low, and high trajectories based on its expertise and consultation with a wide array of Pacific Northwest (PNW) experts. This forecast is bullish about the prospects of large scale LNG export terminals emerging in the PNW. FEI's BC CPR natural gas price forecast is less bullish about these prospects as it uses more recent input data.

The 2017 LTGRP applies the low-high range from the 2015 NPCC forecast to the BC CPR natural gas price forecast in order to generate LTGRP High and Low natural gas price outcomes. In doing so, FEI avoids having to average multiple third party forecast values to create High and Low natural gas price outcomes. This also enables FEI to take advantage of the newer input data in the BC CPR natural gas price forecast and to facilitate the BC CPR informing the 2017 LTGRP DSM analysis.

FEI validated the resulting natural gas price trajectories against a range of existing recent third party forecasts, including the International Energy Agency (IEA) and GLJ Petroleum Consultants Ltd. (GLJ). Figure B1-7 below displays the resulting Reference Case, High, and Low natural gas price trajectories. The range between High and Low serves as a proxy not only for price changes due to shifting demand-supply conditions but also potential policy actions that may impact the commodity price, such as upstream GHG reduction initiatives.

Figure B1-7: Sumas Natural Gas Price Forecast – Annual Prices



1.2.1.3 Carbon Price

FEI and FBC collaborated to develop their long term carbon pricing trajectories by consulting internal and external subject matter experts. The resulting carbon pricing trajectories take into account the Canadian federal carbon pricing backstop mechanism. The trajectories have been validated via the LTERP RPAG and have also received support from the LTGRP stakeholders (in the RPAG and FEI's community engagement workshops).

Figure B1-8 below displays the 2017 LTGRP's carbon pricing outcomes. These include one addition in relation to the 2016 LTERP. FEI added a Low trajectory at BC's 2016 carbon tax level since the possibility exists that BC's carbon price may remain constant at this level if BC's government does not increase it and if the Canadian federal carbon pricing backstop mechanism does not proceed or flounders during its interim review. The Low and Reference carbon price outcomes assume that prices will increase by inflation after 2022. This prevents the carbon prices in these outcomes from dropping back to or even below current levels in real terms by the end of the planning period. This carbon pricing range intends to account for considerable policy uncertainty in relation to BC provincial, Canadian federal, and wider North American developments (as discussed in Section 2 of the Application).[1]

Figure B1-8: Carbon Price Forecast – Per Metric Tonne

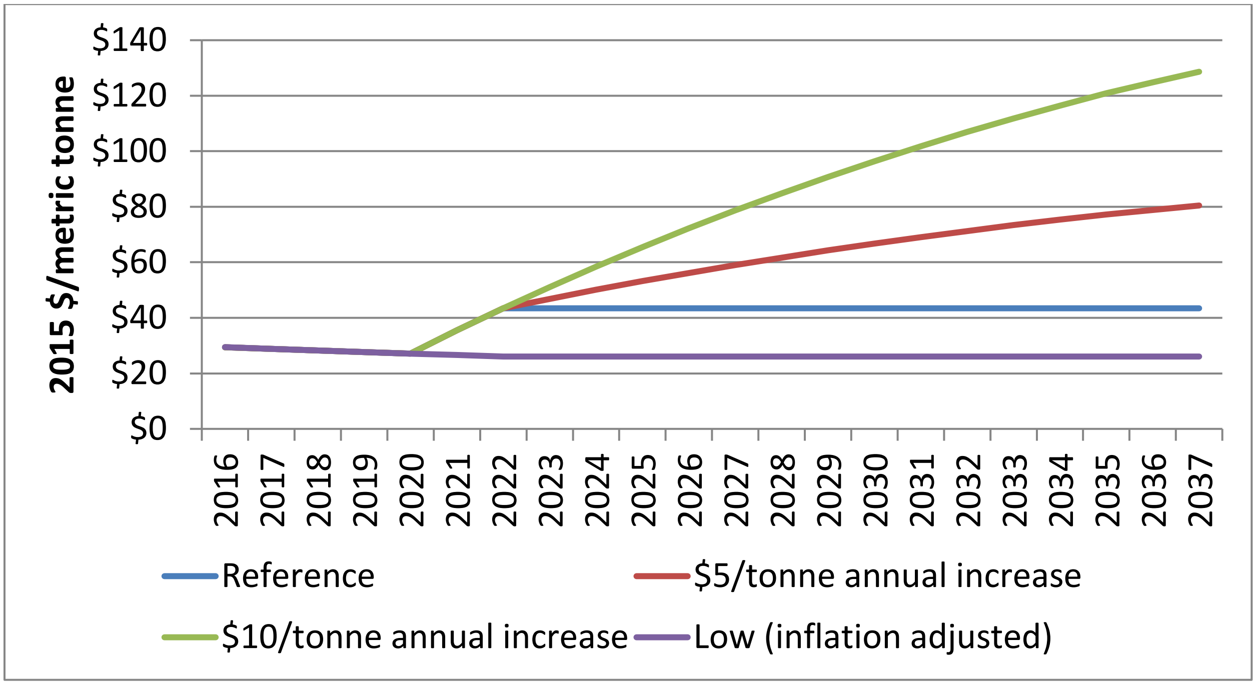


Figure B1-9 below illustrates that, in dollar per GJ terms, the carbon pricing critical uncertainty is significant when compared with the natural gas price critical uncertainty range in Figure B1-7 above. As such, carbon pricing represents considerable risk for annual demand across the planning period.

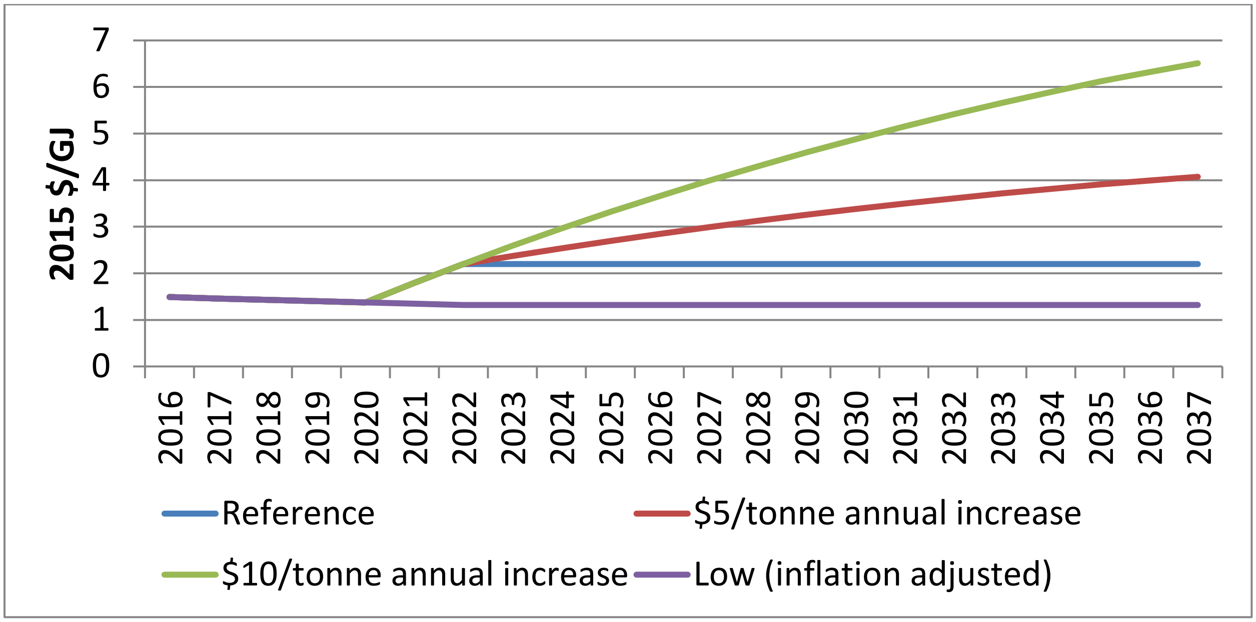
[1] The September 11, 2017, BC budget update proposes to increase the carbon tax by $5 per tonne per year for the next four years, beginning April 1, 2018, until the carbon tax rate is equal to $50 per tonne in 2021. If this increase is maintained each year, as proposed in the updated budget, the carbon tax will increase to $50 per tonne one year earlier than FEI's Reference Case carbon price assumption. The current BC budget does not provide any indication that increases to the carbon tax will continue to occur once the tax rate reaches $50 per tonne. Between 2018 and 2021, the BC budget update causes the proposed BC carbon price to be higher than FEI's Reference Case carbon price assumption. In the long run, however, the variance between FEI's Reference Case carbon price assumption and the information provided in the BC budget update is immaterial.

Figure B1-9: Carbon Price Forecast – Per GJ



1.2.1.4 Non-Price Carbon Policy Action

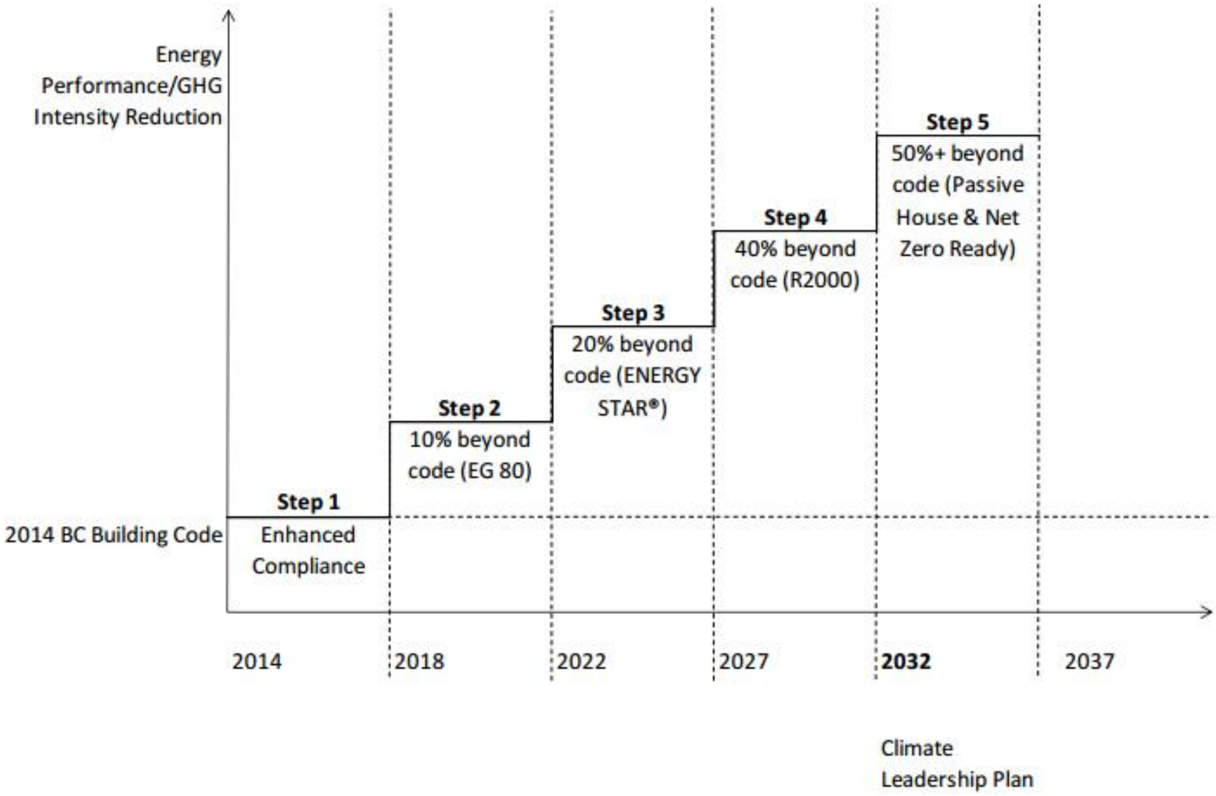
Non-price carbon policy accounts for the impact of building codes (for new construction), appliance standards (for retrofits in existing buildings or appliance installations during new construction), and any other undetermined effects or policy actions that may result in customers switching away from natural gas to another end-use fuel type.

1.2.1.4.1 <u>Building Codes</u>

The Reference Case, which is based on known, legally enshrined and mandatory requirements, assumes that the 2014 iteration of the BC Building Code (BCBC) will remain unchanged across the planning period. This is an important starting point against which to compare other outcomes on this critical uncertainty.

Nevertheless, BC has enacted the BC Energy Step Code and the provincial CLP declares a goal of net zero ready new construction for 2032. To account for the plausibility of future changes in the BCBC, the 2017 LTGRP progressively applies the voluntary and non-time bound steps from the BC Energy Step Code across relatively even time periods throughout the planning horizon in order to achieve the CLP's 2032 target. As such, 2017 LTGRP scenarios that are subject to the Accelerated outcome on the Non-Price Carbon Policy critical uncertainty, assume that the entire province moves along this step code ladder over time as the BCBC is updated. Figure B1-10 below illustrates this dynamic for a subset of dwellings:

Figure B1-10: Lower Mainland Single Family Dwellings – Accelerated Non-Price Carbon Policy Illustration



Similarly, the possibility exists that extraneous factors may hamper new building performance or introduction of enhanced building codes. To account for this, the 2017 LTGRP assumes that scenarios which are subject to the Delayed outcome on the Non-Price Carbon Policy critical uncertainty see new buildings performing at discounted rates in relation to the code-mandated level. Based on industry research of how well BC buildings actually perform in relation to mandatory new construction performance requirements, the 2017 LTGRP assumes such buildings to perform at 63 and 70 percent of mandated performance, respectively, for residential and commercial buildings.

1.2.1.4.2 Appliance Standards

The Reference Case assumes that currently mandatory or legally enshrined appliance standards continue across the entire planning period. The Reference Case also accounts for some natural change in average appliance efficiencies across the planning period, such as commercial domestic hot water tanks changing from 0.75 Thermal Efficiency (TE) to 0.80 TE as they are replaced.

Scenarios that are subject to the Accelerated outcome on the Non-Price Carbon Policy Action critical uncertainty include the following additional performance requirements for residential appliances:

- Minimum 50 percent Fireplace Efficiency (FE) starting in 2018;
- For boilers, minimum 90 percent Annual Fuel Utilization Efficiency (AFUE) in 2020 and 95 percent AFUE in 2025; and
- For furnaces, minimum 95 percent AFUE in 2020.

When the 2017 LTGRP performed its annual demand scenario analysis, Natural Resource Canada (NRCan) published preliminary information on its Amendment 15 with likely impacts for residential and commercial water heaters. Amendment 15 represents one of successive updates to Canada's national energy efficiency regulations which govern appliances that are sold in Canada across national or provincial boundaries. Despite consultation with external and FEI's internal experts, the performance details of these impacts remained unclear until the annual demand scenario analysis had reached its point of no return for including additional information. Sensitivity analysis of the above regulatory impacts on space heating on annual demand, suggest that any impact of NRCan Amendment 15 on water heating annual demand will be less than 1.2 percent by the end of the planning horizon.

1.2.1.4.3 Other Policy Actions that May Result in Fuel Switching

In the 2017 LTGRP, fuel switching occurs as function of price response (to natural gas cost or carbon price) but not as function of efficiency increases in new construction. For example, a home that is built to the ENERGY STAR® standard rather than current BCBC levels in the model, does not automatically switch from one fuel to another. This treatment of efficiency increases is consistent with how the BC CPR treats such increases.

To account for the impact of such effects and the effects of undetermined policy actions that may compel customers to switch from natural gas to another fuel type (e.g. Orders in Council 100 and 101, discussed in Section 2.3.3.5 of the 2017 LTGRP), the 2017 LTGRP scenario analysis includes a backstop mechanism that mandates minimum levels of fuel switching across the planning period for scenarios that are subject to the Accelerated outcome on the Non-Price Carbon Policy Action critical uncertainty. The backstop levels are based on updates of research conducted for the 2014 LTRP and, for the residential sector specifically, extrapolated fuel share change data from the BC CPR. The backstop levels break out as follows:

- Across the planning period, 15 percent of commercial buildings connect to district energy systems and are thus removed from FEI's natural gas system;
- If not motivated by price response already, at least the following amount of switching from natural gas to other fuels occurs for the following buildings across the planning period:
    - Depending on their location and building type, 26 to 36 percent of residential dwellings and apartment buildings switch their space heating and 16 to 25 percent switch their domestic hot water away from natural gas;

- In addition to district energy connections, 2 percent of commercial buildings switch their hot water loads away from natural gas; and
- 1 percent of industrial facilities switch their hot water loads away from natural gas.

1.2.2 CRITICAL UNCERTAINTY IMPACTS ON THE FORECAST MODEL

Table B1-2 below summarizes how each critical uncertainty impacts the mechanics of the 2017 LTGRP forecast model and discusses specific attributes of individual critical uncertainties.

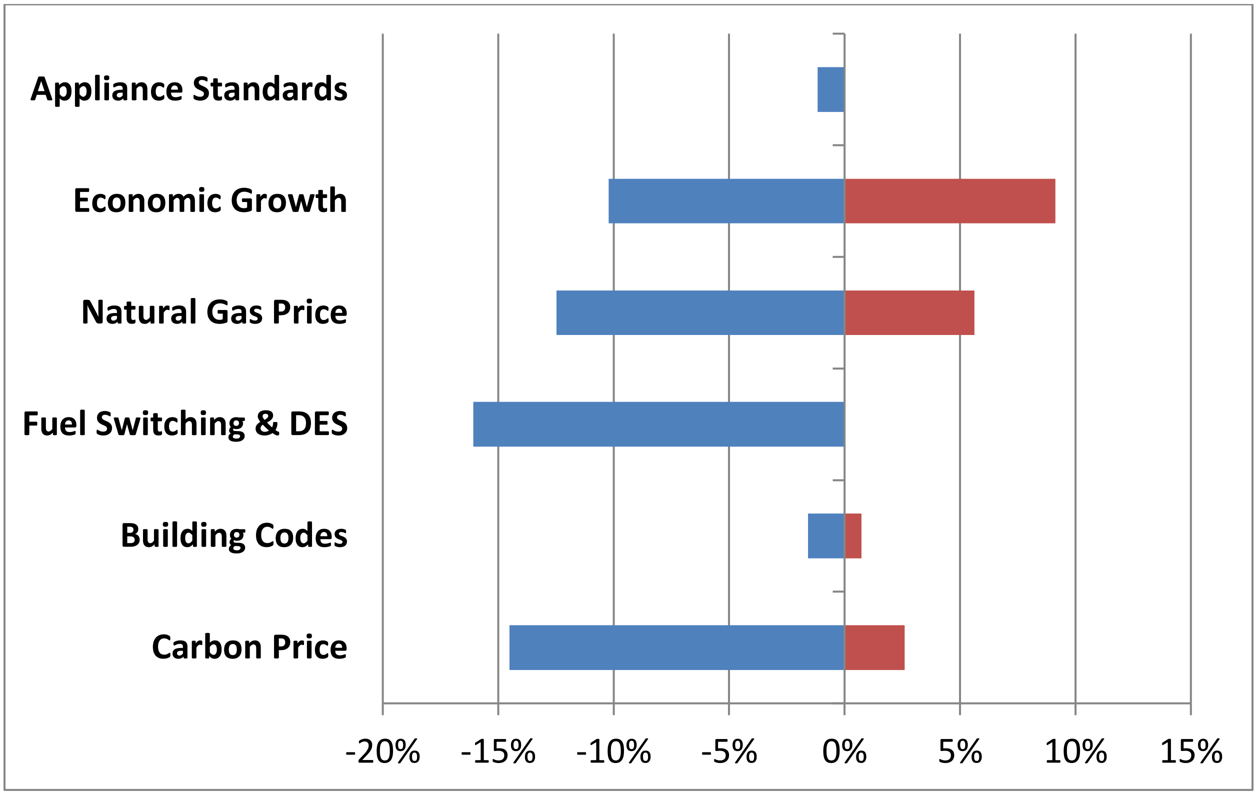
Table B1-2: Summary of Critical Uncertainty Impacts on the Forecast Model

Critical Uncertainty	Model Levers	Comments
Economic Factors		
Economic Growth	- Residential building stock - Commercial floor area - Industrial facilities	See Table B1-1 above.
Natural Gas Price	Long run natural gas fuel share	Based on a literature review of existing research by FEI and Posterity, the 2017 LTGRP uses -0.2 and -0.5 as the long run price sensitivity values for residential and commercial/industrial customers, respectively. Since these are long run values, the 2017 LTGRP forecast model calculates the total fuel share change from these values by the end of the planning period and subsequently solves for the required annual change rates required to produce the total change. The model ensures that the calculated annual change rates are achievable in relation to the rate of end-use equipment replacements.
Policy Factors		
Carbon Price	Long run natural gas fuel share	This critical uncertainty relies on the same mechanics as the Natural Gas Price critical uncertainty.

Critical Uncertainty	Model Levers	Comments
Non-Price Carbon Policy Action	- Long run natural gas fuel share - Natural gas use per customer - Natural gas appliance efficiency	See Table B1-1 above.
Extraneous Factors		
RNG Demand	- RNG fuel share - Conventional natural gas fuel share	See Table B1-1 above.
CNG and LNG Demand for Vehicles	- Commercial rate schedule demand - Industrial rate schedule demand	See Table B1-1 above. The 2017 LTRGP forecast implements the forecast NGT volumes by multiplying forecast vehicle numbers by average use per vehicle rates.
Large Industrial Point Loads	- Industrial rate schedule demand	See Table B1-1 above.

Figure B1-11 below illustrates how sensitive total annual demand is to the High versus Low (Accelerated versus Delayed) outcomes for each individual critical uncertainty. This figure emphasizes that the 2017 LTGRP gives healthy consideration to factors that may reduce annual demand across the planning period. Individually, the critical uncertainties have no more than 17 percent impact on annual demand, but the 2017 LTGRP scenarios combine these critical uncertainties. The manner in which critical uncertainties combine to form alternate future scenarios is important since their outcomes may either reinforce or offset each other. The Economic Growth uncertainty shows significant impact. In light of this, please note that FEI's method for developing the quantitative inputs for this uncertainty represents a proxy only to estimate the potential impact of different economic growth climates. The Fuel Switching and District Energy lever from the Non-Price Carbon Policy Action critical uncertainty has the highest individual impact. This illustrates the significance for annual demand of this backstop that FEI included in the 2017 LTGRP scenario analysis.

Figure B1-11: 2036 Annual Demand Sensitivity to High/Low Critical Uncertainties – All Sectors



1.3 Conclusion

Section 2 of the Application discusses how the 2017 LTGRP is embedded within the context of a complex and partially uncertain planning environment. In response, the 2017 LTGRP builds on the end-use forecast method scenario analysis from the 2014 LTRP and includes a significant range of critical uncertainties to account for potential changes in the planning environment across the planning period.

These uncertainties range from economic growth and natural gas price, via carbon price and non-price carbon policy action, to the impact of emerging markets, such as RNG and NGT as well as the potential impact of large new industrial point loads, such as LNG export terminals. FEI used a rigorous process for developing the inputs for each critical uncertainty and for implementing these into the 2017 LTGRP forecast model. In doing so, FEI drew on the expertise of its internal LTGRP working groups, its forecast consultant (Posterity), and the experience of stakeholders in the RPAG and across FEI's community engagement workshops.

The resulting critical uncertainty data and implementation accounts for a wide range of possible alternate future scenarios and enables FEI to account for planning environment risks in its 2017 LTGRP analysis. The critical uncertainties also serve as signposts for FEI to evaluate which future scenarios may be unfolding as it proceeds through the planning period.

END-USE DEMAND FORECAST METHODS ANALYSIS

boreas consulting ltd.

FortisBC Energy Inc.

Long Term Demand Forecasting

Benchmarking Study on End-Use Methods

Industry Practices Review

Prepared by: **Boreas Consulting Ltd.**

4 January 2017

Table of Contents

1. EXECUTIVE SUMMARY

In the regulatory proceeding reviewing the 2014 Long Term Resource Plan for FortisBC Energy Utilities (2014 FEU LTRP), FEU was asked by the BC Utilities Commission ('the Commission') whether it had compared its End-Use forecasting model with forecasting models used by other utilities. The Commission and interveners expressed some reservations about FEU's end-use model including the complexity and associated cost of updating the model. Accordingly, the Commission directed FEU to "provide a detailed analysis of the relative benefits/shortcomings of their particular End-Use Method as compared to other end-use methods". As a result, FEU retained Boreas Consulting (Boreas) to review long term forecasting practices of North American gas utilities to determine whether there is a preferred method for conducting demand forecasts for use in integrated resource planning activities.

Boreas completed a comparison of long-term (over 10 years) annual demand forecasting activities among gas distribution utilities in North America – particularly in Canada, the U.S. Pacific Northwest and California.

Boreas completed this work by reviewing publicly available documents from 30 gas utilities and one utility regulator. These documents primarily consisted of regulatory filings by the utilities and included Integrated Resource Plans (IRPs), Capacity Supply Plans, Energy Efficiency Plans, Rate Applications, and Testimonies. Furthermore, Boreas identified the person and/or people responsible for forecasting at some utilities and interviewed them to obtain more detailed insight into their forecasting methods.

Companies with forecasting horizons of 10 years or more often use their long term forecast as part of their IRP, which often has a longer term horizon.

Approximately 44% of the companies that use long term forecasts of 10 years or more use some form of end-use modeling combined with econometric modeling. The end-use models are often used to forecast use per account, while econometric models are used to forecast growth in the number of accounts. The rationale being that as energy efficiency becomes more important, end-use modeling provides a much more detailed understanding of the impact of efficiency improvements on the energy use and long term forecasts, particularly in new construction and replacement of old equipment.

Some of the jurisdictions that are leaders in energy efficiency policy and regulation have used end-use modeling since the introduction of energy efficiency regulation over 20 years ago and continue to do so. The one regulatory body that prepares its own long term forecasts for the state and the utilities in the state has used end-use forecasting models since 1975.

In most cases, annual demand forecasts for residential and commercial customer classes are developed by multiplying the forecasted number of customers in each rate class by the average use per account for that rate class. Economic forecasts from government agencies or other organizations are used to forecast the growth in number of customers. Average use per account forecasts are based on either econometric models or end use models. Econometric models often use weather normalized historical consumption data and apply regression modeling to the data to forecast average use per account. End-use models often use end-use data from end-use surveys to forecast average use per account based on different end-uses.

End-use models tend to be much more data intensive than econometric models. However, the companies that use them believe as energy efficiency policies and standards become more important, end-use modeling provides them the level of detail required to assess the impact of energy efficiency standards and regulations. Similar to econometric models, the parameters used in end-use forecasting models vary from company to company, but in most cases, include energy prices, saturation levels of different end-uses, saturation levels of different energy sources, vintage or age of dwellings, dwelling type, dwelling size, and vintage or age of different end-use equipment. This data is often collected from end-use surveys.

Most jurisdictions, among those investigated, with high levels of DSM activity and IRPs use end-use modeling for their long-term forecasting. All end-use models require a medium to high degree of data intensiveness and can examine end-use trends within different scenarios, which in turn allow the utilities to show how changes to model inputs affect the results. Most utilities perform some form of testing of the forecasts against actual data. However, because long-term forecasts are based on forecasts of many input parameters, such as whether, energy prices, economic conditions, employment levels, new construction activity, etc. a straight comparison of forecasts to actuals without any adjusting for the input parameters does not necessarily reflect the effectiveness of the forecasting model. Thus, comparison of the forecast results to actuals may be quite resource intensive.

2. Introduction

In the regulatory proceeding reviewing the 2014 Long Term Resource Plan for FortisBC Energy Utilities (2014 FEU LTRP), FEU was asked by the BC Utilities Commission ('the Commission') whether it had compared its End-Use forecasting model with forecasting models used by other utilities. FEU provided a high level description of forecasting models from eight other utilities and characterized their approaches as one of: "top-down", "bottom-up statistical", "bottom-up engineering". In its Decision, the Commission agreed that FEU's intention to discontinue using a traditional method and to move towards an end-use forecasting approach had merit, but expressed reservations about the added expense related to further development of a model for forecasting the annual demand when it is the peak demand forecast that is the primary driver for infrastructure planning purposes. The Commission and interveners also expressed reservations regarding the complexity and associated cost of updating the FEU End-Use model, as well as with the lack of testing with historical data to ascertain the accuracy of the model. Accordingly, the Commission directed FEU to "provide a detailed analysis of the relative benefits/shortcomings of their particular End-Use Method as compared to other end-use methods".

As a result, FEU retained Boreas Consulting (Boreas) to review long term forecasting practices of North American gas utilities to determine whether there is a preferred method for conducting demand forecasts for use in integrated resource planning activities. Specifically, FEU desires:

- A comparison of long-term (~20 year) annual demand forecasting activities among gas utilities in North America – particularly in Canada, the U.S. Pacific Northwest and California.
- A characterization of forecasting methods as either top-down (aggregated trends) or bottom-up (end-use based), or as based on some alternative characterization.
- A survey of the granularity of forecasts. In other words, are forecasts typically presented on a yearly basis, using milestone years (i.e. every 5 years), or on some other frequency?
- A survey of the variables and parameters altered in order to develop alternative forecast scenarios, such as different customer growth scenarios, use per customer scenarios, or economic and climate change scenarios.
- When possible, an assessment of the costs for updating and maintaining various forecasting models (within ranges).
- Depending on the information available, assess how different models have performed against historical data.
- Where possible, a description of how other utilities link their long-term annual demand to their long-term peak demand forecasts.

3. FortisBC Model

FEU's end-use forecasting model was developed by ICF International Canada (formerly known as ICF/Marbek). The model is built on top of the model that was used to develop the Conservation Potential Review (CPR), which allows for applying energy efficiency measures to a reference case

FEU's long term annual demand forecast starts by developing a detailed annual demand forecast for the base year. The base year demand forecast is built on demand forecasts for geographic regions, sectors and subsectors, rate classes, and different end-uses. FEU's annual demand forecast considers saturation levels of different end-uses, the market share of natural gas, and energy consumption for various end-uses. The base year forecast is then calibrated against FortisBC's sales, using the most recent data available.

The forecast is built from the base year by growing the number of accounts based on FortisBC's 20-year forecast number of accounts by rate class. FEU's end-use model forecasts new accounts based on the most recent vintage of buildings and building codes; it incorporates anticipated efficiency improvements (such as natural replacement of furnaces with condensing units), as well as anticipated changes in saturation and gas share for specific end uses.

The model makes use of saturation levels of different end-uses, natural gas market share, the vintage of buildings, rate class, dwelling type, and number of accounts.

4. Method

Boreas completed a comparison of long-term (over 10 years) annual demand forecasting activities among gas distribution utilities in North America – particularly in Canada, the U.S. Pacific Northwest and California.

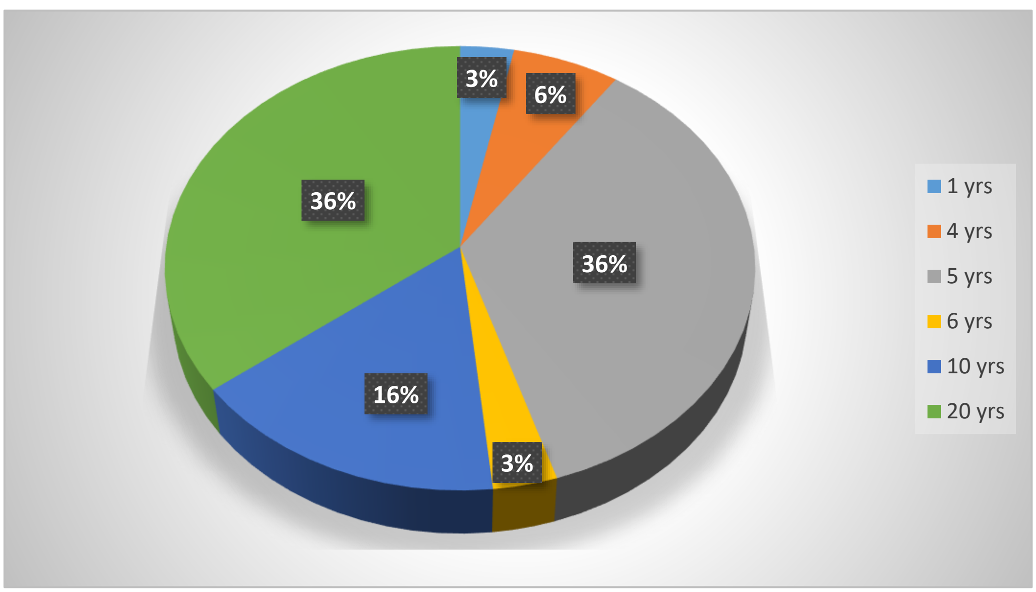
Boreas completed this work by reviewing publicly available documents from 30 gas utilities and one utility regulator. These documents primarily consisted of regulatory filings by the utilities and included Integrated Resource Plans (IRPs), Capacity Supply Plans, Energy Efficiency Plans, Rate Applications, and Testimonies. Furthermore, Boreas identified the person and/or people responsible for forecasting at some utilities and interviewed them to obtain more detailed insight into their forecasting methods.

5. Findings

Boreas' findings are summarized in this section, with detailed findings included in Appendix A.

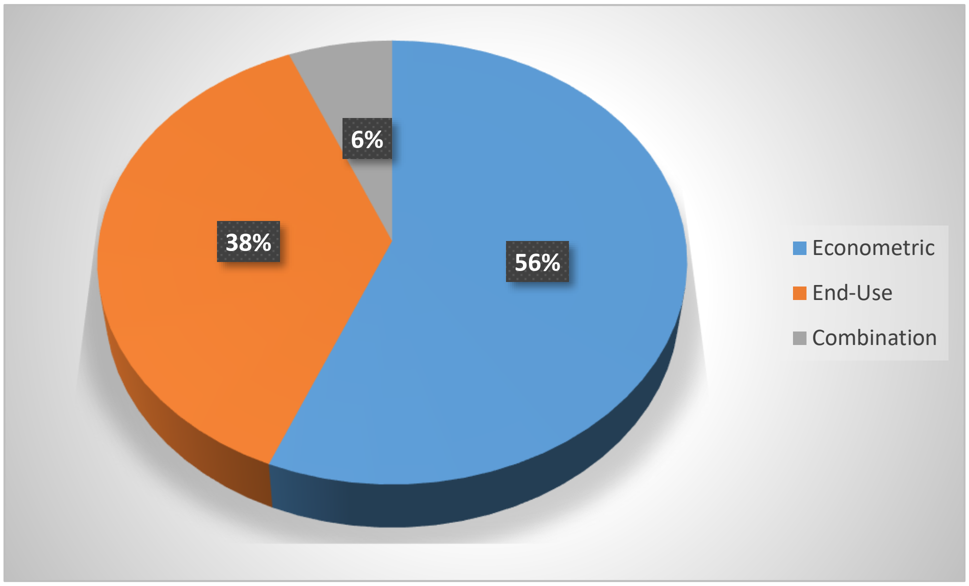
As illustrated by Figure 1, the companies are relatively evenly distributed among those that prepare long term forecasts of 10 years or more and those that prepare forecasts of less than 10 years. The companies with forecasting horizons of less than 10 years often prepare their forecast for supply planning purposes or rate applications, while companies with forecasting horizons of 10 years or more often use their long term forecast as part of their IRP, which often has a longer term horizon.

Figure 1. Distribution of Forecast Horizon



As illustrated by Figure 2, approximately 44% of the companies that use long term forecasts of 10 years or more use some form of end-use modeling combined with econometric modeling. The end-use models are often used to forecast use per account, while econometric models are used to forecast growth in the number of accounts. The rationale being that as energy efficiency becomes more important, end-use modeling provides a much more detailed understanding of the impact of efficiency improvements on the energy use and long term forecasts, particularly in new construction and replacement of old equipment.

Figure 2. Distribution of Forecasting Method for Companies w/ Forecast Horizon Over 10 yrs



Some of the jurisdictions that are leaders in energy efficiency policy and regulation have used end-use modeling since the introduction of energy efficiency regulation over 20 years ago and continue to do so. The one regulatory body that prepares its own long term forecasts for the state and the utilities in the state has used end-use forecasting models since 1975.

In most cases, annual demand forecasts for residential and commercial customer classes are developed by multiplying the forecasted number of customers in each rate class by the average use per account for that rate class. Economic forecasts from government agencies or other organizations are used to forecast the growth in number of customers. Average use per account forecasts are based on either econometric models or end use models. Econometric models often use weather normalized historical consumption data and apply regression modeling to the data to forecast average use per account. End-use models often use end-use data from end-use surveys to forecast average use per account based on different end-uses.

Most companies build their annual demand forecast for their large industrial customers from individual customer forecasts, which are often based on historical trends with adjustments that are based on customer feedback and future plans.

The parameters used in econometric forecasting models vary from company to company but in most cases include energy prices, GDP growth, population growth, household growth, income, and employment levels. Some econometric models also include an energy efficiency index, which takes into account improvements in energy efficiency standards and building codes.

End-use models tend to be much more data intensive than econometric models. However, the companies that use them believe as energy efficiency policies and standards become more important, end-use modeling provides them the level of detail required to assess the impact of energy efficiency standards and regulations. Similar to econometric models, the parameters used in end-use forecasting models vary from company to company, but in most cases, include energy prices, saturation levels of different end-uses, saturation levels of different energy sources, vintage or age of dwellings, dwelling type, dwelling size, and vintage or age of different end-use equipment. This data is often collected from end-use surveys.

Irrespective of the type of forecasting model used, most companies run a number of forecast scenarios. The forecast scenarios typically include a base case, which is the mostly likely scenario, plus a high and low case, which are based on high and low growth. Some companies also run forecast scenarios to assess the potential impact of climate change and carbon taxes.

The companies with long-term forecasts, where the forecast horizons are 10 years or more, provide annual demand forecasts for either every year or every five years during the forecast period.

Most companies evaluate the performance of their forecasting model by comparing forecasted annual demand to actuals. However, this may sometimes be challenging because of the number of adjustments that may have to be done to parameters, such as weather, energy prices, and economic conditions as these parameters can have a significant impact on the output from the model. In general, performance of the models is assessed by comparing the long term average of the adjusted actuals to forecast over several years.

Most end-use models are developed by external resources but are operated by internal resources. Because econometric models often use regression analysis techniques, they are sometimes developed internally.

Most companies use their annual demand forecast to develop their peak-day demand forecast. Some of the common methods used in developing peak-day demand forecasts is to start with the annual demand forecast and to apply the load factor of the different customer classes to the average-day demand for the applicable class, applying load shapes for different customer classes or end uses to the annual demand, and adjusting the average-day demand for the peak-day weather conditions.

Table 1 summarizes the characteristics of the end-use models for the utilities and organizations that use end-use modeling in their long-term forecasting.

Most jurisdictions with high levels of DSM activity and IRPs use end-use modeling for their long-term forecasting. All end-use models require a medium to high degree of data intensiveness and can examine end-use trends and different scenarios, which in turn allow the utilities to show how changes to model inputs affect the results. Most utilities perform some form of testing of the forecasts against actual data. However, because long-term forecasts are based on forecasts of many input parameters, such as whether, energy prices, economic conditions, employment levels, new construction activity, etc. a straight comparison of forecasts to actuals without any adjusting for the input parameters does not necessarily reflect the effectiveness of the forecasting model. Thus, comparison of the forecast results to actuals may be quite resource intensive.

Table 1. End-Use Model Characteristics

Utility End-use Forecasting Model	No. of Gas Customers	Utility Ownership	DSM Activity	Degree of Data Intensiveness	Degree of Customization	Ability to Examine End-use Trends/Scenarios	Ability to Show How Changes to Model Inputs Affect Results	Informs both Annual and Peak Demand	Cost to Maintain	Forecast Tested Against Actuals
So-Cal Gas (2016 CGR)	5.9 million	IOU	High	High	High	Yes	Medium	Yes	Moderate	Some
Manitoba Hydro (2012 Gas Forecast)	275,000	Crown	High	Moderate	High	Yes	Medium	No	Moderate	Yes
San Diego Gas & Electric (2016 CGR)	873,000	IOU	High	High	High	Yes	Medium	Yes	Moderate	Some
Colorado Springs Utilities (2011 IRP)	192,000	Municipal	Low	Moderate	High	Yes	High	Yes	N/A	Yes
Pacific Northern Gas (2015 IRP)	40,000	IOU	Low	Moderate	High	Yes	High	Yes	Moderate	Some
Black Hills Energy (2014 EE Report)	N/A	IOU	Medium	High	High	Yes	Low	No	N/A	N/A
California Energy Commission (2015 IEPR)	--	Regulator	High	High	High	Yes	Medium	Yes	Moderate	Yes
FEI (2014 LTRP)	1.1 million	IOU	High	High	High	Yes	Yes	No*	Moderate	Not Yet**

Notes:

* Linkage with peak demand is being addressed as part of the ongoing improvement to the forecasting model.

** To date there has not been enough actual history to compare to the end-use demand forecast. Once enough historic data is available, FEI plans to compare end-use demand forecast to actual consumption.

Appendix A. LONG TERM DEMAND FORECASTING PRACTICES

1. Southern California Gas Company and San Diego Gas & Electric[1]

1.1. Overview

The companies are investor owned utilities that are owned by the same parent and often share forecasting resources. Although the two companies develop individual forecasts for each company, they use the same models to develop their long term forecasts.

One of the companies is one of the largest natural gas distribution utilities and serves 21.6 million consumers through 5.9 million meters in more than 500 communities, with a service territory encompassing approximately 20,000 square miles in diverse terrain throughout Central and Southern California, from Visalia to the Mexican border.

The other company is combination gas and electric utility that provides energy service to 3.6 million people through 1.4 million electric meters and 873,000 natural gas meters in southern California with a service area that spans 4,100 square miles.

The companies forecast total annual gas demand across all market sectors, including residential, commercial, and industrial sectors, to decline from 2013 to 2035. The decline in annual demand is due to modest economic growth, mandated energy efficiency (EE) standards and programs, renewable electricity goals, increases in the marginal gas rates, high costs of compliance with environmental regulations, conservation savings linked to Advanced Metering Infrastructure (AMI), and the expected implementation of regulations to aggressively reduce CO_2 emissions by effectively increasing the gas commodity price for many large industrial customers.

1.2. Forecasting Method

Prior to 2013 the companies used both econometric and end-use modeling to forecast gas demand. However, in their 2013 cost allocation proceedings the companies stopped using econometric modeling and only used the end-use modeling. The companies switched to only using end-use modeling, which include an equipment choice module, in their regulatory filings for the following reasons:

1. End-use models with an equipment choice module are a more effective forecasting tool in an environment that is focused on energy efficiency
2. To save resources
3. End-use models are the basis for long term gas demand forecasting for the companies' California Gas Reports

[1] 2014 California Gas Report – Prepared by the California Gas and Electric Utilities

4. End-use models are used by the California Energy Commission for its long-term energy demand forecasts

The companies use End Use Forecaster (EU Forecaster), formerly known as Quant.sim to prepare their forecast. It is a market segmentation, competitive assessment, and sales projection application developed to respond to market needs and overcome the limitations of existing demand forecasting and market planning tools. The application, originally developed in 1993, is constructed using SAS software.

EU Forecaster has a sufficiently generic structure that could readily be applied to specific market segments for each company so that the companies could separate the specific underlying data needs from a general methodology. As a result, the companies can maintain and support gas demand forecasting capability for both companies by using the underlying data for each company. Furthermore, the structure embedded in EU Forecaster is readily adaptable to addressing questions related to the growing emphasis on incorporating energy efficiency policy goals and emissions regulation into demand forecasts, thereby making end-use modeling more effective.

The companies' econometric models produced forecasts that relied on historical data to fit an equation. The fitted equation was used to explain how changes in the independent variables drove changes in the dependent variable. The models forecasted future demand by extrapolating the same relationship over the forecast period and assumed that there were no structural changes in the fitted relationship into the future. Improvements in energy efficiency were included in econometric models by including an efficiency index as an explanatory variable. This efficiency index was only a proxy that accounted for the downward trend in gas use because of energy efficiency improvements. In prior econometric work, the companies used end-use models to develop the energy efficiency index.

EU Forecaster tracks energy use (e.g., natural gas or electricity) by simulating customers' energy consumption into two key steps:

1. Simulates the choices in the selection of end-use equipment from two fuel types (gas or electric), and various equipment efficiency levels and then
2. Forecasts the energy use derived from the customers' end-uses from the set of customers' equipment.

The model takes into account the age of the equipment to determine when the equipment is replaced. As the model iterates from one year to the next, it distinguishes, in each year, between the load added due to new meters in addition to changes in the load due to existing customers replacing old equipment with newer, more energy efficient appliances or other equipment. Historical accounts are segmented into the total number of accounts in the base year and their distribution among the historical vintages. The model produces a forecast over the planning horizon by applying a forecast of equipment capital costs, energy consumption, and fuel price forecasts to the customer choice parameters. It calculates energy use for each customer type by optimizing the underlying customer choices.

EU Forecaster's structure is designed to keep track of energy use for each market segment, each end use and for each vintage as the model steps through the entire forecast time horizon. In contrast, the companies' previously-used econometric models stepped through the forecast period by using the same structure for predicting energy consumption from the independent variables (e.g., energy prices, employment levels, meter counts), from one year to the next.

The companies use five residential segment types: single family, small and large multi-family customers, master meter and sub-metered customers and 14 commercial sectors identified by the customer's NAICS codes.

1.3. Forecasting Parameters

The companies use data from End Use Surveys conducted by the California Energy Commission in their forecasting model. The parameters used in the forecasting model include:

- Equipment usage equation forecast drivers
- Coefficients describing how usage varies by weather, customer characteristics, prices, and other variables
- Choice forecast drivers, including capital costs for equipment in existing, conversion, and new construction buildings, plus future availability of each equipment type
- Average and marginal market shares for existing, conversion, and new customers
- Fuel, product, or service price forecasts in native units
- Decay functional form indicator and parameters for existing, conversion, and new accounts
- Number of existing accounts, non-accounts on main, and non-accounts off main
- Forecast of new construction (economic activity driving demand), capture rates, units per account, and number of units (i.e., units are a scale of measurement consistent with results of the usage forecast, such as buildings, square footage, apartments, etc.)
- Mean age of end uses by historical vintage in the baseline (i.e., 0th) year of the forecast, used to initialize the age dimension in the turnover/vintage module
- Decay functional form indicator and parameters for equipment (end-uses) in existing, conversion, and new buildings
- Saturation (percentage of accounts that have the equipment) independent of fourth dimension market shares
- Total actual sales in base year
- Exogenous parameters that change market shares for existing, conversion, and/or new customers through 'what if' intervention strategies

- Exogenous parameters that adjust product usage through 'what if' convention strategies

1.4. Forecasting Scenarios

Forecasting scenarios included sensitivity to temperatures and non-cogeneration electric generation.

Core demand forecasts are prepared for two design temperature conditions – average and cold – to quantify changes in space heating demand due to weather. The cold design temperature conditions are based on a statistical likelihood of occurrence of 1-in-35 on an annual basis, with a typical recurrence period of 35 years.

The average year HDDs were calculated as the simple average of annual HDD's from 1994 to 2013.

The non-cogeneration EG forecasts are prepared for two hydro conditions – average and dry. The dry hydro case refers to gas demand in a 1-in-10 dry hydro year.

1.5. Forecast Period and Update Frequency

As part of the California Gas Report, the companies prepare a 20-year forecast of customers, annual demand, peak-day demand every two years. While the companies prepare a forecast for each year during the forecast period, they only report forecasts in five year intervals.

1.6. Forecast Evaluation

The companies find evaluating the performance of their long term forecast to be very difficult as there are numerous assumption and inputs into the model. As result, there is no formal evaluation process in place. However, they do compare their forecast for annual demand to actuals.

1.7. Forecast Resources

The companies share forecasting resources. While the team responsible for forecasting consists of four analysts who are responsible for long and short term forecasts as well as other tasks, approximately 1.5 of an FTE is responsible for long term forecasting.

1.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The companies use their annual demand forecast and apply peak day design temperature to forecast their peak-day demand.

The peak-day design temperature conditions are based on a statistical likelihood of occurrence of 1-in-35 on an annual basis, with a typical recurrence period of 35 years.

2. California Energy Commission[2]

2.1. Overview

Since 1975 the organization has been responsible for forecasting electricity and natural gas (and other fuels) demand for the primary purpose of insuring adequate, but not excessive, electricity supplies. These include forecasts of statewide and regional electricity and natural gas consumption; annual and seasonal peak demand; factors contributing to projected demand growth; and the impacts of electricity and natural gas efficiency, load management and other demand response activities.

Residential and commercial natural gas consumption in California has remained relatively flat for the past two decades despite increases in population, jobs, and gross state product. This has been attributed to increasingly stringent California Building Energy Efficiency Standards and increasing investments in statewide utility energy efficiency programs have.

California Building Energy Efficiency Standards are advancing toward a goal of Zero Net Energy buildings by 2020. California's Senate Bill 350 requires the doubling of energy efficiency savings by 2030 for electricity and natural gas combined. Natural gas end-use assessments are expected to evolve over time toward a similar level of granularity as in the electricity forecast to support the provisions of Senate Bill 350.

A critical part of the demand forecast is estimating energy savings from DSM activities. The organization is required to include all such demand reductions which are "reasonably expected to occur" during the forecast period in its forecasts.

2.2. Forecasting Method

The organization forecasts natural gas demand in California as part of each Integrated Energy Policy Report (IEPR) cycle. The organization uses end-use and econometric models structured along utility planning area boundaries for the residential, industrial, commercial, agricultural, transportation, communications, and utilities sectors.

End-use modeling is used for forecasting residential and commercial demand, while econometric/trend modeling is used for forecasting industrial and agricultural demand.

Residential use is forecasted for different building arch-types based on demographic and economic data and the forecasted number of households in each geographic area from Moody's. Vintage of the dwellings is used to adjust for changes in building code and standards.

Commercial use is forecasted for different building types by building gross area.

End-use surveys are used to collect average use per appliance, saturation levels, and equipment and building vintages. These are conducted every four to five years.

[2] 2015 Integrated Energy Policy Report

End-use energy consumption estimates are developed using analytical engineering and econometric techniques for extracting information from customer use data. The early generation end-use models were developed using primarily engineering methods. As better data became available, disaggregate econometric techniques were incorporated into the model.

End-use modeling is used rather than other forecasting techniques because of its ability to better explain how energy is actually used and how various factors effect changes in energy use. For example, models involving different levels of end-use detail are used to characterize how efficiency programs affect both energy requirements and peak demand.

Table 2 lists the end use and consumer characteristics of each of the sectoral models used.

Table 2. Characteristics of Forecast Sectoral Models

Sector	Consumer Type/NAICS Code	End uses Covered
Residential	Residential consumers 3 housing types	24 major appliance and space conditioning categories
Commercial	12 building types 21 NAICS codes	10 equipment and space conditioning categories
Transportation, Communications and Utilities (TCU)	NAICS codes 221, 48 (excluding 48841), 49, 513, 56151, 56152, 562, 62191, and 92811	Consumption is estimated for aggregated of the ten NAICS codes, not for specific end uses
Industrial	Process, extraction, and assembly industries included in NAICS 1133, 21, 23; 31-33, 511, and 516	Thermal processes, HVAC, process steam, and cogeneration.
Agriculture	Crop production, livestock, and related commodities.	Irrigation pumping, building heating, crop drying

Planning area forecasts are developed by aggregating county data to the planning area level. For example, county-level housing construction, population and income estimates form the basis of a planning-area residential consumption forecast. Each county is apportioned to one or more of sixteen climate zones and each climate zone is assigned to a planning area.

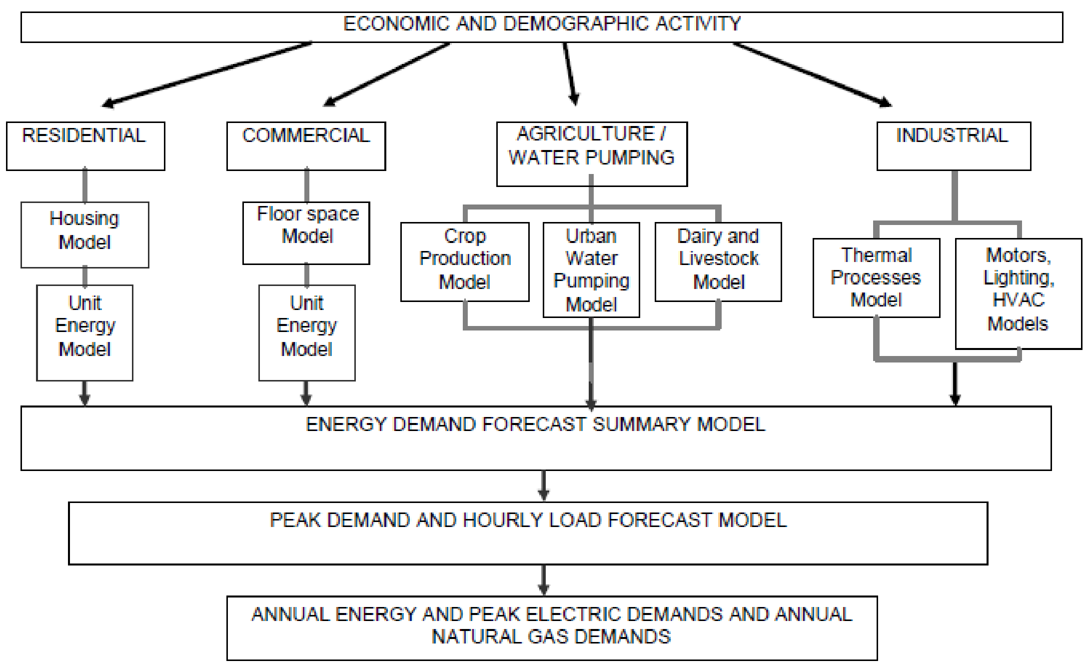
The same models are used to forecast electricity and natural gas demand.

The aggregate demand for energy services increases with growth in economic activity and population and as new energy services become available due to technological development.

In addition, updated forecasts must reflect the penetration rates at which more efficient equipment and new energy services come into use. In addition to the energy and peak demand sectoral models that forecast final demand, the organization sometimes develops models that generate the values of economic variables used to drive the energy or peak sectoral models. This work has been necessary because suitable specific variables have not been readily available.

Figure 3 illustrates a schematic diagram of the major elements of the energy and peak demand forecasting models. The results from the energy forecasting models flow directly into the peak demand forecasting model.

Figure 3. Framework for Energy Demand Forecast Models



Source: California Energy Commission staff, May 2005

2.2.1. Residential Energy Demand Forecast Model

The residential model forecasts energy demand for 24 end uses, three housing types and three fuel types.

End uses include space heaters, air conditioners, refrigerators, color televisions, lighting, water heating, etc. Electricity and natural gas consumption are fully modeled for all relevant end uses, while saturations are maintained for other fuels (principally wood, liquid propane gas, and solar).

Three housing types single-family, multi-family, and mobile homes are modeled; these are further grouped by climate zone. Sixteen climate zones are modeled; these are intended to capture differences in residential energy use for space conditioning across the state's microclimates.

Five vintages of housing construction are used to represent the eras in which building codes and revisions significantly influenced the thermal characteristics of residential buildings.

The residential model forecasts energy demand in three principal components:

1. The number of households of each housing type is forecasted.
2. The saturation of appliances for each of three fuel types is projected
3. The model determines the amount of energy expected to be used by each end use appliance; this depends, in part, on the age profile of the appliance stock.

Total residential energy consumption is the product of projected households, the number of households possessing a particular appliance, and the yearly average energy use for that appliance, summed over all end uses.

2.2.2. Commercial Energy Demand Forecast Model

The commercial energy forecasting model is similar to the residential model with respect to the degree of disaggregation. The model first forecasts the amount of building floor-space and vacancy rates for twelve different building types. The model then determines the fraction of floor-space in each building with commercial equipment for each of three fuel types. The nature of the energy-using equipment in each building type determines the commercial end uses (for example, restaurants contain ovens and stoves, therefore, cooking is a principle end use for that building type). The amount of energy required per square foot of floor-space is then determined for each fuel type. Total commercial energy demand is the product of these three factors and summed for all end uses and building types. The model considers the effects on energy use of changes in floor space, vacancy rates, energy prices, building and appliance standards, and other major efficiency programs.

The commercial model uses end use intensities (EUIs), which are the energy use estimates per square foot by building type with corresponding end uses and equipment.

2.2.3. Industrial Energy Demand Forecast Model

The industrial sector is divided into process and assembly groups.

Projections of industrial energy demand for most sectors except extraction industries are driven by forecasts of GDP. For extraction industries forecasts of employment are used because the volatility of the prices of such commodities as oil, natural gas and precious metals leads to volatility in values of shipments or GDP.

To forecast annual electricity and natural gas demand, the organization used to use the Industrial End-Use Forecasting Model (INFORM), developed by the Electric Power Research Institute (EPRI) until 2014. However, because EPRI does not support the model any longer, the organization decided to develop a new model for its 2014 report based on the INFORM method. The INFORM program accounted for energy use trends, price effects, and exogenous improvement in efficiency by end use and industry.

The major end uses in the model are motors, thermal processes, lighting, HVAC and miscellaneous. The organization used to use the model to forecast demand for electricity, natural gas and other fuels for these five major end uses over a 12-year period.

The new model forecasts industrial energy demand based on a number of factors, including:

- Projected growth in dollar output or employment for 28 categories
- Projected average industrial rates
- Changes in end-use characteristics, including energy intensities, which measures energy use per dollar of output

The marginal impact of economic growth on energy use in each of the 28 categories is estimated using regression analysis. Estimated coefficients are applied to the appropriate economic indicator to provide "business as usual" forecast for each industrial category. This forecast is adjusted for rate increases, using price elasticities estimated in the sector econometric models. Finally, the forecast is adjusted to account for changes in end-use energy intensity.

Since a full statewide industrial end use survey has not been completed for more than 20 years, recent data on industrial end-use energy intensities and other characteristics to fully populate the model are not available for California. As a result, the organization started to populate end-use characteristics in the model using national data and smaller-scale state surveys. However, the organization expects the new model will require a full California industrial end-use survey to reach its full potential as a forecasting tool.

2.2.4. Energy Demands Summary Forecast Model

Individual sectoral model energy demand forecasts are processed by the Energy Demands Summary Forecast Model in order to calculate planning area total forecasts. The summary model adjusts the sectoral forecasts for weather and DSM program savings. The results are calibrated using recorded energy consumption.

Energy demand for weather sensitive end uses is adjusted to accommodate the deviation between actual weather and normal weather for each climate zone in the planning area. After the weather adjustment, minor adjustments are performed to account for DSM programs that have not been incorporated into the input data used in the sectoral models. The final adjustment to the forecasts is to calibrate the results using the recorded energy consumption.

2.3. Forecasting Parameters

The latest historical natural gas consumption data are used for the forecast.

Factors that affect natural gas supply and demand include production, population growth, pipeline capacity, economic outlook, weather, national and global markets, environmental concerns, and the effects of energy policies. Supply and demand, in turn, affect natural gas prices.

Four classes of data are needed as inputs to disaggregated forecast models:

- Consumer characteristics data such as end use appliance saturations, dwelling size and age, occupants' income and demographic makeup, utility bills for the residential sector, and equipment saturations, hours of operation, etc. for the commercial sector
- Aggregated energy consumption data for the non-residential sectors (most notably the industrial sector) classified by the North American Industry Classification (NAIC) codes devised by the federal government
- Disaggregated economic and fuel price projections at a level of detail matching the customer sectors of the energy forecasting models
- Characteristics of demand side management programs

Customer surveys are the principle source of information on consumer characteristics. These surveys are used to collect data on customer electric and natural gas use, which form the core data needed for the end use forecasting models.

A major secondary data source on consumer attributes are federal activities under the Bureau of the Census.

Acquisition of reliable commercial floor-space data remains a difficult and unresolved problem for forecasters.

Monthly consumption data for different NAICS codes are used in the sector models.

Essential inputs into the forecasting models are economic and fuel price projections for each planning area annually for 10 years into the future. Several translation models are used to convert available economic data into the actual "energy driver variables" which are used in the models to forecast energy use. For example, in the commercial sector, the key energy driver is floor space by building type, while the economic variables are employment of various types, taxable sales, and various groupings of population.

The sector-specific economic variables used in developing the forecast are summarized in Table 3.

Table 3. Economic Variables Used in Forecast Models

Sector	Energy Driver	Economic Variable	Constructed Economic Variable
Residential	• Fuel Prices	• Population • Personal income • Households	• Household population • Persons per household • Group quarters • Income per capita
Commercial	• Floor-space, by building type • Fuel prices	• Employment • Retail sales • Population	
Industrial	• Output by industry • Fuel prices	• Output by industry • Employment (extraction sectors only)	
Agriculture	• Crop production • Rainfall • Electricity price • Diesel price • Cooling degree days • Dairy and livestock production	• Personal income • Population • Households	• Total households • Persons per household • Income per capita

2.4. Forecasting Scenarios

The organization develops high, mid, and low use scenarios. These scenarios are developed using various natural gas prices and committed efficiency program impacts. Statewide and major planning area results are shown with and without estimates of incremental achievable efficiency, referred to as baseline and adjusted forecasts, respectively. The three future energy demand scenarios are:

- Business-as-usual or mid demand case – mid population, income, and energy prices
- A high demand case – high population and income, and low energy prices.
- A low demand case – low population and income, and high energy prices

The mid demand case represents a future in which the economy and commercial activity remain consistent with trends experienced over the last several years. The high demand and low demand cases are created by altering assumptions, which move natural gas prices. The assumptions that are varied included economic growth, technology improvements, renewable portfolio standards, coal-fired generation retirements, natural gas supply cost curves, demand, and the production cost environment.

The mid case includes potential climate changes in the forecast, while the high and low cases do not include the impact of potential climate changes. This results in mid case demand being lower than the low case in some instances.

2.5. Forecast Period and Update Frequency

The forecast provides annual demand forecast for every year over the 10-year forecast period. It is updated every year as part of each Integrated Energy Policy Report (IEPR) cycle.

2.6. Forecast Evaluation

The new forecasts begin at a higher point in 2015, as actual natural gas consumption in California was higher in 2015 than forecasted in the CED 2013 mid case. This was attributed to an expected steep increase in forecasted prices that did not materialize.

The organization evaluates the performance of its forecasts by having an expert panel review the forecasts. It also examines annual demand compared to subsequent actual consumption at the statewide level. In addition, it compares model backcasts, or predictions of historical outcomes, to historical consumption.

The organization also compared CED 2013 Final end-user natural gas results for 2024 by major planning area and statewide with those from a full econometric forecast. Differences range from around five percent higher for the econometric forecast to over 11 percent higher. Most of the differences are in the residential sector, reflecting increases in efficiency impacts not fully reflected in the econometric results.

2.7. Forecast Resources

Although the original model was developed externally, the forecasts are prepared by internal resources.

Two full time equivalent (FTE) staff prepare the forecast for both gas and electricity in the residential sector.

One FTE prepares the forecast for both gas and electricity in the commercial sector.

One FTE prepares the forecast for both gas and electricity in the industrial sector.

One FTE prepares the forecast for both gas and electricity in the agricultural sector.

One FTE prepares the forecast summary for both gas and electricity for all sectors.

2.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The organization uses hourly load shapes for each end-use and applies the load shapes to the annual demand forecast from the end-use model to determine the hourly demand for each end-use. It then aggregates all the hourly demand for all the end-use to forecast the peak-day demand.

2.9. The Impacts of Climate Change

The potential incremental impacts of climate change on both energy consumption and peak demand are incorporated into the forecast using temperature simulations developed by the Scripps Institution of Oceanography (Scripps).

The effect on annual energy consumption is estimated through projected changes in the number of annual heating and cooling degree days, while the impact on peak demand is estimated using increases in annual maximum daily average temperatures.

Heating degree days in California in the last few decades have been declining. HDD in some areas has declined by approximately 15% percent from 1960 to 2014. Since approximately 88% of natural gas consumption in the residential sector is weather-dependent, the decline in HDD should result in significant decline in demand.

3. Pacific Gas & Electric[3]

3.1. Overview

The company provides natural gas and electric service to approximately 16 million people throughout a 70,000-square-mile service area in northern and central California. The company has 42,141 miles of natural gas distribution pipelines and 6,438 miles of transportation pipelines. It serves 5.4 million electric customer accounts and 4.3 million natural gas customer accounts.

The company has experienced declining growth rate in its annual demand in the core market and forecasts this decline in annual growth rate to continue primarily due to increasing emphasis on energy efficiency.

3.2. Forecasting Method

The company's gas demand forecasts for the residential, commercial, and industrial sectors are developed using econometric models. Forecasts for other sectors (Natural Gas Vehicle (NGV), wholesale) are developed based on market information. Forecasts of gas demand by power plants are developed by modeling the electricity market using the MarketBuilder software.

The company uses the current levels of energy efficiency programs included in its latest Integrated Energy Policy Report in the forecast.

3.3. Forecasting Parameters

While variations in short-term gas use depend mainly on prevailing weather conditions, longer term trends in gas demand are driven primarily by changes in customer usage patterns influenced by underlying economic, demographic, and technological changes, such as growth in population and employment, changes in prevailing prices, growth in electricity demand and in electric generation by renewables, changes in the efficiency profiles of residential and commercial buildings and the appliances within them, and the response to climate change.

[3] 2016 California Gas Report

3.4. Forecasting Scenarios

The company uses alternative demand forecasts to assess the possible variations in gas demand that result from changes in various factors such as weather, economic activity, appliance saturation, and efficiencies.

For the high demand scenario, the company forecasts total gas demand with the weather conditions set to match the conditions that have an approximately 1-in-10 likelihood of occurrence.

Space heating accounts for a large portion of the gas use by the company's residential and commercial customers. In previous forecasts, the company used the average of observed temperatures during the past 20 years. However, the company is now building into its forecast an assumption of climate change. The climate change scenario is developed from work done at the National Center for Atmospheric Research, downscaled to the company's service area.

Annual water runoff for hydroelectric plants has varied by 50 percent above and below the long-term annual average. The company also assesses the impact of 1-in-10 dry conditions, which impacts hydro power generation and in turn demand for natural gas power generation.

Since gas prices and rate assumptions are important for forecasting gas demand, especially in price sensitive sectors such as industrial sectors and electric generation, the company models the impact of gas commodity prices in its forecast scenarios.

3.5. Forecast Period and Update Frequency

As part of the California Gas Report, the company prepares a 20-year forecast of customers, annual demand, peak-day demand every two years. While the company prepares a forecast for each year during the forecast period, it reports forecast results for every year for the first five years of the forecast period and at five year intervals after that.

3.6. Forecast Evaluation

This information was not available.

3.7. Forecast Resources

This information was not available.

3.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses a 1-in-90-year cold-temperature event as the design criterion for its peak-day demand forecast. The core market peak-day demand forecast is developed using the observed relationship between historical daily weather and core usage data. This relationship is then used to forecast the core load under peak-day conditions.

4. Enbridge Gas

4.1. Overview

The company is an investor owned utility that serves over two million customers.

Residential average use per customer has declined steadily over the period of 2005 through 2014, at an average rate of 1.1% per year.

4.2. Forecasting Method

The company prepares a five-year forecast, which it files with the regulator. It also prepares five to 30 year forecasts for internal use, but these are not filed with the regulator. Forecasts are prepared for different rate classes.

The company uses an econometric model for forecasting. The same model is used for preparing short and long term forecasts. While the company prefers to use an end-use model for forecasting demand, it does not have the resources to develop and collect the data required for an end-use model for forecasting.

The company moved to a more objective forecasting methodology starting in the 2001 budget year in order to address the regulator's concern with the systemic bias attributed to the grassroots forecasting process[4]. This forecasting methodology removes systemic or subjective bias by developing regression models to forecast average use for the company's residential and small commercial customers.

For the residential and small commercial customers, the forecast is derived using forecasted number of customers and normalized average use per customer forecast generated from the average use forecasting models. The company's econometric model allows the company to produce separate forecast for each rate class. While the forecasting model does not use specific end-uses in determining average use per account, it includes bundles of end-uses grouped together. The model uses historical data to forecast annual demand for each rate class using regression techniques. The model determines average use per account for each bundle of end-uses and allows the company to adjust for efficiency improvements within the bundle.

For large customers, the model can provide forecasts for different sectors.

The forecast incorporates economic assumptions from the Economic Outlook documents from government agencies.

4.3. Forecasting Parameters

The parameters used in the forecasting model include:

[4] The '**grassroots forecasting process**' is based on the concept of asking the people who are close to the eventual consumer, such as sales representatives.

- Gas prices
- Historical annual demand
- Weather
- Vintage for residential customers
- Employment
- Real GDP
- Vacancy rates
- Time trend

The vintage variable is constructed to reflect the impact that new homes, associated with more energy efficient gas equipment and enhanced building codes, have on average use.

The time trend, including the dynamic variable in the regression model, captures the historical actual average trend of the sectorial average use, conservation initiatives originated by customers themselves or promoted by government programs, stock turnover, and other historical impact not reflected in the mentioned driver variables.

4.4. Forecasting Scenarios

The company develops a number of alternative forecast scenarios based their requirements in a given year. Alternative forecasts are developed using different customer growth rates and extensions to new communities, cold and warm weather scenarios, changes in gas prices, different economic conditions, improved energy efficiency standards, and a cap & trade mechanism for emissions.

4.5. Forecast Period and Update Frequency

The forecast is typically updated annually but the forecast period varies.

When changes to the building code and efficiency standards are introduced, the company updates its forecast to reflect the improved energy performance of buildings and appliances.

The company provides a forecast for each year during the forecast period.

4.6. Forecast Evaluation

The company evaluates the performance of its forecasting model by comparing forecasted annual demand to actuals. In general, the difference between the forecasted annual demand and actual annual demand has been less than 1% for residential and small to medium commercial customers.

4.7. Forecast Resources

The company only uses internal resources in preparing its forecast. The forecasting department consists of three FTE and approximately 1/3 of FTE is dedicated to preparing the long term forecast.

4.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company applies the load factor for each rate class to the annual demand forecast to determine the peak-day demand forecast for each rate class. It then sums up the peak-day demand for each customer class to forecast the peak-day demand for the system.

5. Manitoba Hydro

5.1. Overview

The company is a crown corporation that serves approximately 567,000 electricity customer and 275,000 gas customers.

5.2. Forecasting Method

The company prepares both a natural gas and an electricity demand forecast using the same model. It includes fuel switching in its forecast.

The company uses a combination of end-use modeling and econometric modeling for forecasting its annual demand. It uses an end-use model for forecasting annual demand for its residential customers and an econometric model for forecasting annual demand for its core market commercial and industrial customers. It forecasts annual demand for its largest industrial customers individually in the short term and as a group using trend analysis in the long term.

The company conducts a REUS approximately every five years to collect data, which it then uses in its end-use forecasting model. It uses REUS to collect data on end-use saturation levels, detailed information on newly constructed dwellings, and appliance age distributions and their expected lifetimes. It uses the results of the REUS together with conditional demand analysis in its forecasting model to forecast the average use per account. The company uses economic forecasts from government agencies to forecast the number of customers.

The end use assumptions used in the model include current usage information and efficiency improvement information. The number of appliances and their estimated usage are multiplied together to calculate an energy forecast for each end use. All uses are then combined to calculate the total use for the residential end-use forecast.

The company forecasts the number of small commercial gas customers based on economic forecasts from government agencies. It forecast the average use per account based on historical average use per account for each rate class. Since commercial rate classes are based on annual gas use, the average use per account for the commercial rate classes is relatively stable, as customers whose gas use changes move to the appropriate rate class based on their gas use.

The effect of weather is determined in any class by regressing the last two years of actual monthly energy use against the actual HDD for the month. This results in a m^3 per HDD effect for that particular sector. These effects are additive as they are estimated from a linear model.

Annual demand forecast for the company's approximately 140 large industrial customers is based on each customer's average annual demand over the previous three-year period and is kept constant over the forecast period.

the forecast reflects future DSM savings associated with the company's energy efficiency programs. Savings due to DSM programs to date are embedded in the historical data that is the basis for the forecast. The current level of past achieved DSM savings is assumed to remain in place throughout the future. Future DSM savings arising from future energy efficiency programs and market engagement above those already achieved are included in the forecast as outlined in the company's DSM plan.

5.3. Forecasting Parameters

The parameters used in the forecasting model include:

- End use saturation rates
- Detailed information on newly constructed dwellings
- Dwelling type
- Appliance age distributions
- Appliance expected lifetimes

5.4. Forecasting Scenarios

The company only prepares a base case forecast for its natural gas annual demand forecast. In the past, the company used to include scenarios that considered different weather conditions.

The company prepares its forecast with the goal of being an unbiased and accurate predictor of future volumes. It expects the forecast to have a 50% chance of exceeding actual annual demand and 50% chance of being lower than actual annual demand.

The company presents a probability-based estimate of how much future actual volumes might vary from forecast. This can be used to produce forecasts with a specific probability of occurrence, or can be used to determine the probability of specific volumes occurring. The company determines the standard deviation and correlation coefficient of historical weather adjusted volume and applies to the forecast to give an estimate of the width of the volume confidence bands. It used 10% and 90% confidence bands (-/+ 1.28 standard deviations) to represent a low and high scenario. This calculation gives the variability due to economic effects and the year-to-year variation in natural gas use. It does not include variability due to weather which was removed through the use of weather adjusted volumes.

5.5. Forecast Period and Update Frequency

The company prepares a 10-year annual demand forecast, which it updates annually and prepares a forecast for each year during the forecast period.

The company also prepares 20-year annual demand forecast, which it uses internally for financial planning.

5.6. Forecast Evaluation

The company evaluates its model regularly by comparing the forecasted annual demand for the first two years of the forecast period to actuals and has found that over the long term after accounting for heating value and weather the absolute average variance is within 1% in the first year and within 2.6% in the second year.

5.7. Forecast Resources

The company's forecasting department included seven full time staff including the manager. Approximately three FTE prepare the forecast over a four-month period. The other staff members work on the surveys and maintaining the databases.

The economic forecast is provided by the Economic Analysis Department, who purchase the documents.

5.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company does not prepare a long term peak-day demand forecast as it is only used for gas purchase planning. As a result, the peak-day demand forecast is based on the previous year's peak-day demand.

6. Union Gas

6.1. Overview

The company is an investor owned utility that serves over 1.4 million natural gas customers in over 400 communities.

The company does not prepare a long term annual demand forecast. It only prepares a four-year forecast, which included the current year. The company is however, exploring the possibility of preparing long term forecasts. The company has not settled on the forecasting horizon for a long term forecast, if it decides to prepare a long term forecast, however, a 10-year forecasting period is a possible time horizon for a long term forecast.

6.2. Forecasting Method

The company uses an econometric model in preparing its forecast for the residential and commercial sectors. It uses the most recent annual demand for its less than 500, large contract customers.

The company's econometric model for residential and commercial customers uses actual monthly average use per account for each rate class for the previous 10 years and runs a regression analysis of the data against demographic and econometric indicators. The regression model includes an "efficiency index", which represents a weighted average efficiency of furnace efficiencies from the company's REUS. The company conducts a REUS annually.

For the less than 500 large contract customers, the company's forecast uses the most recent annual demand for each customer. These customers have dedicated key account managers, who then review the forecasts for their customers and adjust the forecasts if the customers have advised them of any changes to their expected gas use.

6.3. Forecasting Parameters

The parameters used in the forecasting model include:

- Efficiency Index, which represents the weighted average furnace efficiency from the company's REUS
- Number of people per household
- Total gas bill in dollars
- Weather

The company evaluates its model annually and in some years some parameters used in the model may be replaced.

6.4. Forecasting Scenarios

The company runs sensitivity analysis on its forecast for the residential and commercial sectors. It runs alternative scenarios to assess elasticity of demand in response to changes in gas prices, weather and number of customers.

6.5. Forecast Period and Update Frequency

The company does not prepare a long term annual demand forecast. It only prepares a four-year forecast, which included the current year. The company is however, exploring the possibility of preparing long term forecasts. The company has not settled on the forecasting horizon for a long term forecast, if decides to prepare a long term forecast, however, a 10-year forecasting period is a possible time horizon for a long term forecast.

The company updates its forecast annually and prepares a forecast for each year during the forecast period.

6.6. Forecast Evaluation

The company evaluates its model annually. It has a good understanding of the impact of each parameter on it forecasts. It compares the forecasted annual demand to actuals and has found that over the long term the actuals are within 2.5% of the forecasted demand.

In 2003/04 the company was directed by the regulator to retain a consultant to evaluate its forecasting method. The consultant found the company's method to be acceptable and in line with other forecasting practices.

6.7. Forecast Resources

The company only uses internal resources in preparing its forecast. The forecast is prepared by 2 FTEs one prepares the forecast for residential and commercial customers and the second prepares the forecast for large contract customers.

6.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company forecasts its peak-day demand by applying a weather factor to the average daily demand from annual demand forecast.

7. SaskEnergy & TransGas

7.1. Overview

The company is a crown corporation and owns and operates a natural gas distribution system that serves over 385,000 residential, farm, commercial and industrial customers through its natural gas distribution systems. Through one of its subsidiaries, the company's operates natural gas transmission system with over 14,000 kilometres of high pressure natural gas pipelines and gas storage sites as well as serve the large industrial customers.

The transmission company uses its forecasts primarily to assess load requirements, urban growth, which may encroach on its assets and result in potential relocation of the assets.

7.2. Forecasting Method

The gas distribution company does not prepare a long term annual demand forecast. However, the company's subsidiary that operates the gas transmission system prepares a long term forecast, which includes the demand from the distribution company.

The distribution company uses a top-down qualitative model to prepare its forecast for each rate class. This model is based on an econometric model that uses economic forecasts from government agencies.

The forecast for growth in the number of accounts is based on economic forecasts and most recent historical trends.

The forecast for average use per account for residential and small commercial customers is based on weather normalized historical data, while the annual demand forecast for large commercial customers is based on the annual demand from the previous year.

Since the transmission company's customers are large industrial customers and the distribution company, its annual demand forecasts are based on forecasts provided by customers. When it receives new service requests, it includes a probability of the customer coming online during the forecast period.

The transmission company also works with the electric utility to assess conversion of coal-fired power plants to natural gas plants over 20 to 30 years.

7.3. Forecasting Parameters

The company's econometric model uses a number of parameters, which include:

- Economic forecasts from various government agencies
- Input from builders to assess housing starts
- Economic and housing starts forecasts from CMHC and Statistics Canada

7.4. Forecasting Scenarios

The distribution company develops a base case and two alternative scenarios based on warm weather and cold weather with two standard deviations from the base case forecast.

The transmission company develops a base case, which is based on the probability of new customer additions coming online. In addition, it also develops a high case scenario.

7.5. Forecast Period and Update Frequency

The distribution company prepares an annual demand forecast every year.

The transmission company prepares five to 10-year forecasts with results for each year across the forecast horizon and updates these annually as part of its budget planning cycle. However, most of its forecasts are five year forecasts.

The transmission company also works with the electric utility to assess conversion of coal-fired power plants to natural gas plants over 20 to 30 years.

7.6. Forecast Evaluation

The distribution company evaluates the performance of its forecasting model by comparing weather normalized actual annual demand to weather normalized forecasted annual demand. Forecasts are generally within one to two percent of actuals.

The transmission company evaluates the performance of its forecasting model by comparing its budgeted annual demand to its actual throughput. Forecasts are generally within one to two percent of actuals.

7.7. Forecast Resources

The distribution company only uses internal resources to develop its annual demand forecast and estimates approximately ¼ of an FTE is required in preparing the forecast.

The transmission company only uses internal resources to develop its annual demand forecast. While four people from different departments are involved in preparing the forecast, it estimates approximately one FTE is required.

7.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The distribution company does not prepare a peak-day demand forecast. The peak-day demand forecast is provided by the transmission company.

The transmission forecasts the maximum daily demand for its customers based on historic customer demand and customer feedback. It then compares the correlation of the peak-day demand to annual demand for each customer to other customers in the same sector based on the sector load factor. Its peak-day demand is generally 20% higher than its average daily demand.

8. Pacific Northern Gas

8.1. Overview

The company serves approximately 40,000 customers. The company used end-use forecasting in its most recent long term forecast, which was part of its long term resource plan.

The company has experienced declining use per account in its residential and small commercial sectors, which is likely due to building code improvements and increased appliance efficiencies.

8.2. Forecasting Method

The company uses three different approaches to forecasting annual demand for its three customer classes.

The company forecasts annual demand for its large industrial and commercial customers based on the results of a customer survey. The company sends out a survey to its large customers asking for customers to provide a forecast of their gas use. In cases when a customer forecasts significant change from its historical trend, the company follows up with the customer to verify the customer's forecast.

Forecasts for small commercial customers are based on historical trend analysis coupled with forecasted population growth in the company's service area. Historical trend analysis is used to determine the average use per account, while population growth forecast is based on data from government agencies. The company uses population growth rather than growth in number of housing units because it has found that population growth provides a better correlation to growth in the number of commercial customers.

The company uses an end-use model to forecast the average use per residential customer. The model uses a number of parameters to forecast gas use based on type of dwelling and number of appliances. It uses conditional demand analysis to determine the relationship between the various parameters and gas use per residential customer. The number of residential customers used in the forecast is based on forecasted additions to the number of household in the company's service area provided by government agencies.

The company completed a Residential End Use Survey (REUS) to collect the data on the demographic makeup and consumption behavior of its residential customers. It used this data together with historical customer billing data as key inputs into its residential forecasting model. The model accounts for building code improvements in new homes as well as replacement of appliances with more efficient appliances as customers replace appliances at the end of their useful life. The company used conditional demand analysis techniques to develop end-use models for single family dwellings (SFD), duplexes (DUP), multi-family dwellings (MFD) such as triplexes and townhouses, apartments and condominiums in vertical subdivisions (VS), and mobile homes (MH). It takes into account various characteristics of the natural gas consumption by residential customers such as the distribution of annual demand, the penetration rate and portion of the overall demand of each end-use based on the results of the REUS.

8.3. Forecasting Parameters

The parameters used in the company's residential forecasting model for forecasting average use per residential customer include:

- Dwelling type
- Type of construction
- Number of gas appliances in the home
- Type of gas appliances in the home
- Behaviour of the residents

The company collected this data from its REUS.

8.4. Forecasting Scenarios

The company prepared a base case forecast as well as a high case and a low case for its forecast. These were based on the addition or loss of a large customer and different average use per account for the residential sector based on the REUS.

Alternative demand scenarios were developed to provide some indication of the sensitivity of the demand forecasts to changes in forecast economic and climatic conditions as well as to provide a range of demands that could reasonably be expected. The sensitivity analysis reflected increase in electricity prices and the carbon tax. The scenarios were based on changes to the residential and small commercial demand resulting from changes in the penetration of natural gas versus electricity as the fuel for space and water heating applications. The underlying growth in households and small commercial enterprises remains the same in the base case and competitive electricity price, while the capture rates were adjusted to reflect varying degrees of probability that new households and commercial enterprises use natural gas. Additional growth was reflected in the competitive gas price scenario to account for growth.

8.5. Forecast Period and Update Frequency

The company updates its long term forecast when it files its resource plan. PNG expects to file its resource plan with the BC Utilities Commission every four years.

The company prepares a forecast for each year during the forecast period.

8.6. Forecast Evaluation

The company does not explicitly evaluate the performance of its long term forecast model by using the actual number of customers in the model and adjusting for different assumptions used in the model, however, it does compare actual annual demand to forecasted annual demand. It has found that the forecasts are reasonable and there are no significant variations.

8.7. Forecast Resources

The company was using external resources to prepare its long term forecast, but plans to use internal resources, which are estimated at approximately one third of an FTE.

8.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company has determined the load factor for each customer class using regression analysis of energy consumption against HDD. It then applies the load factor to the annual demand forecast for each customer class to forecast the peak-day demand for each customer class. As a final step in forecasting peak-day demand, the company sums up the peak-day demand for each customer class and adds the forecast for company gas use to forecast the peak-day demand for the system.

The company used a 50-year period in determining the design day demand.

9. Colorado Springs Utilities[5]

9.1. Overview

The company is municipally owned utility that provides water, electricity, and natural gas. The city has a population of approximately 416,000 and its economy is based substantially on employment attributable to service industries, retail businesses, construction industries, military installations, the high technology

[5] 2011 – Gas Integrated Resource Plan (GRIP)

industry and tourism. The company serves over approximately 192,000 gas customers and 217,000 electricity customers

The company's forecasts were developed as part of its 2011 Gas Integrated Resource Plan (GIRP). The 2011 GIRP included an annual demand forecast, a peak-day demand forecast, and a peak-hour demand forecast.

The annual demand forecast was used to prepare revenue budgets and develop long term natural gas procurement plans, while the peak-day and peak-hour demand forecasts were used to assess the adequacy of its transportation capacity, storage deliveries, the need for new capacity, and on-system propane-air production against future demand.

Over the past two decades the company's annual use per residential customer has declined by approximately 25% and is forecasted to decline further and then stabilize in the future due to replacement of older furnaces with higher efficiency furnaces and higher efficiency standards. The company forecasted efficiency standards for water heaters and clothes dryers to also contribute to declining use per residential customer.

The company forecasted that its use per non-residential customer to decrease slightly in the near term in response to price increases and more efficient buildings. It forecasted that longer term, gas use per non-residential customer to stabilize because of increasing average building size to accommodate more employees.

9.2. Forecasting Method

The company's annual demand forecast uses a combination of econometric and end-use (or engineering) modeling. The company's traditional econometric models were based on historical data and the interactions of different economic indicators. With the introduction of Federal efficiency standards, the company believed that the historical relationship could change. The company accounted for these new appliance efficiency standards by using an end-use model to adjust the results of the econometric model for the residential sector. The company continues to use the econometric approach for the commercial sector.

The primary driver of overall demand forecast for the company is the customer count. The second factor in the overall demand forecast is the use per customer.

The company bases its customer count forecast on the population and employment forecasts developed by the state agencies. It also uses other economic variables from Moody's Economics forecast for the U.S. and local economies.

The company bases its residential use per customer forecast on an end use model. The end use model accounts for the effects of appliance efficiency standards, which subsequently impact the forecasted use per customer. The company accounts for the impact of more efficient furnaces, water heaters, range/ovens and clothes dryers in its forecast.

9.3. Forecasting Parameters

The company considers the following parameters in developing its demand forecast:

- Population
- Employment trends
- Inflation
- Traffic area zones (TAZ) based on government planning information
- Construction trends and housing permits, and
- New use development (e.g. natural gas vehicles).
- Average daily temperatures data dating back to 1946, and determined -13 °F average daily temperature to be a one in twenty-year occurrence.
- Wind speed
- Customer growth rate
- Demand response of existing residential, commercial, and industrial customers

9.4. Forecasting Scenarios

The company uses a number of demand scenarios, which included:

- Expected
- High Growth
- Low Growth
- Get the Green Back
- Supply Constraints

These demand scenarios do not represent the maximum bounds of possible demands, but offered a broad range of potential outcomes.

“Expected” demand is based on normal weather and growth. It represents the most likely scenario. The company aligns its long-term strategies to support this scenario. Since the company’s interruptible customers have the option of converting to firm service, the demand scenarios assume that interruptible customers are not curtailed except for two power plants.

9.5. Forecast Period and Update Frequency

The company prepares a forecast which includes the annual demand forecast for every year during the 20-year forecast period.

9.6. Forecast Evaluation

The company uses a separate analysis using single and multiple factor linear regression to validate the corporate sales and load forecast for peak-day and peak-hour forecasts. The company's separate analysis demonstrated statistical agreement with the corporate sales and load forecast.

9.7. Forecast Resources

This information was not available.

9.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses peak-day and peak-hour demand forecasts to determine the adequacy of existing supply resources, or the timing for new resource acquisitions or capital investments required to meet customers' natural gas needs during a peak event. The company has determined that these peak conditions occur once every 20 to 30 years and typically last no more than 3 consecutive days.

Prior to the 2011 GIRP the demand forecast was developed through multiple linear regression analysis. The key inputs into this model included daily load, customer count, and temperature data from multiple years for loads greater than 160,000 Mscf/day.

In February 2011, the company experienced a significant cold weather event, which revealed gaps in the company's demand modeling methodology. As a result, the company revised its forecasting method to better correlate forecasts with an actual peak-day and peak-hour event. The improvements included:

- Widening the data set with hourly load data
- Eliminating weekend data from the data set
- Including wind effects and
- Switching to a use per customer approach to determine daily peak loads for temperatures less than 50° F

Based on actual peak events, the company determined a multiplier that it applied to peak-day load to determine peak-hour load forecasts.

10. Black Hills Energy – Iowa[6]

10.1. Overview

The company operates natural gas and electric utilities that serve 1.2 million customers in eight states: Arkansas, Colorado, Iowa, Kansas, Montana, Nebraska, South Dakota and Wyoming.

[6] Black Hills Energy Natural Gas Energy-Efficiency Plan 2014-2018: Appendices E-H

Forecasts were developed as part of its 2014 to 2018 Natural Gas Energy Efficiency Plan. The company developed an annual demand forecast and a peak-day demand forecast for each customer class.

10.2. Forecasting Method

In its filing, the company stated that it used a combination of econometric and end-use models to forecast monthly and peak-day demand. However, the description of their models does not clearly describe how the company used an end use model. Further review of the company's supporting documents submitted as part of its 2008 filing, including a file with the common assumptions, showed that the company used hourly load shapes for various end uses to determine end use forecasts. This model may be what the company referred to in its 2014 to 2018 Natural Gas Energy Efficiency Plan.

The company developed separate forecasts for each of the major customer classes, which included residential, commercial, industrial, transportation, and other.

The company's models quantify the impact of the significant factors that determine residential, commercial and industrial annual demand and peak-day demand. Econometric/end-use class sales models were developed to take into consideration as many of the important factors as possible.

The company used its most current historic data over a four-year period in the models for residential, commercial, and industrial classes to determine the factors which could significantly impact the monthly demand and peak-day demand. Monthly HDD was used to capture the effect of weather variation on seasonal gas usage. The company also used economic and natural gas price variables together with a heating index (end-use efficiencies and market shares).

The company's annual demand forecast included the impact of previous improvements in energy efficiency and shows a declining annual use per customer for the following five years. Impacts of future energy efficiency programs are not included in the forecast.

The company's residential use per customer was based on actual monthly use per customer explained by weather and historical trends, while annual demand growth in commercial, industrial, and transportation classes were affected by the state's real GDP, natural gas prices, and customer class migration.

The company used monthly data in its class end-use models to better capture the weather impact on monthly demand.

10.3. Forecasting Parameters

The data used to develop the annual demand forecasts included the monthly number of customers, sales volumes, use per customer, and gas prices over the most recent four-year period for each customer class.

Actual HDD and normal HDD from NOAA for four weather stations, weighted by usage were used to normalize the forecast for weather.

The key assumptions used to develop demand forecasts for each customer class included:

1. In the short run, appliance stocks are fixed. Consumption arises from the varying utilization rates.
2. Appliance utilization rates are determined by the price of natural gas, real personal income, housing size, and heating degree days.
3. In the long run, the equipment stock is not fixed and energy-efficient equipment can be installed by households and firms.

The primary factors that impact demand forecast were:

- Customer Growth
- Personal Income Growth
- Price of natural gas and elasticity
- Price of alternate fuels
- Real state GDP for gas utility service area

10.4. Forecasting Scenarios

The company conducted sensitivity analysis to quantify margins of error for two major peak-day demand assumptions:

1) growth in the number of households and
2) growth in commercial, industrial and transportation demand forecasts

The sensitivity analysis presented the relative impact of changes in the number of residential customers, as well as high and low gas prices on peak-day demand.

The company developed a base case, a low case, and a high case for its annual demand forecast and its peak-day demand forecast. In the high case, the number of customers and use per customer were forecasted to grow at higher rates than in the base case forecast; and in the low case, the number of customers and use per customer were forecasted to grow at lower rates, or decline, compared to the base case forecast.

10.5. Forecast Period and Update Frequency

The company's forecast period was from 2013 to 2017. The company developed forecasts for each year during this period.

10.6. Forecast Evaluation

This information was not available.

10.7. Forecast Resources

This information was not available.

10.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

Peak-day demand forecast was based on the peak weather experienced in the last twenty years.

The forecast for peak-day demand was based on an analysis of historical actual peak-day total throughput and actual HDD on dates when peak-days occurred.

11. Avista Utilities[7]

11.1. Overview

The company is an investor owned utility that serves more than 600,000 electric and natural gas customers. Its service territory covers 30,000 square miles in eastern Washington, northern Idaho and parts of southern and eastern Oregon, with a population of 1.5 million.

The company's forecasts were developed as part of its 2014 GIRP. The company developed an annual demand forecast and a peak-day demand forecast.

The company uses annual average demand forecast to prepare revenue budgets, develop natural gas procurement plans, and prepare purchased gas adjustment filings. It uses its peak-day demand forecast to determine the adequacy of existing resources or the timing for acquiring new resources to meet customers' needs in extreme weather conditions.

The company's recent usage data indicated that long run use per customer has been declining. The company attributes this to a confluence of factors including high unemployment, increased investments in energy efficiency measures, building code improvements, behavioral changes, and heightened focus on consumers managing their household budgets.

11.2. Forecasting Method

The company uses an econometric model to prepare its annual demand forecast.

The primary drivers of the company's overall demand forecast are customer growth and use per customer.

The company forecasts the number of customers for each customer class using national economic forecasts and then drills down into regional economies. US GDP growth, US and regional employment growth, and regional population growth forecasts are the key drivers in regional economic forecasts and are used to estimate the number of customers. The company combines this data with local knowledge

[7] 2014 Gas IRP

about sub-regional construction activity, age and other demographic trends, and historical data to develop its 20-year customer forecasts.

The company forecasts its use per customer using regression modeling. The company develops base and weather sensitive demand coefficients that are combined and applied to HDD weather parameters to determine average use per customer.

The company uses historical daily gas flow data from all of its city gate stations. It uses city gate data over revenue data because of the high correlation between weather and demand. The company's revenue system does not capture daily data; therefore, it could not be used in the daily regression modeling. The company, however, reconciles city gate station data against revenue data to ensure the total demand is properly captured. The company uses three years of historical data in its regression modeling and to derive the use per customer coefficients. The company also considered using five years of historic data in its regression modeling and found that five years of data resulted in slightly lower use per customer, which may understate demand as the economy recovers and customer usage pattern return to pre-recession patterns. The regression modeling is performed for each of the company's service territories and temperature zones.

The base usage calculation uses three years of July data to derive coefficients. The base usage coefficient is determined by dividing the average usage in these months by the average number of customers. The company performs this calculation for each area and each customer class.

The company defines eight distinct demand areas in its IRP. These areas are structured around the pipeline transportation and storage resources that serve them.

The company uses the most current 20 years of daily weather data from the NOAA as the base weather forecast to prepare the annual average demand forecast.

The company analyzes an alternate planning standard using the coldest temperature in the last 20 years.

As a final step, the company checks the reasonableness of its coefficient by applying the coefficients to actual customer count and weather data to backcast demand. This compares to actual demand with satisfactory results.

Figure 4 below illustrates the company's method in developing its forecast.

Figure 4. Forecasting Method

Financial Planning and Analysis (FPA) Gas Forecast

Accounting revenue reports for ID, WA, and OR customer count and load data.

Forecast Drivers: HDD, GDP, IP, non-farm employment, and population.

Update spreadsheet with new data each month.

Gas forecast is done twice a year, in June and December. During IRP years, one of these forecasts will be extended to produce the long-run customer projections. The FPA forecast is largely based on an ARIMA based approach with historical billed load data.

Generate a monthly forecast of customers and load by rate schedule. The forecast is 5-years out non-IRP years and 20-years out in IRP years. All forecasts assume average weather using a 20-yer moving average of HDD.

FPA customer forecasts sent to Gas Supply. Customer forecasts are used in Sendout® to (1) generate an aggregate load forecast for firm customers and (2) verify that it lines up with the annual aggregated load forecast from FPA. This process is a cross verification of both forecasts and ensures there are no material differences between the forecasts used for financial forecasting and gas purchase decisions. A 20-year moving average also applied in the Sendout®. forecast.

Sendout® and FPA forecasts are sent to Resource Accounting. The FPA firm load forecast is converted into load shares by schedule, and these shares are applied to the Sendout® forecast to generate the load forecast by firm class and schedule. The forecast is allocated from the Sendout® total to capture the unbilled portion that is not present in the billed data used by FPA. The forecasted loads are converted to revenues that reflect both billed and unbilled dollars. Forecasts for transportation and interruptible schedules come directly from the FPA forecast, and not Sendout®.

The final revenue forecast from Resource Accounting is sent back to FPA for use in the company's earnings model.

11.3. Forecasting Parameters

Weather is the most significant factor influencing demand. Other factors that the company uses include population, employment trends, age and income demographics, construction trends, conservation technology, new uses (e.g. natural gas vehicles), and use-per-customer trends.

The company also analyzes factors that could influence natural gas prices and demand through price elasticity, as customers may adjust consumption in response to changes in price. These include:

- **Supply Trends:** shale gas, Canadian supply availability, and export LNG.
- **Infrastructure Trends:** regional pipeline projects, national pipeline projects, and storage.
- **Regulatory Trends:** subsidies, market transparency/speculation, and carbon legislation.
- **Other Trends:** thermal generation and energy correlations (i.e. oil/gas, coal/gas, liquids/gas).

11.4. Forecasting Scenarios

The company recognizes that historical energy use trends may fundamentally change. The company developed a dynamic demand forecasting model that is flexible to changing assumptions. This helps the company examine a range of potential outcomes.

The company uses a reference case based on historical data and conducted sensitivity analysis on key demand drivers. The company uses this information and input from a technical advisory committee to create several alternate demand scenarios for detailed analysis.

The company groups the demand drivers into two categories:

- Demand Influencing Factors, which directly influence natural gas consumption of core customers.
- Price Influencing Factors, which indirectly influence natural gas consumption of core customers through a price elasticity response.

The company analyzes 17 demand sensitivities to determine the results relative to the reference case. These are summarized in Table 4.

Table 4. Demand Sensitivities and Sensitivity Analysis

Scenario	Influence	Weather	Growth	Use per Customer	Price Curve	Carbon Adder	LNG Adder	DSM	New Markets	Elasticity
Reference Case	Direct	Normal	Expected	3 year	Expected	No	No	No	No	No
Reference Case plus Peak Weather	Direct	Peak	Expected	3 year	Expected	No	No	No	No	No
High Growth Case	Direct	Peak	High	3 year	Expected	No	No	No	No	No
Low Growth Case	Direct	Peak	Low	3 year	Expected	No	No	No	No	No
Alternate Use per Customer	Direct	Peak	Expected	5 year	Expected	No	No	No	No	No
New Markets Case	Direct	Peak	Expected	3 year	Expected	No	No	No	Yes	No
DSM	Direct	Normal	Expected	3 year	Expected	No	No	No	No	No
Peak plus DSM	Direct	Peak	Expected	3 year	Expected	No	No	Yes	No	No
Alternate Weather Planning Standard	Direct	Coldest in 20	Expected	3 year	Expected	No	No	Yes	No	No
Expected Elasticity	Indirect	Peak	Expected	3 year	Expected	No	No	No	No	Yes
Low Price	Indirect	Peak	Expected	3 year	Low	No	No	No	No	No
High Price	Indirect	Peak	Expected	3 year	High	No	No	No	No	No
Carbon Legislation - Low	Indirect	Peak	Expected	3 year	Expected	Yes	No	No	No	No
Carbon Legislation - Medium	Indirect	Peak	Expected	3 year	Expected	Yes	No	No	No	No
Carbon Legislation - High	Indirect	Peak	Expected	3 year	Expected	Yes	No	No	No	No
Exported LNG	Indirect	Peak	Expected	3 year	Expected	No	Yes	No	No	No

After testing the sensitivities, the company groups them into meaningful combinations of demand drivers to develop demand forecasts representing scenarios. These demand scenarios include:

- Average case – this case represents the case used for normal planning purposes, such as corporate budgeting, procurement planning, and General Rate Cases
- Expected case – this case reflects the demand forecast Avista believes is most likely given peak weather conditions
- High growth, low price case – this case represents high customer growth and low future prices
- Low growth, high price case – this case represents low customer growth and high future prices
- Alternate weather standard – this case utilizes the coldest day in Avista's service territories in the last 20 years

The company also analyzes three carbon sensitivities and their impact on the demand forecasts based on different levels of carbon tax to assess the impacts of uncertain carbon legislation.

11.5. Forecast Period and Update Frequency

The company's IRP planning period was from 2014 to 2033. The company developed forecasts for each year during this period.

Even though the company publishes an IRP every two years, it updates its forecast with new information and developments in the years between IRP filings.

11.6. Forecast Evaluation

As a final step in its forecasting process, the company checks the reasonableness of the coefficients from its regression model by applying the coefficients to actual customer count and weather data to backcast demand. This compares to actual demand with satisfactory results.

11.7. Forecast Resources

This information was not available.

11.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company uses a five-day cold weather event to forecast its peak-day demand. The peak-day demand forecast includes adjustments to average weather to reflect a five-day cold weather event. This consists of adjusting the middle day of the five-day cold weather event to the coldest temperature on record for a service territory, as well as adjusting the two days on either side of the coldest day to temperatures slightly warmer than the coldest day.

The company develops a super peak coefficient to capture gas use in extreme weather conditions because in extreme weather conditions demand can begin to flatten out relative to the linear relationships at less extreme temperatures.

The model for deriving super peak coefficients is derived by averaging the heat coefficients for December, January and February. Because of the lack of sufficient data points to develop a strong linear relationship, the company continues to test this theory and monitor trends.

11.9. Global Warming

In previous IRP's the company adjusted NOAA weather data to incorporate estimates for global warming. This adjustment was based on analysis of historical weather data in each of the areas served. In its 2014 IRP, the company moved away from adjusting the weather data and moved from a rolling 30-year average to a 20-year average. The company moved to a 20-year average because NASA climate studies indicated that the distribution of temperatures in North America began to shift upwards significantly about 20 years ago and although a 10-year moving average captures turning points in climate trends more quickly than 15, 20 or 30-year averages, it will do so at the cost of larger year-to-year changes in the measurement of normal weather.

The company was unable to find any definitive evidence to support a peak-day warming trend. After discussion with the TAC, the company decided to discontinue global warming trend adjustments to the peak day weather events in the HDD forecast. Therefore, the modeling and analysis with respect to peak day planning is unaffected by global warming.

12. Cascade Natural Gas Corporation[8]

12.1. Overview

The company serves more than 272,000 customers in 96 communities in western and central Washington and central and eastern Oregon.

The company developed a long-term forecast of natural gas demand in its service territory as part of its 2011 IRP. The company uses an econometric model to develop its demand forecast.

Residential and commercial load growth is primarily a result of increased customer counts.

The forecast is used in short-term (annual budgeting) and long-term (distribution and integrated resource planning) planning processes.

The number of residential and commercial customers is expected to increase faster than energy use per customer. Factors that have resulted in lower user per customer are believed to be soft conservation (such as behavioural changes), building codes, and heat pump penetration. The reduction in use per account is more prevalent among residential customers than commercial.

12.2. Forecasting Method

The company retained a consultant to develop its forecasting model. The model is based on an Excel spreadsheet. However, the forecasting department is seeking budget approval to acquire a commercial forecasting software.

The company starts its forecast process by developing separate econometric models representing the company's three main core customer classes (residential, commercial and industrial) for each of the company's 15 districts for a total of 45 models. These models forecast the number of customers for each of the three main core customer classes. These customer count forecasts are designed to reflect both demographic trends and economic conditions both in the short and long term in each district.

The models are built up from the district level, because it is the smallest level where consistent raw data is available. This is a change from previous years where certain models were built from the town level and others from the district. The company expected to improve the reliability of its forecast by unifying its forecasting method. The district models are rolled up into zones based on the pipelines serving the districts and weather.

In addition to these 45 customer count forecasting models, a separate and parallel set of 45 models are used to estimate energy use per customer for each customer class in each district. The use per customer forecasts are developed based on multi-variable regression analysis for each customer class using

8 2011 Integrated Resource Plan

historical weather and energy use data. The historical data used in the regression models extended back to 1980 for customer counts and 1994 for energy use.

The results of the customers count and energy use per customer models are then used to determine the annual gas demand by customer class and district.

These forecasts exclude any saving that may result from the company's energy efficiency programs. The company's energy efficiency and conservation group reviews the forecast and adjusts these forecasts based on the forecasted energy savings from their energy efficiency programs.

The company uses the same model for short term and long term forecasting.

12.3. Forecasting Parameters

The parameters used in the model for forecasting customer count include:

- Employment forecast
- Number of households forecast
- Mortgage rates (for residential customer counts)
- Prime rate (for commercial and industrial customer counts)

The parameters used in the model for forecasting use per account include:

- Median household income forecast
- Weather and
- Natural gas prices

The company uses economic indicator forecasts from Woods & Poole and mortgage rate and prime rate forecasts from Freddie Mac and the Federal Reserve, respectively.

Past weather data is obtained from NOAA and future weather data is based on the company's 20-year normal weather developed for its last rate case.

Natural gas prices are obtained from Wood Mackenzie and equal weights are assigned different price indexes based on the company's general portfolio mix.

These indicators are used over other indicators as they are the most consistent in returning statistically valid results.

12.4. Forecasting Scenarios

The company's customer count and energy use forecasts are augmented by revising the base data and output to create a portfolio of potential scenarios. Low and high growth scenarios are created by altering Woods & Poole's forecasts to reflect the company's strongest and weakest performing decades over the last 30 years. These scenarios, along with the original best-estimate mid case scenario, form a range of most-likely possibilities.

High and low scenarios are created by examining the best and poorest performing years from the historical data period, 1980 to 2009. They provide a range for the annual load and peak-day demand forecasts should the underlying indicators vary from Woods & Poole's long range estimates.

12.5. Forecast Period and Update Frequency

The company develops a 20-year forecast of customers, annual demand, and peak-day demand for each year during the forecast period.

The company develops a 20-year forecast of customers, annual demand, and peak-day requirements for use in short (annual budgeting) and long-term (distribution and integrated resource planning) planning processes each year. Updates to the forecasts may be prepared three to four times per year for use in annual budgets, rate cases, and IRP filings. IRPs are prepared every two years.

12.6. Forecast Evaluation

The company evaluates its forecasting model by using actual weather conditions and actual number of customers in the model and comparing the results to previous forecasts. While the model has performed well overall, it has under-forecasted demand in the winter and over-forecasted demand in mild summers.

12.7. Forecast Resources

The forecasts are prepared internally by the forecasting department which obtains economic forecast reports from Woods & Poole and also consults with other consultants as needed.

One person in the forecasting department maintains the models, while three people in the energy efficiency and conservation department update the forecast prepared by the forecasting department to reflect impact of energy efficiency programs.

12.8. Peak-Day Demand Forecast vs. Annual Demand Forecast

The company develops peak-day forecasts in conjunction with annual demand forecasts to ensure it can meet the demand by its core customers on the coldest days.

Historically the company developed peak-day forecasts based on a 65 HDD day (0°F) to reflect the coldest day in its 60-year weather history. The company's 2008 IRP changed this practice to reflect the coldest day during the past 30 years. The peak-day forecast is developed by adjusting the energy use on the coldest day in recent history upwards to an estimate of what energy use would have been had that day been the coldest day in the past 30 years. The energy use is then applied to each district and escalated into the future at the forecasted annual growth rate for energy use.

This method assumes that core market load shape does not significantly change throughout the forecast period. The company believes that the peak-day forecast conservatively overestimates peak-day demand as the base forecast does not explicitly include future conservation measures implemented by customers.

Appendix B. GLOSSARY

AMI – Advanced Metering Infrastructure

CEC – California Energy Commission

CED – California Energy Demand

CGR – California Gas Report

CMHC – Canada Mortgage and Housing Corporation

CO_2 – Carbon Dioxide

DSM – Demand Side Management

EE – Energy Efficiency

EG – Electricity Generation

EPRI – Electric Power Research Institute

EU – End Use

EUI – End Use Intensity

FTE – Full Time Equivalent

FEU – FortisBC Energy Utilities

GDP – Gross Domestic Product

GHG – Greenhouse Gas

GIRP – Gas Integrated Resource Plan

HDD – Heating Degree Day

HVAC – Heating, Ventilation, and Air Conditioning

IEPR – Integrated Energy Policy Report

IOU – Investor Owned Utility

IRP – Integrated Resource Plan

LNG – Liquefied Natural Gas

LTRP – Long Term Resource Plan

m^3 – Cubic Metre

MFD – Multifamily Dwelling

MH – Mobile Home

Mscf – Million Standard Cubic Feet

MURB – Multi-Unit Residential Building

NAICS – North American Industry Classification System

NAMGas Model – North American Market Gas-Trade Model

NASA - National Aeronautical and Space Agency

NGV – Natural Gas Vehicle

NOAA – National Oceanic and Atmospheric Administration

PNG – Pacific Northern Gas

PSE – Puget Sound Energy

REUS – Residential End Use Survey

SFD – Single Family Dwelling

TAC – Technical Advisory Committee

UPC – Use Per Customer

UPA – Use Per Account

VS – Vertical Subdivisions

ZNE – Zero Net Energy

Appendix B-3

TRADITIONAL ANNUAL DEMAND FORECAST

APPENDIX B-3: TRADITIONAL ANNUAL DEMAND FORECAST

This appendix provides further background on and key results from the Traditional Annual Method. Just like the end-use method, the Traditional Annual Method uses a 2015 base year.

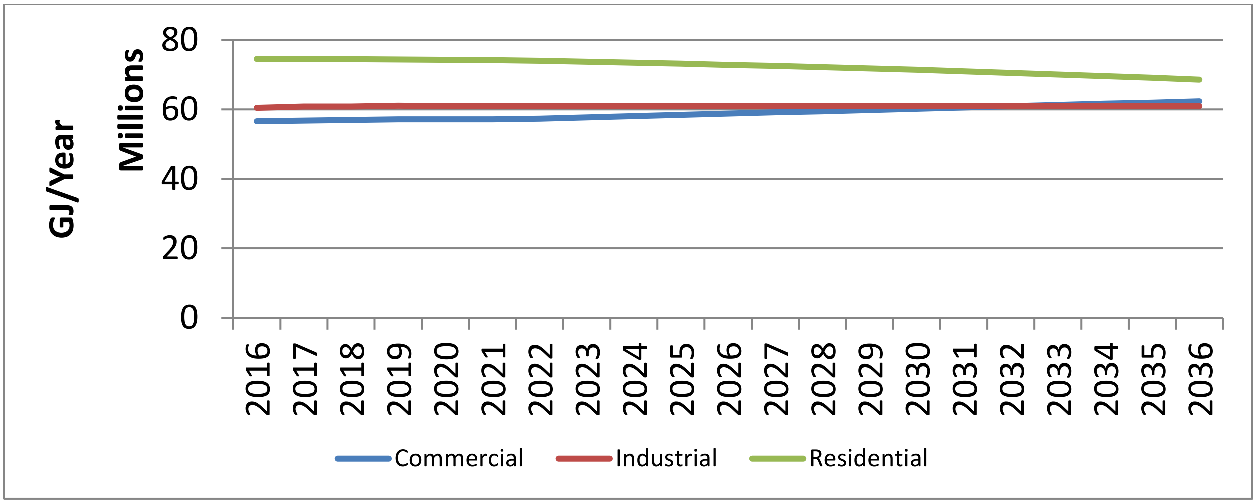
1.1 Traditional Annual Demand Method – Residential, Commercial and Industrial

The Company's Traditional Annual Method for forecasting residential and commercial demand involved determining a forecast natural gas Use per Customer (UPC) and multiplying it by the number of customers forecasted for each year of the study period. UPC was determined by examining weather normalized historical actual demand. A regression analysis was used to identify any significant trends in the use rates. These trends implicitly included the impact of broad changes in consumption patterns that might have been caused by such factors as energy efficiency, economic activity, policies and equipment standards up to the time of the most recently available annual usage data. The analysis was conducted for each residential and commercial rate class, based on the most recent three years of data. The trends were then extended into the next 20 years for the purposes of providing a long term forecast.

FEI utilized the results of the annual industrial customer survey to identify expected changes in industrial customer demand. The survey was conducted as part of FEI's short term demand forecasting process used for gas supply planning, revenue requirements and other BCUC submissions. The intentions of industrial customers over the next five years were held constant over the LTRP planning horizon as this represents the best available information using the Traditional Annual Method.

The annual demand in each year of the forecast for each rate class in each customer category (i.e. residential, commercial, industrial) was then summed to determine the total overall residential, commercial and industrial demand. The result is a Reference Case demand scenario using the Company's Traditional Annual Method. Figure B3-1 shows the Traditional Annual Method Reference Case demand for each of the rate class categories and is followed by a general description of the forecast results for each category.

Figure B3-1: Long Term Annual Demand by Customer Category – Traditional Annual Method



1.1.1 RESIDENTIAL DEMAND

Declining residential UPC in the FEI service territories is resulting in an overall decline in residential annual demand, even though the Company continues to add residential customers through the forecast period. This decline in residential UPC is now a common occurrence affecting mature natural gas utilities across North America. Declining use rates are driven by a number of factors, such as efficiency improvements, changes in building stock, changes in appliance uptake and switching between energy sources (from gas to electricity). Efficiency improvements include the retrofit of older, less efficient appliances with new high efficiency units, and also upgrades to insulation, window, doors, and more generally speaking, building shells. Efficiency improvements are driven by a number of factors such as technological advances, construction of smaller, less energy-intensive multifamily dwellings, public policies and programs and the state of the economy. This declining trend is expected to continue through the planning period.

1.1.2 COMMERCIAL DEMAND

In the Traditional Annual Method forecast, the recent demand increases seen in the commercial rate classes are assumed to continue into the long term and thus, commercial demand grows over the 20 year planning horizon.

1.1.3 INDUSTRIAL DEMAND

Overall industrial demand is forecast to be stable through the planning horizon.

1.2 Conclusion

The Traditional Annual Method represents an extension across the planning period of intrinsic end-use trends from the most recent three years (in relation to the base year). The resulting annual demand forecast is largely flat with moderate growth in the commercial sector. Section 2 of the 2017 LTGRP discusses an uncertain and complex planning environment. Projecting existing end-use trends across the long term planning period may be unsuitable to account for uncertainty in such a complex planning environment. For this reason, FEI discusses the end-use forecast method in Section 3 of the Application. This method enables FEI to prepare a Reference Case end-use annual demand forecast but to also plan to alternate future scenarios.

DISCLAIMER

This report was prepared by Navigant Consulting, Inc. (Navigant) for FortisBC Energy Inc. The work presented in this report represents Navigant's professional judgment based on the information available at the time this report was prepared. Navigant is not responsible for the reader's use of, or reliance upon, the report, nor any decisions based on the report. NAVIGANT MAKES NO REPRESENTATIONS OR WARRANTIES, EXPRESSED OR IMPLIED. Readers of the report are advised that they assume all liabilities incurred by them, or third parties, as a result of their reliance on the report, or the data, information, findings and opinions contained in the report.

EXECUTIVE SUMMARY

FortisBC Energy Inc. (FortisBC Gas) and the other BC Utilities engaged Navigant Consulting, Inc. (Navigant or the team) to prepare a conservation potential review (CPR) for electricity and natural gas across all of British Columbia over a 20-year forecast horizon from 2016 to 2035. The CPR's objective is to assess the energy efficiency potential in the residential, commercial, and industrial sectors by analyzing energy efficiency and peak-load-reduction measures, defining operational and maintenance activities to keep existing devices or equipment in good working order, and improving end-user behaviors to reduce energy consumption. These analysis efforts provide input data to Navigant's Demand Side Management Simulator (DSMSim™) model, which calculates technical and economic savings potential across FortisBC Gas's service territory. FortisBC Gas may use these results as input to their own DSM planning and long term conservation goals, energy efficiency program design, integrated resource planning (IRP), and load forecasting models.

The first stage of this CPR is to estimate technical and economic conservation potential, which is presented in this report. Further analyses, which will be presented in ensuing reports as part of the CPR's Additional Scope Services, include estimation of the province-wide technical and economic potential for electricity and natural gas, achievable market potential for gas savings and potential from fuel switching.

Approach

This section provides an overview of the methods Navigant employed for conducting the 2016 CPR for British Columbia.

Base Year and Reference Case Forecast

Navigant developed the Base Year (2014) Calibration (base year) based on an assessment of energy consumption in each utility's service territory, by customer sector and segment, end-use, fuel, and types of equipment used. The objective of the base year is to establish a profile of energy consumption by utility, which is consistent with the total energy consumption (gas and electricity) reported by each utility. The team used the base year as the foundation to develop the Reference Case Forecast of energy demand through 2035.

The Reference Case Forecast estimates the expected level of energy demand over the CPR period from 2016-2035 absent incremental demand-side management (DSM) activities and absent rate impacts on consumption. The significance of the Reference Case in the context of this CPR study is that it acts as the point of comparison (i.e., the reference) for the calculation of the technical and economic potential scenarios.

The Reference Case Forecast uses the base year calibration as the foundation for analysis. Navigant used two key inputs to construct the Reference Case forecast for each customer sector: building stock growth rates, and end-use intensity (EUI) trends. Applying building stock growth rates to the base year stocks of each customer segment results in a forecast of stocks through 2035. Similarly, applying the EUI trends to the base year EUIs results in a forecast of EUIs through 2035. The final step of this process involves multiplying the stock forecast with the corresponding EUI forecast in order to obtain a consumption forecast.

To construct the Reference Case Forecast, Navigant developed growth projections of residential building stock, commercial floor area, and industrial energy consumption. The team then modeled the potential for energy efficiency based on the resulting stock projections of each sector, while accounting for the changing mix of newly constructed versus existing building stock. The team applied EUI trends to the Base Year EUIs for each customer segment, and used these trends to represent natural change (i.e., naturally occurring increases or reductions in consumption not attributable to DSM programs) in end-use consumption over time.

Navigant compared the forecasts developed as part of the Reference Case for the residential, commercial, and industrial sectors with the long-term load forecast developed by each utility. The team performed this comparison to ensure that the Reference Case forecast is consistent with each utility's current expectations for load growth over the 2015 to 2035 period.

Measure Characterization

Navigant fully characterized over 200 measures across the BC Utility's residential, commercial, and industrial sectors, covering electric and natural gas fuel types. The team prioritized measures with high impact, data availability, and likelihood to be cost-effective as criteria for inclusion into DSMSim™.

The team reviewed current BC program offerings, previous CPR and other Canadian programs, and potential model measure lists from other jurisdictions to identify which energy efficient measures to include in the study. The team supplemented the measure list using the Pennsylvania, Illinois, Mid-Atlantic, and Massachusetts technical resource manuals (TRMs), and partnered with CLEAResult to inform the list of industrial measures. Navigant worked with the BC Utilities to finalize the measure list and ensure it contained technologies viable for future BC program planning activities. Appendix A.2 provides the references to the final measure list and assumptions.

Estimation of Potential

Navigant employed its proprietary DSMSim™ potential model to estimate the technical and economic savings potential for gas energy in FortisBC Gas's service territory.[1] DSMSim™ is a bottom-up technology diffusion and stock-tracking model implemented using a System Dynamics[2] framework. The DSMSim™ model explicitly accounts for different types of efficient measures such as retrofit (RET), replace-on-burnout (ROB), and new construction (NEW) and the impacts these measures have on savings potential. The model then reports the technical and economic potential savings in aggregate by service territory, sector, customer segment, end-use category, and highest-impact measures.

Technical potential is defined as the energy savings that can be achieved assuming that all installed measures can immediately be replaced with the efficient measure, wherever technically feasible, regardless of the cost, market acceptance, or whether a measure has failed (or "burned out") and is in need of being replaced. Technically feasible measures are commercially available measures that are compatible with and may replace the existing baseline technology. Economic potential is a subset of technical potential, using the same assumptions regarding immediate replacement as in technical potential, but limiting the calculation only to those measures that have passed the benefit-cost test chosen for measure screening, in this case the TRC test. Similar to technical potential, economic potential does not represent an achievable level of savings potential because it does not account for market adoption and acceptance, desired customer payback period, etc. The estimation of achievable market potential will be completed as part of this CPR's Additional Scope Services.

Savings reported in this study are "gross", rather than "net," meaning they do not include the effects of natural change (as described in Section 2.3.2). The technical potential results section concludes with a comparison of aggregate potential before consideration of natural change and after including natural change. Providing gross potential is advantageous because it permits a reviewer to more easily calculate net potential when new information about net-to-gross ratios or changing end-use intensities become available.

Findings

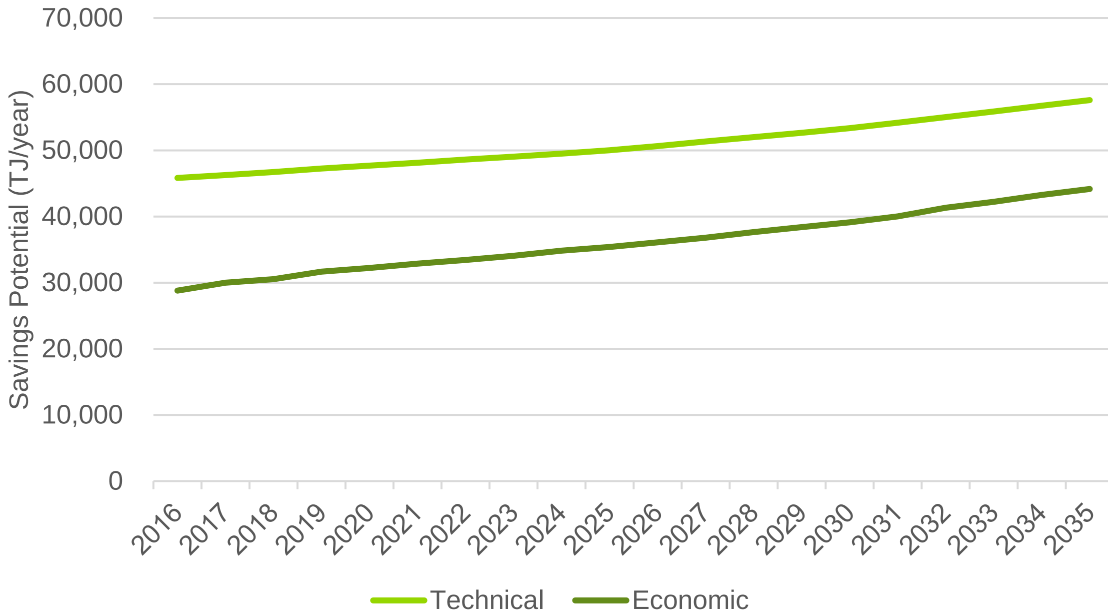
Figure ES-1 compares the total technical and economic gas energy savings potential in FortisBC Gas's service territories, and Table D-1 of Appendix D provides the associated data. Technical gas savings potential begins at approximately 46,000 TJ/year in 2016 and increases by 26% to 58,000 TJ/year by 2035. Economic gas savings potential grows by 53% from a 2016 value of 29,000 TJ/year to a 2035 value of 44,000 TJ/year. On average across the study period, 71% of technical potential is cost-effective, as reflected by the economic potential.

---

[1] The study also identified the impacts on electric consumption caused by gas measures with either dual-fuel savings or cross-fuel interactive effects. Since the electric impacts are negligible, they are included in Appendix A.1, but not within the body of the report.
[2] See Sterman, John D. *Business Dynamics: Systems Thinking and Modeling for a Complex World*. Irwin McGraw-Hill. 2000 for detail on System Dynamics modelling. Also see http://en.wikipedia.org/wiki/System_dynamics for a high-level overview.

The residential and commercial sectors' contributions to the growth of technical potential are nearly equal, whereas technical potential from the industrial sector declines slightly over the forecast period. The commercial sector drives the majority of the growth in economic potential.

Figure ES-1. Total Gas Energy Savings Potential (TJ/year)



Source: Navigant

Figure ES-2 provides the technical and economic gas savings potential as a percentage of total gas consumption within the FortisBC Gas's service territories, and Table D-2 of Appendix D provides the associated data. The technical savings potential grows faster than the gas consumption forecast, such that the technical potential as a percentage of total gas consumption increases from 24% in 2016 to 28% by 2035. Economic savings potential increases from 15% in 2016 to 21%.

1. INTRODUCTION

1.1 Conservation Potential Review Background and Goals

The BC Utilities—defined in this report as BC Hydro, FortisBC Inc. (FortisBC Electric), FortisBC Energy Inc. (FortisBC Gas), and Pacific Northern Gas Ltd.—engaged Navigant Consulting, Inc. (Navigant or the team) to prepare a conservation potential review (CPR) for electricity and natural gas across all of British Columbia over a 20-year forecast horizon from 2016 to 2035. The CPR's objective is to assess the energy efficiency potential in the residential, commercial, and industrial sectors by analyzing energy efficiency and peak-load-reduction measures, defining operational and maintenance activities to keep existing devices or equipment in good working order, and improving end-user behaviors to reduce energy consumption. These analysis efforts provide input data to Navigant's Demand Side Management Simulator (DSMSim™) model, which calculates technical and economic savings potential across the BC Utilities' service territories. The BC Utilities may use these results as input to their own DSM planning and long-term conservation goals, energy efficiency program design, integrated resource planning (IRP), and load forecasting models.

1.2 Organization of Report

This report is organized as follows:

Section 2 describes the methodologies and approaches Navigant used for estimating energy efficiency and demand reduction potential, including discussion of base year calibration, Reference Case forecast, the frozen end-use intensity case, and measure characterization.

Section 3 offers the technical potential savings forecast for FortisBC Gas, including the methods for estimating technical potential and the modeling results by customer segment and end-use.

Section 4 offers the economic potential savings forecast for FortisBC Gas, including the methods for estimating economic potential and the modeling results by customer segment and end-use.

Accompanying Appendices provide detailed model results and additional context around modeling assumptions.

1.3 Caveats and Limitations

There are several caveats and limitations associated with the results of this study, as detailed below.

1.3.1 Forecasting Limitations

Navigant obtained future energy sales forecasts from each BC Utility. Each of these forecasts contain assumptions, methodologies, and exclusions which could differ by utility. Navigant has leveraged the assumptions underlying these forecasts, as much as possible, as inputs into the development of the Reference Case stock and energy demand projections. Where sufficient and detailed information could not be extracted, as a result of the granularity of the information available or customer data protection requirements, Navigant developed independent projections of stock for each utility. The team developed these independent projections based on secondary data resources and in collaboration with the utilities. These secondary resources and any underlying assumptions are referenced throughout this report.

1.3.2 Program Design

The results of this study provide a big picture view of the unmet savings potential in each of the BC Utilities’ service territories. However, this study is not considered to be a detailed program design tool, as it does not consider incentive, marketing, advertising and budget levels, nor customers’ willingness to adopt efficient measures. As such, the magnitude of the results should not be interpreted as the savings potential that could be realistically achieved by utility-sponsored energy conservation programs.

1.3.3 Measure Characterization

Efficiency potential studies may employ a variety of primary data collection techniques (e.g., customer surveys, on-site equipment saturation studies, and telephone interviews), which can enhance the accuracy of the results, though not without associated cost and time requirements. The scope of this study did not include primary data collection, but rather relied on data from the BC Utilities, other regional efficiency programs, Natural Resources Canada (NRCan), and technical reference manuals (TRMs) from Pennsylvania, Illinois, Mid-Atlantic, and Massachusetts to inform inputs to DSMSim™.

Furthermore, the team considers the measure list used in this study to appropriately focus on those technologies likely to have the highest impact on savings potential over the potential study horizon. However, there is always the possibility that emerging technologies may arise that could increase savings opportunities over the forecast horizon, and broader societal changes may impact levels of energy use in ways not anticipated in the study.

1.3.4 Measure Interactions

This study models energy efficiency measures independently .[3] As a result, the total aggregated energy efficiency potential estimates may be different from the actual potential available if a customer installs multiple measures in their home or business. Multiple measure installations at a single site generate two types of interactions: within-end-use interactions, and cross-end-use interactions. An example of a within-end-use interaction is when a customer implements an operational program to review and maintain steam traps, but also installs a more efficient boiler. To the extent that the steam trap program reduces heating requirements at the boiler, the savings from the efficient boiler would be reduced. An example of a cross-end-use interaction would be when a homeowner replaces a number of heat producing incandescent light bulbs with efficient LEDs. This impacts the cooling and heating load of the space—however slightly—by increasing the amount of heat required from the HVAC system, and decreasing the amount of cooling required.

[3] A small number of measures accounted for interactions among multiple efficient measures. For measures whose characterization was based on building energy model simulations evaluating bundled measures, interactive effects among those measures were included in the savings estimates (e.g., ENERGY STAR New Homes, Net-Zero New Homes, etc.).

Navigant employed the following methods to account for interactive effects:

- Where measures clearly compete for the same application (e.g., CFL and LED), the team created competition groups to eliminate the potential for double counting savings
- For measures with significant interactions (e.g., industrial process and boilers), the team adjusted applicability percentages to reflect varying degrees of interaction
- Wherever cross-end-use interactions were appreciable (e.g., lighting and HVAC), the team characterized those interactions for both same-fuel (e.g., lighting and electric heating) and cross-fuel (e.g., lighting and gas heating) applications

B.1 provides further discussion on the challenges involved with accurately determining interactive effects.

1.3.5 Measure-Level Results

This report includes a high-level account of savings potential results across the FortisBC Gas's service territories and focuses largely on aggregated forms of savings potential. However, Appendix A.1 provides results at the finest level of granularity, which is at the measure-level within each customer segment. The measure-level data is mapped to the various regions, customer segments and end-use categories to permit a reviewer to easily create custom aggregations

1.3.6 Gross Savings Study

Navigant and BC Utilities agreed to show savings from this study at the gross level, whereby natural change and free ridership, as it relates to program implementation, are not included in the savings estimates but rather are estimated separately. Providing gross potential is advantageous because it permits a reviewer to more easily calculate net potential when new information about changing end-use intensities or net-to-gross ratios become available. However, the team calculated natural change at end-use level, which is available in Appendix A.1. Additionally, each results section concludes with a comparison of aggregate potential before consideration of natural change and after including natural change.

2. APPROACH TO ESTIMATING ENERGY AND DEMAND SAVINGS

This section describes the methodologies Navigant employed for estimating energy and demand savings across the BC Utility's service territories including base year calibration, reference case forecast, the frozen end-use intensity case, and measure characterization.

2.1 Base Year Calibration

Navigant developed a Base Year Calibration (base year) based on an assessment of energy consumption in each utility's service territory, by customer sector and segment, end-use, fuel, and types of equipment used. The objective of the base year is to define a detailed profile of energy consumption by utility which matches the total energy consumption (gas and electricity) reported by each utility. The team used the base year as the foundation to develop the Reference Case Forecast of energy consumption through 2035. Section 2.2 discusses the development of the Reference Case.

Navigant developed the Base Year analysis for the province as a whole relying on data provided by the BC Utilities. This report presents data that is specific to FortisBC Gas. The resources provided by FortisBC Gas included the following data sources:

- Historical gas consumption;
- Residential accounts data;
- Residential and Commercial End-Use Surveys;
- Program evaluation reports, conditional demand analyses (CDA); and
- The 2010 and 2006 CPR reports.

Where utility- or FortisBC-specific information was not available, Navigant utilized data from publicly available sources such as BC Statistics (BC Stats), Statistics Canada (StatsCan), and Natural Resources Canada (NRCan) and the Office of Energy Efficiency (OEE) in addition to internal Navigant data sources. Navigant's review of these sources supported the data provided by FortisBC Gas and to ensure consistency among all data used in the study. In order to develop the final estimates of energy consumption, Navigant compared and calibrated preliminary estimates with actual sales data obtained from FortisBC Gas.

Navigant focused the calibration analysis on volumetric energy (e.g., MWh or GJ) consumed in each region by customer segment, end-use, and equipment type in order to develop the base year energy profile for each utility. Navigant chose not to perform calibration based on peak demand (e.g., MW or GJ/hr.) for several reasons. First, each utility reports sales and self-generation amounts at the level of aggregation required for this analysis (e.g., by residential, commercial, and industrial segments) exclusively by volumetric energy. Second, utilities rarely aggregate and report peak demand data (other than for billing purposes) at the level of aggregation required. Third, each utility had readily available (and granular) volumetric energy data.

2.1.1 Segmentation of Customer Sectors

Navigant disaggregated FortisBC Gas's base year gas consumption by region in the province, sector, and customer segment. Navigant worked with the BC utilities to determine an appropriate level of segmentation for each sector and an acceptable geographic representation resulting in four regions consistent with regional definitions used by FortisBC Gas.
Table 2-1 indicates the relationship between the four utilities' service territories and the regions considered in the CPR.

Table 2-1: Mapping of Utility Service Territories to CPR Regions

	Vancouver Island	Lower Mainland	Southern Interior	Northern BC
BC Hydro (Electric)	✓	✓	✓	✓
FortisBC (Electric)			✓	
FortisBC Energy (Gas)	✓	✓	✓	✓
PNG (Gas)				✓

Source: Navigant

The first major task to develop the base year gas calibration involved the disaggregation of the three main sectors—the residential, commercial, and industrial sectors—into specific customer segments. Each sector was segmented according to several factors including the availability and level of detail of the data provided by each utility, supporting information from secondary resources, level of consumption within segments, and consistency with previous CPRs.

The segmentation also reflects Navigant's modeling approach for representing efficiency measures within the DSMSim™ model. DSMSim™ models energy efficiency measures at the segment level, and tracks building and equipment stocks for each segment within each region and utility. Differences in fuel choices (i.e., space and water heating market shares), types of equipment used (i.e., use of a furnace or boiler for space heating), and equipment and system efficiency levels are all represented within the model for each segment, region, and utility, as required.

This modeling approach represents all measures separately within each customer segment, and does not require the duplication of segments using different space heating sources or different industrial processes. For example, the model represents space conditioning measures separately by heating type (e.g., characterizing thermal envelope measures for homes with electric or gas heat), eliminating the need to define a customer segment with electric heat versus a segment with gas heat.

Table 2-2 shows the segmentation used for the residential, commercial, and industrial sectors, with additional detail provided for each sector in the following sections. Although the streetlights/traffic signals segment is included in the commercial sector in Table 2-2, it has been analyzed and referenced separately throughout this report.

Table 2-2: Customer Segments by Sector

Residential	Commercial	Industrial
Single Family Detached	Accommodation	Agriculture
Single Family Attached/Row	Colleges/Universities	Cement
Apartments =< 4 stories	Food Service	Chemical
Apartments > 4 stories	Hospital	Food & Beverage
Other Residential	Logistics/Warehouses	Greenhouses
	Long Term Care	Mining - Coal
	Office	Mining - Metal
	Other Commercial	LNG Facilities
	Retail - Food	Oil and Gas
	Retail - Non Food	Manufacturing
	Schools	Pulp & Paper - Kraft
	Streetlights/Traffic Signals*	Pulp & Paper - TMP
		Wood Products
		Other Industrial
		Transportation

**Although the streetlights/traffic signals segment is included in the Commercial sector, it is only applicable to the electric utilities.*

2.1.1.1 FortisBC Gas Sales

FortisBC Gas supplies natural gas to residential, commercial and industrial customers across the four CPR regions. For internal purposes, FortisBC Gas distinguishes the location of its customers based on seven regions - different to the four CPR regions. As a result, to aggregate the FortisBC Gas sales data according to the four CPR regions, Navigant and FortisBC Gas developed a mapping to allocate sales and customer account data based on the seven FortisBC Gas regions and the four CPR regions.

The seven regions used by FortisBC Gas include Columbia, Fort Nelson, Inland, Lower Mainland, Revelstoke, Vancouver Island, and Whistler. Table 2-3 shows the mapping used to allocate sales to each of the CPR regions.

Table 2-3: Mapping of FortisBC Gas to CPR Regions

Code	Region	Vancouver Island	Lower Mainland	Southern Interior	Northern BC
COL	Columbia			✓	
FTN	Fort Nelson				✓
INL	Inland			✓	✓
LML	Lower Mainland		✓		
RSK	Revelstoke			✓	
VI	Vancouver Island	✓			
WH	Whistler		✓		

Source: Navigant analysis of FortisBC Gas data

A second step was also required in order to allocate FortisBC Gas sales and customers appropriately across customer sectors. This step deals specifically with apartment buildings. In this CPR, apartment buildings have been included in the residential sector. However, for billing purposes, FortisBC Gas includes apartment buildings in the commercial sector. As a result, a fraction of the commercial sector sales –attributed to apartment buildings- has been re-allocated to the residential sector. The fraction of sales attributed to apartment buildings was calculated as part of the analysis of Base Year sales, and is based on the stock of apartment units and the corresponding EUIs. Overall, relative to the initial allocation of sales the resulting residential sales are higher and the commercial sales are lower.

2.1.1.2 Residential Sector

Navigant divided residential customers into five segments based on the type of dwelling they occupied, as shown in Table 2-4.

Table 2-4: Description of Residential Segments

Segment	Description
Single Family Detached/Duplexes	Detached and duplex residential dwellings
Single Family Attached/Row	Attached, row and/or townhouses
Apartments < 4 stories	Apartment units located in low-rise apartment buildings made up of four stories or fewer
Apartments >= 4 stories	Apartment units located in high-rise apartment buildings made up of more than four stories
Other Residential	Manufactured, mobiles or other types of residential dwellings

Source: Navigant

This segmentation is largely consistent with the dwelling types employed in the FortisBC Gas 2010 CPR, with the following three exceptions:

» **Space heating system** - The 2010 CPR duplicated each residential dwelling type in order to model archetypes for different types of heating (e.g., electrically heated homes vs. gas heated homes). Based on Navigant's modelling approach, it is not necessary to duplicate residential segments to analyze dwelling types using different heating fuels.

» **Dwelling vintage** - The 2010 CPR divided the residential sector according to dwelling vintage (e.g., pre-1976 homes, and post-1976 homes). While Navigant recognizes that this approach is meant to reflect differences in gas consumption as a result of different types of equipment found in older and newer homes, Navigant's segmentation does not require this differentiation. These differences in gas consumption and the types of equipment used by different vintage homes can be, and are, captured in Navigant's *DSMSim* model.

» **Apartments -** The 2010 CPR included apartment buildings in the commercial sector, and divided them as large and medium apartment buildings to reflect differences in energy consumption that may appear in low and high rise buildings. For the base year and reference case analysis, this

CPR includes apartment buildings in the residential sector. This CPR also divides apartments based on buildings with less than or equal to 4 stories, and buildings with more than 4 stories. [4]

Navigant developed the breakdown of the residential sector into dwelling types based on FortisBC Gas billing data and supported by BC Hydro apartment unit counts. The team also used the same data sources to divide the total stock of each dwelling type by service region, provided in Table 2-5. While apartment buildings are reported in the residential sector for purposes of the base year analysis and the reference case forecast, they are moved to the commercial sector in the technical and economic potential results. Gas savings from apartment buildings are reported in the commercial sector because FortisBC Gas's conservation programs for apartment buildings are categorized as commercial programs.

Table 2-5: Base Year Housing Stocks (Residential units) – FortisBC Gas

Housing Type	Lower Mainland	Southern Interior	Vancouver Island	Northern BC	Total
Single Family Detached/Duplexes	475,475	170,298	89,448	45,448	780,669
Single Family Attached/Row	53,890	10,417	7,109	2,550	73,965
Apartments < 4 stories	216,678	52,875	59,179	10,195	338,927
Apartments >= 4 stories	158,724	6,853	17,195	1,007	183,779
Other Residential	10,348	8,940	2,198	2,405	23,891
Total	915,115	249,384	175,129	61,604	1,401,231
Apartments Excluded					
Apartments Total	375,402	59,729	76,374	11,202	522,707
Non-Apartments Total	539,713	189,655	98,755	50,402	878,525

The number of apartment units represents individual apartment suites and not single-meter apartment buildings which FortisBC Gas considers and bills as a single account.
Source: Navigant analysis based on data provided by FortisBC Gas and BC Hydro

2.1.1.3 Commercial Sector

Navigant divided the BC commercial sector into twelve (12) segments. The last segment listed below, streetlights and traffic signals, is only applicable to electric utilities.

[4] This CPR analyzes apartments units in the residential sector based on several factors. First, apartment buildings are generally characterized through Residential End Use Surveys (REUS) in parallel with non-apartment residential dwellings (e.g., detached and attached) – as is the case for BC Hydro's REUS studies but not FortisBC Gas. Second, end-use equipment – other than centralized systems for space heating, cooling and water heating – can be characterized in a consistent manner across apartments and non-apartment residential dwellings.

Table 2-6: Description of Commercial Segments

Segment	Description
Accommodation	Short-term lodging including related services such as restaurants and recreational facilities
Colleges/Universities	Post-secondary education facilities such as colleges, universities and related training centers
Food Service	Establishments engaged in preparation of meals, snacks and beverages for immediate consumption including restaurants, taverns, and bars.
Hospital	Diagnostic and medical treatment services such as hospitals and clinics
Logistics/Warehouses	Warehousing/storage facilities for general merchandise, refrigerated goods, and other wholesale distribution
Long Term Care	Residential care, nursing, or other types of long term care
Office	Administration, clerical services, consulting, professional, or bureaucratic work but not including retail sales.
Other Commercial	Establishments, not categorized under any other sector, including but not limited to recreational, entertainment and other miscellaneous activities
Retail - Food	Engaged in retailing general or specialized food and beverage products
Retail - Non Food	Engaged in retailing services and distribution of merchandise but not including food and beverage products
Schools	Primary and secondary schools (K to 12)
Streetlights/Traffic Signals	Roadway lighting and traffic signal loads

Source: Navigant

Navigant selected the commercial segments with the goal that the building types within those segments be reasonably similar in terms of gas and electricity use, operating and mechanical systems, and annual operating hours. This approach allowed for consistency in building characteristics within each segment as required by the measure characterization and modeling processes.

The selection of these commercial segments is similar to those for previous CPRs with the exception that Navigant does not distinguish commercial segments based on the size of facilities (e.g., large vs. medium facilities) as was done in the 2010 CPR. The analysis of gas consumption in the commercial sector is *scaled* based on the stock of commercial floor space in FortisBC Gas's territory. Using this approach, gas consumption is expressed in terms of GJ per square meter (GJ/m^2) of floor space. This approach assumes that the GJ/m^2 intensity within a commercial segment is constant, and independent of building size.[5] Another distinction, relative to the 2010 CPR, is that for the base year and reference case analysis, apartments units are included the residential sector. However, to report technical and economic savings potential results, apartments are moved to the commercial sector for consistency with the way FortisBC Gas delivers programs.

[5] While this CPR's modelling approach is different to the 2010 CPR, each modelling approaches has its own strengths and weaknesses. For example, the archetype-based approach provides increased visibility into the energy usage patterns of large vs. medium buildings. At the same time, the archetype based approach also introduces the risk of skewing energy consumption within a segment should the archetype analysis be based on a commercial building not representative of a segment-wide average. This potential shortcoming is addressed by Navigant's approach since developing a GJ/m2 intensity attempts to reflect segment-wide consumption patterns.

To determine the base year floor space stock for each commercial segment, Navigant applied the end-use intensities (EUIs) of each segment to the gas sales data provided by FortisBC Gas. Appendix B.3 describes in greater detail the methodology used to estimate the commercial EUIs. Table 2-7 summarizes the resulting floor space estimates developed for each commercial segment.

Table 2-7: Base Year Commercial Floor Area (million m^2) – FortisBC Gas

Segment	Lower Mainland	Southern Interior	Vancouver Island	Northern BC	Total
Accommodation	2.55	1.56	0.33	0.25	4.69
Colleges/Universities	4.10	0.39	0.74	0.07	5.30
Food Service	2.17	0.54	0.15	0.08	2.93
Hospital	1.56	0.64	0.05	0.10	2.35
Logistics/Warehouses	10.56	3.30	0.29	0.48	14.64
Long Term Care	2.05	0.87	0.36	0.04	3.33
Office	22.06	7.08	3.84	1.24	34.22
Other Commercial[6]	-	-	-	-	-
Retail - Food	2.10	0.99	0.27	0.11	3.47
Retail - Non Food	7.34	3.08	0.65	0.48	11.55
Schools	5.81	2.03	0.53	0.35	8.71
Total	**60.31**	**20.49**	**7.19**	**3.19**	**91.18**

Source: Navigant analysis of FortisBC Gas Sales and EUIs

[6] The Other Commercial segment was distributed across all other commercial segments proportionally. As a result, the Other Commercial segment does not include any floor area. FortisBC Gas directed Navigant to perform this distribution because of the wide variety of commercial building types reflected in the Other Commercial segment.

2.1.1.4 Industrial Sector

Navigant divided the BC industrial sector into 15 segments as shown in Table 2-8.

Table 2-8: Description of Industrial Segments

Segment	Description
Agriculture	Engaged in growing crops, raising animals, harvesting timber, fish and other animals, including farms, irrigation, ranches, or hatcheries.
Cement	Cement manufacturers and related operations including asphalt and concrete
Chemical	Industrial facilities that produce industrial and consumer chemicals including paints, synthetic materials, pesticides, and pharmaceuticals
Food & Beverage	Food and beverage industrial facilities including breweries, tobacco, meat/dairy and animal food manufacturers
Greenhouses	Engaged in growing nursery stock and flowers, including greenhouses, and nurseries.
Mining - Coal	Thermal and metallurgical coal mines
Mining - Metal	Copper, gold and other metal mines
LNG Facilities	Natural gas liquids processing facilities
Oil and Gas	Industries that explore, operate or develop oil and gas resources including the production of petroleum, mining and extraction of shale oil and oil sands.
Manufacturing	Industrial facilities that engage in light and heavy manufacturing processes including fabricated metal, metal manufacturing, machinery, and textiles.
Pulp & Paper - Kraft	Pulp and Paper industrial facilities dedicated specifically to the chemical kraft process
Pulp & Paper - TMP	Pulp and Paper industrial facilities dedicated to the thermo-mechanical pulp (TMP) process
Wood Products	Industrial facilities that manufacture wood products including lumber, plywood, veneer, boards, panel boards and pellets.
Other Industrial	Other industrial facilities and related production operations not categorized under any other industrial segment, including construction, contracting services, waste management and municipal water.
Transportation	Facilities providing transportation of passengers/cargo/resources and support activities related to common modes of transportation including air, rail, water, road, and pipeline.

Source: Navigant

Navigant selected these industrial segments to group industries with similar manufacturing processes, operations, outputs, and patterns of electricity and gas use. Some sectors such as and Pulp & Paper, which contribute significantly to FortisBC Gas energy sales, were further sub-divided into Pulp & Paper - Kraft and Pulp & Paper -TMP. This subdivision allowed differences in processes or patterns of energy use for each segment to be characterized more accurately than if they were combined into one segment. While this approach attempts to better characterize and analyze energy consumption in certain industrial segments, the proposed segmentation is not intended to accurately represent energy consumption at individual industrial facilities. The team also notes that, in general, the industrial sector exhibits much greater diversity regarding energy usage compared to the commercial or residential sectors.

2.1.2 End-Use Definitions

The next step in the base year calibration analysis involved the establishment of specific end-uses for each customer sector. This CPR defines end-uses as a specific activity or customer need that requires energy, such as space heating or domestic water heating, without specifying the particular type of equipment used to satisfy that need. There are two industrial end-uses, however, that do not align to this definition and represent specific types of industrial equipment; Boilers and Pumps. These two end-uses were defined as specific industrial equipment to better reflect the nature of energy consumption and to enable the model to capture and analyze savings potential arising from these sources.

Table 2-9 presents the list of end-uses by sector used in the CPR, with end-use definitions provided in Appendix B.1. These end-use categories have significant impact on the base year calibration since Navigant calculated the energy consumption for a given baseline measure based on the gas intensity of the end-use to which that measure is assigned. These end-uses also allow Navigant's model to incorporate changes in electric and gas end-use intensity over time.

Table 2-9: End-Uses by Sector

Residential	Commercial	Industrial
Appliances	Cooking	Boilers
Electronics	HVAC Fans/Pumps	Compressed Air
Hot Water	Hot Water	Fans & Blowers
Lighting	Lighting	Industrial Process
Other	Office Equipment	Lighting
Space Cooling	Other	Material Transport
Space Heating	Refrigeration	Process Compressors
Ventilation	Space Cooling	Process Heating
Whole Facility	Space Heating	Product Drying
	Whole Facility	Pumps
		Refrigeration
		Space Heating
		Whole Facility

Source: Navigant

2.1.3 Fuel Share and Equipment Data

Navigant developed fuel share and equipment data for each end-use based on the segmentations defined in the previous sections. The team followed two approaches, depending on sector, as described below:

- **Residential and Commercial Sectors**

  Navigant developed estimates of the distribution of fuel shares for each end-use and the types of equipment that contribute to energy consumption within each end-use based on available data from prior FortisBC Gas end-use surveys. Navigant analyzed FortisBC Gas's *2012 Residential End-Use Survey* (2012 REUS) and *2015 Commercial End-Use Survey* (2015 CEUS). Navigant's review of these resources was supported by data from BC Hydro's *2014 Residential End-Use Survey* (2014 REUS) and *2015 Commercial End-Use Survey* (2015 CEUS). The team also relied on program evaluation reports, conditional demand analysis (CDA) studies, and monitoring surveys provided by both utilities[7]. Appendix B.2 and Appendix B.3 summarize the fuel shares and equipment shares used for the residential and commercial sectors, respectively.

- **Industrial Sector**

  Navigant subcontracted CLEAResult, who has considerable expertise in the industrial sector in BC, to develop an estimate of the distribution of energy consumption by each end-use for each industrial customer segment. CLEAResult determined these estimates based on a detailed database of industrial equipment such as pumps, fans, blowers, motors, compressed air equipment, etc. This database contains information on equipment types, key equipment characteristics including system efficiency and/or equipment efficiency levels, and equipment market shares. CLEAResult developed this database based on *Power Smart* industrial reviews, industrial energy assessments, equipment inventories, and ongoing audit and market assessment work with BC Hydro and FortisBC.

Appendix B.2 and Appendix B.3 provide the information developed for each sector and the resulting estimates of energy intensity.

2.1.4 Calibration Process

This section describes the calibration process Navigant used for the residential, commercial, and industrial sectors.

2.1.4.1 Residential and Commercial Sectors

For the residential and commercial sectors, Navigant developed a base year calibration model to analyze gas consumption at an equipment level, at an end-use level, and at a segment level. The team developed this calibration model to accurately calibrate the estimated gas consumption of each sector to the Fortis Gas sales.

The calibration process began at an equipment level for each of the energy-intensive end-uses—the primary end-uses—and at an end-use level for the less energy-intensive end-uses—the secondary end-uses. Navigant determined the primary end-uses as those that make up more than 15% of gas consumption and for which the availability of equipment data enabled a detailed analysis of equipment data. The calibration model for primary end-uses involved a complete bottom-up buildup of detailed equipment information including various efficiency levels, unit energy consumption (UEC) for each efficiency level, equipment market shares, and fuel types for different equipment. The team extracted these inputs primarily from FortisBC Gas and BC Hydro's REUS and CEUS studies. For the secondary end-uses, calibration focused primarily on analyzing and establishing end-use intensities based on previous CPR studies, CDA reports, and other secondary resources. This process ensured that the segment-level EUIs approximated the sales targets with reasonable precision.

The calibration model used these inputs to aggregate gas consumption by end-uses and by customer segment, and compared the results to the FortisBC Gas sales at the lowest level of disaggregation available. The calibration of the base year was an iterative process to estimate energy consumption from

[7] We note that the BC Utilities provided some data sources on a confidential basis and thus they are not publically available.

the lowest level of granularity (i.e., equipment types) to the sector level. Each calibrated iteration required refining of key variables and inputs such as the market share of equipment types, UECs by equipment, and fuel shares.

Table 2-10 shows an example of the calibration process followed for single family detached/duplexes in the Southern Interior region. The process used to calibrate the estimate of energy use builds on an estimate of the percentage of homes with a particular end-use and fuel type, using a particular type of equipment and efficiency within an end-use. The fuel shares (column B), equipment shares (column E), and an estimated level of energy use for each equipment type (column F) are multiplied to obtain an estimated UEC (column G). In the example below, column G sums the total consumption across all water heating equipment. The team summed the resulting EUCs across end-uses to obtain the segment-level intensity (GJ per year), and then calibrated to match the actual target intensity stemming from FortisBC Gas sales data. Navigant repeated this same process across all residential and commercial segments in each region.

Table 2-10: Example of Calibration Process (Single Family Detached/Duplexes – Southern Interior)

A	B	C	D	E	F	G	H	I
End Use	**Fuel Share (%)**	**Equipment**	**Efficiency**	**Equipment Share (%)**	**Annual Energy Use (GJ)**	**End-Use Weighted Avg. Use (GJ)**	**Total Uncalibrated Consumption (GJ)**	**Total Calibrated Consumption (GJ)**

Other	0%	…	…	…	…	…	2.5	2.8
Ventilation	0%	…	…	…	…	…	0.0	0.0
Estimated Consumption (GJ per year)							67.7	**75.6**
Target Consumption (GJ per year)			- calculated based on Fortis Gas 2014 sales data				75.6	**75.6**
	Uncalibrated vs. Target						**90%**	**100%**

Appliances are assigned a fuel share of 100%. This implies that all gas appliances have a fuel share of 100% gas. Similarly, electric utilities have an appliances fuel share of 100%. The actual penetration of individual gas appliances (e.g., x% of homes have a gas clothes dryer) is represented by the equipment shares column.
Source: Navigant

Navigant developed the calibration process to operate across all of the dimensions of the model as listed below (e.g., energy types, sectors, regions, etc.). The following sections present the key estimates of energy use by end-use, sector, and region. Most inputs to the calibration process, including efficiency levels and shares, equipment types, equipment shares, fuel shares, and EUIs by end-use, segment, and region, are presented in Appendix B.2 for the residential sector and Appendix B.3 for the commercial sector.

Table 2-11: Base Year Calibration Dimensions (Residential and Commercial Sectors)

Element	No. of Dimensions	Dimensions	
Energy Types	2	**Electricity**	**Natural Gas**
Sectors	2	Residential, Commercial	
Regions	4	Lower Mainland Southern Interior Vancouver Island Northern BC	
Utilities	4	BC Hydro FortisBC Inc.	FortisBC Energy Inc. Pacific Northern Gas
Segments	17	Residential (5), Commercial (12)	
End-Uses	17	Residential (8), Commercial (9)	
Equipment Types	<5	Varies by end-use—generally less than five	
Efficiency Levels	>2	Generally two for each equipment type	

Source: Navigant

2.1.4.2 Industrial Sector

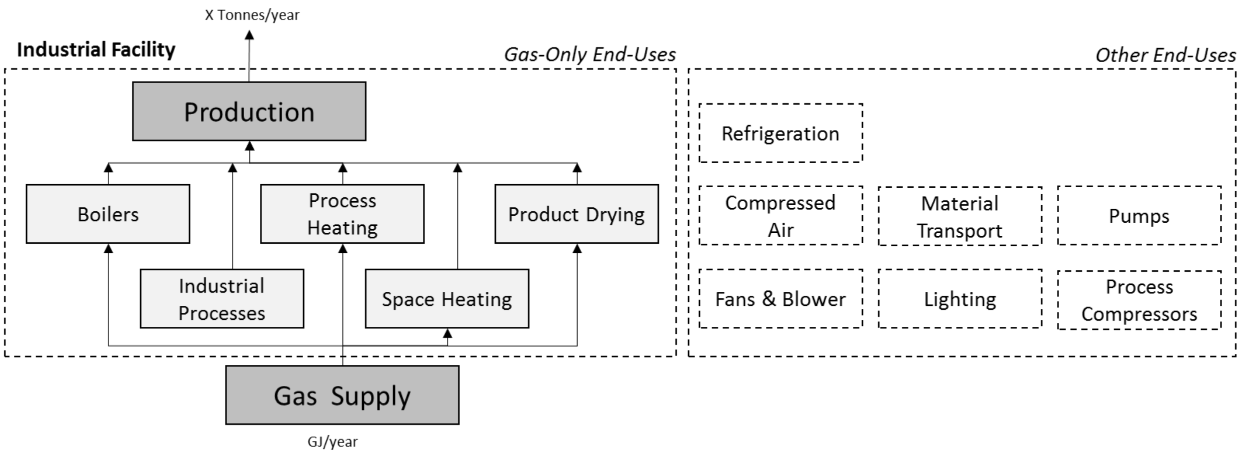
CLEAResult developed estimates of the distribution of energy consumption by end-use for each industrial segment. To calculate the energy consumption by end-use, CLEAResult utilized detailed data on industrial facilities for each of the industrial segments from numerous resources including:

- *BC Hydro* Industrial Electricity Analysis Reviews of industrial customers
- Prior industrial energy assessments performed for BC Hydro and FortisBC
- Detailed energy audits of large industrial facilities in BC
- Inventories of industrial equipment
- CLEAResult professional experience and literature review

Over many years of data collection, CLEAResult has used these resources to build a detailed database of industrial equipment such as pumps, fans, blowers, motors, compressed air equipment, etc. For each equipment type, CLEAResult determined key equipment characteristics including overall system efficiency and/or equipment efficiency levels and equipment market shares, and developed industrial models for BC Hydro and FortisBC. CLEAResult has used these models on a continuous basis to assist BC Hydro and FortisBC with market assessments and DSM program business-case developments. For this CPR, Navigant and CLEAResult aligned the industrial models with up-to-date billing account information broken down into the various industrial segments, and developed end-use allocation factors to estimate the proportion of energy use attributed to each end-use.

CLEAResult's industrial models are broken down into separate sub-models for the major industrial energy end-use categories. Figure 2-1 shows a schematic example of one of these industrial models. As illustrated, a subset of all industrial end-uses are served by natural gas.

Figure 2-1: Schematic of Industrial Model



Source: Navigant schematic of CLEAResult model

The production occurring in each particular segment drives the models for the major energy use industrial segments. A given amount of production requires a certain amount of electricity or natural gas consumption, and this energy can be broken down into each of the end-uses based on the installed equipment.

This detailed modeling approach is not appropriate for certain diverse segments such as food and beverage, manufacturing, and "other" industrial. These three segments involve such a large variety of processes and equipment types that it is not practical to setup an energy model for them. For these industrial segments, the team used end-use information from over 200 facility audits—sponsored by BC Hydro and FortisBC, and including industry groups such as the *BC Food Processors Association* and *Canadian Manufacturers & Exporters*—to estimate the end-use breakdown of each segment. For each of these audits, CLEAResult developed a breakdown of equipment and energy end-use, which Navigant used to develop the end-use breakdown of the food and beverage, manufacturing, and "other" industrial segments.

Table 2-12 shows the resulting end-use consumption percentages developed by CLEAResult, as a distribution of gas consumption by end-use for each industrial segment.

Table 2-12: Industrial End-use Allocation Factors (%)

Source: CLEAResult

The next step of the industrial sector analysis was to determine the total gas consumption by each segment. Navigant worked with FortisBC Gas to determine the total sales in each industrial segment during the base year. Table 2-13 shows the total gas consumption of each industrial segment region in the base year (2014).

Table 2-13: Base Year Industrial Gas Consumption by Segment (TJ) – FortisBC Gas

Segment	All Regions
Agriculture	1,601
Cement	908
Chemical	1,284
Coal Mining	2,517
Food & Beverage	4,000
Greenhouses	5,473
LNG Facilities	-
Manufacturing	5,710
Metal Mining	10
Oil and Gas	8,761
Pulp & Paper - Kraft	14,585
Pulp & Paper - TMP	3,450
Transportation	921
Wood Products	7,567
Other Industrial	789
Totals	**57,577**

Source: Navigant analysis of FortisBC Gas data

The final step of this analysis was the application of the end-use consumption percentages to the gas consumption corresponding to each industrial segment. Table 2-14 shows the resulting distribution of gas consumption by end-use and by industrial segment.

Table 2-14: Base Year Industrial Gas Consumption by End-use (TJ) – FortisBC Gas

2.1.5 FortisBC Gas Base Year Consumption

Each of the BC utilities provided Navigant with information on actual sales and customer numbers for the base year (2014). Table 2-15 shows FortisBC Gas's total gas consumption by customer sector in 2014 (the "actual consumption").

Note that for the base year and reference case analysis, Navigant included apartment units in the residential sector. However, to report technical and economic savings potential in Section 3 and 4, apartments are included in the commercial sector. For reference, the second half of Table 2-15 shows the breakdown of the residential segment excluding apartment units.

Table 2-15: Actual Consumption in 2014 (TJ) – FortisBC Gas

Segment	Lower Mainland	Southern Interior	Vancouver Island	Northern BC	Total
Residential	65,227	16,103	6,789	4,949	**93,069**
Commercial	25,595	9,859	2,969	2,211	**40,634**
Industrial	22,019	12,281	8,587	14,690	**57,577**
Total	**112,841**	**38,243**	**18,346**	**21,850**	**191,280**
Apartments Excluded					
Residential (excl. Apts.)	49,192	13,917	5,539	4,469	**73,117**
Apartments	16,035	2,186	1,251	480	**19,952**
Commercial	25,595	9,859	2,969	2,211	**40,634**

2.1.6 Comparison between Base Year and Actual Consumption

Navigant used the calibration process—described in previous sections—along with the actual consumption targets to develop calibrated estimates of gas consumption (the "base year consumption").

Table 2-16 shows the result of the base year calibration by sector and region. This table compares the actual consumption targets (based on FortisBC Gas sales) with the base year consumption (determined through the calibration process). As illustrated by the last column, the base year consumption values developed for the CPR study matches the 2014 actual consumption of each sector and region.

Table 2-16: 2014 Actual Consumption vs. Base Year Consumption (TJ) – FortisBC Gas

Region	Sect or	Actual Consumption (TJ)	Base Year (TJ)	Difference (%)
Lower Mainland	Residential	65,227	65,227	0.0%
	Commercial	25,595	25,595	0.0%
	Industrial	22,019	22,019	0.0%
Southern Interior	Residential	16,103	16,103	0.0%
	Commercial	9,859	9,859	0.0%
	Industrial	12,281	12,281	0.0%
Vancouver Island	Residential	6,789	6,789	0.0%
	Commercial	2,969	2,969	0.0%
	Industrial	8,587	8,587	0.0%
Northern BC	Residential	4,949	4,949	0.0%
	Commercial	2,211	2,211	0.0%
	Industrial	14,690	14,690	0.0%
Total	**Residential** *(includes apartments)*	**93,069**	**93,069**	**0.0%**
	Commercial	**40,634**	**40,634**	**0.0%**
	Industrial	**57,577**	**57,577**	**0.0%**

Source: Navigant analysis

As part of the development of the base year, Navigant determined the gas consumption for each segment within the residential, commercial, and industrial sectors. The distribution of gas consumption by segment and end-use for each sector is shown by Figure 2-2 through Figure 2-7, and the tabulated results are shown by Table 2-17 (residential) and Table 2-18 (commercial). The industrial results were shown by Table 2-14 in Section 2.1.4.2.

Additional information relating to each segment can be found in Appendix B.2 (for the residential sector), Appendix B.3 (for the commercial sector), and Appendix B.4 (for the industrial sector).

[8] Gas sales initially attributed to the *Other Commercial* segment were distributed across all other commercial segments proportionally.

2.2 Reference Case Forecast

This section presents the Reference Case for the CPR study period from 2015 to 2035. The Reference Case estimates the expected level of gas consumption over the CPR period, absent incremental demand-side management (DSM) activities or load impacts from conservation rates. Gas consumption levels in the Reference Case are also based on codes and standards previously included in regulation and reflected in each utility's load forecast.[9] The Reference Case is significant in the context of this CPR study because it acts as the point of comparison (i.e., the reference) for the calculation of the technical and economic potential scenarios.

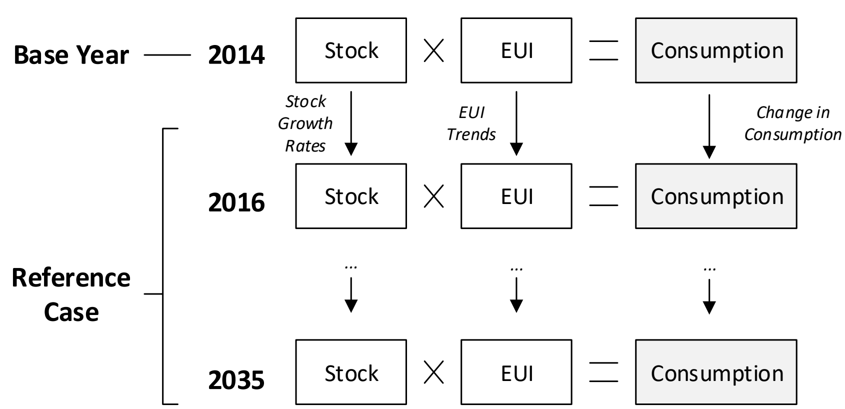
The Reference Case Forecast uses the base year calibration—presented in the previous section—as the foundation for analysis.

Navigant constructed the Reference Case forecast using two different approaches based on sector.

- **Residential and commercial sectors:** For the residential and commercial sectors, Navigant used two key inputs: stock growth rates and EUI trends. Navigant developed stock growth projections of residential accounts and commercial floor area. The team then modeled the potential for energy efficiency based on the resulting stock projections of each customer segment. The team applied EUI trends to the base year EUIs for each customer segment, and used these trends to represent natural change in end-use consumption over time.

  Figure 2-8 illustrates the process used to develop the Reference Case for the residential and commercial sectors. This figure illustrates that applying stock growth rates to the base year stocks of each customer segment results in a forecast of stocks through 2035. Similarly, applying the EUI trends to the base year EUIs results in a forecast of EUIs through 2035. The final step of this process involves multiplying the stock forecast with the corresponding EUI forecast in order to obtain a load forecast.

Figure 2-8: Schematic of Reference Case Development



Source: Navigant

[9] Each utility's load forecast reflects specific effectiveness dates and performance thresholds for codes and standards previously enshrined in regulation. By extension, recently announced performance targets or codes and standards that are not yet enshrined in regulation –such as the target for net zero new construction included in the BC Climate Leadership Plan– are excluded from the analysis.

- **Industrial sector:** The Reference Case for the Industrial sector assumed frozen EUIs over the Reference Case forecast (e.g., frozen EUIs assume that EUIs do not change and are static over time). A more detailed discussion supporting this assumption is presented in Section 2.2.3.3. Based on the frozen-EUI approach, the Industrial Reference Case was established solely by developing energy demand growth assumptions for each industrial segment.

Navigant compared the forecasts developed for the Reference Case for the residential, commercial, and industrial sectors with the long-term load forecast developed by each utility. This comparison ensured that the Reference Case forecast is consistent with each utility's current expectations for load growth over the 2015 to 2035 period.

2.2.1 Approach

This section introduces the overall process for developing the residential and commercial Reference Case. As noted earlier, the Reference Case approach for the industrial sector differed from the residential and commercial sectors.

Navigant's Reference Case started with the base year estimate of stocks and gas consumption for 2014. Two key inputs were the basis for projected change in gas consumption through the CPR study period:

- Stock growth rates
- Gas EUI trends

To develop the Reference Case for each sector, Navigant first developed the stock growth rates based on the CPR segmentation for each sector and region. The second step established appropriate EUI trends that the team applied to each segment and region. Finally, the team applied these two inputs to the base year estimates of stock and EUIs, and projected the results through 2035 to construct the Reference Case.

Navigant developed the growth rates for stock and the EUI trends based primarily on information provided by FortisBC Gas. Secondary sources supported any gaps in these data.

The following two sections provide detailed descriptions of the approach followed to establish stock growth rates and gas EUI trends for each sector.[10] As noted in previous sections, for the base year and reference case analysis apartment units have been included in the residential sector. As such, the following sections will present stock growth rates and EUI trends for apartment units within the residential sector.

[10] For the industrial sector, the stock growth rate section (Section 2.2.2.3) presents the demand forecast established for each industrial customer segment, and the EUI trends section (Section 2.2.3.3) describes the reasoning for a frozen EUI approach.

2.2.2 Stock Growth Rates

This section describes the approach followed to develop stock growth rates for the residential, commercial and industrial sectors.[11]

2.2.2.1 Residential Sector

To develop the residential Reference Case, Navigant first developed and applied growth rates for each residential segment and region over the CPR study period. Navigant established the stock growth rates from household forecasts derived from FortisBC's 2014 Long Term Resource Planning (LTRP) Demand Forecast (as updated)[12]. Based on the residential stock forecasts, average annual growth rates were established for each five-year period in the forecast (e.g., 2015 to 2020, 2021 to 2025, etc.). The team applied these five-year growth rates over the same periods through the end of the CPR study period for each residential segment. A detailed description of the approach used to develop the residential household projections is included in Appendix B.2.

[11] In relation to the natural turnover of commercial floor stock, Navigant's model assumes a stock demolition rate of 0.5% per year for commercial and residential segments and 0% for industrial segments. These demolition rates apply to the existing stock in each year of the analysis. A demolition rate of 0.5% is a conservative assumption used to avoid over-estimation of growth in building stock by recognizing that some new construction is replacing demolished stock and does not add to the total count of building stock. Industrial demolition rates are 0% because industrial facilities are less homogenous than commercial and residential buildings, and the closure of a single plant can represent a significant percentage of a given industrial segment. Given the lack of information about planned closures of industrial facilities, the 0% industrial demolition rate is a more reasonable assumption than representing industrial demolition as a continuous decay of building stock, as is modelled for commercial and residential buildings.

[12] The customer and demand forecast presented in FortisBC Gas's 2014 LTRP was developed from the 2011 year-end actual customer count. A subsequent update was prepared with the only change being the use of the more recent 2012 year-end actual customer count. This update is the most recent long term forecast available and thus has been used in the preparation of the 2016 CPR.

Table 2-19 shows the growth rates employed in the CPR study.

Table 2-19: Annual Growth Rates by Residential Segment and Region (%) – FortisBC Gas

Region	Segment	CPR Period			
		2014-2020	2021-2025	2026-2030	2031-2035

2.2.2.2 Commercial Sector

To develop the commercial Reference Case, the team first selected floor area as the most appropriate driver for gas consumption in the commercial sector. This section describes the development and application of floor space growth rates for each commercial segment and region over the CPR study period. To develop projections of commercial floor area growth by segment, the team relied on three key resources:

- StatsCan's Labour Force Statistics for British Columbia (*BC Labour Force Statistics*)[13]
- NRCan-Office of Energy Efficiency (OEE) Comprehensive Energy Consumption Database
- FortisBC Gas's 2014 LTRP

The primary resource employed to develop stock growth rates was the BC Labour Force Statistics, which tracks labour force levels for 11 commercial segments and 36 commercial sub-segments across seven economic regions in British Columbia. BC Stats uses these statistics for employment forecasting, which represent the most granular publicly available resource reporting commercial sector trends since 2000. The team relied on these data because both employment levels and floor space can serve as the basis for predicting energy demand.[14]

Navigant calculated the statistical relationship between labour force levels and commercial floor space to determine the appropriateness of using labour as a proxy for floor space. The OEE database tracks commercial floor space in BC disaggregated across 10 commercial segments. Since the OEE reports data at a provincial level and not disaggregated across regions, the team summed employment levels across all regions. The team analyzed floor space and labour force levels for the period between 2000 and 2012 for each OEE commercial segment. Table 2-21 below shows the correlation coefficient corresponding to each segment. Most segments show a strong positive correlation with coefficient values ranging between 0.80 and 0.97.

[13] *CANSIM Labor Force Survey Estimates (LFS) (March 2001 to December 2015)* – Table 282-026

[14] For example, vacant floor space can misrepresent the actual stock of floor space in use. As a result, projections of floor space, which account for vacant floor space, can skew energy demand upwards. In Ontario, the Independent Electricity System Operator (IESO) employs a forecasting approach based on employment levels. The IESO utilizes employment figures as an indicator to forecast electricity demand in the near term (i.e., 18-Month Outlook forecasts) and in the long term (i.e., Long Term Energy Plan). The IESO employs non-manufacturing employment levels to forecast demand in the commercial sector, and manufacturing employment for the industrial sector.

Table 2-21: Correlation Coefficient (Floor Space vs. Labor Force) – Commercial Sector

OEE Commercial Segment	Correlation Coefficient (2000 – 2012)
Wholesale Trade	0.80
Retail Trade	0.90
Transportation and Warehousing	(0.27)
Information and Cultural Industries	(0.62)
Offices	0.80
Educational Services	0.87
Health Care and Social Assistance	0.95
Arts, Entertainment and Recreation	0.83
Accommodation and Food Services	0.89
Other Services	0.13

Source: Navigant analysis of OEE and StatsCan data

Three of the commercial OEE segments - Transportation and Warehousing, Information and Cultural Industries, and Other Services - are exceptions with a negative correlation or close to no correlation at all. Two of the commercial segments in this CPR - Logistics and Warehousing and Other Commercial - use employment levels derived from these three OEE segments to establish stock growth rates. To avoid the use of poorly correlated variables, the team adjusted the growth rates for these two segments to follow the growth in commercial gas consumption in each region, determined from Fortis Gas's 2014 LTRP.

Navigant mapped the employment levels of the BC Labour Force Statistics to each of the CPR commercial segments and regions in the Reference Case. The team then analyzed employment growth rates over the 15-year period from 2000 to 2014 to use as a proxy to establish commercial floor space growth rates.

Finally, Navigant analyzed the FortisBC Gas 2014 LTRP to ensure that the stock growth rates applied in the Reference Case aligned with the overall trends in commercial demand projected by FortisBC Gas. The team applied the growth rates derived from the BC Labour Force Statistics to the first five years of the CPR forecast through 2020. For each subsequent five-year period in the forecast, the team applied an adjustment multiplier to the stock growth rates in each region of BC to align with the 2014 LTRP.

For example, the 2014 LTRP projects commercial consumption in the Lower Mainland to grow slightly from 2015 through 2035, with very little incremental demand over time. The team adjusted the Reference Case growth rates established for the Lower Mainland every five-year period to align with these trends in consumption.

Table 2-22 presents the growth rates employed in the CPR study for each segment and across time. The Lower Mainland has the most modest stock growth rates – aligned with the gas sales projections of the load forecast. In general, commercial floor space growth expectations are higher in the Southern Interior, Northern BC, and particularly in Vancouver Island where more aggressive sales projections are forecasted. At a segment level, expectations of commercial floor space growth in the long term care, hospitals, and food service segments are to be at levels significantly higher than the regional average. The following paragraphs provide additional information related to these three segments:

- **Colleges/Universities:** Historical post-secondary enrollment data from StatsCan shows an average annual growth rate of 3.3% across the province.[15] Enrolment in 2000/2001 was reported at 183,000, growing to approximately 278,000 by 2013/2014. BC Labour Force Statistics show that employment growth rates are highest in the Lower Mainland, and slower paced in the Southern Interior, Vancouver Island, and Northern BC.
- **Long Term Care:** BC is experiencing the fastest growth rate of senior citizens across Canada.[16] In absolute numbers, much of this expected growth is in the Lower Mainland and Vancouver Island where retirement homes clusters are most predominant. However, in relative terms, growth rates in the Southern Interior and Northern BC will be higher.[17] BC's Ministry of Health forecasts that demand for long-term care facilities will more than double by 2036 as a result projected growth in the senior population over the next 20 years.[18] Based on BC Labour Force Statistics, employment in nursing and residential care facilities more than doubled in the Southern Interior from 3,700 in 2000 to 9,200 in 2014, at an average annual growth rate of 4.8%.
- **Hospitals:** The Ministry of Health has identified the province's aging hospital infrastructure and current hospital capacity as critical challenges to meet projected provincial demand over the next two decades.[19] Following hospital closures across the province between 2002 and 2004, employment in healthcare has grown from 69,000 in 2005 to 91,700 in 2014, at an annual growth rate of 3.2%.[20] The Ministry of Health forecasts significant increases in demand in all health services through 2036. Projections show hospital floor space growing at rates much higher than each regional average, with highest growth rates in Vancouver Island and Northern BC.

Table 2-23 shows the estimated stock of commercial floor space over time. The base year commercial stock determined for 2014 is the initial basis for the stock of commercial floor space presented in Table 2-23, then the team adjusted future years by applying the growth rates identified in Table 2-22.

Note that as described in Section 2.1.1.3, gas consumption from the Other Commercial segment was distributed across all other commercial segments in proportion to their consumption. Since the base year gas consumption for the Other Commercial segment is zero, growth rates are also zero.

2.2.2.3 Industrial Sector

To develop the industrial Reference Case, the team developed and applied growth rates of gas demand for each industrial segment and region over the CPR study period. The team derived the demand growth rates from the FortisBC Gas 2014 LTRP.

FortisBC Gas's 2014 LTRP reports industrial sector gas sales as a whole and not broken down into individual industrial segments. To disaggregate the sector-wide forecast into industrial segments, Navigant and FortisBC worked together to develop gas sales projections which aligned with the sector-level forecast established for each region. Appendix B.4 describes the approach used to develop the industrial forecast in more detail.

Using this industrial load forecast, the team calculated average annual growth rates for each segment for each five-year period (e.g., 2015 to 2020, 2021 to 2025). The team applied these five-year growth rates to the same periods through the end of the CPR study period. For industrial segments with no presence in any particular region, the team specified a demand growth rate of zero (0.0%).

Table 2-24 presents the demand growth rates employed in the CPR study. Broadly speaking, the demand growth rates for the industrial sector show a gradual decline in gas sales over time across most segments and across each region. The growth rates presented in Table 2-24 lead to the estimated industrial consumption shown in Table 2-25. The base year consumption is the initial basis for the industrial demand in Table 2-25, which is then adjusted in future years by applying the growth rates identified in Table 2-24.

Table 2-24: Annual Growth Rates by Industrial Segment and Region (%) – FortisBC Gas

2.2.3 EUI Trends

This section discusses the EUI trends across the residential, commercial, and industrial sectors.

2.2.3.1 Residential Sector

To develop EUI trends for the Residential sector Reference Case, Navigant reviewed several resources including the FortisBC Gas 2012 REUS study, the accompanying Residential CDA study, BC Hydro's 2014 REUS, and the NRCan-OEE database. The main resource used to estimate the change in EUIs over time was BC Hydro's 2014 REUS study. BC Hydro's REUS was preferred over FortisBC Gas's REUS because it provided more granularity across individual residential segments. BC Hydro's REUS also provides survey results for gas equipment penetration for various years including 2002, 2003, 2005, 2007, and 2014. The team used the REUS data for each of these years to calculate an average annual rate of change for each EUI. A limitation of this approach is that the REUS data reflects the impact of provincial and federal DSM programs while the objective of this analysis is to trend natural change in EUIs in the absence of DSM impacts.

In certain cases, extrapolating recent trends 20 years into the future is uncertain and can result in implausibly high changes in the EUI over the forecast horizon. Recognizing this, Navigant endeavored to temper short-term trends by assuming a reduction in EUI trends further into the future. To determine these reductions in EUI trends over time, the team analyzed the FortisBC Gas 2014 LTRP. The analysis of the load forecast ensured that the Reference Case residential consumption—determined based on the growing residential stock and the EUI trends—aligned with the forecast of residential consumption reported in FortisBC Gas's load forecast. Navigant made these adjustments to the EUI trends across every five-year period of the CPR analysis horizon.

Based on this analysis, the team applied the EUI trends from the REUS analysis to the first five years of the CPR period, and systematically decreased the magnitude of EUI trends over the subsequent five-year periods. Specifically, the EUI trends decrease by a factor of 20% every five-year period. This 20% reduction enables the Reference Case residential consumption to match the load forecast consumption.[21] These EUI trends implicitly reflect natural changes in residential end-use consumption caused by naturally occurring improvements in end-use equipment efficiency, fuel share changes, saturation levels of energy efficient equipment, existing building retrofit activities, and stock turnover.

Table 2-26 shows the EUI trends determined for each residential segment and end-use over time, and Table 2-27 provides the resulting EUIs for each five-year period in the Lower Mainland. Navigant based the EUIs presented in Table 2-27 on the base year EUIs (for 2014) and adjusted them with the EUI trends identified in Table 2-26. The Reference Case EUIs for the Southern Interior, Vancouver Island and Northern BC are presented in Appendix B.2.

Please note that minor year-to-year changes in EUIs may not be explicitly reflected in the tables due to rounding.

As Table 2-26 indicates, gas consumption by most end-uses is expected to decrease over the CPR period. Current trends show that gas consumption from space heating and water heating are expected to decline over time, while consumption from appliances will increase. In general, the magnitude of the expected annual change in EUIs is greater in the near term and will decrease over time.

- **Space heating** – The use of natural gas for space heating has continued a small downward trend over the past decade—primarily in single detached homes and apartment units—resulting in a decrease in the gas space heating EUI. This trend is driven primarily by the lower penetration of gas space heating in new homes.
- **Water Heating** – Electricity consumption from water heating increases across most segments because of increased penetration of electric water heaters. The trend is most prevalent in single detached and attached homes. As a result, gas consumption for water heating has seen a steady decline across these segments. Survey results also show that apartment buildings are increasingly opting for centralized systems, rather than in-suite water heating units. Although, gas penetration of in-suite units has decreased, overall gas consumption is projected to increase due to centralized systems.
- **Appliances** – Gas consumption for appliances is forecast to increase over time, and at higher rates than space heating and water heating. Although gas clothes dryers are becoming less common, the increased adoption of gas-fired stoves and ranges has offset the impact of dryers and is expected to continue increasing gas consumption for appliances.

As noted for some of these end-uses, changing fuel shares for individual residential segments cause change in gas consumption over time.

[21] For example, if the EUI trend determined from the 2014 REUS was a 1.0% decrease in EUI per year, the team applied 1.0% per year from 2015 through 2020, 0.8% per year from 2021 through 2025, 0.64% per year from 2026 through 2030, and 0.51% per year from 2031 through 2035.

2.2.3.2 Commercial Sector

The next step in building the commercial sector Reference Case involved the development and application of EUI trends over the CPR study period. Navigant reviewed several resources including FortisBC Gas's 2015 CEUS, the NRCan-OEE database for British Columbia, and BC Hydro's 2014 CEUS to develop these trends. The main resource for EUI trends in the commercial sector was BC Hydro's 2014 CEUS. The team preferred BC Hydro's 2014 CEUS to FortisBC's 2015 CEUS because it provides detailed survey results for each commercial segment in each region.

BC Hydro's 2014 CEUS surveyed commercial customers in relation to upgrades made to end-use equipment in the past 5 years.[22] Based on the incidence of equipment upgrades made to specific end-uses (e.g., space cooling vs. space heating), Navigant estimated the potential reduction in energy consumption from higher efficiency equipment. This approach is described in more detail in Appendix 0. A limitation of this approach is that the CEUS data reflects the impact of provincial and federal commercial DSM programs, while the objective of this analysis is to trend natural change in EUIs in the absence of DSM impacts. The impact of this limitation on the study is that the EUI trends established for these commercial end-uses may be overstated, which may affect the overall results of this study. Additionally, this EUI trending approach inherently reflects both new and existing buildings because the CEUS customer pool included both new and existing buildings.

This analysis resulted in EUI trends for all the end-uses for which equipment upgrade information was reported in 2014 CEUS. [23] This included the following end-uses:

- Lighting
- Water heating
- Space cooling
- HVAC fans/pumps
- Space heating

Two of these end-uses—water heating and space heating—are applicable to gas consumption. The 2014 CEUS did not report the necessary information to develop EUI trends for the *cooking* and *other* gas end-uses, so the team assumed they would remain flat.

Similar to the residential sector, Navigant analyzed FortisBC Gas's 2014 LTRP to establish changes in the magnitude of commercial EUI trends every five years over the entire CPR analysis period. This ensured that the Reference Case commercial consumption—determined based on the commercial floor space stock and the EUI trends—aligned with the forecast of commercial consumption reported in the 2014 LTRP.

Based on this analysis, the commercial EUI trends determined from the CEUS analysis are applied to the first five years of the analysis, decreasing slightly over the subsequent five-year periods. Specifically, the EUI trends decrease by a factor of 30% every five-year period. This 30% reduction in EUI trends enables the Reference Case commercial consumption to match the load forecast consumption.

---

[22] For example, the incidence of water heating equipment upgrades within the past 5 years was 23% across the entire commercial sector. However, the incidence of water heating upgrades varied across commercial segments (e.g., 38% in Colleges & Universities, 12% in Offices).
[23] The 2014 CEUS did not report equipment upgrade information for the cooking, refrigeration, and office equipment end-uses.

Table 2-28 shows the EUI trends for each commercial segment and end-use, and Table 2-29 shows the resulting EUIs over five-year intervals for the Lower Mainland. The EUIs presented in Table 2-29 were initially derived from the base year EUIs (for 2014) and have been adjusted by applying the EUI trends identified in Table 2-28. The Reference Case EUIs for the Southern Interior, Vancouver Island and Northern BC are presented in Appendix B.3.

As seen in Table 2-28, gas consumption for water heating and space heating is expected to decrease over the CPR period.

These changes in EUIs over time implicitly reflect natural changes in gas end-use consumption caused by naturally occurring improvements in end-use equipment efficiency and saturation levels, fuel switching, and retrofit activities. For example, energy efficient improvements driven by initiatives like ENERGY STAR and the Leadership in Energy and Environmental Design (LEED) certification are expected to influence EUI trends. Although the impact of these two energy performance initiatives remains limited thus far, the initiatives are likely to increase adoption of commercial envelope measures and higher efficiency space heating, lighting and cooking equipment.

Source: Navigant analysis of FortisBC Gas's 2014 LTRP, and BC Hydro 2014 CEUS

2.2.3.3 Industrial Sector

Discussions between Navigant and CLEAResult concluded “natural” change in industrial energy efficiency would be minimal over the study horizon. This assumption is consistent with past CPRs, which forecasted very small changes in industrial EUIs over a 20-year forecast horizon (typically only a few percent over 20 years)[24]. Given the expected small magnitude of natural change in industrial EUIs, inherent EUI forecasting uncertainty, and limited historical data availability for industrial EUIs, this study assumes that EUIs in the industrial sector will remain constant in the absence of conservation programs.

The study represents industrial production levels as an index that begins at 1.0 in 2014 and grows or declines in accordance with expected trends in production. These production levels are analogous to building stocks and are multiplied by EUIs to determine consumption in a given year.

The outline below details key considerations for the industrial consumption forecast.

- **Resource-extraction industries** are much more sensitive to primary cost drivers (timber prices, labor costs), suggesting their consumption is not strongly dependent on electricity and gas prices. The prime reason for upgrading equipment is for increasing production, market expansion, or new product lines, rather than to increase energy efficiency.
- **Non-resource-extraction industries** are unlikely to experience significant changes in EUIs. Many of these customers—particularly food & beverage and manufacturing customers—operate smaller facilities and the tendency is not to invest capital upgrading older facilities but rather in expanding or building new plants.
- The **pulp & paper and wood products** consumption has been declining steadily over the past decade, as is evident by mill shutdowns. By and large, these industrial segments are projected to continue declining through 2020, particularly in other regions where much of the industry is concentrated. Capital constraints in this segment limit the opportunities for energy efficiency. These industries—in addition to the chemical and cement sector—consist mainly of older plants where customers have shown reluctance to upgrade to more efficient equipment due to uncertain market conditions.

2.2.4 Reference Case Forecast and Comparison with Utility Forecast

This section provides the final Reference Case forecast and compares the sector-level results of the Reference Case forecast with FortisBC Gas’s load forecast.

2.2.4.1 Reference Case Forecast

Table 2-30 summarizes the results of the Reference Case for each sector and customer segment. Navigant computed these results by applying the stock growth rates and the EUI trends established in previous sections for each customer segment to the base year results.

---

[24] The base year analysis did not characterize industrial consumption on a per-unit basis, as was done for the residential sector (i.e., kWh or GJ *per* household) and commercial sector (i.e., kWh or GJ *per* m2). Industrial EUIs are expressed directly in electric or gas units of consumption (i.e., kWh or GJ).

Table 2-30: Reference Case Forecast by Segment (TJ)

Sector	Segment	CPR Period

2.2.4.2 Comparison between Reference Case and Utility Forecast

In this section, Navigant compares the Reference Case forecast with FortisBC Gas's 2014 LTRP. Since most of the demand growth assumptions underlying the load forecast were used as inputs to develop the stock growth rates in the Reference Case, the two forecasts are largely consistent.

Table 2-31 compares the projected gas sales in 2035 between the Reference Case and the Load Forecast.

Table 2-31: Reference Case Forecast

Class/Sector	Average Annual Growth Rate (%)		2035 Sales (TJ)		Difference (%)
	Reference Forecast	FortisBC Gas Forecast	Reference Forecast	FortisBC Gas Forecast	
Residential	-0.4%	-0.4%	85,752	85,752	0.0%
Commercial	0.5%	0.5%	45,351	45,351	0.0%
Industrial	-0.2%	-0.2%	55,393	55,393	0.0%
Total	**-0.1%**	**-0.1%**	**186,497**	**186,497**	**0.0%**

2.3 Frozen End-use Intensity Case and Natural Change

Navigant's model uses the building stock projections from the Reference Case forecast to calculate technical and economic potential, but does not use the reference case's time-changing end-use intensities. Rather, it freezes the end-use intensities from the Reference Case forecast at 2016 levels and holds them fixed over time. This section describes the reasons for this approach and the method by which the team links the frozen EUI case back to the reference case using "natural change."

2.3.1 Frozen EUI Case

The Reference Case includes many embedded assumptions derived from observed trends in the market and forward-looking expectations. The Reference Case allows end-use intensities to change over time as a function of:

- Changing mix of efficient versus inefficient equipment
- Changing use of building space (e.g., open plan office spaces)
- Changing mix of commercial activities (e.g., decrease in manufacturing and increase in service industries)
- New trends in consumption (e.g., increase in use of home electronics)
- Fuel switching (e.g., switching from electric appliances to gas appliances, or vice versa)

Modelling these considerations at the *measure* level would require a detailed adoption forecast for every measure in each customer segment. Typically, potential studies forecast measure-level adoption when looking at achievable market potential in the context of utility-sponsored energy efficiency programs. The achievable market potential hinges on expected levels of incentives, program budgets, and marketing/advertising levels, and there is adequate industry experience to provide substance to these forecasts. Conversely, it is notoriously difficult to estimate retrospectively what would have happened with measure adoption in the absence of energy efficiency programs (typically estimated through "net-to-gross" ratio studies), and it is even more difficult and uncertain to *forecast* such "natural" behavior at the measure level. Since program design is outside the scope of this study, and considering the inherent uncertainty in forecasting natural adoption at the measure level, Navigant did not pursue and create detailed measure adoption forecasts for technical and economic potential. Rather, the study uses a "frozen EUI" approach to estimate technical and economic potential combined with an estimation of aggregate end-use intensity trends to calculate the natural change expected at the end-use level.

Navigant calculated technical and economic potential assuming that EUIs are frozen at 2016 levels, ensuring consistency between modelled energy sales and measure characterization. For example, measure characterization assumes a fixed mix of efficient and inefficient measures over time—absent any energy efficiency programs—implying that end-use intensities do not change over time when calculating technical and economic potential. However, building stock changes (e.g., growth in the residential customer count or commercial floor space) can increase overall energy sales and assumed total equipment counts, which would impact the estimates for technical and economic potential.

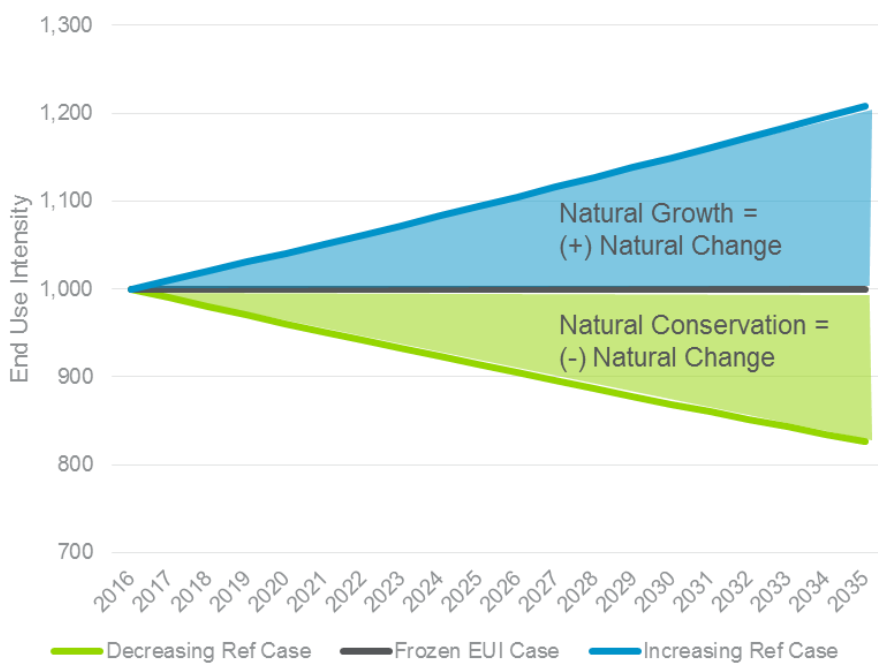
If end-use intensities are changing in the Reference Case, Navigant calculates what this study refers to as the "natural change"—defined in section 2.3.2—of EUIs over time. The team then applies this natural change to the technical and economic potential results using the frozen EUI to estimate the shift in potential savings.

2.3.2 Natural Change

Navigant's definition of "natural change" stems from two related concepts: natural conservation and natural growth. Natural *conservation* is a well-established concept in demand side management programs, and typically refers to actions taken by utility customers—in absence of utility-sponsored programs—to improve energy efficiency and reduce consumption. These actions are occurring naturally, with no influence from utilities or program administrators. Natural *growth* refers to actions taken by utility customers to *increase consumption* without the involvement of utility-guided programs. An example of natural growth is home electronics, where customers may be increasing their electric consumption (e.g., through addition of more televisions, computers, etc.) and causing an increase in the electronics end-use intensity.

This study captures the effects of natural conservation as well as natural growth within the end-use intensities, and defines these effects as "natural change." When natural change is positive for an end-use category, it reflects growth. When natural change is negative, it reflects conservation. Figure 2-9 illustrates this concept of natural change as it relates to the Reference Case end-use intensities as compared with the frozen EUI case.

Figure 2-9. Natural Change in Context of End-use Intensity



Source: Navigant

Navigant calculated natural change by subtracting the energy consumption in the frozen EUI case from the energy consumption in the Reference Case (see Table 2-32). Positive natural change results indicate a quantity of consumption missing from the frozen EUI case, whereas negative natural change indicates an overestimate of consumption in the frozen EUI case. Since Navigant estimates technical and economic potential based on the frozen EUI case, any missing consumption (i.e., positive natural change) is not included in the technical and economic results. Conversely, the model overestimates technical and economic potential when natural change is negative. Natural change helps provide a bound for the technical and economic potential forecasts, as it reflects one component of the uncertainty in energy savings from end-uses with expected changes to intensities over time.

Table 2-32. Illustrative Calculation of Natural Change

Year	Building Stock (homes)	Reference Case EUI (GJ/year-home)	Frozen Case EUI (GJ/year-home)	Reference Case Consumption (GJ/year)	Frozen EUI Case Consumption (GJ/year)	Natural Change (GJ/year)
	A	B	C	D = A x B	E = A x C	F = D - E
2016	1,000	70	70	70,000	70,000	0
2020	1,082	69	70	74,808	75,770	-962
2025	1,195	68	70	81,351	83,656	-2,305
2030	1,319	67	70	88,412	92,364	-3,952
2035	1,457	66	70	96,162	101,977	-5,815

Source: Navigant

Calculating technical and economic potential that includes natural change at the measure level would require measure-level adoption forecasts. As mentioned in section 2.3.1, Navigant's calculation of technical and economic potential does not involve forecasting adoption at the measure level. However, the team does estimate upper and lower bounds on the technical and economic potential inclusive of natural change at the end-use level.[25]

Navigant refined the frozen EUI technical potential by estimating savings potential percentages for natural change. The team calculated the technical potential as a percentage of consumption within a given end-use category, and applied that percentage to the natural change occurring within that end-use. For example, if the model concludes that technical potential for gas appliances is 30% of the total consumption from gas appliances, Navigant can apply that 30% to the natural change occurring within the appliance end-use to find a midway estimate between the technical potential and the upper or lower bound.

Table 2-33 builds off the example in Table 2-32 by estimating adjusted technical potential for the frozen EUI case by applying the example of 30% savings to the natural change estimates.

[25] Adding consumption from natural change directly to savings potential—instead of adding the expected savings from the natural change—typically exaggerates the upper or lower bound results.

Table 2-33. Illustrative Calculation of Bounds on Technical Potential (GJ/year)

Year	Frozen EUI Case Consumption	Natural Change	Tech Potent @ 30% Savings	Tech Potent + Nat Change	Tech Potent + 30% Nat Change
	A	B	C = A x 30%	D = B + C	E = B x 30% + C
2016	70,000	0	24,500	24,500	24,500
2020	75,770	-962	26,520	25,558	26,231
2025	83,656	-2,305	29,280	26,975	28,588
2030	92,364	-3,952	32,327	28,375	31,142
2035	101,977	-5,815	35,692	29,877	33,948

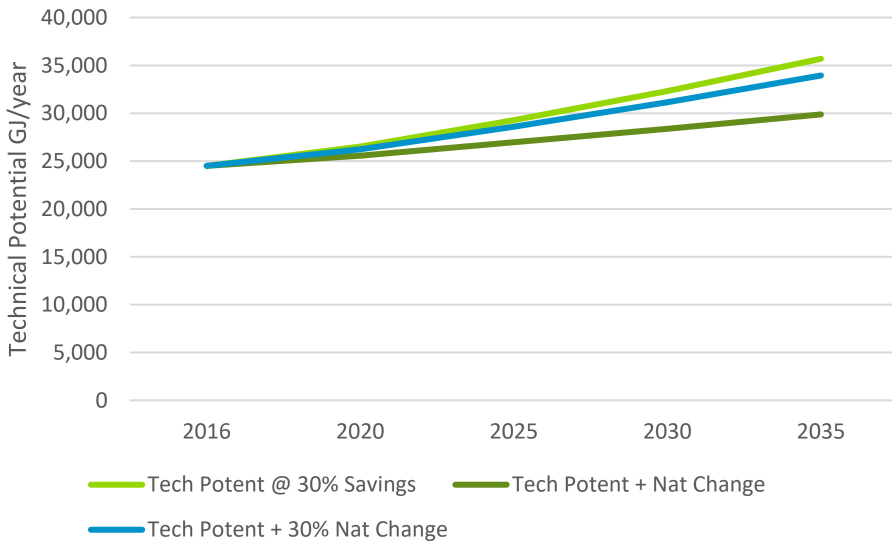
Source: Navigant

Where:

- **Frozen EUI Case Consumption** – the consumption forecast from the frozen EUI case
- **Natural Change** – the natural change between the frozen EUI case and the Reference Case
- **Tech Potent @ 30% Savings** – the technical potential assuming that efficient measures, in aggregate, lead to 30% savings as a percentage of the frozen EUI case's consumption
- **Tech Potent + Nat Change** – the sum of technical potential and natural change. Because natural change is negative, it reduces the total technical potential and indicates an extreme lower bound. This lower bound is overly conservative because it reduces the technical potential by the total natural change, rather than reducing potential by the overestimation of savings from natural change.
- **Tech Potent + 30% Nat Change** – the sum of technical potential and 30% of the natural change. Instead of reducing the technical potential by the total natural change, we reduce the potential by an estimate of the savings from natural change. The savings from natural change is a rough estimate based on the same 30% savings as a percentage of consumption used to estimate the technical potential. In reality, the percentage savings from natural change could be different from the 30% aggregate technical savings for the end-use.

Figure 2-10 plots the illustrative results from Table 2-33.

Figure 2-10. Illustrative Example of Technical Potential and Bounds Derived from Natural Change



Source: Navigant

At the end-use level, the technical potential plus the adjusted natural change (i.e., "Tech Potential + 30% Nat Change") will always fall between the technical potential and the bound created by adding natural change directly to the potential. At the sector level, however, this may not always be the case due to the aggregation of various end-use categories that may have positive or negative natural change. The natural change and estimated savings from natural change can be positive or negative and will cancel each other out, which leads to aggregate natural change and aggregate savings from natural change that can be in different proportions than was calculated at the end-use level. After aggregation, the technical potential plus the adjusted natural change may or may not fall between the technical potential and the bound.[26]

2.4 Measure Characterization

Navigant fully characterized over 200 measures across the BC Utilities' residential, commercial, and industrial sectors, covering electric and natural gas fuel types. The team prioritized measures with high impact, data availability, and most likely to be cost-effective as thresholds for inclusion into DSMSim™.

2.4.1 Measure List

Navigant developed a comprehensive measure list of energy efficiency measures likely to contribute to economic potential. The team reviewed current BC program offerings, previous CPR and other Canadian programs, and potential model measure lists from other jurisdictions to identify EE measures with the highest expected economic impact. The team supplemented the measure list using the Pennsylvania, Illinois, Mid-Atlantic, and Massachusetts technical resource manuals (TRMs), and partnered with CLEAResult to inform the list of industrial measures. Navigant worked with the BC Utilities to finalize the

[26] The effects of natural change by end-use category and customer segment are available in Appendix A.1.

measure list and ensure it contained technologies viable for future BC program planning activities. Appendix A.2 provides the final measure list and assumptions.

Working sessions with the BC Utilities revealed topics of note regarding the following measures:

- **Multi-Unit Residential Building (MURB) measures –** Navigant characterized both in-suite and common area measures for MURBs. In-suite measures are similar to other residential measures such as LED light bulbs, power strips, and televisions. Common area measures include space heating and hot water heating measures such as make-up air units, HVAC controls, central boilers, and roof deck insulation
- **Showerheads for MURBs –** The model currently uses material and labor costs for showerheads assuming the customer installs the measure themselves. However, BC Utilities offer a direct install program for showerheads in the MURB customer segment and may purchase showerheads at a wholesale price. Since the measure is already cost-effective without the direct install cost adjustments, this issue does not impact the technical and economic potential results. This issue would impact any further analysis of achievable potential, but that is outside of the scope of this study.

2.4.2 Measure Characterization Key Parameters

The measure characterization effort consisted of defining nearly 50 individual parameters for each of the 200 measures included in this study. This section defines the top 10 key parameters and how they impact technical and economic potential savings estimates.

1. **Measure Definition**: The team used the following variables to qualitatively define each characterized measure:
    - ***Replacement Type****:* Replacing the baseline technology with the efficient technology can occur in three variations:
        1. Retrofit (RET): where the model considers the baseline to be the existing equipment, and uses the energy and demand savings between the existing equipment and the efficient technology during technical potential calculations. RET also applies the full installed cost of the efficient equipment during the economic screening.
        2. Replace On Burnout (ROB): where the model considers the baseline to be the code-compliant technology option, and uses the energy and demand savings between the current code option and the efficient technology during technical potential calculations. ROB also applies the incremental cost between the efficient and code-compliant equipment during the economic screening.
        3. New Construction (NEW): where the model considers the baseline to be the least cost, code-compliant option, and uses the energy and demand savings between this specific current code option and the efficient technology during technical potential calculations. NEW also applies the incremental cost between the efficient and code-compliant equipment during the economic screening.
    - ***Baseline Definition***: Describes the baseline technology (e.g., the existing equipment).
    - ***EE Definition***: Describes the efficient technology set to replace the baseline technology.
    - ***Unit Basis***: The normalizing unit for energy, demand, cost, and density estimates.

2. **Regional, Sector, and End-use Mapping:** The team mapped each measure to the appropriate end-uses, customer segments, sectors, and climate regions across the BC Utility's service territory. Section 2.1 describes the breakdown of customer segments with each sector in greater detail. Navigant characterized weather dependent measures into four regions: Lower Mainland, Southern Interior, Vancouver Island, and Northern BC to account for changes in climate that impact energy savings.
3. **Annual Energy Consumption:** The annual energy consumption in kilowatt-hours (kWh) or mega joules (MJ) for each of the base and energy-efficient technologies
4. **Coincident Electric Demand**: The peak coincident demand in kilowatts (kW) for each of the base and energy-efficient technologies
5. **Fuel Type Applicability Multipliers**: Assigns the percentage of electric fuel type to measures with electric fuel type such as water heaters and space heating equipment
6. **Measure Lifetime:** The lifetime in years for the base and energy-efficient technologies. The Base and EE lifetime only differ in instances where the two cases represent inherently different technologies, such as light-emitting diodes (LEDs) or compact fluorescent lamp (CFL) bulbs compared to a baseline incandescent bulb.
7. **Incremental Costs:** The incremental cost between the assumed baseline and efficient technology, using the following variables:
    - ***Base Costs***: The cost of the base equipment, including both material and labor costs
    - ***EE Costs:*** The cost of the energy-efficient equipment
8. **Technology Densities**: This study defines "density" as the penetration or saturation of the baseline and efficient technologies across the BC Utility's territory. For residential measures, these saturations are on a per home basis, for commercial they are per 1,000 square meters of building space, and for industrial they are based on energy consumption.[27]
    - ***Base Initial Saturation***: The saturation of the baseline equipment in a territory for a given customer segment
    - ***EE Initial Saturation:*** The saturation of the efficient equipment in a territory for a given customer segment
    - ***Total Maximum Density***: The total number of both the baseline and efficient units in a territory for a given technology
9. **Technology Applicability:** The percentage of the base technology that can be reasonably and practically replaced with the specified efficient technology. For instance, occupancy sensors are only practical for certain interior lighting fixtures (an applicability less than 1.0), while all existing incandescent exit signs can be replaced with efficient LED signs (an applicability of 1.0).
10. **Competition Group**: The team combined efficient measures competing for the same baseline technology density into a single competition group to avoid the double-counting of savings. (Section 3.1.3 provides further explanation on competition groups.)

2.4.3 Measure Characterization Approaches and Sources

This section provides approaches and sources for the main measure characterization variables. The BC Utilities and Technical Advisory Committee reviewed Navigant's measure assumptions for each sector

[27] Navigant sourced density estimates from the residential end-use survey (REUS), commercial end-use survey (CEUS), BC Utility program data, and other related secondary resources.

and provided inputs to refine measure assumptions. Navigant also worked with CLEAResult to further customize industrial measures.

2.4.3.1 Energy and Demand Savings

Navigant took three general bottom-up approaches to analyzing residential and commercial measure energy and demand savings:

1. **TRM Standard Algorithms:** Navigant used TRM standard algorithms for unit energy savings and demand savings calculations for the majority of measures. FortisBC Gas provided coincidence factors for the residential sector.
2. **Program Evaluation Data:** Where available, Navigant used measure specific program evaluation data from the BC Utilities to inform energy savings.
3. **Engineering Analysis:** Navigant used appropriate engineering algorithms to calculate energy savings for any measures not included in BC Utility programs or available TRMs.

2.4.3.2 Incremental Costs

Navigant relied primarily on BC Utility provided program data and TRM data for incremental cost data. Navigant conducted secondary research and used other publicly available cost data sources such as the Database for Energy Efficient Resources (DEER), ENERGY STAR®, RSMeans, and the Michigan Energy Measures Database (MEMD) for all other cost data.[28]

2.4.3.3 Building Stock and Densities

The residential end-use survey (REUS) and commercial end-use survey (CEUS) provided building stock data for the BC Utility's service territory, enabling Navigant to characterize residential and commercial measures. The measure characterization workbooks include full documentation of assumptions applied to each measure. Navigant also used the REUS and CEUS reports to develop measure densities by customer segment. For measures not included in REUS and CEUS, Navigant reviewed other data sources such as NRCan for estimates.

2.4.3.4 Industrial Measures

The industrial sector measure characterization deploys a top-down approach, which differs from the residential and commercial sectors. Navigant characterized industrial measures as a percentage reduction of the customer segment and/or end-use consumption. CLEAResult evaluated past and recent project data from the BC Utilities to estimate the energy savings and incremental cost for all industrial measures.

[28] For example, measure costs for new construction whole-building measures were gathered from a variety of sources. For residential measures, Navigant received data from the BC Utilities, and performed secondary research for measures where data was not provided. For Commercial whole-building new construction measures, Navigant leveraged RSMeans new construction cost data for Vancouver, BC and supplemented those costs with data from LEED and green building reports that reported incremental costs associated with higher energy savings. Navigant determined energy savings and costs for the discrete new construction measures in their entirety without analyzing what bundles of other CPR measures would make up a new construction measure.

2.4.4 Codes and Standards Adjustments

Natural Resources Canada publishes all energy efficiency regulations. Amendment 14[29] states that the intent of the amendment is to "align with energy efficiency standards in force or soon to be in force in the U.S." The U.S. Department of Energy (DOE) Technical Support Documents (TSD)[30] contains information on energy and cost impact of each appliance standard. Engineering analysis is available in Chapter 5 of the TSD; energy use analysis is available in Chapter 7, and cost impact is available in Chapter 8.

As these codes and standards take effect, the energy savings from existing measures impacted by these codes and standards diminishes. Navigant accounts for the impact of codes and standards by baseline energy and cost multipliers—sourced from the DOE's analysis—which reduce the baseline equipment consumption starting from the year a particular code or standard takes effect.[31] The baseline cost of an efficient measure impacted by codes and standards will often increase upon implementation of the code. Technical and economic savings potential presented in the model results includes savings potential from codes and standards, and measure-level results show their contribution to overall potential. Savings potential results do not consider fuel switching.[32]

The City of Vancouver By-Law (VBBL) varies from the National Building Code for insulation measures and water heating equipment. Navigant did not estimate the impact of the VBBL as the model segmentation does not drill down to city level granularity. City specific stock and sales data are not available to estimate the impact of the VBBL. Navigant expects the impact of VBBL to be small compared to the EE potential of the entire province. The majority of energy efficient savings from Part 9 buildings come from existing buildings in the near future. The VBBL does not require a specific upgrade level if the retrofit project is less than $5,000, which represents most residential measures in the model. Part 3 Buildings from VBBL references the National Building Code and ASHRAE 90.1 standards. The model assumes the National Building Code as the baseline for Part 3 buildings, therefore, the discrepancy in impact is minimal for commercial buildings.

29 Natural Resources Canada Amendment 14 to the Energy Efficiency Regulations. Access at: http://www.nrcan.gc.ca/energy/regulations-codes-standards/18437

30 Appliance standards rulemaking notices and Technical Support Documents can be found at: http://energy.gov/eere/buildings/current-rulemakings-and-notices

31 Navigant uses a similar method of applying multipliers for changes in measure economics over time if sufficient data exists for extrapolating such changes, e.g. reducing measure costs over time for Commercial High Efficiency Gas-Fired Condensing Rooftop Units (RTU).

32 For example, if a natural gas heated new home is upgraded from the code-mandated performance level to an R-2000 home, the savings potential analysis assumes that this home remains natural gas heated.

3. TECHNICAL POTENTIAL FORECAST

This section describes Navigant's approach to calculating technical potential and presents the results for FortisBC Gas's service territory.

3.1 Approach to Estimating Technical Potential

This study defines technical potential as the total energy savings available assuming that all installed measures can *immediately* be replaced with the "efficient" measure/technology—wherever technically feasible—regardless of the cost, market acceptance, or whether a measure has failed and must be replaced.

Navigant used its DSMSim model to estimate the technical potential for demand side resources in the regions considered for this study. Navigant's modelling approach considers an energy-efficient measure to be any change made to a building, piece of equipment, process, or behaviour that could save energy. The savings can be defined in numerous ways, depending on which method is most appropriate for a given measure. Measures like condensing water heaters are best characterized as some fixed amount of savings per water heater; savings for measures like commercial automated building controls are typically characterized as a percentage of customer segment consumption; and measures like industrial ventilation heat recovery are characterized as a percentage of end-use consumption. The model can appropriately handle savings characterizations for all three methods.

The calculation of technical potential in this study differs depending on the assumed measure replacement type. Technical potential is calculated on a per-measure basis and includes estimates of savings per unit, measure density (e.g., quantity of measures per home) and total building stock in each service territory. The study accounts for three replacement types, where potential from retrofit and replace-on-burnout measures are calculated differently from potential for new measures. The formulae used to calculate technical potential by replacement type are shown below.

3.1.1 New Construction Measures

The cost of implementing new construction (NEW) measures is incremental to the cost of a baseline (and less efficient) measure. However, new construction technical potential is driven by equipment installations in new building stock rather than by equipment in existing building stock.[33] New building stock is added to keep up with forecast growth in total building stock and to replace existing stock that is demolished each year. Demolished (sometimes called replacement) stock is calculated as a percentage of existing stock in each year, and this study uses a demolition rate of 0.5% per year for residential and commercial stock and 0% for industrial stock. New building stock (the sum of growth in building stock and replacement of demolished stock) determines the incremental annual addition to technical potential, which is then added to totals from previous years to calculate the total potential in any given year. The equations used to calculate technical potential for new construction measures are provided below.

Equation 1. Annual Incremental NEW Technical Potential (AITP)

$AITP_{YEAR}$ = New $Buildings_{YEAR}$ (e.g., buildings/year[34]) X Measure Density (e.g., widgets/building) X $Savings_{YEAR}$ (e.g., GJ/widget) X Technical Suitability (dimensionless)

Equation 2. Total NEW Technical Potential (TTP)

$$TTP = \sum_{YEAR=2016}^{YEAR=2035} AITP_{YEAR}$$

3.1.2 Retrofit and Replace-on-Burnout Measures

Retrofit (RET) measures, commonly referred to as advancement or early-retirement measures, are replacements of existing equipment before the equipment fails. Retrofit measures can also be efficient processes that are not currently in place and that are not required for operational purposes. Retrofit measures incur the full cost of implementation less a deferred replacement credit, rather than incurring a cost incremental to some other baseline technology or process because the customer could choose not to replace the measure and would therefore incur no costs.[35] In contrast, replace-on-burnout (ROB) measures, sometimes referred to as lost-opportunity measures, are replacements of existing equipment that have failed and must be replaced, or they are existing processes that must be renewed. Because the failure of the existing measure requires a capital investment by the customer, the cost of implementing replace-on-burnout measures is always incremental to the cost of a baseline (and less efficient) measure.

---

[33] In some cases, customer-segment-level and end-use-level consumption are used as proxies for building stock. These consumption figures are treated like building stock in that they are subject to demolition rates and stock-tracking dynamics.

[34] Units for new building stock and measure densities may vary by measure and customer segment (e.g., 1,000 square meters of building space, number of residential homes, customer-segment consumption, etc.)

[35] This study's approach subtracts a deferred replacement credit from the full cost of implementation whenever the average remaining useful life of currently installed measures can be reasonably approximated. This methodology leads to a similar outcome as subtracting a salvage value from the full incremental cost. For more discussion of deferred replacement credits, see "Retrofit Economics 201: Correcting Commons Errors in Demand-Side Management Cost-Benefit Analysis" by Rachel Brailove, John Plunkett, and Jonathan Wallach.

Retrofit and replace-on-burnout measures have a different meaning for technical potential compared with new construction measures. In any given year, we use the entire building stock for the calculation of technical potential.[36] This method does not limit the calculated technical potential to any pre-assumed rate of adoption of retrofit measures. Existing building stock is reduced each year by the quantity of demolished building stock in that year and does not include new building stock that is added throughout the simulation. For retrofit and replace-on-burnout measures, annual potential is equal to total potential, thus offering an *instantaneous* view of technical potential. The equation used to calculate technical potential for retrofit and replace-on-burnout measures is provided below.

Equation 3. Annual/Total RET/ROB Technical Savings Potential

Total Potential = Existing Building Stock$_{YEAR}$ (e.g., buildings[37]) X Measure Density (e.g., widgets/building) X Savings$_{YEAR}$ (e.g., GJ/widget[38]) X Technical Suitability (dimensionless)

3.1.3 Competition Groups

Navigant's modelling approach recognizes that some efficient technologies will compete against each other in the calculation of potential. The study defines "competition" as an efficient measure competing for the same installation as another efficient measure. For instance, a consumer has the choice to install a condensing or a near-condensing water heater, but not both. These efficient technologies compete for the same installation.

General characteristics of competing technologies used to define competition groups in this study include the following:

- Competing efficient technologies share the same baseline technology characteristics, including baseline technology densities, costs, and consumption
- The total (baseline plus efficient) measure densities of competing efficient technologies are the same
- Installation of competing technologies is mutually exclusive (i.e., installing one precludes installation of the others for that application)
- Competing technologies share the same replacement type (RET, ROB, or NEW)

To address the overlapping nature of measures within a competition group, Navigant's analysis only selects one measure per competition group to include in the *summation* of technical potential across measures (e.g., at the end-use, customer segment, sector, service territory, or total level). The measure with the largest energy savings potential in a given competition group is used for calculating total technical potential of that competition group. This approach ensures that the aggregated technical potential does not double-count savings. However, the model still calculates the technical potential for

[36] In some cases, customer-segment-level and end-use-level consumption/sales are used as proxies for building stock. These consumption/sales figures are treated like building stock in that they are subject to demolition rates and stock-tracking dynamics.
[37] Units for building stock and measure densities may vary by measure and customer segment (e.g., 1,000 square meters of building space, number of residential homes, customer-segment consumption/sales, etc.).
[38] To determine energy savings, Navigant consistently applies one measure-specific baseline across the entire measure life of each respective measure.

each individual measure outside of the summations.

3.2 Technical Potential Results

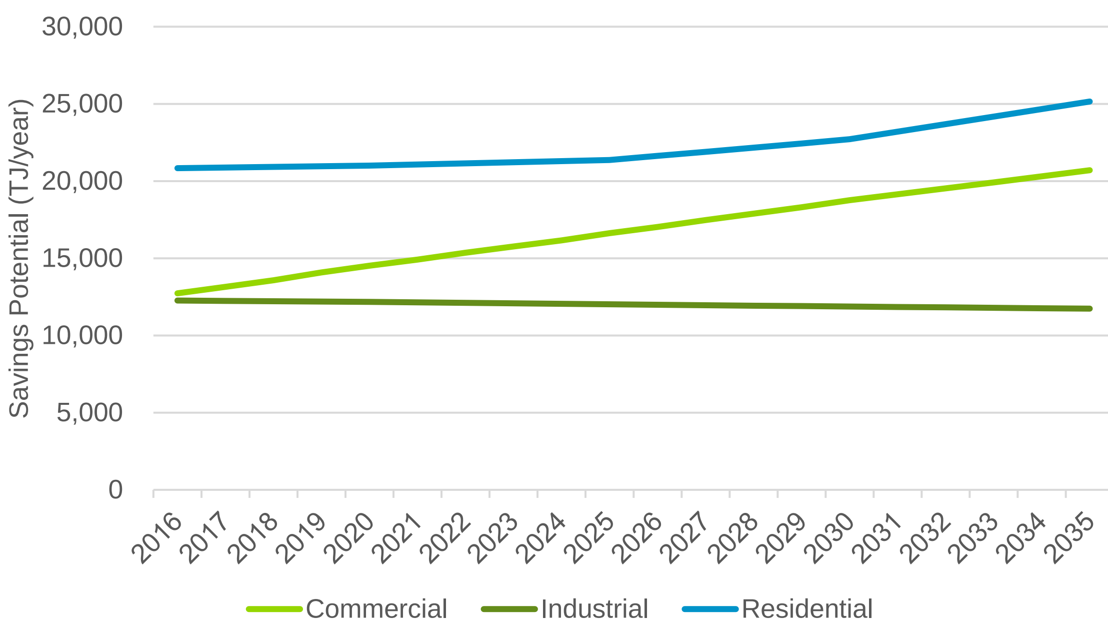
This section provides the technical savings potential calculated by the model at varying levels of aggregation. Results are shown by sector, customer segment, end-use category, and highest-impact measures. The section concludes with a review of natural change and its impacts on technical potential.

3.2.1 Results by Sector

Figure 3-1 shows the total gas energy technical savings potential split by sector, and Table D-3 in Appendix D provides the associated data. As noted in previous sections, although apartments were included in the residential sector for the Base Year and Reference Case analyses, technical and economic savings potential from apartments are reported with the commercial sector to align with FortisBC Gas's categorization for conservation programs.

The increased rate of growth in residential technical potential beginning around 2025 is due to improvements in whole-building energy efficiency practices for single-family detached homes. The upward trend in the commercial sector stems largely from high-impact whole-building new construction measures as well. Of the largest contributing industrial customer segments, reductions in potential from greenhouses and food and beverage outpace the increase in potential from manufacturing, leading to a slight decrease in industrial potential over the forecast period.

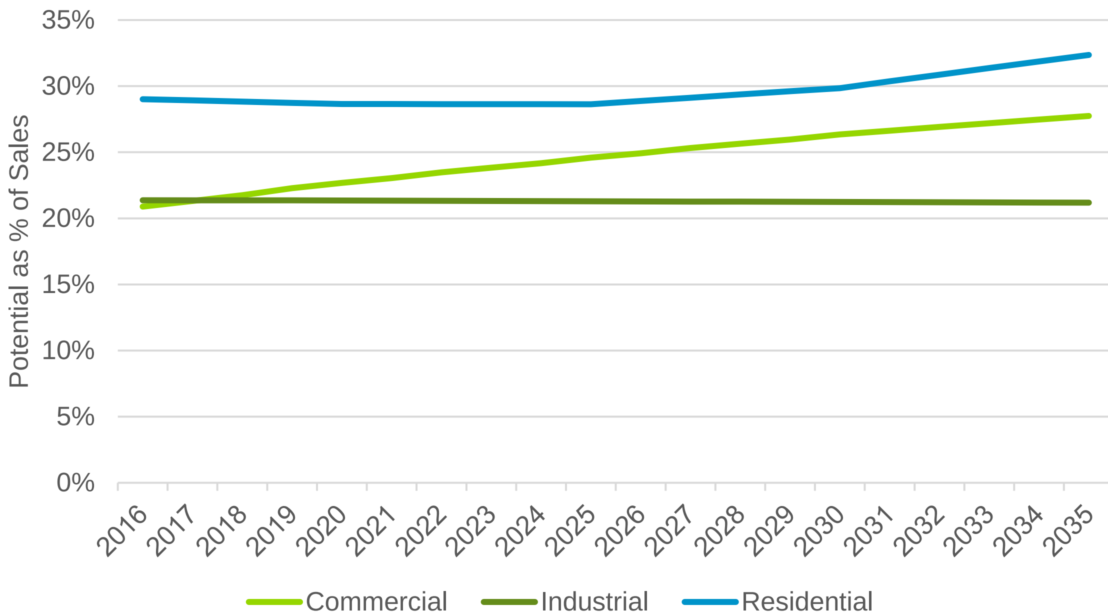
Figure 3-1. Gas Energy Technical Savings Potential by Sector (TJ/year)



Source: Navigant

Figure 3-2 shows the gas energy technical savings potential as a percentage of each sector's total forecasted consumption. Table D-4 in Appendix D provides the associated data. The percentages reflect a weighted average savings among measures applicable to existing building stock and new building stock constructed during the study period. As such, upward-sloping sectors indicate that savings opportunities—on a percentage of consumption basis—are larger in new construction than existing construction. Although growth in total residential consumption declines over time, the high impact new construction measures—several of which were not available until later years—help the residential percentages recover an upward trend by 2026. The commercial sector benefits from new construction measures with significant savings. New construction opportunities in the industrial sector are limited because many of the customer segments show no growth in the consumption forecasts. As such, the vast majority of savings from the industrial sector come from existing facilities rather than facilities constructed during the forecast period.

Figure 3-2. Gas Energy Technical Savings Potential by Sector as a Percent of Sector Consumption (%)

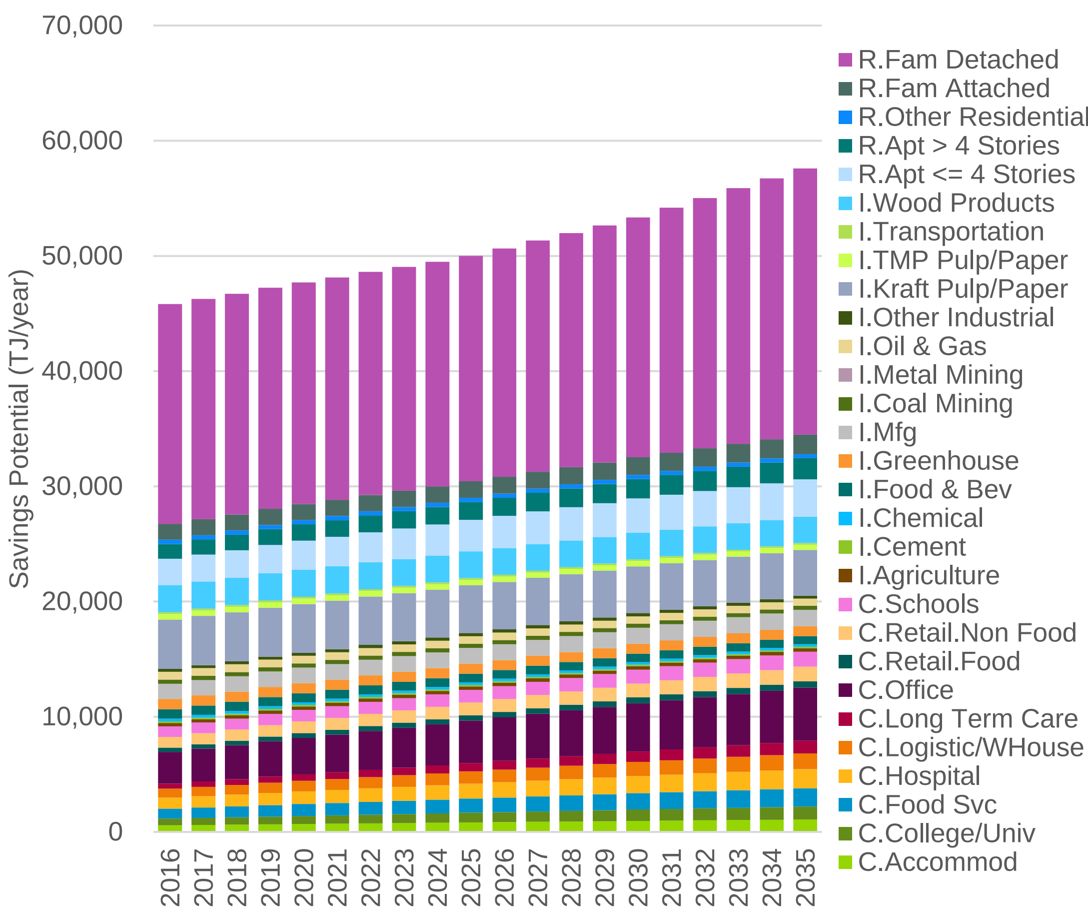


Source: Navigant

3.2.2 Results by Customer Segment

Figure 3-3 shows the gas energy technical savings potential across all customer segments, and Table D-5 in Appendix D provides the associated data.[39] This figure highlights the large savings potential of the residential detached single-family home customer segment relative to other customer segments. The growth in potential for the detached single-family home segment is the largest contributor to the increase in savings potential in the last ten years of the study. This coincides with the improvements to efficient home construction practices that reach maturity toward the end of the forecast. The savings opportunities from new construction buildings (45% above code) boost potential for most commercial segments. [40]

Figure 3-3. Gas Energy Technical Savings Potential by Customer Segment (TJ/year)



Source: Navigant

[39] The LNG segment does not appear in this figure because FortisBC Gas does not supply natural gas to LNG facilities. Gas sales to LNG facilities are zero across the Reference Case forecast, hence, the savings potential is also zero.

[40] Note that whole-building, new construction measures do not necessarily align with provincial energy *step* codes. For example, while the new construction 30% and 45% better than code measures were selected to broadly align with step codes, savings attributed to these measures are calculated based on overall energy consumption, and not based on a particular building code requirement stated in the step codes.

Figure 3-4, Figure 3-5, and Figure 3-6 break out the gas energy technical savings potential for each sector by customer segment. For the residential sector, detached single-family homes represents the largest savings potential of any customer segment by far, accounting for 91% of the total savings potential. Offices and apartments provide approximately half of the savings in the commercial sector. In general, the distribution of savings among customer segments aligns well with the distribution of gas consumption among segments. In the industrial sector, kraft pulp and paper accounts for the largest share of energy savings at 35%. Wood products and manufacturing also provide significant savings among industrial segments.

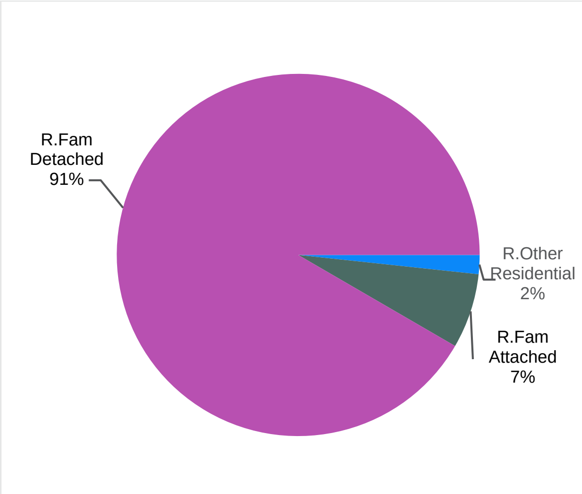

Figure 3-5. Commercial Gas Energy Technical Potential Customer Segment Breakdown in 2025

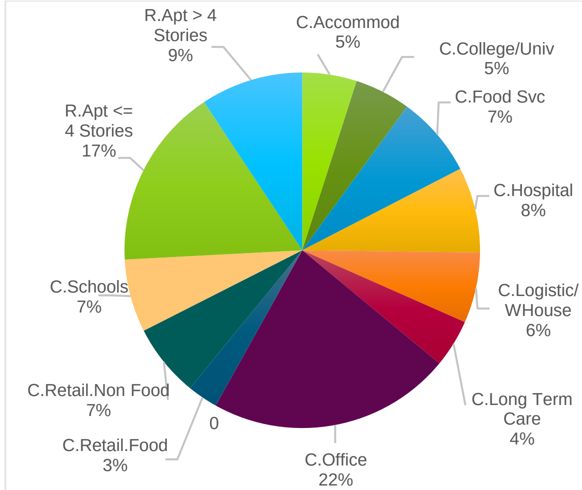

Figure 3-6. Industrial Gas Energy Technical Potential Customer Segment Breakdown in 2025

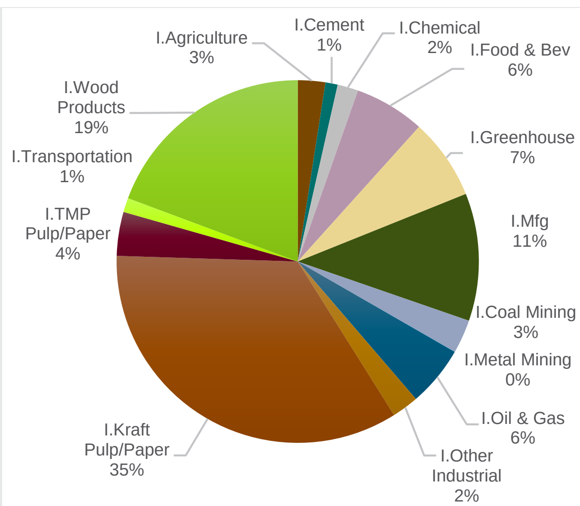
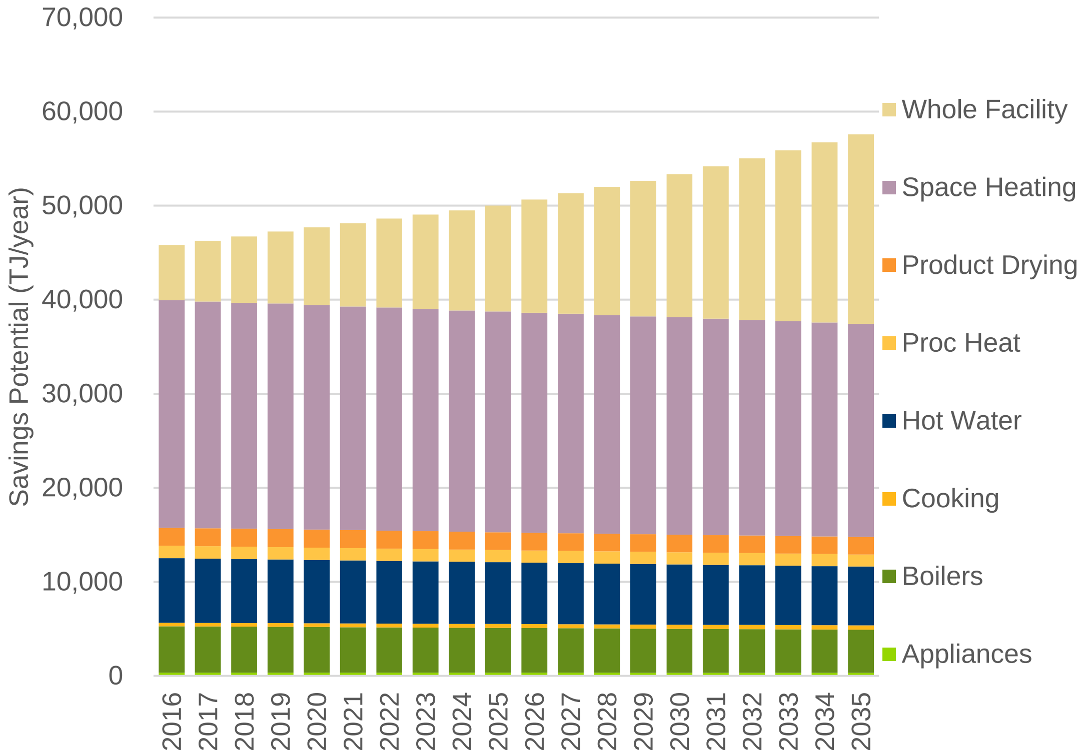


Source: Navigant

3.2.3 Results by End-use

Figure 3-7 shows the gas energy technical savings potential across end-uses. The data used to generate the figure are in Table D-6 in Appendix D. The dominant end-uses are space heating and whole facility. The bulk of savings potential in the space heating end-use come from smart thermostats. The whole facility end-use primarily consists of savings from comprehensive whole-facility new construction practices and energy management programs. As such, these whole-facility savings implicitly include savings from multiple end-uses.

Figure 3-7. Gas Energy Technical Savings Potential by End-Use across sectors (TJ/year)



Source: Navigant

Figure 3-8, Figure 3-9, and Figure 3-10 break out the gas energy technical savings potential for each sector. The space heating and hot water end-uses dominate the residential sector, together accounting for 87% of the total savings potential. In the residential sector, smart thermostats and efficient fireplaces are the two largest space heating measures, while condensing and non-condensing gas tankless water heaters contribute significantly to the hot water end-use's savings.[41] In the commercial sector, the space heating and whole facility end-uses account for roughly 89% of the total technical savings potential. Savings in commercial space heating come largely from wall insulation, HVAC control upgrades, and condensing make-up air units. Boilers measures, which are included in the hot water and space heating end-uses account for roughly 13% of the technical potential. The whole-facility end-use's savings are driven by new building construction practices that are at least 45% above code. While the appliances end-use is not inherent to the commercial sector, the inclusion of apartment buildings in the commercial sector means that savings from appliances are also reported in the commercial sector. In the industrial sector, the boiler end-use plays the largest role, consisting of high savings measures like process boiler load control and heat recovery systems.

[41] Note that efficient fireplaces and envelope upgrade measures are classified as space heating measures.

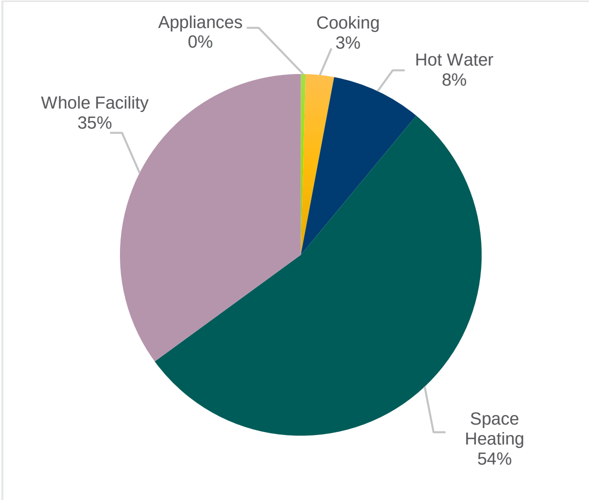

Figure 3-10. Industrial Gas Energy Technical Potential End-Use Breakdown in 2025[42]

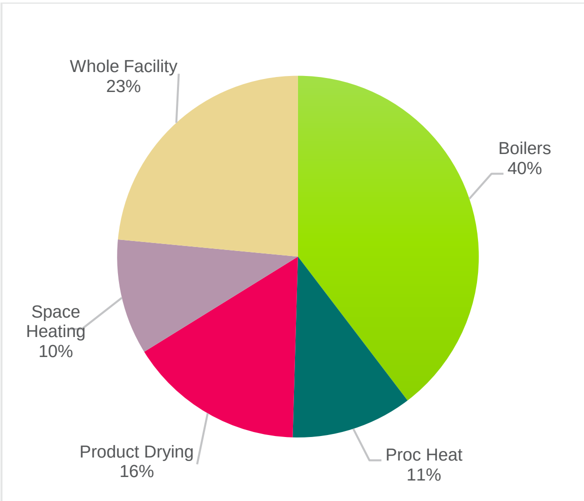


Source: Navigant

3.2.4 Results by Measure

The measure-level savings potential shown in Figure 3-11 is prior to adjustments made to competition groups. Some of the measures shown here are not included in the customer segment, end-use, sector and portfolio totals because they are not the measures with the greatest savings potential for their respective competition group.

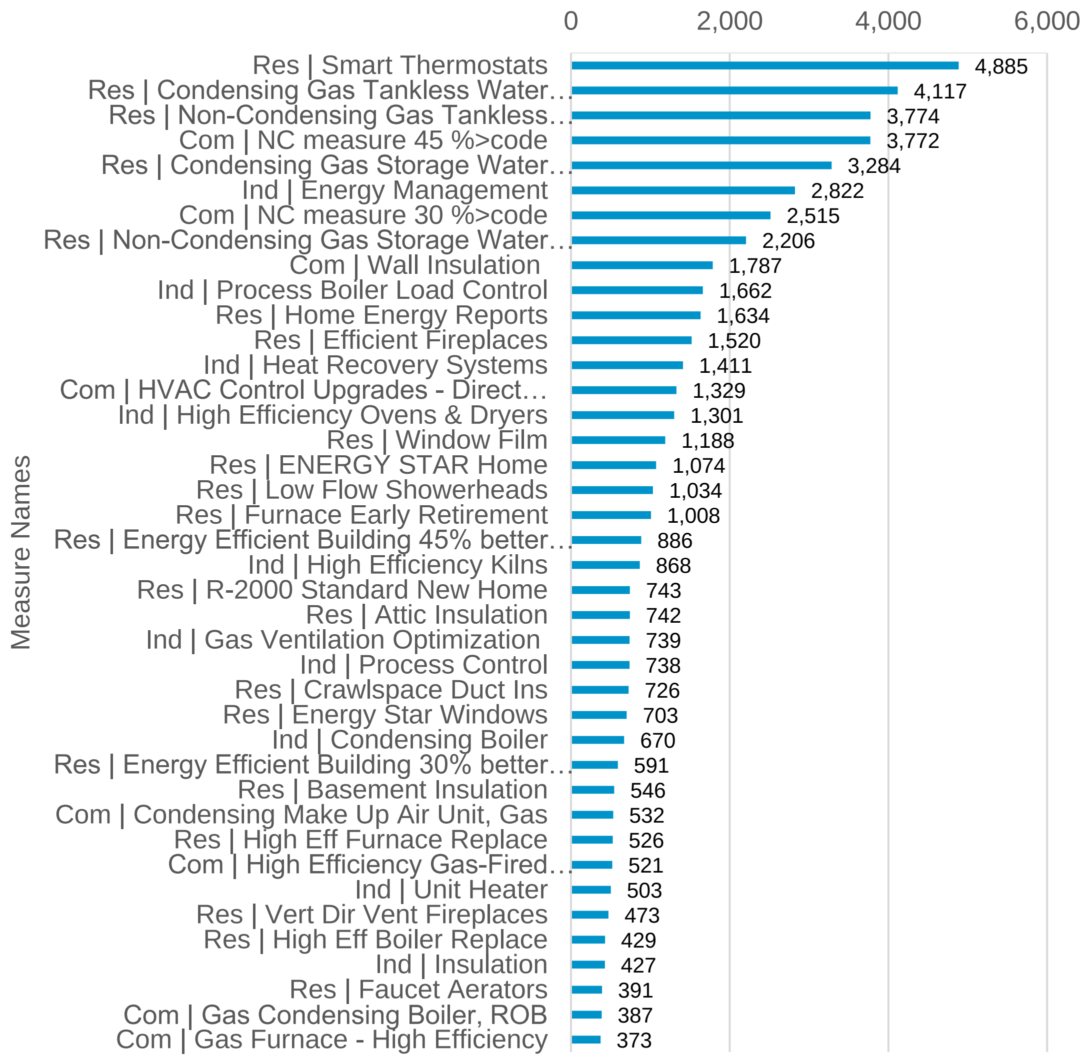
[42] Note that no natural gas energy savings measures are assigned to the *industrial process* end use. As a result, no energy savings potential is reported for this end use.

The figure presents the top forty measures ranked by their gas energy technical savings potential in 2025. Wherever a group of measures were similar in nature, Navigant consolidated their potential into a representative measure name to produce a more succinct view at the measure level. For example, the energy management potential in the figure represents the technical savings potential for industrial energy management and commercial energy management, which encompass energy savings opportunities unique to each sector.

When code-change measures become applicable, they “steal” savings potential from other related measures that may display significant savings in absence of the code. In this way, the sum of the total savings potential between the code and the related energy-efficient measure is the same before and after a code takes effect. This ensures there is no double counting of savings from codes and the energy efficient measures impacted by the code.

The top ten measures come from the space heating, whole-facility, and hot water end-uses. However, non-condensing gas tankless water heaters, new construction building practices at least 30% better than code, and condensing storage water heaters are in competition with other higher impact measures, so their savings do not contribute to aggregate potential results. Smart thermostats and energy management are two of the top ten measures that provide savings in multiple sectors. Thermostats contribute to residential and commercial savings.

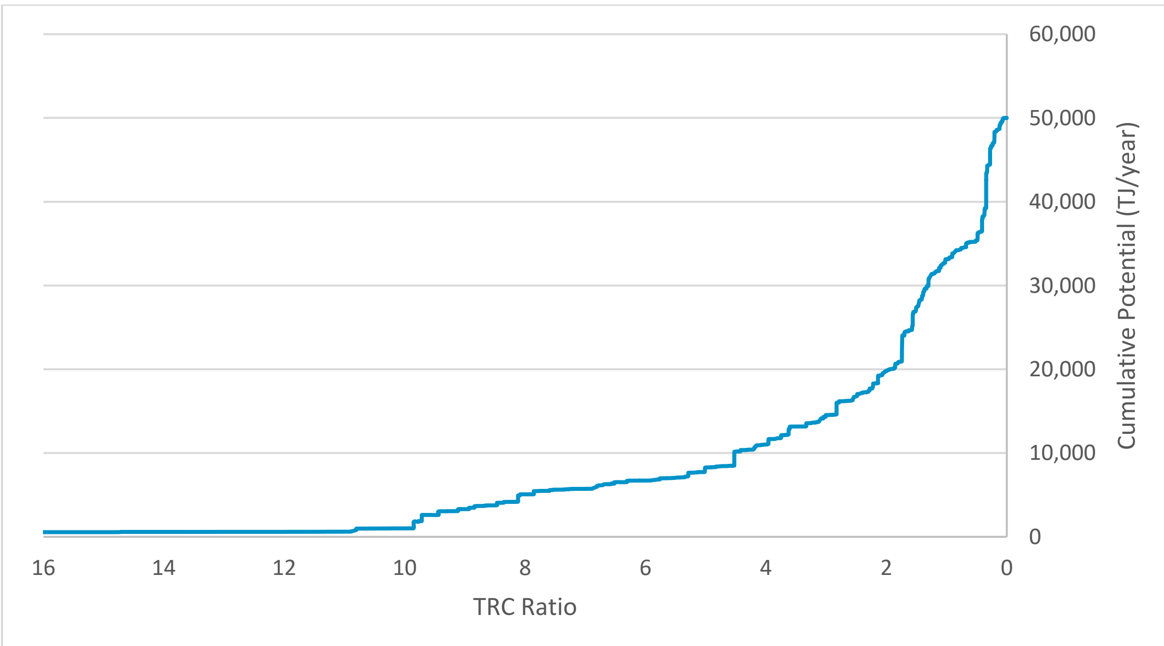
Figure 3-11. Top 40 Measures for Gas Energy Technical Savings Potential in 2025 (TJ/year)



Source: Navigant

Figure 3-12 provides a supply curve of technical savings potential versus the TRC ratio for all measures considered in the study. Navigant truncated this curve only to show TRC ratios below 16, although the full curve would extend well beyond this ratio. Much of the potential with TRC ratios larger than 16 come from new codes and standards measures, which the team modelled as having zero costs and infinite TRC ratios. There is a distinct “elbow” in the supply curve at a TRC ratio of about 4.0, indicating the majority of savings coming from measures with TRC ratios less than 4.0. For TRC ratios below 4.0, cumulative potential increases to about 33,000 TJ/year at a ratio of 1.0. Measures with TRC ratios less than 1.0 are non-cost-effective and do not appear in the economic potential.

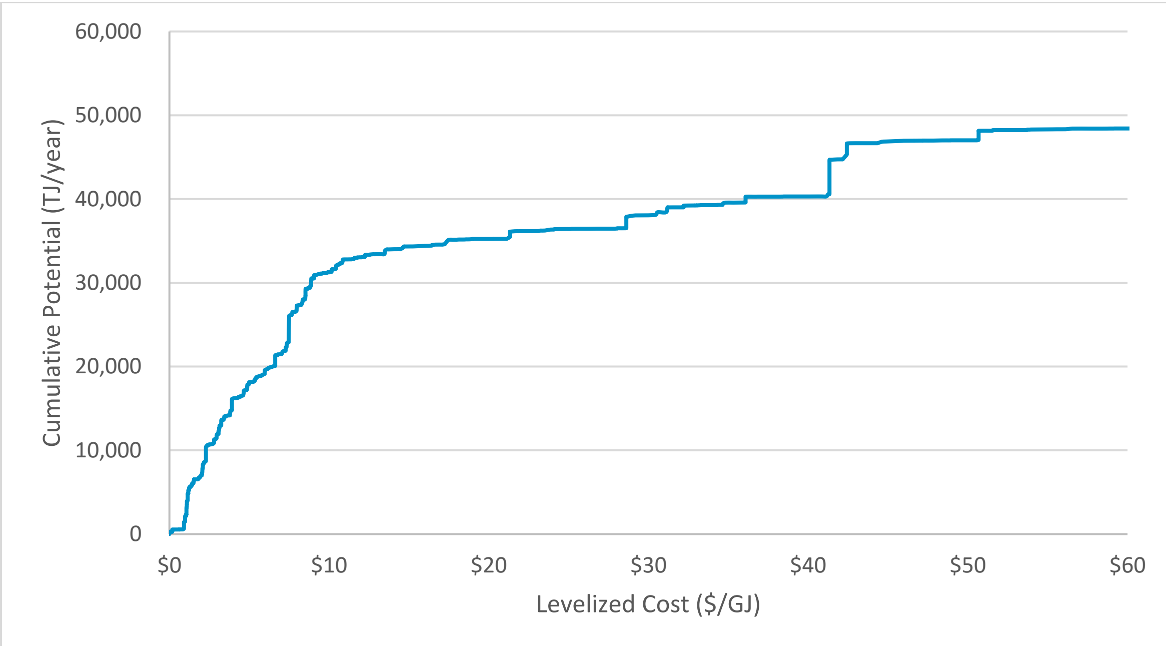
Figure 3-12. Supply Curve of Gas Energy Technical Potential (TJ/year) vs. TRC Ratio (ratio) in 2025



Source: Navigant

Figure 3-13 provides a supply curve of savings potential versus levelized cost of savings in $/GJ for all measures considered in the study. Navigant truncated this curve to show only those measures with a levelized cost less than $60/GJ, though the full curve would extend beyond this to measures with costlier savings. The savings potential having a cost of $0/GJ is due to code-change measures, which Navigant modelled as having zero costs. Total cumulative savings potential increase steadily to just over 48,000 TJ/year at a cost of $60/GJ, beyond which costlier modes of savings add minimal cumulative potential.

Figure 3-13. Supply Curve of Gas Energy Technical Potential (TJ/year) vs. Levelized Cost of Savings ($/GJ) in 2025



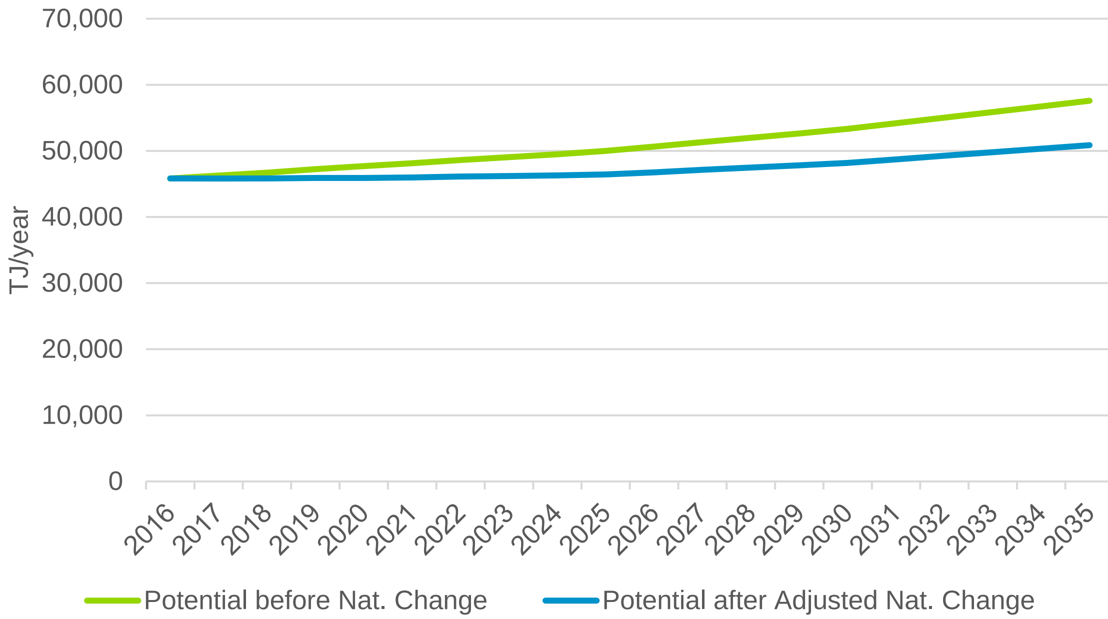
Source: Navigant

3.2.5 Adjustments for Natural Change

As discussed in section 2.3.2, Navigant estimated natural change to account for differences in end-use consumption in the Reference Case compared to the frozen EUI case. Natural change accounts for changes in consumption that are naturally occurring and are not the result of utility-sponsored programs or incentives. Adding natural change to the frozen EUI case required adjusting the technical potential forecasts accordingly.

Figure 3-14 shows the total technical potential across all sectors before and after adjusting for natural change. The total natural change across all sectors is negative in all years, indicating an overall natural tendency toward increased energy conservation rather than growth. The adjusted natural change is computed by accounting for the percentage of the gross natural change that could reasonably be attributed to energy savings for each end-use. On average across the study period, the technical potential after adjusted natural change is roughly 7% lower than the potential prior to natural change.

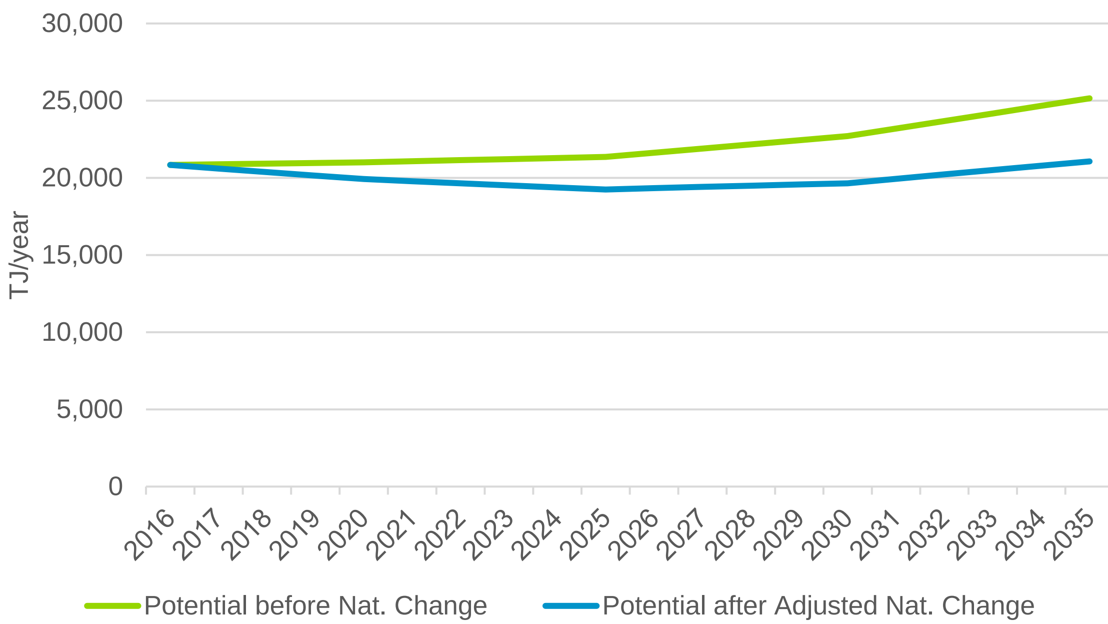
Figure 3-14. Gas Energy Technical Savings Potential with Natural Change – All Sectors (TJ/year)



Source: Navigant

Figure 3-15 shows the effect of adjustments for natural change in the residential sector. Space heating and hot water end-uses account for significant natural conservation. In contrast, appliances account for a minor amount of natural growth. When aggregated to the sector level, natural conservation has a much larger effect than natural growth. On average across the study period, the residential technical potential after adjusted natural change is roughly 10% lower than the potential prior to natural change.

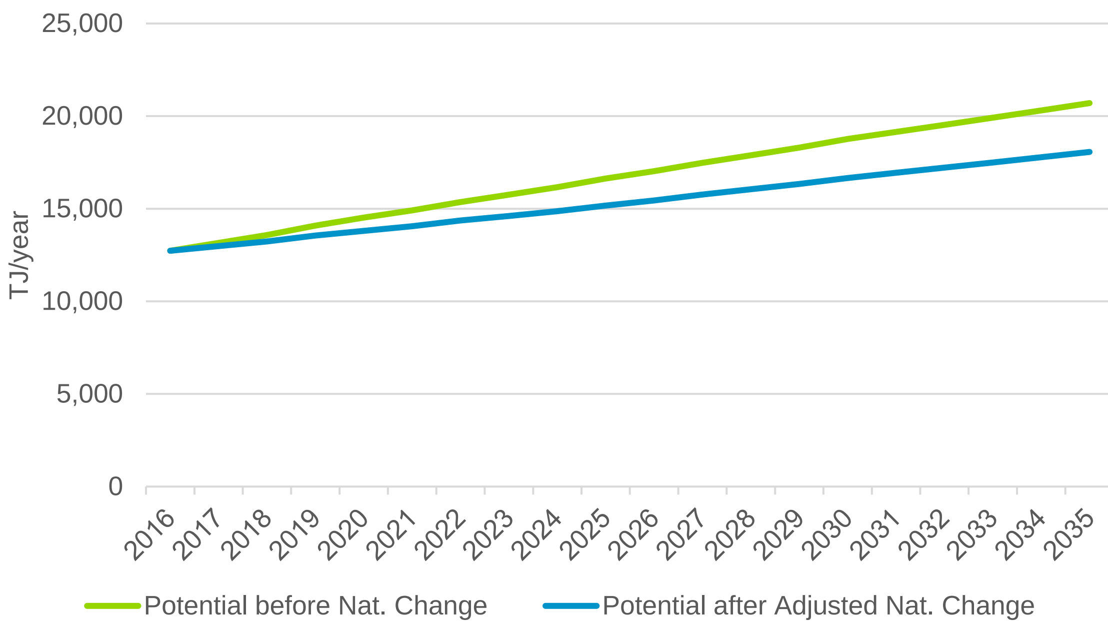
Figure 3-15. Residential Gas Energy Technical Savings Potential with Natural Change (TJ/year)



Source: Navigant

The effect of adjustments for natural change on the commercial sector's technical potential is slightly less than for the residential sector, as seen in Figure 3-16. Space heating and hot water are the commercial end-uses contributing to natural change, and both exhibit natural conservation. On average across the study period, the commercial technical potential after adjusted natural change is roughly 9% lower than the potential prior to natural change.

Figure 3-16. Commercial Gas Energy Technical Savings Potential with Natural Change (TJ/year)



Source: Navigant

For the industrial sector, there was no forecasted natural change, so adjustments to the technical potential results presented in previous sections were not necessary.

4. ECONOMIC POTENTIAL FORECAST

This section describes the economic savings potential, which is potential that meets a prescribed level of cost effectiveness, available in the BC Utilities' service territories. The section begins by explaining Navigant's approach to calculating economic potential. It then presents the results for economic potential.

4.1 Approach to Estimating Economic Potential

Economic potential is a subset of technical potential, using the same assumptions regarding immediate replacement as in technical potential, but including only those measures that have passed the benefit-cost test chosen for measure screening (in this case the Total Resource Cost (TRC) test, per the BC Utilities' guidance). The TRC ratio for each measure is calculated each year and compared against the measure-level TRC ratio screening threshold of 1.0. A measure with a TRC ratio greater than or equal to 1.0 is a measure that provides monetary benefits greater than or equal to its costs. If a measure's TRC meets or exceeds the threshold, it is included in the economic potential.

The TRC test is a cost-benefit metric that measures the net benefits of energy efficiency measures from combined stakeholder viewpoint of the utility (or program administrator) and the customers. The model calculates the TRC benefit-cost ratio using the following equation:

Equation 4. Benefit-Cost Ratio for Total Resource Cost Test

$$TRC = \frac{PV(Avoided\ Costs + O\&M\ Savings)}{PV(Technology\ Cost + Admin\ Costs)}$$

Where:

- *PV( )* is the present value calculation that discounts cost streams over time;
- *Avoided Costs* are the monetary benefits resulting from gas and electric savings (e.g., avoided costs of infrastructure investments, as well as avoided commodity costs due to gas and/or electric energy conserved by efficient measures);
- *O&M Savings* are the non-energy benefits such as operation and maintenance cost savings;
- *Technology Cost* is the incremental equipment cost to the customer;
- *Admin Costs* are the administrative costs incurred by the utility or program administrator.

Navigant calculated TRC ratios for each measure based on the present value of benefits and costs (as defined above) over each measure's life. Appendix A.3 presents the avoided costs, discount rates, and other key data inputs used in the TRC calculation, and Appendix A.2 provides measure-specific inputs. As agreed upon with the BC Utilities, effects of free ridership are not present in the results from this study, so no net-to-gross (NTG) factor was applied. Providing gross savings results will allow the BC Utilities to easily apply updated NTG assumptions in the future, as well as allow for variations in NTG assumptions by reviewers.

Although the TRC equation includes administrative costs, the study does not consider these costs during the economic screening process because an individual measure's cost effectiveness "on the margin" is the primary focus. Additionally, Navigant excluded administrative costs from this analysis because those costs are largely driven by program design, which is outside of the scope of this evaluation.

Similar to technical potential, only one "economic" measure (meaning that its TRC ratio meets the 1.0 threshold) from each competition group is included in the summation of economic potential across measures (e.g., at the end-use category, customer segment, sector, service territory or total level). If a competition group is composed of more than one measure that passes the TRC test, then the economic measure that provides the greatest gas savings potential is included in the summation of economic potential. This approach ensures that double counting is not present in the reported economic potential, though economic potential for each individual measure is still calculated and reported outside of the summation.

4.2 Economic Potential Results

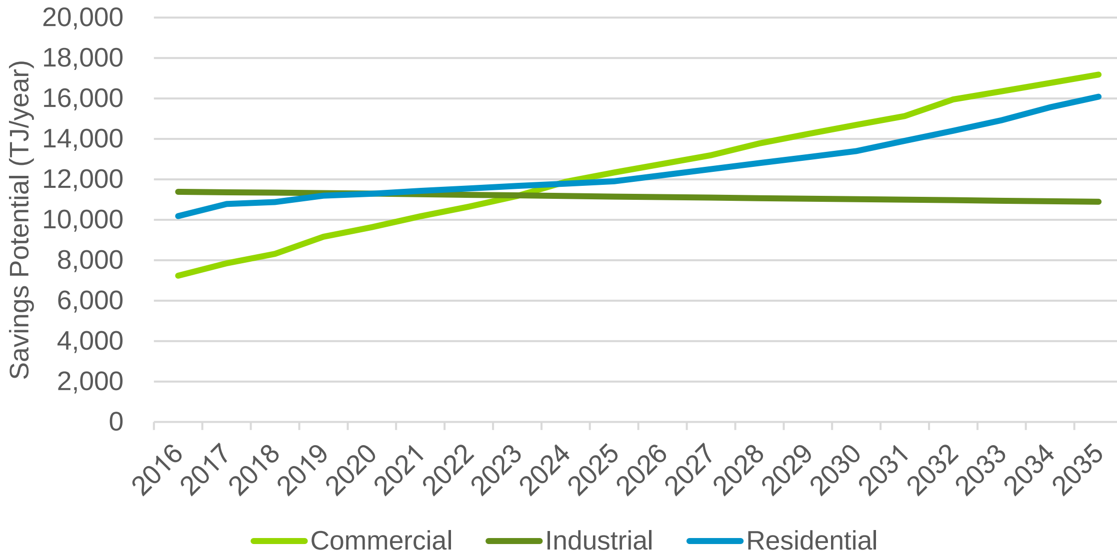
This section provides the results pertaining to economic savings potential at different forms of aggregation. Results are shown by sector, customer segment, end-use category and highest-impact measures.

4.2.1 Results by Sector

Figure 4-1 shows economic gas savings potential across all sectors. The data used to generate the figure are in Table D-7 in Appendix D. In contrast to technical potential, the residential economic potential shows a steady growth through 2035. The commercial economic potential grows nearly twice as fast as the technical potential. The industrial sector's economic potential exhibits similar decay trends as the technical potential. On average across the study period, 57% of residential, 74% of commercial and 93% of industrial technical potential pass the economic screening process.[43]

[43] The BC Utilities Commission (BCUC) allows for the use of a modified-TRC test (mTRC) for evaluating cost-effectiveness of energy efficiency measures. The mTRC test is based on higher avoided energy costs, and produces different results in comparison with the standard TRC test. The use of the mTRC test for economic potential is not in the scope of this portion of the BC CPR.

Figure 4-1. Gas Energy Economic Savings Potential by Sector (TJ/year)



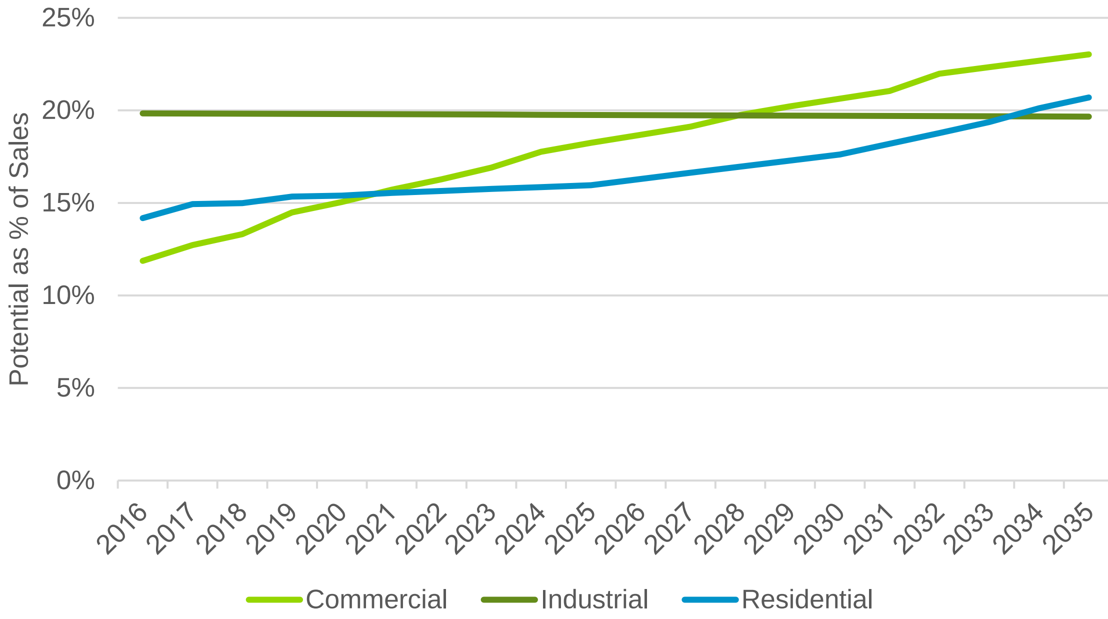
Source: Navigant

The bumps in select years of the residential and commercial economic potential occur whenever one or more measures cross the cost-effectiveness threshold in one or more customer segments. The slope of energy savings over time reflect changes in gas sales and the roll-out of high-efficiency, new construction measures. These measures having TRC ratios slightly less than 1.0 at the beginning of the study period become economically feasible as ***avoided gas costs—which escalate at a faster rate than equipment, operation and maintenance costs***—increase throughout the study the period. For example, smart thermostats become cost-effective in 2017 for the residential sector. The bumps in commercial economic potential prior to 2026 result from HVAC control upgrades using direct digital data control becoming cost-effective in various customer segments and years. When vertical direct-vent fireplaces become economically feasible in 2031, it induces the final visible jump in commercial potential.

Technical and economic energy potential are similar in the industrial sector because the measures included in the study are selected on the premise that they are currently or could become reasonably attractive to industrial customers and have some likelihood of adoption given a wide range of market environments. Considering many industrial customers purchase gas in bulk at rates lower than other customers, market experience has shown industrial customers require measures to be more economic than residential and commercial customers do. Thus, the measures deemed reasonably attractive to industrial customers tend to fair very well in a TRC ratio using the utility's avoided costs, which are often higher than industrial gas retail rates.

Figure 4-2 shows the economic gas savings potential as a percentage of gas consumption, with associated data presented in Table D-8 in Appendix D. Though it had the lowest technical potential as a percentage of consumption, the industrial sector had the highest percentages for economic potential. For the residential sector, the introduction of new whole-home new construction measures allowed the sector to increase economic savings despite the limited growth in residential consumption. Similarly, whole-building new construction practices in the commercial sector enable the increase in savings potential as a percent of commercial-sector consumption over time.

Figure 4-2. Gas Energy Economic Savings Potential by Sector as a Percent of Sector Consumption (%)

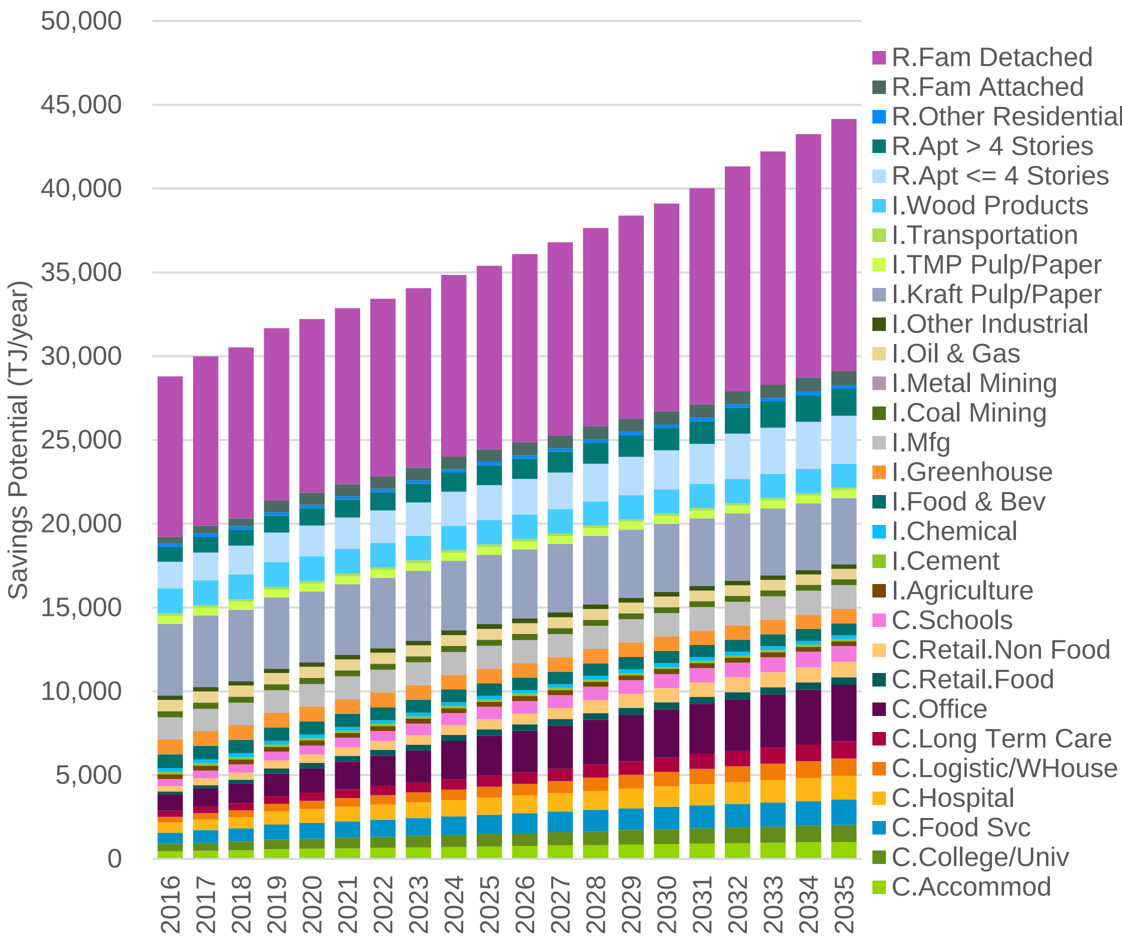


Source: Navigant

4.2.2 Results by Customer Segment

Figure 4-3 depicts the economic energy savings potential for all customer segments, and Table D-9 in Appendix D provides the corresponding data values. Depending on the customer segment, between 49% and 57% of the technical energy potential pass the economic screening threshold within the residential sector. The greatest reduction from technical potential to economic potential appeared in single-family attached homes, while the smallest reduction occurs in single-family detached homes. For the commercial customer segments, the reduction in economic potential relative to technical potential ranges from 59% to 92%. Non-food retail establishments see the greatest loss from non-economic potential, while long term care facilities are the most resilient. In the industrial sector, high-efficiency kilns do not pass the economic screen.

Figure 4-3. Gas Energy Economic Savings Potential by Customer Segment (TJ/year)



Source: Navigant

In general, the mix of economic energy savings from various customer segments within a given sector is similar between economic and technical potential. Detached single-family homes is the segment with the highest fraction of savings potential that are economic, and they provide the largest share of economic savings potential within the residential sector. Similarly, the mix of economic potential from the commercial segments do not change appreciably relative to the technical potential. The wood products segment falls from 19% of the industrial technical potential mix to 13% of the economic potential. Figure 4-4, Figure 4-5 and Figure 4-6 provide a breakdown of economic energy potential by customer segment and sector.

Figure 4-4. Residential Gas Energy Economic Potential Customer Segment Breakdown in 2025

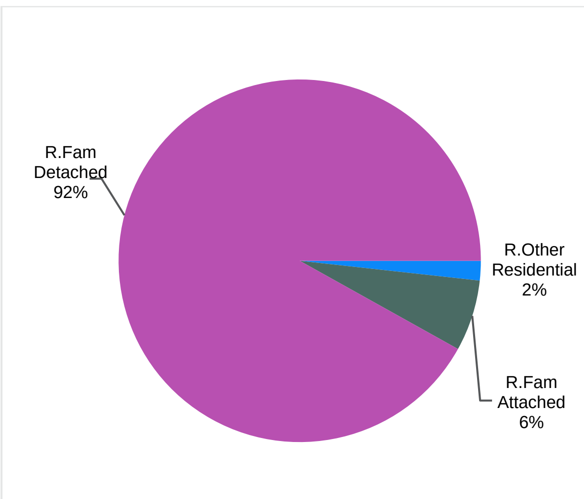


Figure 4-5. Commercial Gas Energy Economic Potential Customer Segment Breakdown in 2025

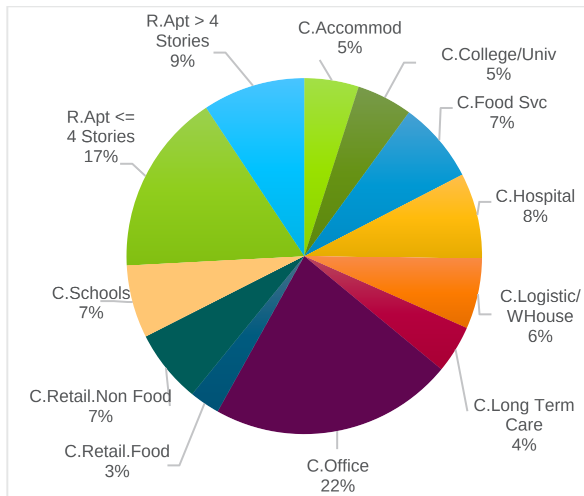

Figure 4-6. Industrial Gas Energy Economic Potential Customer Segment Breakdown in 2025

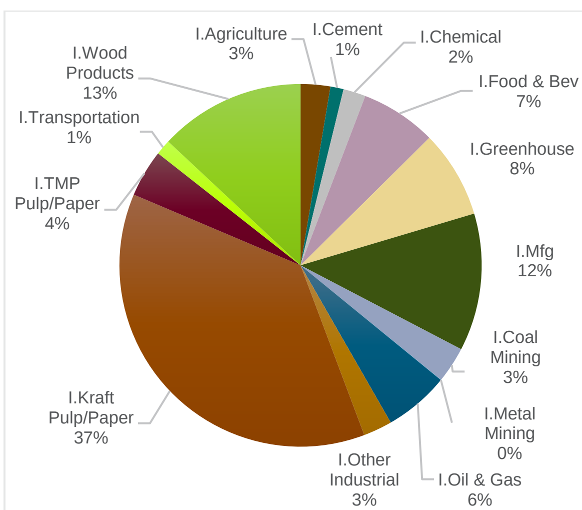
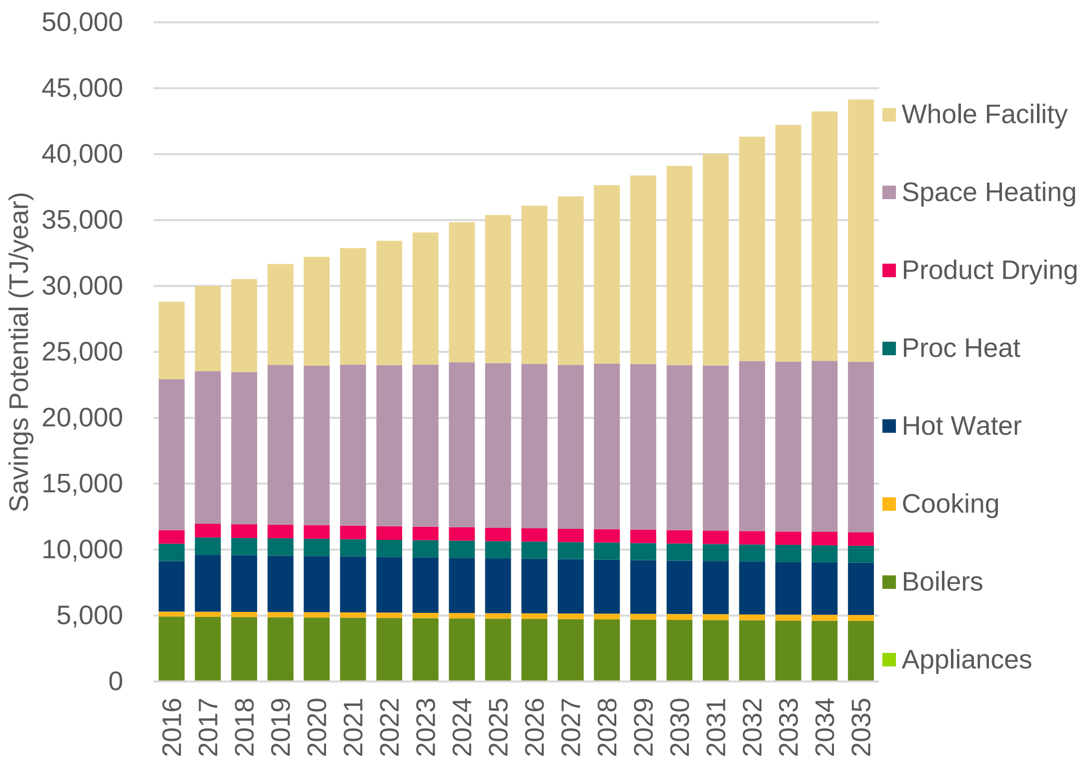


Source: Navigant

4.2.3 Results by End-use

Depending on the end-use category, between 0% and 100% of the technical energy potential is cost-effective. The least economic end-uses across all customer sectors are appliances (0% of technical potential), space heating (53% of technical potential), and product drying (54% of technical potential). Boilers, cooking, and process heat are end-use categories that have economic potential of 100% of technical potential. Figure 4-7, shows the economic gas potential by end-use, with associated data in Table D-10 in Appendix D.

Figure 4-7. Gas Energy Economic Savings Potential by End-Use (TJ/year)



Source: Navigant

Figure 4-8, Figure 4-9 and Figure 4-10 provide the breakdown of economic energy potential by end-use categories within each sector. In the residential sector, space heating decreases from 62% to 52%, while whole facility increases from 12% to 22%. Similarly, in the commercial sector, space heating decreases from 54% to 41% of the total, while whole facility increases from 35% to 47%. Product drying declines by 7 percentage points in the makeup of industrial potential.

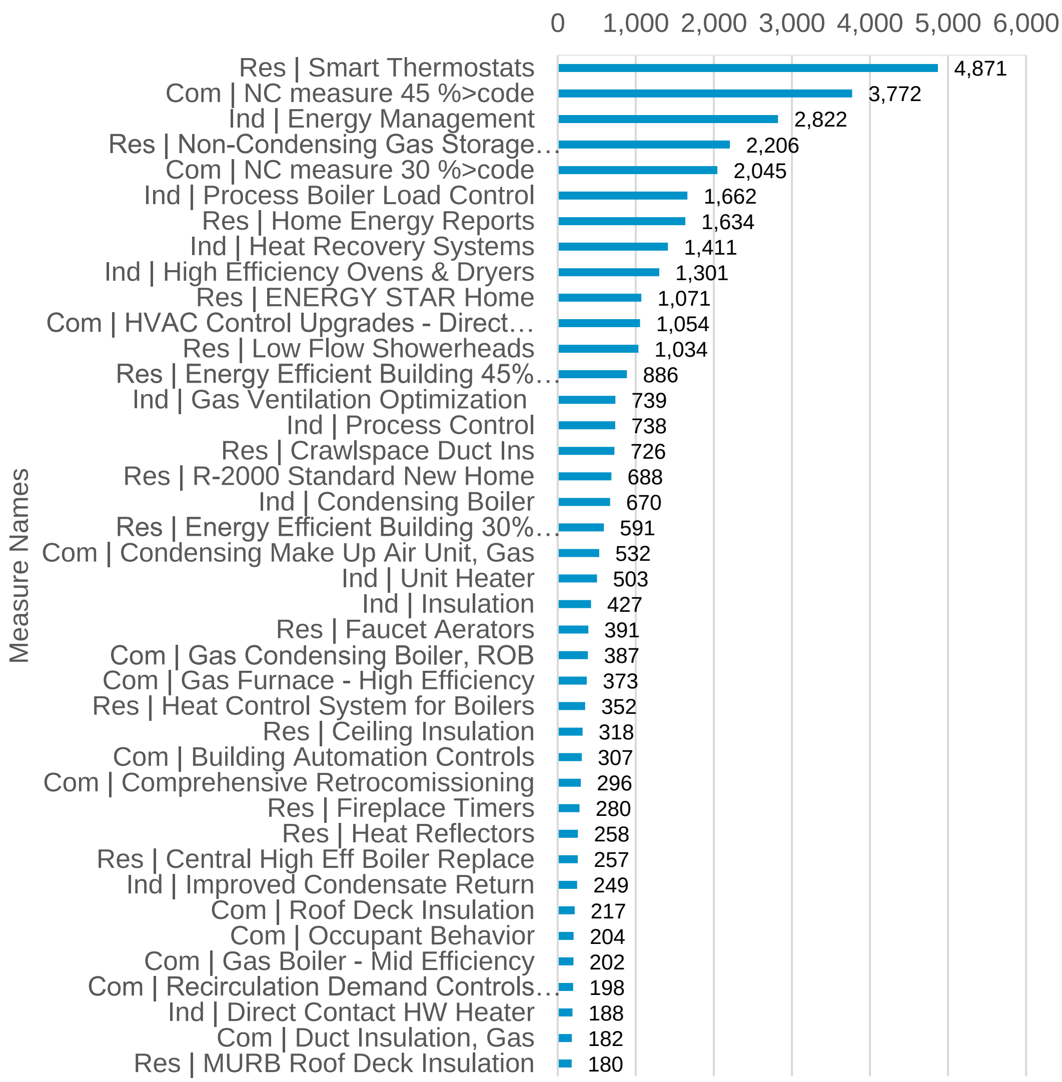
4.2.4 Results by Measure

The measure-level economic energy savings potential shown in Figure 4-11 is prior to adjustments made to competition groups as detailed in Section 3.2.4. The figure highlights the economic potential from the top 40 highest-impact measures. When compared with the top 10 technical potential measures, three residential measures (condensing and non-condensing tankless water heaters and condensing storage water heaters), and one commercial measure (wall insulation) are not economic and fall out of the top 40. Measures pertaining to the industrial sector, such as energy management and process boiler load control, move up the rankings due to their economic potential remaining similar to their respective technical potential.

Figure 4-11. Top 40 Measures for Economic Potential in 2025 (TJ/year)



Source: Navigant

Figure 4-12 provides a supply curve of savings potential versus levelized cost of savings in $/GJ for all measures considered in the study. This curve shows only those measures with a levelized cost less than $12/GJ. While the full curve extends beyond the $12/GJ point to measures with costlier savings, savings from these measures is negligible since the curve flattens out. The savings potential seen at a cost of $0/GJ is due to code-change measures, which have zero costs in the model.

Figure 4-12. Supply Curve of Gas Economic Potential (TJ/year) vs. Levelized Cost of Savings ($/GJ) in 2025

APPENDIX A. ADDITIONAL MODEL RESULTS AND INPUT ASSUMPTIONS

A.1 Detailed Model Results

See attachment, "FortisGas_Appendix_A1_2017-01-23.xlsx," for granular results from the model.

A.2 Measure List and Characterization Assumptions

See attachment, "FortisGas_Appendix_A2_2017-01-23.xlsx," for granular measure input to the model.

A.3 Other Key Input Assumptions

See attachment, "FortisGas_Appendix_A3_2017-01-23.xlsx," for key assumptions about building stocks, end-use intensities, avoided costs, discount rates, etc. used by the model.

APPENDIX B. APPROACH TO BASELINE CALIBRATION

B.1 End-Use Definitions

Table B-1. Description of End-Uses[44],

Segment	End-Use	Definition
Residential	Appliances	Large/small appliances including ovens, refrigerators, freezers, clothes washers, etc.
	Electronics	Televisions, computers and related peripherals, and other electronic systems
	Water Heating	Heating of water for domestic hot water use
	Lighting	Interior, exterior and holiday/seasonal lighting
	Other	Miscellaneous loads
	Space Cooling	All space cooling, including both central AC and room or portable AC
	Space Heating	All space heating, including both primary heating and supplementary heating
	Ventilation	Ventilation requirements for space heating/cooling including furnace fans
	Whole Facility	The whole facility end-use reflects the total customer load. The residential whole facility end-use is used to characterize new construction and behavioral measures that impact overall energy consumption. In the residential sector this includes as home energy reports, and new construction home/building measures such as ENERGY STAR and Net Zero homes.
Commercial	Cooking	Food preparation equipment including ranges, broilers, ovens, and griddles
	HVAC Fans/Pumps	HVAC auxiliaries including fans, pumps, and cooling towers
	Hot Water	Hot water boilers, tank heaters, and others
	Lighting	Interior, exterior and holiday/seasonal lighting for main building areas and secondary areas
	Office Equipment	Computers, monitors, servers, printers, copiers and related peripherals
	Other	Miscellaneous loads including elevators, gym equipment, and other plug loads
	Refrigeration	Refrigeration equipment including fridges, coolers, and display cases
	Space Cooling	All space cooling equipment, including chillers, and DX cooling.
	Space Heating	All space heating equipment, including boilers, furnaces, unit heaters, and baseboard units
	Whole Facility	The whole facility end-use reflects the total customer load. The commercial whole facility end-use is used to characterize new construction and behavioral measures that impact overall energy consumption. In the commercial sector this includes building automation controls, new construction measures, occupant behavior, and retro-commissioning.
Industrial	Boilers	Boilers for industrial applications
	Compressed Air	Air compressors and related equipment
	Fans & Blowers	Fans and blowers for ventilation, combustion and pneumatic conveyance
	Industrial Process	Industrial processes for various applications including mechanical, electrical, and chemical processes
	Lighting	Interior, exterior, and seasonal lighting loads
	Material Transport	Feedstock and product movement by conveyance or stackers
	Process Compressors	Process compressors
	Process Heating	Process heating including heat treatment and industrial ovens
	Product Drying	Industrial drying equipment and systems
	Space Heating	All non-process space heating equipment (e.g., comfort heating)
	Pumps	Process pump systems
	Refrigeration	Industrial refrigeration

[44] While not all end-uses are applicable to FortisBC Gas, this table shows definitions for all electric and gas end-uses.

Whole Facility	The whole facility end-use reflects the total customer load. The industrial whole facility end-use is used to characterize new construction and behavioral measures that impact overall energy consumption. In the industrial sector this includes energy management, and new plant measures.

B.2 Residential Sector – Additional Detail

In order to characterize the residential sector energy usage, Navigant developed a bottom-up analysis based on the mix of fuel shares and the types of equipment used for each end-use. Navigant developed these estimates based on a review of FortisBC Gas's 2012 REUS study and BC Hydro's 2014 REUS. Both of these end-use surveys provides detailed residential household data, and detailed information in relation to each of the end-uses, existing equipment, main and secondary fuel systems, and saturation levels for common energy efficiency measures. Using the data provided by the residential survey, Navigant developed specific fuel share and equipment estimates for each residential segment. The following sections summarized the approach for developing the following:

- **Residential Stock** for each residential segment
- **Fuel shares** and **equipment shares** for each residential segment in each region
- **End-use intensities (EUIs)** for each residential segment in each region

Fuel Shares and Equipment Shares

Using the data provided by the FortisBC 2012 REUS study, Navigant developed specific fuel share and equipment estimates for each residential segment in each region. The translation of data from the 2012 REUS study to Navigant's analysis was relatively straightforward given the granularity of the REUS data. For example, the residential survey reports most information aggregated based on four types of dwellings (Single Detached, Single Attached, Apartments, and Other), which are largely consistent with the residential segments employed for this CPR.

- Table B-2 shows the mix of fuel shares for each residential segment by region[45]
- Table B-3 shows the types of equipment used for the **Space Heating**, and **Water Heating** end-uses by residential segment and region
- Table B-4 shows the types of **Appliance** equipment by residential segment and region

[45] This table shows the gas share of appliances at 100% and the electric share at 0%. This does not mean that all appliances use gas and that no appliances use electricity, but rather reflect the fact that - from the perspective of a gas utility (FortisBC Gas and PNG) - all gas appliances are fueled by gas. For the electric utilities (BC Hydro and Fortis Electric), the opposite is true – all electric appliances are fueled by electricity such that the electric fuel share is 100%.

Table B-2. FortisBC Gas Residential Fuel Shares (Percentage of FortisBC Customers Using Each Energy Type)

Building Type	End-use	Lower Mainland		Vancouver Island		Southern Interior		Northern BC	
		Gas	Electric	Gas	Electric	Gas	Electric	Gas	Electric
Single Family Detached/Duplexes	Space Heating	89%	9%	64%	32%	85%	11%	86%	9%
	Water Heating	84%	15%	70%	29%	72%	27%	75%	24%
Single Family Attached	Space Heating	76%	23%	61%	39%	89%	11%	91%	9%
	Water Heating	69%	30%	66%	34%	85%	15%	79%	21%
Apartments <= 4 Storeys	Space Heating	30%	69%	18%	80%	35%	62%	29%	71%
	Water Heating	69%	30%	50%	48%	64%	36%	63%	37%
Apartments > 4 Storeys	Space Heating	30%	69%	18%	80%	35%	62%	29%	71%
	Water Heating	69%	30%	50%	48%	64%	36%	63%	37%
Other Residential	Space Heating	89%	9%	64%	32%	85%	11%	86%	9%
	Water Heating	89%	3%	82%	10%	79%	13%	81%	11%

End-Use Intensities (EUIs)

The next step of the residential calibration to FortisBC Gas's Reference Forecast process required the roll up of the fuel share and equipment share estimates in order to establish EUIs for each residential segment in each region. Based on this approach, Navigant developed bottom-up EUI estimates for Space Heating, Water Heating, and Appliances. The EUIs for the Other end-use was estimated based on the 2010 FortisBC Gas CPR.

Table B-5 shows an example of the calibration process followed for Single Family Detached/Duplexes in the Southern Interior. The process used to calibrate the estimate of energy use builds on an estimate of the percentage of homes with a particular end-use and fuel type, using a particular type of equipment and efficiency within an end-use. The fuel shares (column B), equipment shares (column E), and an estimated level of energy use for each equipment type (column F) are multiplied to obtain an estimated UEC (column G). In the example below, column G sums the total consumption across all water heating equipment. The team summed the resulting EUCs across end-uses to obtain the segment-level intensity (GJ per year), and then calibrated to match the actual target intensity stemming from FortisBC Gas sales data.

This same process is repeated across all residential and commercial segments in each region. Ultimately, EUIs that matched the segment-level sales targets in the base year were determined for each end-use and segment, and across all regions.

With the base year EUIs established, the Reference Case EUIs were determined based on the residential and commercial sector EUI trends. The approach for developing the EUI trends is described in the body of the report.

Table B-7, Table B-8, and Table B-9 show the residential EUIs used in the Reference Case for the Southern Interior, Vancouver Island, and Northern BC regions. The EUIs presented in these tables start with the base year EUIs shown in Table B-6 and adjusted based on the EUI trends. The Lower Mainland EUIs are included the main body of the report.

B.3 Commercial Sector – Additional Detail

To characterize the Commercial sector, Navigant first developed a bottom-up analysis based on the mix of fuel shares and the types of equipment used for each end-use. Navigant developed these estimates based primarily on a review of BC Hydro's 2014 CEUS. BC Hydro's CEUS was preferred over the FortisBC 2015 CEUS given the increased granularity provided by the BC Hydro data. BC Hydro's 2015 CEUS study provides detailed information for several commercial segments across the CPR regions, including commercial building characteristics, main and secondary fuel systems, fuel shares and common commercial equipment, and saturation levels for common energy efficiency measures.

The following sections summarized the approach for developing the following:

- **Fuel Shares** and **Equipment Shares** for each commercial segment
- **End-use intensities (EUIs)** for each commercial segment
- **Commercial Floor Space Stock** for each commercial segment

Fuel Shares and Equipment Shares

Fuel share estimates were developed for end-uses that generally show a split across gas and electricity supply: Cooking, Hot Water, and Space Heating. All other end-uses were treated as electric-only end-uses, with the exception of the Other end-use.

Using the data provided by BC Hydro's 2014 CEUS, Navigant developed fuel share and equipment estimates for each commercial segment. The 2014 CEUS results are disaggregated across each region and are reported for each commercial segment.

Table B-10 and Table B-11Table B-11 shows the space heating equipment shares. The team used these space heating equipment shares to develop space heating EUIs, while EUIs for other end-uses were determined based on the 2010 CPR and did not require equipment shares.

Table B-11 summarize the results of this analysis. These tables show the estimated fuel shares and equipment shares for each commercial segment and climate region.

Table B-10. Commercial Fuel Shares (Percentage of Segment Using Each Energy Type)

Building Type	End-use	Lower Mainland		Vancouver Island		Southern Interior		Northern BC	
		Gas	Electric	Gas	Electric	Gas	Electric	Gas	Electric

Table B-11 shows the space heating equipment shares. The team used these space heating equipment shares to develop space heating EUIs, while EUIs for other end-uses were determined based on the 2010 CPR and did not require equipment shares.

Table B-11. Commercial Equipment Shares (%)

End-Use Intensities (EUIs)

The next step of the commercial calibration process required the roll up of the fuel share and equipment share estimates in order to establish EUIs for each commercial segment in each region. Based on this approach, Navigant developed bottom-up EUI estimates for the Space Heating end-use. For other end-uses including Water Heating, Cooking, and Other, EUI estimates were developed based on a review of the 2010 CPR, and adjusted to the base year (2014) according to the EUI trends established for the Reference Case for FortisBC Gas.

Table B-12 presents the EUIs established for each end-use, and commercial segment. With the EUIs established for the base year, the Reference Case EUIs were determined based on the commercial EUI trends. The approach for developing the commercial EUI trends is described in the body of the report.

Table B-12: Base Year Commercial EUIs (MJ/m2) by Segment and Region

Description of EUI Trending Approach

BC Hydro's 2014 CEUS surveyed commercial customers across each commercial segment in relation to upgrades made to end-use equipment in the past 5 years. The annual incidence of end-use equipment upgrades is then used to estimate the reduction in energy consumption from the adoption of higher efficiency equipment. Table B-13 summarizes an example of the incidence of water heating equipment upgrades.

Table B-13: Incidence of Water Heating Commercial Equipment Upgrades (2014 CEUS)

Segment	Equipment Upgrades	
	Past 5 years (%)	Estimate per year (%)
Accommodation	25.0%	5.0%
Colleges & Universities	33.0%	6.6%
Food Service	32.5%	6.5%
Hospital	20.0%	4.0%
Logistics & Warehouses	22.0%	4.4%
Long Term Care	29.0%	5.8%
Offices	12.0%	2.4%
Other	12.0%	2.4%
Retail - Food	27.0%	5.4%
Retail - Non Food	27.0%	5.4%
Schools	19.0%	3.8%

Source: Navigant analysis of BC Hydro 2014 CEUS

Although the 2014 CEUS did not survey the type of equipment or the efficiency of the upgrades, Navigant estimated the potential reduction in consumption by analyzing the inputs used to characterize conservation measures corresponding to each end-use. For example, the team estimated the average improvement in water heating measure efficiency at approximately 17% such that the efficient consumption is 83% of the base consumption. Navigant determined this improvement from characterization of water heating measures. The difference between the efficient and base consumption of the water heating measures listed below is, on average, 17%:

- Natural Gas On-Demand Water Heaters
- Natural Gas Storage Water Heaters
- Low-Flow Showerheads
- Faucet Aerators
- Natural Gas Hot Water Supply Boilers
- Recirculation Demand Controls for Hot Water

Navigant followed this process across all commercial segments for end-uses for which equipment upgrade information is reported in the 2014 CEUS. This includes the following end-uses:

- Lighting;

- Water Heating;
- Space Cooling;
- HVAC Fans/Pump; and
- Space Heating

Two of these end-uses – water heating and space heating – are applicable to gas consumption. For the remaining gas end-uses – cooking and other – survey information needed to develop EUI trends was not reported and are assumed to remain flat. Table B-14 summarizes the results for each end-use.

Table B-14: Commercial Measure Efficiency – Base vs. EE

End-Use	Improvement in End-Use Efficiency (%)	EE as % of Base consumption (%)
Water Heating	17%	83%
Space Heating	42%	58%

Source: Navigant analysis of measure characterization

Based on this approach, if the Water Heating EUI for the Accommodation segment is estimated at approx. 250 MJ/m2 in 2014, the EUI is estimated to decrease by 0.8% in 2015, down to 248 MJ/m2. This calculation is included below:

$$EUI_{2015} = EUI_{2014} * (EE\ equipment_{\%} * EE\ consumption_{kWh} + Base\ equipment_{\%} * Base\ consumption_{kWh})$$

$$248\frac{MJ}{m2} = 250\frac{MJ}{m2} * (5\% * 83\% + 95\% * 100\%)$$

A limitation of this approach is that the estimated decrease in EUI inherently reflects the impact of DSM programs. Navigant has not attempted to extract the impact of DSM participation from the EUI trends.

Table 2-28 in the main body of this report, shows the EUI trends determined for each end-use and commercial segment.

Table B-15,
Table B-16, and Table B-17, show the commercial EUIs used in the Reference Case for the Southern Interior, Vancouver Island, and Northern BC regions. The Lower Mainland EUIs are included in the main body. The EUIs presented in these tables were initially based on the Base Year EUIs shown in

Table B-12 and then were adjusted based on the EUI trends. The Lower Mainland EUIs are included the main body of the report.

B.4 FortisBC Gas Industrial Sector – Additional Detail

This section describes the approach used to develop the Reference Case for the industrial sector.

FortisBC Gas's load forecast reports industrial sector gas sales as a whole and not broken down into individual industrial segments. To disaggregate the sector-wide forecast into industrial segments, Navigant and FortisBC worked together to develop gas sales projections which aligned with the sector-level forecast established for each region.

As a starting point, Navigant applied the electricity demand growth rates established for BC Hydro's Reference Case. FortisBC Gas reviewed those assumptions and directed Navigant to make adjustment to certain industrial segments which did not align with FortisBC Gas projections. These adjusted growth rates were used to estimate a forecast of gas consumption for each segment through 2035. A key aspect of this analysis is that this estimated forecast - determined based on adjusted growth rates – needed to reconcile with FortisBC Gas's sector-level forecast FortisBC Gas.

The steps to develop the Reference Case forecast are outlined below:

- Apply the adjusted growth rates to the base year (2014) consumption and sum the projected sales across each region to obtain a sector-level sales forecast (the "estimated" consumption forecast).
- Compare the estimated consumption across every 5-year period (e.g., 2020, 2025, 2030, and 2035) against the forecast 2035 consumption, and determine the difference (e.g., a surplus or a deficit)
- If the estimated consumption is greater than (or less than) the forecast consumption in each milestone year, reallocate the surplus or deficit across each segment according to each segment's contribution (%) to the regional total (e.g., if Pulp & Paper TMP accounts for 20% of industrial consumption then reallocate 20% of the surplus/deficit to the TMP segment) – this is the "re-adjusted" consumption
- Using the re-adjusted consumption determined in each milestone year, re-calculate the 5-year growth rates of each segment. These re-adjusted growth rates will ensure that the estimated consumption reconciles with the forecast consumption.
- These re-adjusted growth rates are used to develop the industrial sector Reference Case.

APPENDIX C. FORTISBC GAS - INTERACTIVE EFFECTS OF EFFICIENCY STACKING

The results shown throughout the body of this report assume that measures are implemented in isolation from other efficient measures and do not include adjustments for interactive effects of efficiency stacking (with some exceptions).[46] Interactive effects from efficiency stacking are different from cross-end-use interactive effects (e.g., efficient lighting impacts heating/cooling loads), which are present regardless of stacking assumptions and are included in the reported savings estimates. This appendix describes the challenges related to accurately determining the impacts of efficiency stacking, and why Navigant has modelled savings as though measures are implemented independently from others. Although the examples in this appendix focus on gas measures, the concepts are dually applicable to electric measures.

C.1 Background on Efficiency Stacking

When two or more measures that impact the same end-use energy consumption are installed in the same building, the total savings that can be achieved are less than the sum of the savings from those measures independently. For example, in isolation, the installation of a high efficiency boiler might save 11% of gas consumption relative to a baseline (lower efficiency) boiler, while ceiling insulation might save 71% of gas consumption relative to a baseline insulation level. However, if both the boiler and the insulation are installed in the same facility, the savings from the high efficiency boiler decrease due to the reduced need for space heating caused by better insulation.

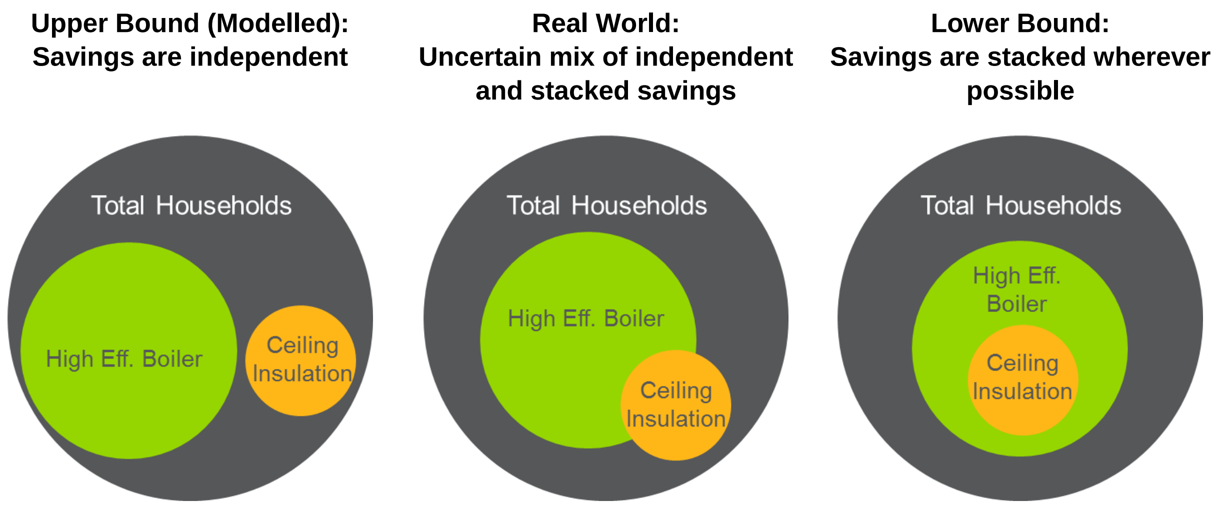
To generalize this concept Navigant refers to measures that actually convert energy as *engines* (boilers, light bulbs, motors, etc.). We refer to measures that impact the amount of energy that engines must convert as *drivers* (insulation, thermostats, lighting controls, etc.). Anytime an engine and driver are implemented in the same building, the expectation is that savings from the engine measure will decrease.[47]

Figure C-1 provides an illustration of three different efficiency stacking approaches. The modelled approach assumes no overlap in measure implementation and no efficiency stacking, which leads to an upper bound on savings potential. The opposite of the modelled approach is to assume all measures are stacked wherever possible, which provides a lower bound on savings. Lastly, there is the real-world approach where some measures are implemented in isolation and others are stacked. Unfortunately, the data is simply not available to accurately estimate the savings from the real-world approach.

[46] Wherever savings were derived from building energy model simulations evaluating bundled measures, interactive effects of efficiency stacking are included in the savings estimates (e.g., ENERGY STAR New Homes, Net-Zero New Homes, etc.).

[47] In practice it does not matter whether one assumes the engine's savings decrease or the driver's savings decrease, as the final savings result is the same. In this discussion, the team has chosen to always reduce the savings from the engine measures, while holding the savings from the driver measures fixed.

Figure C-1. Venn Diagrams for Various Efficiency Stacking Situations



Area of colored circle represents the number of households with a given savings opportunity. Overlapping circles indicate a household has implemented both measures.

C.2 Illustrative Calculation of Savings after Efficiency Stacking

For a very simplistic scenario looking at only two measures, it is possible to determine the stacked savings from the lower bound approach, which assumes efficient measures are stacked wherever possible. To find the high efficiency boiler's savings relative to the baseline after stacking, one must perform several steps:

1. Find the complement of the insulation's savings percentage:

   Insulation Savings Complement = 100% - Insulation Savings
   Insulation Savings Complement = 100% - 71% = 29%

2. Reduce the boiler's unstacked savings by the complement of the insulation's savings:

   Stacked Boiler Savings = Unstacked Boiler Savings x Insulation Savings Complement
   Stacked Boiler Savings =11% x 29% = 3.2%

3. Find the greatest percentage of homes where boiler and insulation stacking is possible:

   % of Homes with Stacking = Homes with Insulation / Homes with Boilers x 100%
   % of Homes with Stacking = 145,300 / 720,200 x 100% = 20.2%

4. Calculate the boiler's weighted average savings across all homes with boilers:

   Weighted Boiler Savings = Stacked Boiler Savings x % of Homes with Stacking +
   Unstacked Boiler Savings x (100% - % of Homes with Stacking)
   Weighted Boiler Savings = 3.2% x 20.2% + 11% x (100% - 20.2%) = 9.4%

Table C-1 provides an example of the technical potential from the boiler and insulation before and after stacking. As expected, the combined savings from the measures treated independently exceeds the combined savings after stacking.

Table C-1. Comparison of Savings Before and After Stacking

	High Efficiency Boiler	Ceiling Insulation	Combined Technical Potential
Applicable Households (households)	720,200	145,300	
Savings treated independently (no stacking)			
Savings Relative to Baseline (%)	11%	71%	
Total Technical Potential in Region (TJ/year)	2,540	1,860	4,400
Savings treated interactively (stacking)			
Savings Relative to Baseline (%)	9.4%	71%	
Total Technical Potential in Region (TJ/year)	2,176	1,860	4,036

C.3 Impetus for Treating Measure Savings Independently

Although it is possible to find the lower bound on savings with just one driver and one engine measure, the process quickly becomes intractable when multiple drivers and engines can be installed in the same facility. Table C-2 lists all of the engine and driver measures included in this study that could have interactive effects within the gas residential space heating end-use (which is just one of many end-uses across multiple sectors where stacking could occur).

Table C-2. Measures with Opportunity for Stacking in Residential Gas Space Heating End-use

Engine Measures	Driver Measures
Boiler Tune Up	Air Infiltration
Central High Eff Boiler Replace	Attic Duct Insulation
Combination System	Attic Insulation
Direct Vent Heaters	Basement Insulation
Efficient Fireplaces	Ceiling Insulation
Furnace Early Retirement	Crawlspace Duct Insulation
High Eff Boiler Replace	Energy Star Windows
High Eff Furnace Replace	Fireplace Timers
Vertical Direct Vent Fireplaces	Heat Reflectors
	Smart Thermostats
	Wall Insulation
	Window Film

Determining the appropriate stacking and correctly weighting the savings percentages from each of the engine measures requires:

- Case-by-case expert judgment about the combinations of driver and engine measures that might realistically be found in the same building, given historic and future construction practices;
- The conditional probability that a building has an inefficient driver “A” and an inefficient engine “B” for all drivers and engines relevant to a given end-use;
- In-depth knowledge of program design and how managers are considering pursuing participants and bundling measure offerings.

Answering the bullets above is beyond the scope of this study.

Lastly, at low levels of customer participation, it’s clear that assuming savings are independent is the best representation of what actual measure stacking would be. When customer participation is high, the “real-world” scenario is the best representation of actual measure stacking. Thus, under the plausible ranges of customer participation, the modelled (upper bound) scenario is likely to be a better representation of actual measure stacking than the lower bound scenario.

As such, this report does not attempt to quantify the impact from efficiency stacking within the modelled service territories.

[48] While apartment buildings are prefaced with a "R" (for residential), their savings are grouped into and reported under the commercial sector. Apartments are labelled with an "R" because they are included in the residential sector for purposes of the base year and reference case analysis.

5. MARKET POTENTIAL FORECAST

This section contains details of the market potential analysis that Navigant conducted for FortisBC Gas's service territory, including the following:

- Section 5.1 describes the approach to estimating market potential, including discussion of the model calibration steps and the strategy selected for simulating incentives in the analysis.
- Section 5.2 provides overall gas market potential estimates, as well as savings by sector, customer segment, end use, and certain measures.
- Section 5.3 follows with details of the associated budgets and cost effectiveness results under the TRC test across all sectors, which is consistent with the methodology Navigant used for the economic potential presented in Section 4.
- Section 5.4 provides the economic, market potential, and cost effectiveness results under the modified-TRC (mTRC) test across all sectors.
- Section 5.5 provides the economic, market potential, and cost effectiveness results under the Hybrid mTRC/TRC case (described below).

5.1 Approach to Estimating Market Potential

Market potential is a subset of economic potential that considers the likely rate of DSM acquisition, given factors like the rate of equipment turnover (a function of a measure's lifetime), simulated incentive levels, consumer willingness to adopt efficient technologies, and the likely rate at which marketing activities can facilitate technology adoption. The adoption of DSM measures can be broken down into calculation of the "equilibrium" market share and calculation of the dynamic approach to equilibrium market share, as discussed in more detail below.

Market potential differs from program potential in that market potential does not specifically take into account the various delivery mechanisms that can be used by program managers to tailor their approach depending on the specific measure or market. Rather, market potential represents a high-level assessment of savings that could be achieved over time, factoring in broader assumptions about customer acceptance and adoption rates that are not dependent on a particular program design. Additional effort is typically undertaken by program designers, using the directional guidance from a market potential study, to develop detailed plans for delivering conservation programs.

This report presents market potential results from three distinct approaches to screening measures for cost effectiveness. The objective for assessing these three approaches was to consider various possible cost effectiveness environments over the future of this long-range analysis by incorporating the different cost effectiveness approaches present at the time of the analysis. The regulatory environment for FortisBC Gas at the time of this analysis allowed the utility to spend up to 33% of its entire DSM portfolio on measures or programs that require an mTRC to be cost effective.[1] To date, FortisBC Gas's experience is that, typically, most programs in the residential sector require the mTRC. Since FortisBC Gas uses a

[1] The formulation of the mTRC benefit-cost test is the same as the TRC test, with the exception that the avoided costs stem from a zero emission energy supply alternative (ZEEA) cost and a 15% non-energy benefits adder increases benefits.

combination of TRC and mTRC benefit-cost tests to screen measures and programs within their portfolio, Navigant estimated market potential using the following benefit-cost tests to screen cost effective measures:

1. **TRC only:** This case uses the TRC test across all sectors and presents results consistent with the screening method used in the previous CPR report focusing on technical and economic potential.
2. **mTRC only:** This case uses the mTRC test across all sectors.
3. **Hybrid mTRC/TRC:** This case uses the mTRC test for the residential sector and the TRC test for the commercial and industrial (C&I) sectors, which is most analogous to FortisBC Gas's actual DSM program environment.[2]

Table 5-1 below summarizes the key methodology considerations and decision points informing the analysis in this report, with more detail provided in the report sections noted in the right-hand column of the table. Navigant and FortisBC Gas agreed upon this methodology through discussions about which approach best serves the needs of the utility for understanding market savings potential. Since this study's scope for market potential estimates are not intended to be program-specific and are most reasonable when results are considered in aggregate, the methodology presented here focuses primarily on portfolio-level or sector-level approaches. However, FortisBC Gas selected five high impact measures for measure-level calibration, which is discussed in Section 5.1.6.

[2] Model limitations prevented the team from implementing a strict 33% cap on spending directed towards measures requiring the mTRC screen. However, the cap was approximated by only allowing residential measures to screen the mTRC test for cost-effectiveness.

Table 5-1. Market Potential Methodology Overview

Methodology Parameters	Approach	Report Section
Benefit-cost test screen	Use the TRC as the primary screen for technical, economic, and market potential, with economic and market potential also calculated using the mTRC and a hybrid of mTRC/TRC tests.	5.1
Diffusion parameters	Adjust diffusion parameters within ranges recommended by industry standard data sources to produce savings that are reasonably aligned with FortisBC DSM sector-level historical achievements. Customize the diffusion parameters for the five high impact measures selected in advance by FortisBC Gas in order to align with historic savings at the measure level.	5.1.1, 5.1.2, and 5.1.6
Budget constraints	Do not apply budget constraints.	5.1.4
Incentive strategy	Set incentives as a percent of the incremental cost for all measures pertaining to each sector, such that the simulated percentages of total spending from incentives versus non-incentive costs aligns with historic values across the sector.	5.1.5 and 5.1.7
Treatment of admin and fixed costs	Exclude portfolio-level fixed costs; use a sector-level $/GJ cost derived from historic non-incentive program spending, which includes fixed and variable administrative costs.	5.3.1 and 5.3.2
Net-to-Gross (NTG)	Focus on gross savings within the report, and include discussion on impacts of NTG factors at the sector level for high-level estimates of net savings (consistent with the approach used for technical and economic potential)	5.2.6
Re-participation	Assume 100% of measures re-participate as an efficient measure at the end of their measure life	N/A
Codes and standards	Use the same assumptions about codes and standards as in technical and economic potential	5.2.5

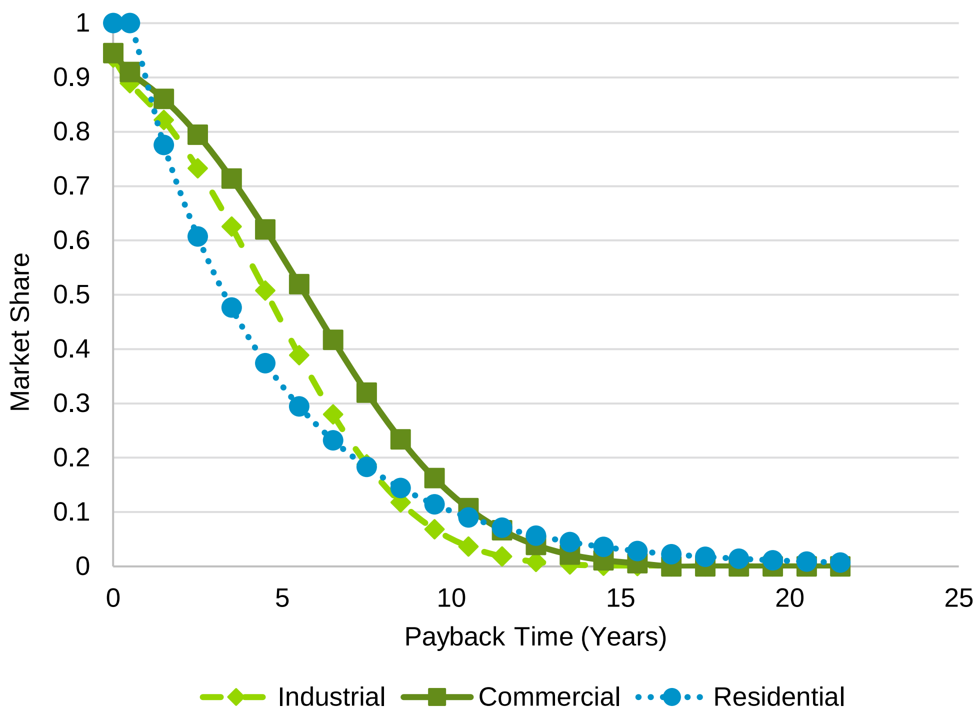
5.1.1 Calculation of "Equilibrium" Market Share

The equilibrium market share can be thought of as the percentage of individuals choosing to purchase a technology provided those individuals are fully aware of the technology and its relative merits (e.g., the energy- and cost-saving features of the technology). For DSM measures, a key differentiating factor between the base technology and the efficient technology is the energy and cost savings associated with the efficient technology. Of course, that additional efficiency often comes at a premium in initial cost. This study calculates an equilibrium market share as a function of the payback time of the efficient technology relative to the inefficient technology. In effect, measures with more favorable customer payback times will have higher equilibrium market share, which reflects consumers' economically rational decision making. While such approaches certainly have limitations, they are nonetheless directionally reasonable and simple enough to permit estimation of market share for the hundreds of technologies appearing in most potential studies.

To inform this CPR, Navigant used equilibrium "payback acceptance" curves that Navigant developed using primary research in the US Midwest in 2012.[3] To develop these curves, Navigant relied on surveys of 400 residential, 400 commercial, and 150 industrial customers. These surveys presented decision makers with numerous "choices" between technologies with low up-front costs, but high annual energy costs, and measures with higher up-front costs but lower annual energy costs. Navigant conducted statistical analysis to develop the set of curves shown in Figure 5-1, which Navigant used in this CPR. Though FortisBC-specific data were not available to estimate these curves, Navigant considers that the nature of the customer decision-making process is such that the data developed using North American customers represents the best industry-wide data available at the time of this study.

As the curves show, the proportion of customers who will accept different payback periods for an energy efficiency investment is different for residential, commercial and industrial customers.[4] The model uses this information to simulate how customers in each sector will accept measures with differing payback periods.

Figure 5-1. Payback Acceptance Curves



Source: Navigant

Since the payback time of a technology can change over time, as technology costs and/or energy costs change over time, the "equilibrium" market share can also change over time. The equilibrium market

[3] A detailed discussion of the methodology and findings of this research are contained in "Demand Side Resource Potential Study," prepared for Kansas City Power and Light, August 2013.

[4] These payback curves represent customer payback acceptance in aggregate across each sector. In practice, customer behavior can vary across sub-sectors. However, there is minimal industry-wide data available on customer payback acceptance at the sub-sector level.

share is therefore recalculated for every year of the forecast to ensure the dynamics of technology adoption take this effect into consideration. As such, “equilibrium” market share is a bit of an oversimplification and a misnomer, as it can itself change over time and is therefore never truly in equilibrium, but it is used nonetheless to facilitate understanding of the approach.

5.1.2 Calculation of the Approach to Equilibrium Market Share

Two approaches are used for calculating the approach to equilibrium market share, one for technologies being modeled as retrofit (RET) measures, and one for technologies simulated as replace-on-burnout (ROB) or new construction (NEW measures).[5] A high-level overview of each approach is provided below.

5.1.2.1 Retrofit Technology Adoption Approach

RET technologies employ an enhanced version of the classic Bass diffusion model[6,7] to simulate the S-shaped approach to equilibrium that is observed again and again for technology adoption. Figure 5-2 provides a stock/flow diagram illustrating the causal influences underlying the Bass model. In this diagram, market potential adopters “flow” to adopters by two primary mechanisms – adoption from external influences, such as marketing and advertising, and adoption from internal influences, or “word-of-mouth.” Navigant estimated the “fraction willing to adopt” using the payback acceptance curves illustrated in Figure 5-1.

Navigant estimated the marketing effectiveness and word-of-mouth parameters for this diffusion model by drawing upon case studies where these parameters were estimated for dozens of technologies.[8] Recognition of the positive, or self-reinforcing, feedback generated by the “word-of-mouth” mechanism is evidenced by increasing discussion of the concepts such as social marketing as well as the term “viral,” which has been popularized and strengthened most recently by social networking sites such as Twitter, Facebook and YouTube. However, the underlying positive feedback associated with this mechanism has been ever present and a part of the Bass diffusion model of product adoption since its inception in 1969.

[5] Each of these approaches can be better understood by visiting Navigant’s technology diffusion simulator, available at: http://forio.com/simulate/navigantsimulations/technology-diffusion-simulation.

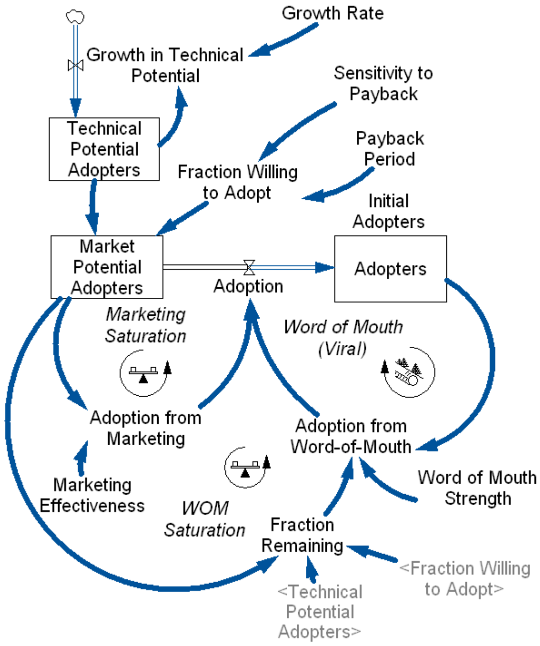
Figure 5-2. Stock/Flow Diagram of Diffusion Model for New Products and Retrofits



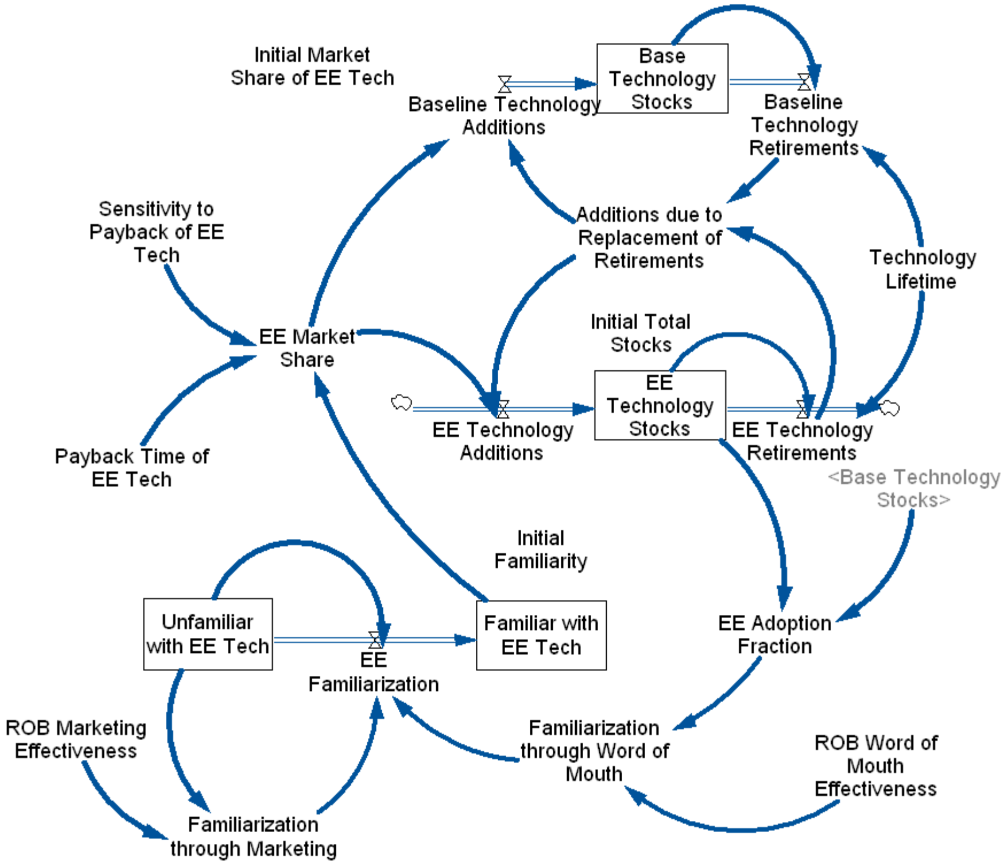
Source: Navigant

The model illustrated above generates the commonly seen S-shaped growth of product adoption and is a simplified representation of that employed in DSMSim™.

5.1.2.2 Replace-on-Burnout Technology Adoption Approach

The dynamics of adoption for ROB technologies are somewhat more complex than for NEW/RET technologies since it requires simulating the turnover of mostly long-lived technology stocks. The DSMSim™ model tracks the stock of all technologies, both base and efficient, and explicitly calculates technology retirements and additions consistent with the lifetime of the technologies. Such an approach ensures that technology “churn” is considered in the estimation of market potential, since only a fraction of the total stock of technologies are replaced each year, which affects how quickly technologies can be replaced. A model that endogenously generates growth in the familiarity of a technology, analogous to the Bass approach described above, is overlaid on the stock tracking model to capture the dynamics associated with the diffusion of technology familiarity. Figure 5-3 graphically illustrates a simplified version of the model employed in DSMSim™.

Figure 5-3. Stock/Flow Diagram of Diffusion Model for ROB Measures



Source: Navigant

5.1.3 Behavioral Measures

Behavior measures typically impose little to no direct costs to the participant[9] and their rate of adoption is highly dependent on the marketing and incentive efforts taken by program administrators. Given these unique characteristics of behavior measures, the payback acceptance curves and technology diffusion models have limited applicability to these types of measures. As such, this study models the adoption of behavior measures in terms of an equilibrium saturation level relative to economic potential and a given amount of time to reach that equilibrium state.

[9] Participants may incur indirect costs through implementation of adjustments to typical operations in response to energy information feedback (e.g., through upgrading a water heater). However, estimating these indirect costs requires additional data on the actions taken by the participant outside of the program and is beyond the scope of this analysis.

This study includes four measures that are distinctly behavioral:

- Commercial Comprehensive Retrocommissioning[10]
- Commercial Occupant Behavior[11]
- Industrial Energy Management[12]
- Residential Home Energy Reports[13]

For each of these measures, the team used multiple sources of information to define the equilibrium saturation level and the duration of time required to reach that level. Figure 5-4 illustrates the saturation trajectory as a percentage of economic potential for each of the behavior measures. Although the adoption of behavior measures is not linked to customers' payback acceptance time, the market potential for behavior measures is still dependent on cost effectiveness by means of the economic potential. As such, the realized market savings from these measures can vary between the TRC and mTRC cases if economic potential varies.

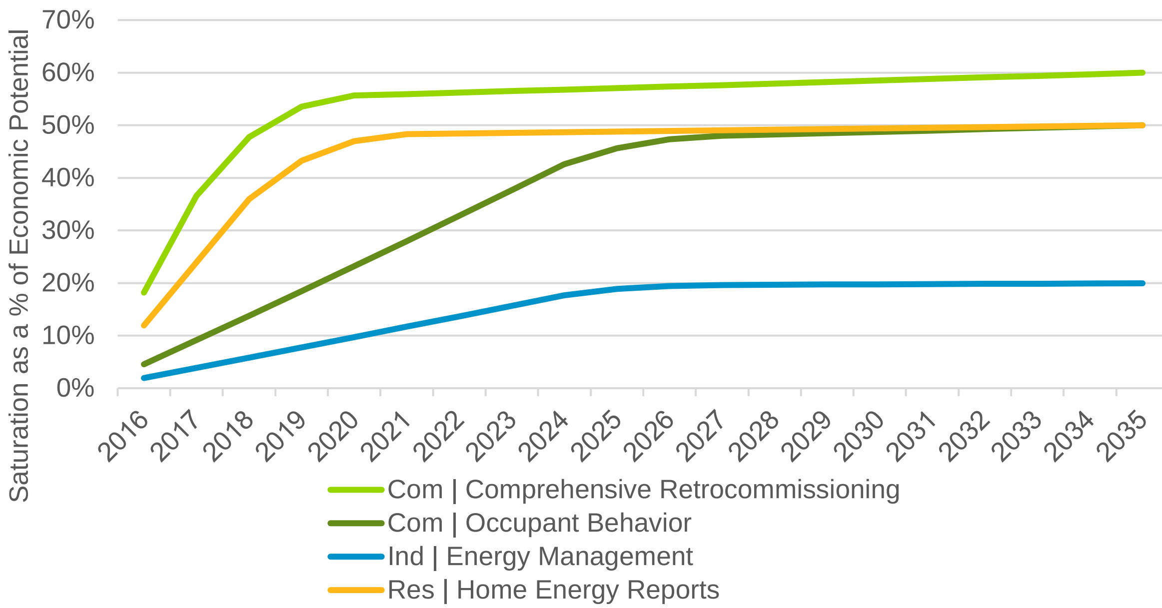
[10] Commercial comprehensive retrocommisioning is similar to FortisBC Gas's Continuous Energy Optimization offering, so the annual ramp rate was trended with historic savings from that measure. Differing from the other behavioral measures, the characterization of retrocommisioning includes some upfront costs to the participant (e.g., paying for a portion of staff training). Since it is uncertain whether comparable training would be available absent program offerings and enrollment efforts, the study treats this measure as a behavior measure that is dependent on on-going support from program administrators.

[11] The team chose the adoption trajectory for the commercial occupant behavior measure after reviewing research conducted for the California Public Utilities Commission on similar measures and after reviewing the trends in historic savings from similar measures within FortisBC Gas's Energy Specialist program.

[12] Navigant designed the rollout of industrial energy management to mimic historical participation levels within BC Hydro's more mature program focusing on industrial energy management. This trajectory implies participation of about nine customers/sites per year, which aligns well with the number of annual customers that participated in BC Hydro's programs, given the different size of each utility's customer base.

[13] The team developed the saturation curves for residential home energy report using information attained through interviews with OPower staff and their experience with typical offerings of these reports. These energy reports encompass many of Fortis Gas's current activities focused on residential behavior.

Figure 5-4. Behavior Measure Market Saturation as a Percentage of Economic Potential (%)



Source: Navigant

5.1.4 Budget Strategy

FortisBC Gas elected to view market potential without imposing any budget constraints on the simulated results. The implication of this decision is that market potential is only constrained by stock turnover and customer willingness to adopt efficient measures. Without future budget constraints, the utility spending falls out naturally from the input assumptions for per-unit-of-savings incentive and administrative costs and a given year's level of market savings, without tying spending to a given budget level. In this case, the per-unit-of-savings incentive and administrative spending levels are fixed at the same levels (in real dollars) over the study horizon. Therefore, changes in spending (in real dollars) only reflect a changing mix and magnitude of savings among measures.

5.1.5 Incentive Strategy

Per FortisBC Gas's guidance, this study calculates measure-level incentives based on a specified percentage of incremental measure costs. For example, if the specified incentive percentage was 50% and a measure's incremental cost was $100, then the calculated incentive for that measure would be $50. The incentive percentage differs by sector and is applied uniformly to all measures within a given sector.[14] Section 5.1.7 discusses how the model calibration process informed the specified incentive percentage in more detail.

[14] Navigant applied incentive percentages at the sector level, as opposed to the measure level, per the focus of this study's scope on sector-level market potential, rather than program-level potential. Actual program design would define incentive levels for each measure.

5.1.6 High Impact Measures

FortisBC Gas selected five measures that merit a more granular measure-level analysis, with the intent that Navigant would perform measure-level calibration customized to each measure's historic savings trajectories. These five high impact measures include:

1. Residential Condensing Storage Water Heater
2. Residential Condensing Tankless Water Heater
3. Residential Efficient Fireplaces
4. Residential Furnace Early Retirement
5. Residential High Efficiency Boiler Replacement

Section 5.1.7 discusses how Navigant customized the calibration of these measures in more detail.

5.1.7 Model Calibration

Any model simulating *future* product adoption faces challenges with "calibration," as there is no future world against which one can compare simulated results to actual results. Engineering models, on the other hand, can often be calibrated to a higher degree of accuracy since simulated performance can be compared directly with performance of actual hardware. Unfortunately, DSM potential models do not have this luxury, and therefore must rely on other techniques to provide both the developer and the recipient of model results with a level of comfort that simulated results are reasonable. For this CPR, Navigant took a number of steps to ensure that forecast model results were reasonable, including:

- Identifying the subset of CPR measures that were included in historic program offerings in order to have a basis for comparison with historic program achievements.
- Ensuring similar trends and magnitudes between average historic sector-level savings between 2013-2015 and simulated sector-level savings from the measure subset in 2016.[15]
- For the five high-impact measures, ensuring similar trends and magnitudes between historic measure-level savings and 2016 simulated savings. Additionally, the team calibrated long-term trends to align reasonably with FortisBC Gas's projections for these measures.
- Seeking general alignment between 2015 historic sector-level incentives as a percentage of total sector-level spending and simulated 2016 values.[16]

Before making comparisons of model results to historic achievements, it was first necessary to identify the CPR measures that were included in historic program offerings. The simulated savings from this subset of CPR measures became the basis for comparing modelled savings to historic savings during the calibration process. It is important to note that although the team reached good alignment in trends between historic and simulated results for this subset of measures, this study's results for *total* market potential significantly exceed the historically achieved program savings. This is because the study includes many additional measures that have historically not been included in programs, and those extra

[15] The team compared simulated savings to 2013-2015 historic averages, rather than a single historic year, because historic savings varied appreciably from one near to the next within each sector.
[16] The team compared the percentage of simulated spending derived from incentives to the 2015 historic percentages because 2015 was deemed to be most representative of expectations about future spending allocations between incentives and non-incentives.

measures contribute significant savings to the total market potential results.

When comparing residential results to historic program achievements, Navigant used results from the mTRC case because they are most analogous to FortisBC Gas's program environment (as described in Section 5.1). When comparing commercial and industrial results to historic program achievements, Navigant used results from the TRC case.

To obtain close agreement with FortisBC Gas's historic savings across a wide variety of metrics, Navigant adjusted incentive levels, technology diffusion coefficients and payback acceptance curves. Calibration required an iterative process of modifying the aforementioned parameters until all goals of calibration were reasonably satisfied. For example, the marketing effectiveness parameters are the key lever for calibrating the magnitude of 2016 savings for each sector, whereas the word-of-mouth parameter strongly influences how rapidly adoption and savings ramp up over time. Navigant varied these diffusion parameters within the commonly observed ranges until simulated savings were trending reasonably compared with historic savings at the sector level.[17]

For the five high impact measures, the team made several custom adjustments to align simulated savings with the historic trends. First, the team automatically included these measures in the market potential (for the mTRC and Hybrid cases, but not the TRC case) regardless of their sub-sector cost effectiveness.[18] The team made this provision to ensure that these measures, which are currently offered through FortisBC Gas's programs, would also appear in the market potential.[19] Second, Navigant customized the marketing effectiveness and payback acceptance curves for these measures to achieve similar magnitudes and trends between modelled savings and historic savings.

Lastly, the team adjusted sector-level incentive levels to be different percentages of incremental costs until the percentage of 2016 total spending attributable to incentives was similar to 2015 historic values. The calibrated incentive levels produce a weighted average incentive percentage of 56% for the simulated portfolio. This calibrated value coincides well with the initial target of having modelled incentives cover roughly 50% of incremental costs across the portfolio.

To summarize, the calibration process ensures that forecast potential is grounded against real-world results considering the many factors that determine likely adoption of DSM measures, including both economic and non-economic factors.

[17] This study uses a value of 0.255 for the word-of-mouth strength, which is the 25th percentile of values observed by Mahajan 2000. The marketing effectiveness parameter varied between 0.010 and 0.053, depending on the sector. These values span from roughly the 25th percentile to 75th percentile of observed marketing effectiveness, per Mahajan 2000.

[18] While these measures are cost effective overall, some measures are not cost effective for certain sub-sectors and regions within the analysis. Since actual programs focus on overall cost effectiveness across the sector, rather than within sub-sectors, Navigant forced the five high impact measures to pass across all sub-sectors to better reflect actual program implementation.

[19] Each of the five high impact measures are currently offered through FortisBC Gas's residential programs. Because programs look at the collective cost effectiveness of a group of measures (e.g., several water heater technologies), it is possible that a technology within the group may not be cost-effective. However, the group as a whole can be cost-effective, and therefore any technology within the group can be offered through programs.

5.2 Market Potential Results

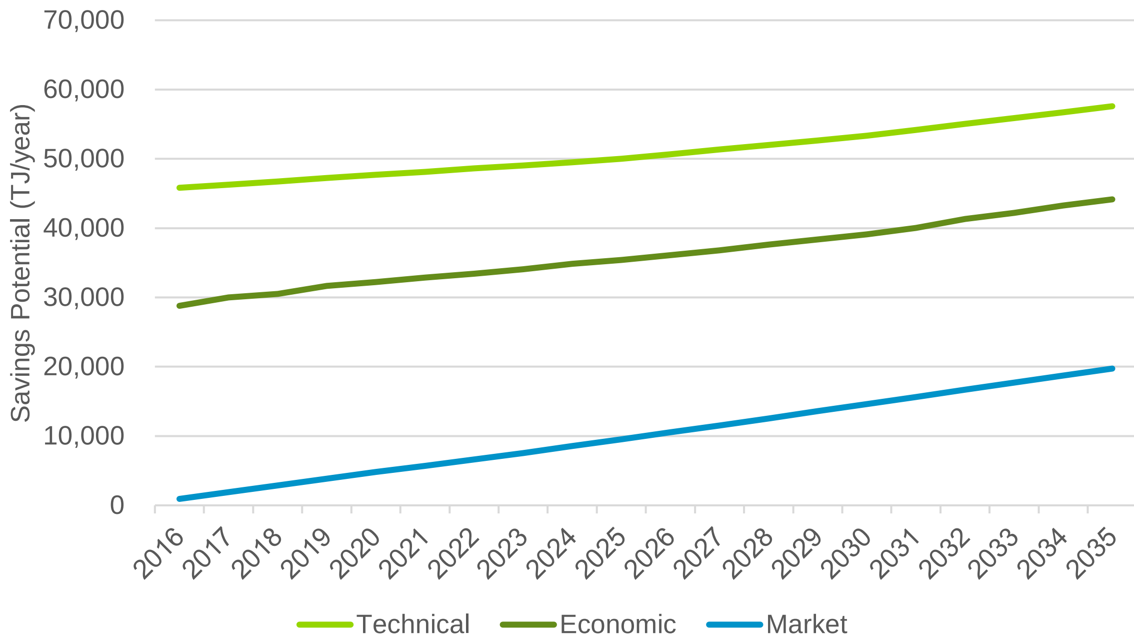
This section provides the market potential results calculated by the model at varying levels of aggregation, using the TRC benefit-cost test as a screen (as consistent with the representation of economic potential in Section 4). Results are shown by sector, customer segment, end-use category, and by highest-impact measures. The section concludes with a review of natural change and its impacts on market potential.

5.2.1 Comparison of Savings by Potential Type

Values shown below for market potential are termed “cumulative market” potential, in that they represent the accumulation of each year’s annual incremental market potential (e.g., an annual incremental market potential of 0.8% per year for ten years would result in a cumulative market potential of 8.0% of forecast consumption). Economic potential, as defined in this study, can be thought of as a bucket of potential from which programs can draw over time. Market potential represents the draining of that bucket, the rate of which is governed by a number of factors, including the lifetime of measures (for ROB technologies), market effectiveness, incentive levels, and customer willingness to adopt, among others. If the cumulative market potential ultimately reaches the economic potential, it would signify that all economic potential in the “bucket”’ had been drawn down, or harvested.

As shown in Figure 5-5 and Table B-1 in Appendix B, the market potential, which accounts for the rate of DSM acquisition, increases steadily throughout the CPR period, reaching 19,736 TJ/year in 2035. By 2035, market potential reaches nearly 46% of the economic potential. Incremental annual market potential added year-over-year to the cumulative potential averages 987 TJ/year over the study horizon.[20]

Figure 5-5. Total Cumulative Gas Savings Potential (TJ/year)

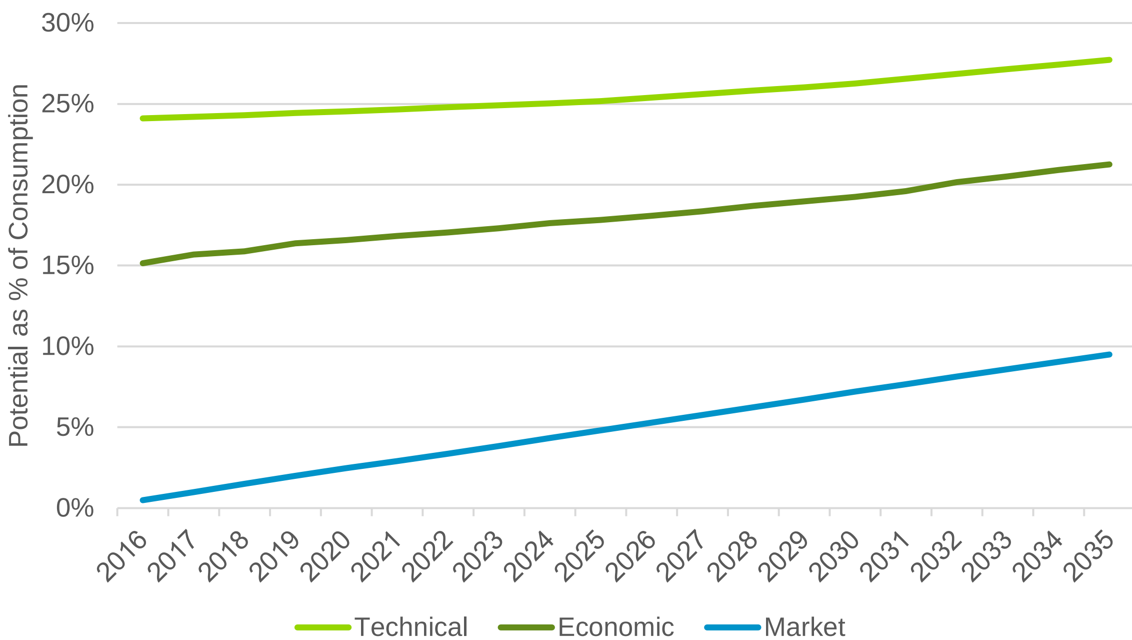


Source: Navigant

[20] The time horizon for the CPR is 2016-2035 (20 years).

Under the TRC screen, market potential grows from 0.5% in 2016 to 9.5% of forecast gas consumption by 2035, as shown in Figure 5-6 and in Appendix B. The annual incremental market potential is approximately 0.5% per year on average over the CPR time horizon.

Figure 5-6. Total Cumulative Gas Savings Potential as a Percentage of Consumption (%)

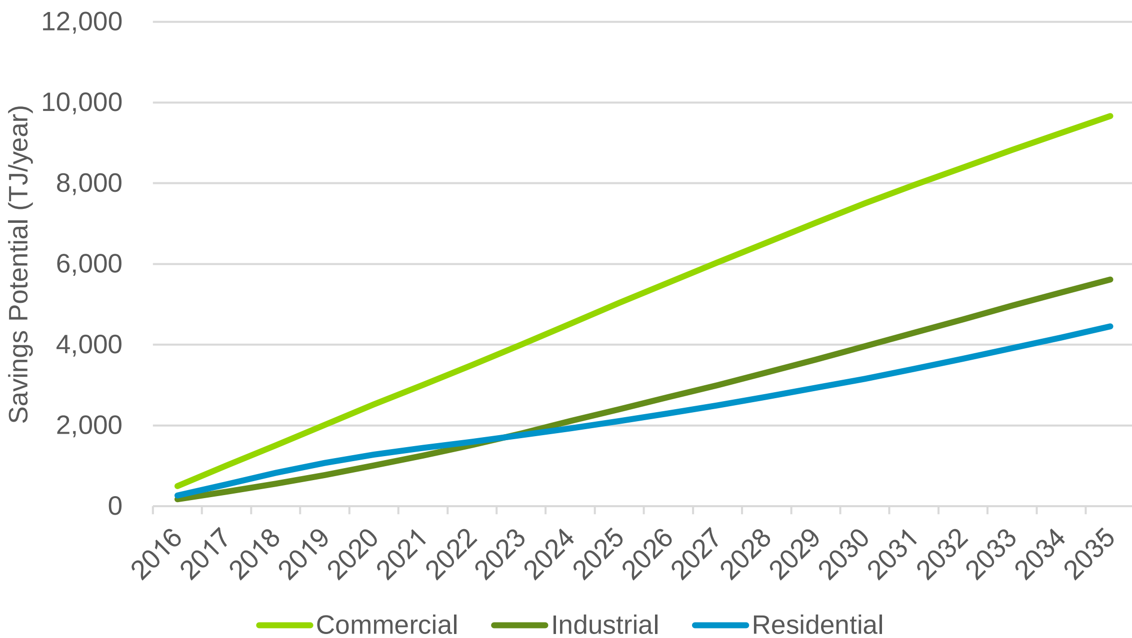


Source: Navigant

5.2.2 Results by Sector

Figure 5-7 and in Appendix B show the magnitude of gas market potential by sector. Navigant found the greatest potential exists in the commercial sector in terms of TJ/year and as a percentage of consumption. The commercial and industrial sectors captured just over 50% of economic potential by 2035, while the residential sector captured 28% of the economic potential.

Figure 5-7. Cumulative Gas Savings Market Potential by Sector (TJ/year)



Source: Navigant

When viewed as a percentage of consumption, similar sector-level trends in the market potential are evident, as shown in Figure 5-8 and Table B-4. The commercial sector's market potential reaches 13% of commercial consumption by 2035, and the industrial sector achieves slightly over 10%. The residential sector increases to nearly 6% of consumption by the final study year, and this lower percentage reflects the lower cost-effectiveness and longer payback times of the residential sector on the whole.

Figure 5-8. Cumulative Gas Savings Market Potential as a Percentage of Consumption by Sector (%)

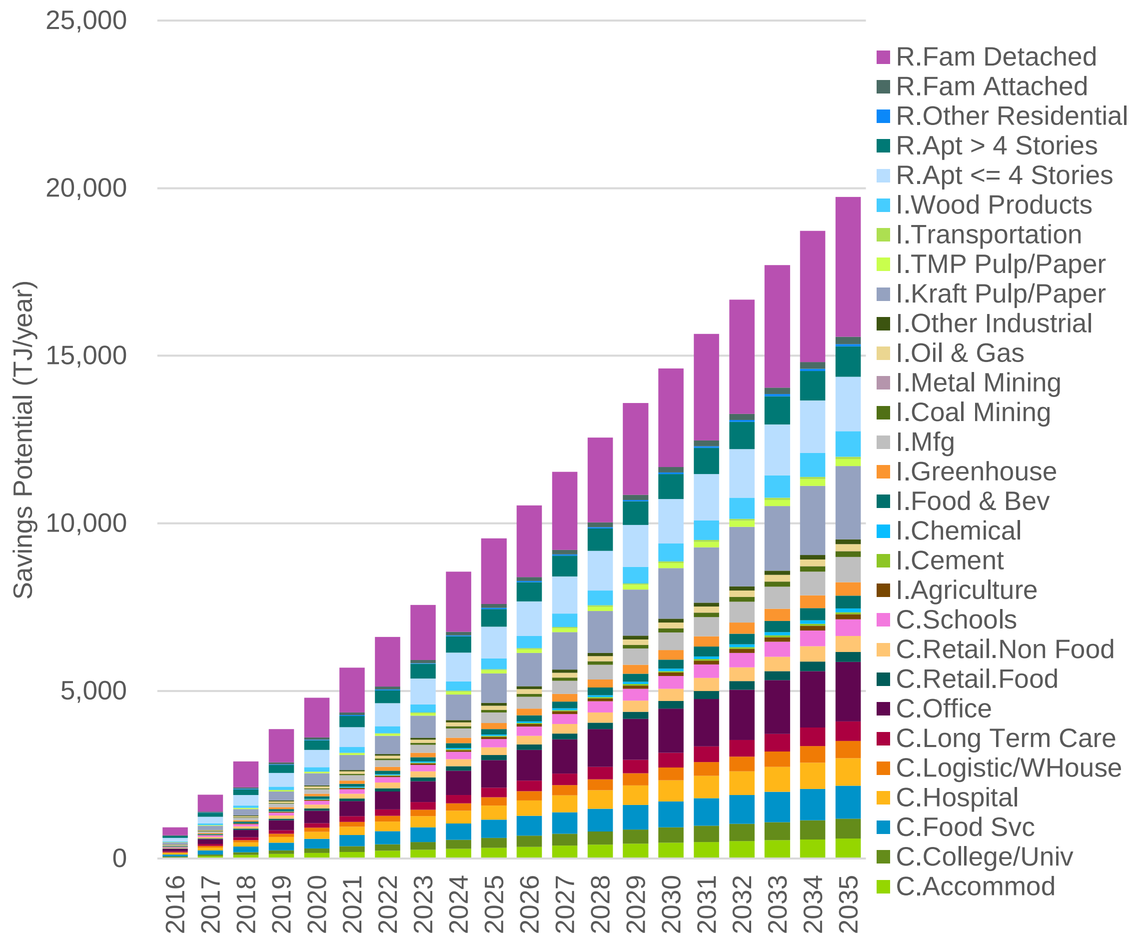
5.2.3 Results by Customer Segment

Figure 5-9 shows the gas energy market savings potential across all customer segments, and Table B-5 in Appendix B provides the associated data.[21] This figure highlights the large savings potential of the residential detached single-family home customer segment relative to other customer segments. Other segments with significant savings potential are kraft pulp and paper, apartments less than 4 stories, and offices. The segments with high savings are also segments with high consumption.

Figure 5-9. Cumulative Gas Savings Market Potential by Customer Segment (TJ/year)



Source: Navigant

[21] The LNG segment does not appear in this figure because FortisBC Gas does not supply natural gas to LNG facilities. Gas sales to LNG facilities are zero across the Reference Case forecast; hence, the savings potential is also zero.

Figure 5-10, Figure 5-11, and Figure 5-12 break out the gas energy market savings potential for each sector by customer segment. For the residential sector, detached single-family homes represents the largest savings potential of any customer segment by far, accounting for 93% of the total savings potential. Offices and apartments provide nearly half of the savings in the commercial sector. In general, the distribution of savings among customer segments aligns well with the distribution of gas consumption among segments. In the industrial sector, kraft pulp and paper accounts for the largest share of energy savings at 37%. Wood products and manufacturing also provide significant savings among industrial segments.

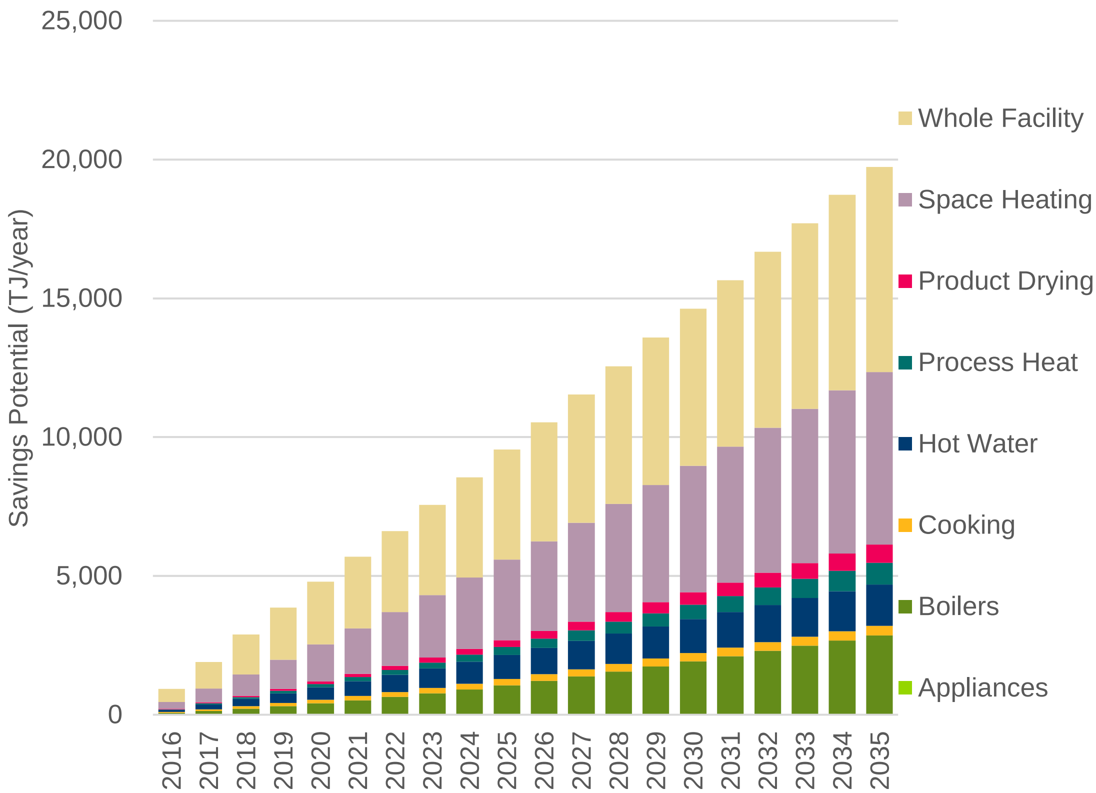
5.2.4 Results by End-use

Figure 5-13 shows the gas energy market savings potential across end-uses.[22] The data used to generate the figure are in Table B-6 in Appendix B. The dominant end-uses are space heating and whole facility. The bulk of savings potential in the space heating end-use comes from smart thermostats. The whole facility end-use primarily consists of savings from comprehensive whole-facility new construction practices, home energy reports, and energy management programs. As such, these whole-facility savings implicitly include savings from multiple end-uses.

Figure 5-13. Cumulative Gas Savings Market Potential by End-Use (TJ/year)



Source: Navigant

Figure 5-14, Figure 5-15, and Figure 5-16 break out the gas energy market savings potential for each sector. The whole facility end-use dominates the residential sector, accounting for 50% of the total savings potential. This is largely driven by home energy reports, which have by far the most market potential of all residential measures, and ENERGY STAR Homes, which is the third highest residential potential saver. In the commercial sector, the space heating and whole facility end-uses account for roughly 86% of the total market savings potential. Savings in commercial space heating come largely from HVAC control upgrades, condensing make-up air units and high efficiency furnaces. The whole-facility end-use's savings are driven by new building construction practices that are at least 45% above

[22] This study evaluated several gas appliances (convection ovens, gas ranges, and clothes washers and dryers) and found all to be non-cost-effective. As such, the appliances end use shows no market potential. For a list of measures associated with each end use, please refer to Appendix A.2 of the technical and economic potential report.

code. In the industrial sector, the boiler end-use plays the largest role, consisting of high savings measures like process boiler load control and heat recovery systems.

Figure 5-14. Residential Gas Savings Market Potential End-Use Breakdown in 2025

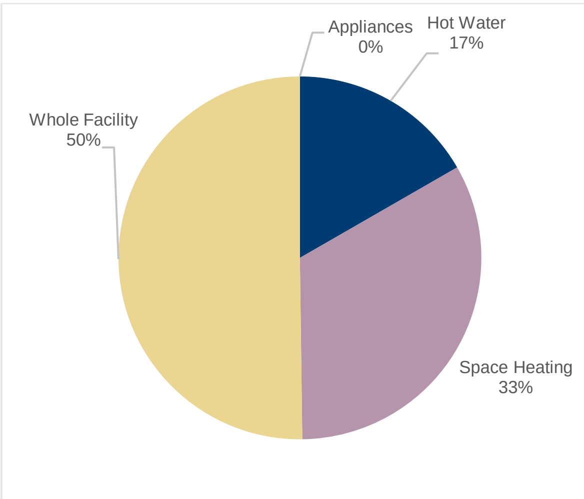


Figure 5-15. Commercial Gas Savings Market Potential End-Use Breakdown in 2025

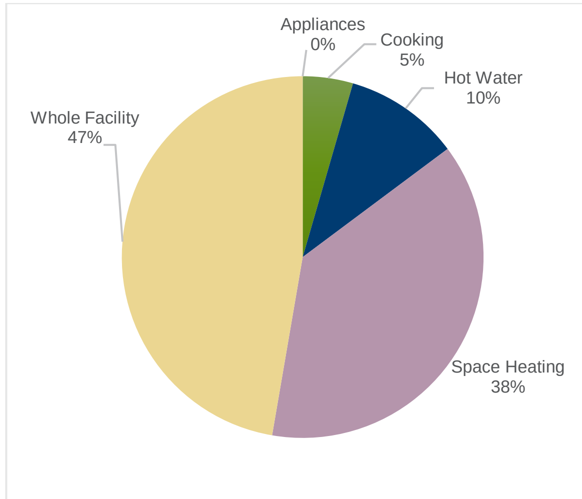

Figure 5-16. Industrial Gas Savings Market Potential End-Use Breakdown in 2025

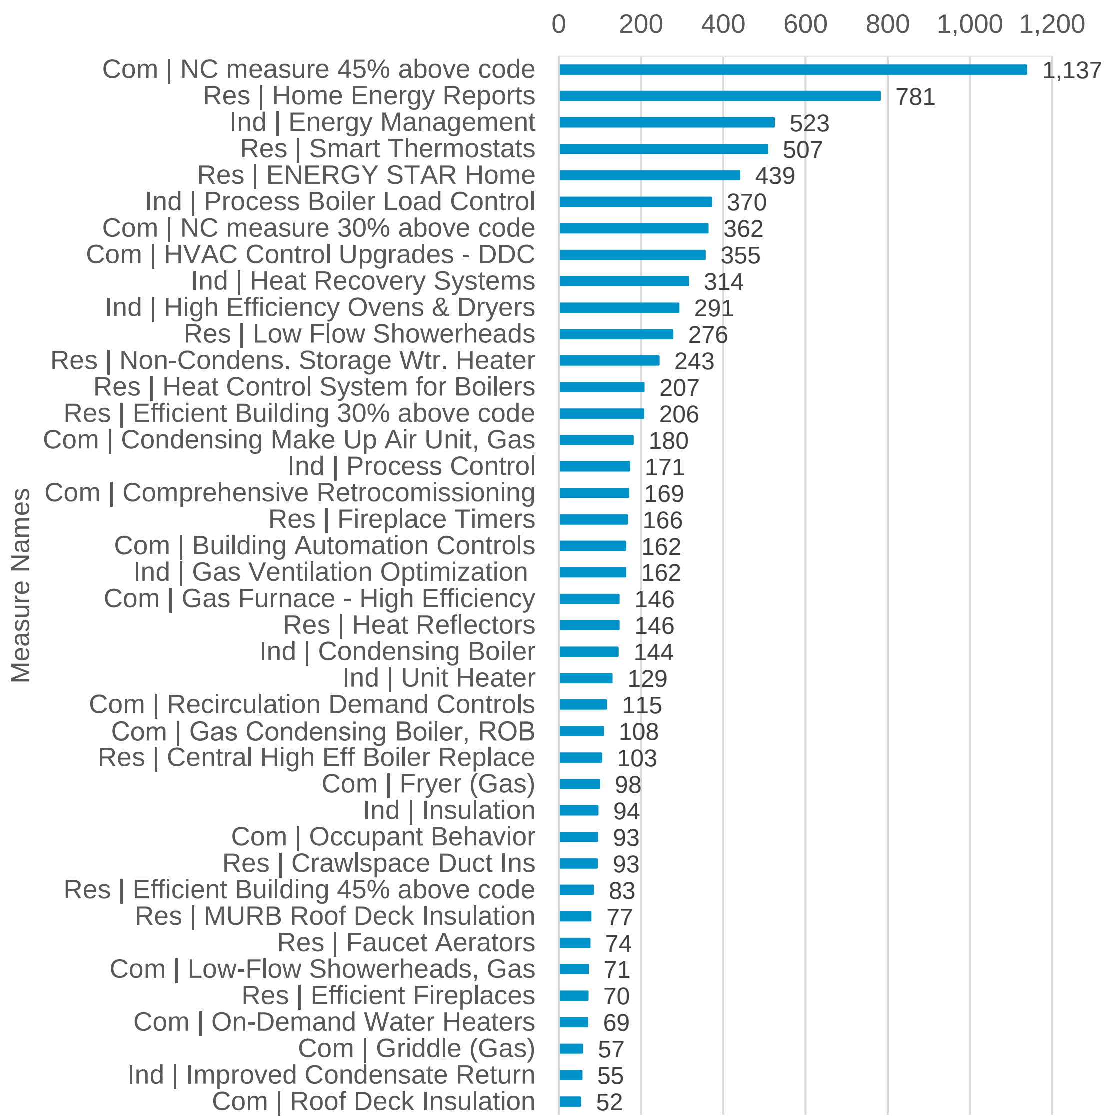
5.2.5 Results by Measure

Figure 5-17 and Table B-7 present the top 40 measures ranked by their gas energy market savings potential in 2025. Wherever a group of measures were similar in nature, Navigant consolidated their potential into a representative measure name to produce a more succinct view at the measure level. Unlike similar figures for economic and technical potential, these rankings already account for competition among measures providing the same service. Thus, one can add the potential shown without encountering issues of double counting.

When code-change measures become applicable, they “steal” savings potential from other related measures that may display significant savings in absence of the code. In this way, the sum of the total savings potential between the code and the related energy-efficient measure is the same before and after a code takes effect. This ensures there is no double counting of savings from codes and the energy efficient measures impacted by the code.

The top ten measures come from the whole-facility, space heating, boiler, and industrial process heating end-uses. Notably, five of the top ten measures are associated with the whole facility end-use. New construction practices 45% better than code ranks as the highest impact market potential measure. Smart thermostats, which has the highest economic savings potential, ranks fourth in terms of market potential. Home energy reports move from the 7th position in economic potential to the 2nd position in market potential.

Figure 5-17. Top 40 Measures for Gas Energy Market Savings Potential in 2025 (TJ/year)



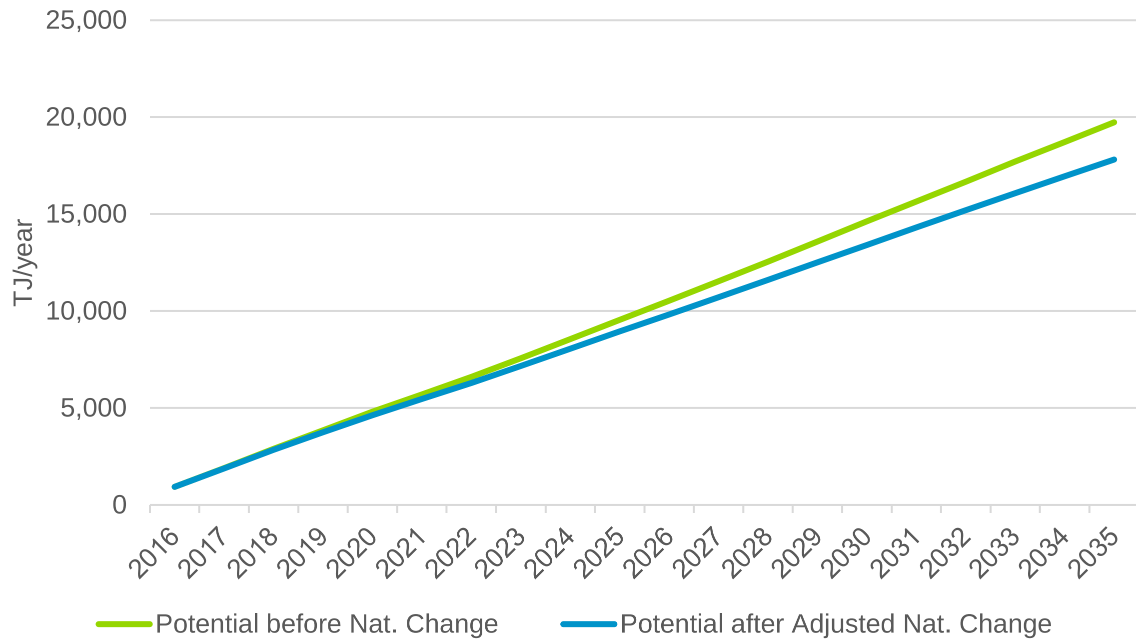
Source: Navigant

5.2.6 Adjustments for Natural Change

As discussed in Section 2.3.2, Navigant estimated natural change to account for differences in end-use consumption in the Reference Case compared to the frozen EUI case. Natural change accounts for changes in consumption that are naturally occurring and are not the result of utility-sponsored programs or incentives. Adding natural change to the frozen EUI case required adjusting the market potential forecasts accordingly.

Figure 5-18 and Table B-8 in Appendix B show the total market potential across all sectors before and after adjusting for natural change. The total natural change across all sectors is negative in all years, indicating an overall natural tendency toward increased energy conservation rather than growth. The adjusted natural change is computed by accounting for the percentage of the gross natural change that could reasonably be attributed to energy savings for each end-use. Market potential after adjustment for natural change is on average about 10% lower than potential before natural change by 2034.

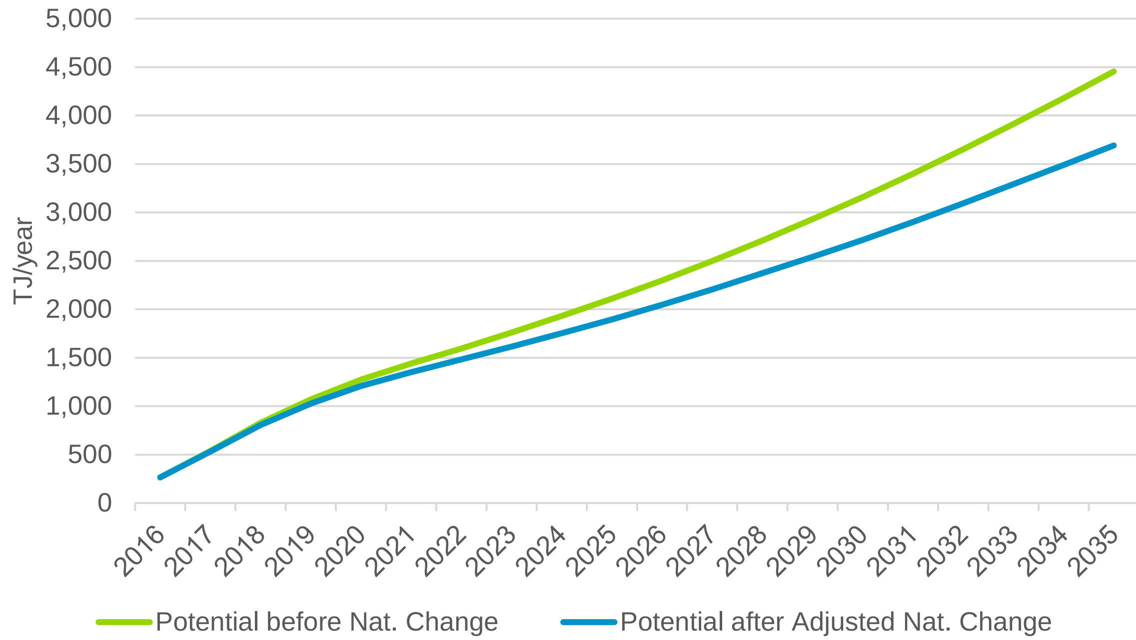
Figure 5-18. Gas Energy Market Savings Potential with Natural Change – All Sectors (TJ/year)



Source: Navigant

Figure 5-19 and Table B-9 show the effect of adjustments for natural change in the residential sector. Space heating and hot water end-uses account for significant natural conservation. In contrast, appliances account for a minor amount of natural growth. When aggregated to the sector level, natural conservation has a much larger effect than natural growth. On average across the study period, the residential technical potential after adjusted natural change is roughly 12% lower than the potential prior to natural change.

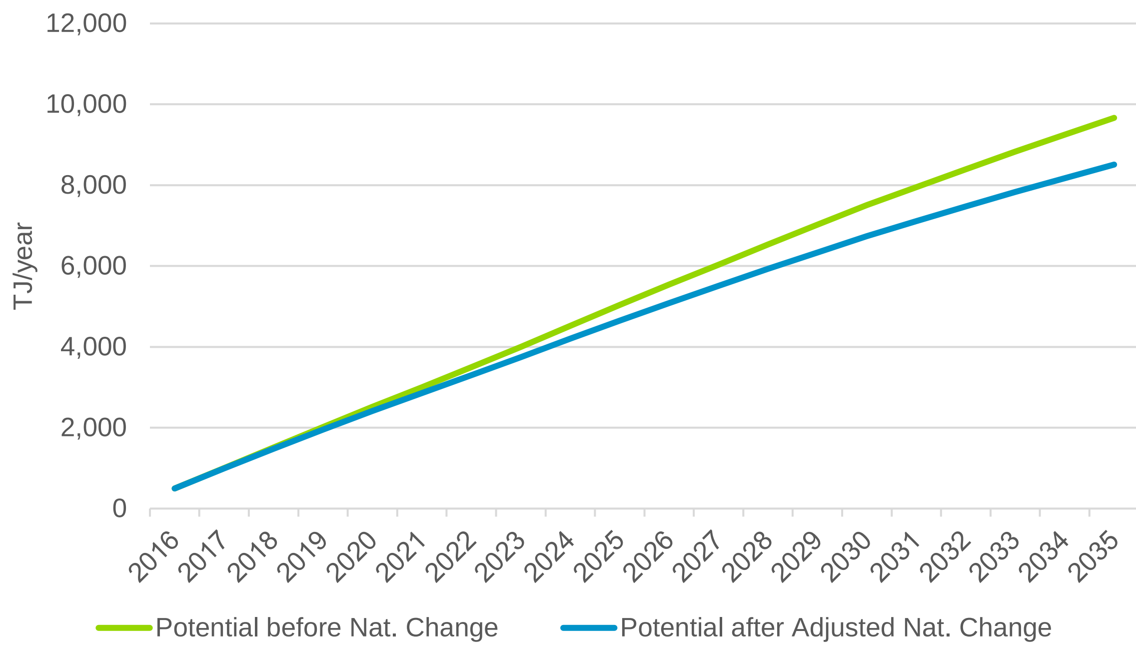
Figure 5-19. Residential Gas Energy Market Savings Potential with Natural Change (TJ/year)



Source: Navigant

The effect of adjustments for natural change on the commercial sector's market potential is slightly less than for the residential sector, as seen in Figure 5-20 and Table B-10. Space heating and hot water are the commercial end-uses contributing to natural change, and both exhibit natural conservation. On average across the study period, the commercial technical potential adjusted for natural change is roughly 9% lower than the potential prior to natural change.

Figure 5-20. Commercial Gas Energy Market Savings Potential with Natural Change (TJ/year)



Source: Navigant

For the industrial sector, there is no forecasted natural change, so adjustments to the market potential results presented in previous sections are not necessary.

5.3 Market Potential Budget Estimates

The following section describes the approach that Navigant used to develop the budget estimates for the market potential savings presented in this report, as well as the results of the market potential budget and cost effectiveness assessments when using the TRC test as an economic measure screen.

5.3.1 Approach to Budget Estimation

Navigant developed estimates of the portfolio-level DSM spending that FortisBC Gas would need to support the market potential savings forecast over the study period. Navigant calculated these estimates in the DSMSim™ model using incentive levels calibrated to align simulated 2016 incentive values with historic sector-level incentives as a percentage of total sector-level spending (as described in Section 5.1.7). The incentive budgets reflect the amount of spending that would result from the level of adoption for each measure that makes up the market potential estimates. Incentive budgets grow over time due to changes in the mix of DSM measures and cost inflation. The sector and total administration budgets result from the amount of savings potential in a given year multiplied by the historical per-unit-of-savings administrative expenditures ($/GJ) reported by FortisBC Gas, which the study escalates over time at the assumed inflation rate.[23]

5.3.2 Total Market Potential Budget

Table 5-2 presents the estimated spending levels for incentives, administrative costs (non-incentives), and the total portfolio. As can be seen from the table, the total simulated funding for market potential is roughly $21 million in 2016, and more than doubles to almost $54 million by 2035 as the portfolio mix changes and low-hanging fruit is harvested.

Table 5-2. Budgets by Sector – TRC Case (Million $)

Sector	Spending Type	2016	2020	2025	2030	2035	2016-2035 Total*
Commercial	Incentives	$9.52	$14.21	$18.58	$21.55	$23.05	$351.38
	Non-Incentives	$1.51	$1.62	$1.85	$1.90	$1.81	$34.83
	Total	$11.03	$15.83	$20.43	$23.45	$24.86	$386.22
Industrial	Incentives	$2.33	$3.94	$6.53	$8.93	$9.75	$131.07
	Non-Incentives	$1.14	$1.67	$2.35	$2.87	$3.08	$46.02
	Total	$3.47	$5.61	$8.89	$11.81	$12.83	$177.09
Residential	Incentives	$2.73	$4.28	$5.39	$7.83	$10.82	$123.04
	Non-Incentives	$3.55	$2.99	$2.85	$4.04	$5.36	$72.87
	Total	$6.27	$7.27	$8.24	$11.87	$16.18	$195.92
Portfolio	Incentives	$14.58	$22.43	$30.50	$38.31	$43.62	$605.50
	Non-Incentives	$6.19	$6.27	$7.06	$8.81	$10.25	$153.73
	Total	$20.77	$28.71	$37.56	$47.13	$53.87	$759.23

*The 2016-2035 Total column represents the sum of all forecasted years (2016-2035), not just those shown in the table.
Source: Navigant

The costs borne by the utility to acquire market savings—on a dollar-per-savings basis—increase 2 to 3 percent per year, on average and in real terms, for each sector. This contrasts with recent program experience, where per-unit-of-savings utility costs have shown declining trends. There are several factors creating this difference:

- Actual program implementation may be dynamically allocating incentive spending to measures providing lower cost savings than the incentive strategy employed in this analysis (refer to Section 5.1.5). Though the modeling approach captures customers' tendency to favor the adoption of economically attractive measures over less economically attractive measures, it does not preferentially incentivize the most economic measures.

[23] The study includes administrative costs directly tied to programs and measures providing energy savings. Outreach and enabling costs and portfolio-level administrative costs (i.e., not tied to a program) were not included in this study. This study's portfolio total administrative costs are a summation of sector-level administrative costs, so this analysis is likely to underrepresent total administrative budgets at the portfolio level. However, this underrepresentation may be partially offset by not accounting for efficiencies gained through program experience, which would reduce per-unit-of-savings administrative costs over time.

- Actual programs may not be experiencing significant saturation yet in the uptake of certain low cost measures. This study's upward trend in the percentage of spending directed to incentives indicates that low-cost savings are harvested early in the study horizon and the remaining savings opportunities become increasingly costlier.
- This study did not attempt to estimate the reduction in per-unit-of-savings administrative costs that could be realized as experience in program administration leads to greater efficiency in administrative spending.
- Compliancy to codes and efficiency standards enacted during the study horizon reduces the savings potential and cost-effectiveness of impacted measures, resulting in higher costs to the utility to capture those measures' savings potential.

5.3.3 TRC Cost Effectiveness

Table 5-3 shows the benefit-cost test ratios by sector and for the portfolio for each benefit-cost test. The benefit-cost test ratios are greater than 1.0 for all benefit-cost test types at the sector and portfolio level across all analysis years, with an exception for the RIM test, which very rarely has a benefit-cost test greater than 1.0 for DSM measures.

Table 5-3. Benefit-Cost Test Ratios for the Portfolio and by Sector

Sector	Year	Total Resource Cost Test	Utility Cost Test	Participant Cost Test	Rate Impact Measure Test
Commercial	2016	1.86	2.78	2.63	0.75
	2020	1.83	2.71	2.38	0.80
	2025	1.82	2.69	2.21	0.84
	2030	1.78	2.63	2.05	0.88
	2035	1.76	2.60	1.92	0.92
	2016-2035	1.84	2.71	2.27	0.83
Industrial	2016	2.07	2.23	3.50	0.75
	2020	2.47	2.67	3.60	0.85
	2025	2.81	3.05	3.60	0.95
	2030	2.99	3.25	3.48	1.02
	2035	3.22	3.50	3.47	1.10
	2016-2035	2.75	2.98	3.54	0.94
Residential	2016	1.16	1.59	3.14	0.51
	2020	1.70	2.43	3.45	0.61
	2025	1.93	2.75	3.41	0.67
	2030	1.98	2.78	3.28	0.70
	2035	2.02	2.81	3.16	0.74
	2016-2035	1.79	2.51	3.38	0.65
Portfolio	2016	1.68	2.33	2.84	0.69
	2020	1.89	2.63	2.77	0.75
	2025	2.03	2.79	2.68	0.82
	2030	2.07	2.82	2.59	0.86
	2035	2.12	2.88	2.53	0.90
	2016-2035	1.99	2.72	2.72	0.80

Source: Navigant

Table 5-4 presents the net benefits by sector and for the portfolio under each benefit-cost test. As with the benefit-cost test ratios, net benefits are positive in all cases, with the exception of the RIM test. The analysis estimates that the total net present value for the portfolio over the 2016-2035 analysis timeframe is more than $450 million from the TRC perspective.

Table 5-4. Cost Test Net Benefits for the Portfolio and by Sector (Million $)

Sector	Year	Total Resource Cost Test	Utility Cost Test	Participant Cost Test	Rate Impact Measure Test
Commercial	2016	$14.16	$19.58	$24.35	-$10.19
	2020	$19.47	$27.13	$30.87	-$10.97
	2025	$24.78	$34.46	$35.74	-$10.27
	2030	$26.94	$38.16	$35.94	-$8.37
	2035	$27.92	$39.81	$33.75	-$5.40
	2016-2035*	$218.08	$302.17	$319.53	-$96.98
Industrial	2016	$4.00	$4.27	$6.52	-$2.52
	2020	$8.89	$9.35	$11.43	-$2.54
	2025	$17.45	$18.19	$18.91	-$1.46
	2030	$25.53	$26.56	$24.69	$0.84
	2035	$31.01	$32.13	$26.79	$4.22
	2016-2035*	$143.16	$149.48	$156.42	-$13.26
Residential	2016	$1.39	$3.72	$10.82	-$9.43
	2020	$7.25	$10.40	$18.81	-$11.27
	2025	$10.96	$14.44	$23.02	-$11.18
	2030	$16.32	$21.09	$31.98	-$13.80
	2035	$22.94	$29.27	$42.01	-$15.94
	2016-2035*	$96.08	$130.83	$220.95	-$116.74
Portfolio	2016	$19.55	$27.57	$41.69	-$22.14
	2020	$35.61	$46.88	$61.11	-$24.77
	2025	$53.18	$67.09	$77.68	-$22.92
	2030	$68.78	$85.80	$92.61	-$21.34
	2035	$81.87	$101.22	$102.56	-$17.12
	2016-2035*	$457.31	$582.48	$696.90	-$226.97

**Total net benefits for 2016-2035 represent the total present values in 2016 dollars. Other yearly values represent non-discounted single-year net benefits.*

5.4 mTRC Results

This section describes the approach taken for estimating DSM potential using the mTRC benefit-cost test as a screen, rather than the TRC benefit-cost test. Given that the economic potential results will differ under the mTRC test from the results presented in Section 4, this section provides the results for both economic and market potential using the mTRC, as well as the sector and portfolio cost effectiveness.

5.4.1 Approach to Estimating mTRC Results

The primary change between the TRC benefit-cost test and mTRC benefit-cost test is the application of different values for avoided costs, with the mTRC avoided costs roughly six times higher than the TRC avoided costs.[24] The use of higher avoided costs increases the benefits calculated for each measure and results in more measures screening as cost-effective. Based on input from FortisBC Gas, Navigant also included the five high impact measures in the mTRC market potential, regardless of cost-effectiveness,[25] to capture additional market dynamics with these measures (as described in Section 5.1.7). All other calculations are the same between the TRC and mTRC tests.

5.4.2 mTRC Economic Potential Results

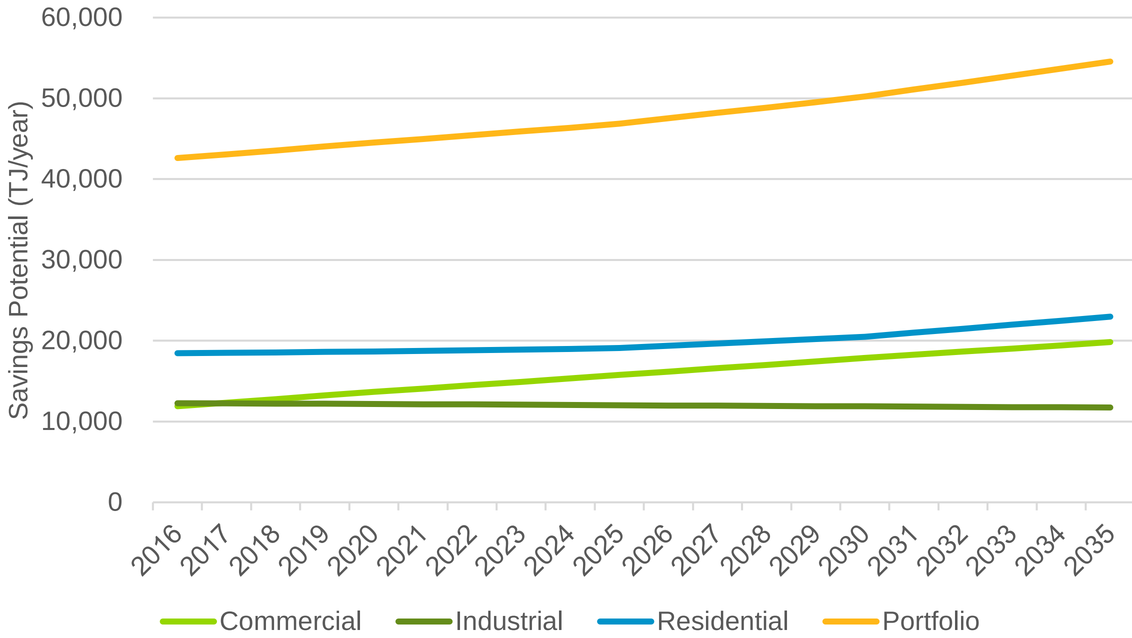
Figure 5-21 shows the cumulative gas economic potential by sector in TJ/year. The data used to generate the figure are in Table B-11 in Appendix B. The use of the mTRC screen instead of the TRC screen increases the proportion of technical savings potential that are economic. Economic potential increases from 71% of technical potential based on the TRC screen, to 94% based on the mTRC screen.

mTRC economic potential for the commercial and residential sectors increases significantly over the study period to 25% and 67%, respectively. This increase in economic potential over time is a result of whole-facility, high-impact measures such as new construction practices 45% more efficient than code and ENERGY STAR homes. Industrial sector economic potential stays roughly the same as the TRC case (see Section 4.2), decreasing by 4% over the study period, primarily because industrial gas consumption is not forecast to increase over time.

[24] The formulation of the mTRC benefit-cost test is the same as the TRC test, with the exception that the avoided costs stem from a zero emission energy supply alternative (ZEEA) cost and benefits are increased by a 15% non-energy benefits adder.

[25] As stated in Section 5.1.7, while these measures are cost effective overall, some measures are not cost effective for certain sub-sectors and regions within the analysis. Since actual programs focus on overall cost effectiveness across the sector, rather than within sub-sectors, Navigant forced the five high impact measures to pass across all sub-sectors to better reflect actual program implementation.

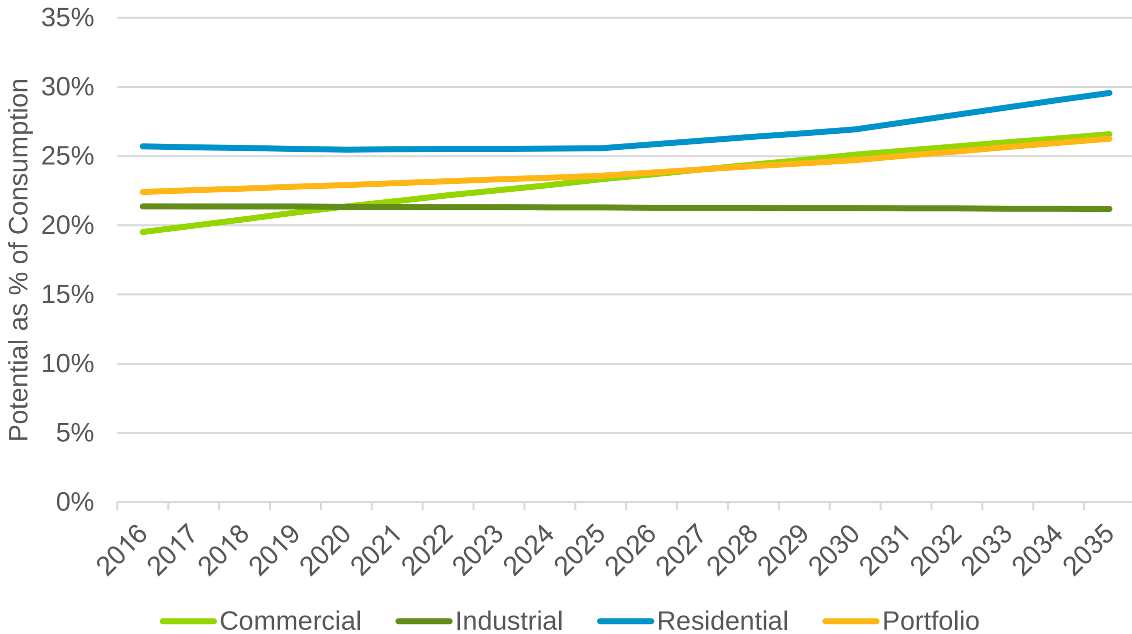
Figure 5-21. mTRC Cumulative Gas Savings Economic Potential by Sector (TJ/year)



Source: Navigant

Figure 5-22 shows the cumulative gas economic potential as a percent of sector consumption. The data used to generate the figure are in Table B-12 in Appendix B. Whole-facility, new construction measures in the residential and commercial sectors enable the increase in savings potential as a percent of sector consumption over time. Industrial savings as a percent of consumption do not increase because limited growth in the sector result in limited opportunities for high-impact measures. While the overall shape of the mTRC economic savings curves are similar to the TRC economic curves, the use of the mTRC screen increases the percentage of technical savings that are economic. Economic savings as a percent of consumption in 2016 increase from 15.1% (based on the TRC screen) to 22.4% (based on the mTRC screen). The 2035 economic savings increase from 21.3% to 26.3%.

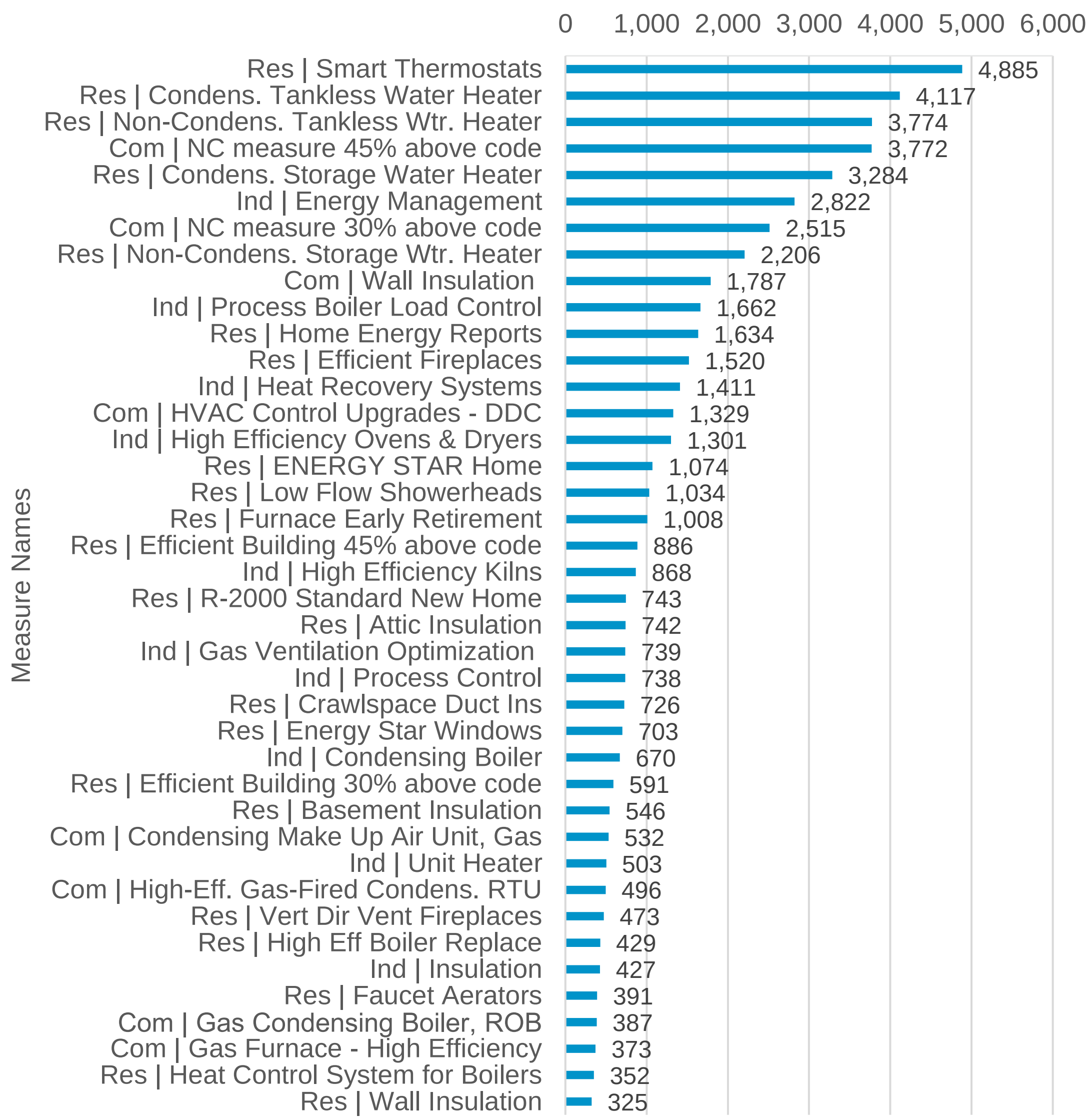
Figure 5-22. mTRC Cumulative Gas Savings Economic Potential as Percent of Sector Consumption (%)



Source: Navigant

Figure 5-23 and Table B-13 list the top 40 gas saving measures with the highest economic potential prior to adjustments made to competition groups. There are no changes in ranking or savings potential in results when compared with the top 10 technical potential measures. The four measures (residential condensing and non-condensing tankless water heaters, residential condensing storage water heaters, and commercial wall insulation) that were not economic using the TRC screen are economic using the mTRC screen.

Figure 5-23. mTRC Top 40 Measures for Gas Energy Economic Savings Potential in 2025 (TJ/year)

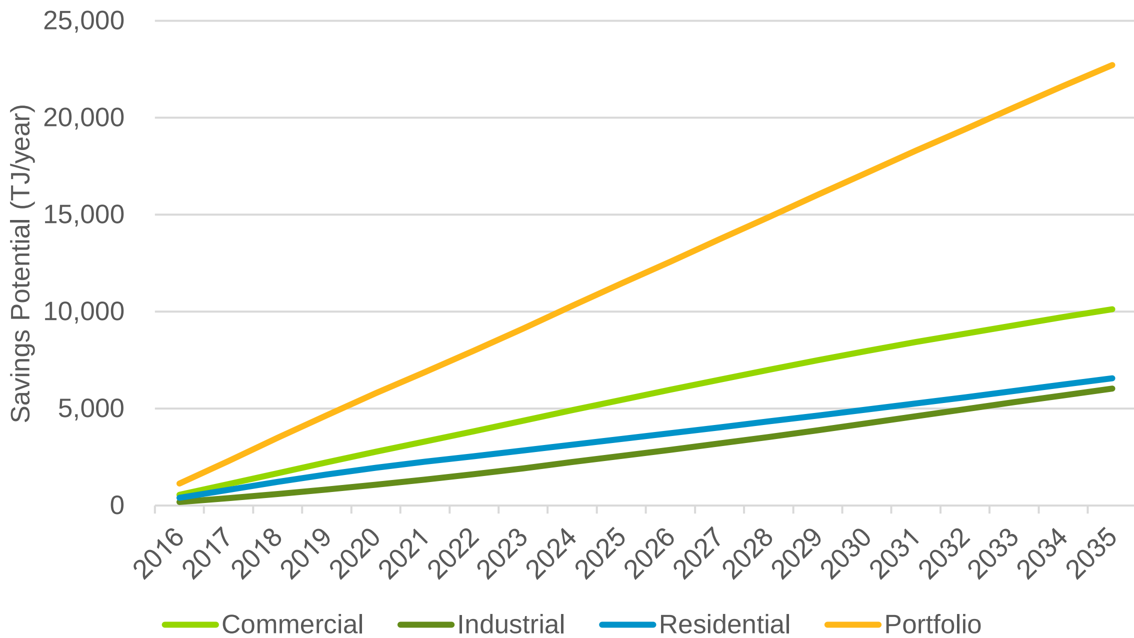


Source: Navigant

5.4.3 mTRC Market Potential Results

The following figures show the market potential results for the mTRC case. Figure 5-24 and Table B-14 show the cumulative gas market potential by sector in TJ/year. The commercial sector contributes approximately 46% of the cumulative gas savings market potential over the study period, down from approximately 50% using a TRC screen. The residential and industrial sectors contribute 30% and 24%, respectively. Relative to the TRC market potential savings, the residential sector's market potential increased 45%, while the commercial and industrial sectors only increased 5% and 7%, respectively.

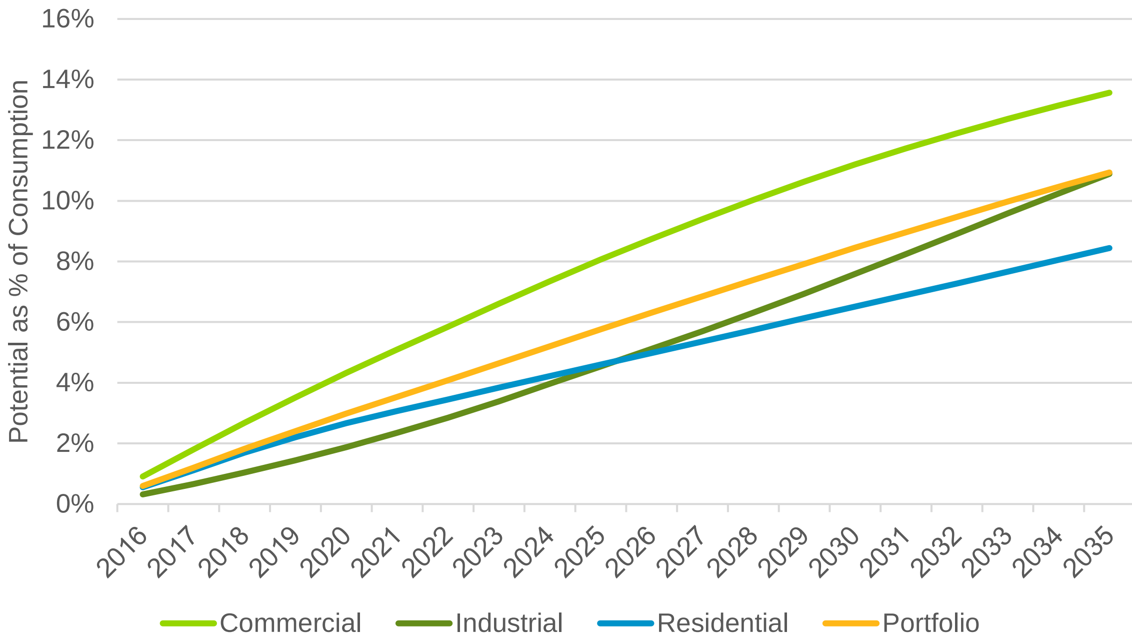
Figure 5-24. mTRC Cumulative Gas Savings Market Potential by Sector (TJ/year)



Source: Navigant

Figure 5-25 and Table B-15 show the cumulative gas market potential as a percent of sector consumption, with portfolio savings increasing from just under 0.6% to 10.9% of gas consumption over the timeframe of the analysis. Compared to the TRC market potential savings, the 2035 savings increased from 9.5% using the TRC screen to 10.9% using the mTRC screen. The residential sector saw the largest increase as a percent of consumption, rising from 5.8% using the TRC screen to 8.4% using the mTRC screen.

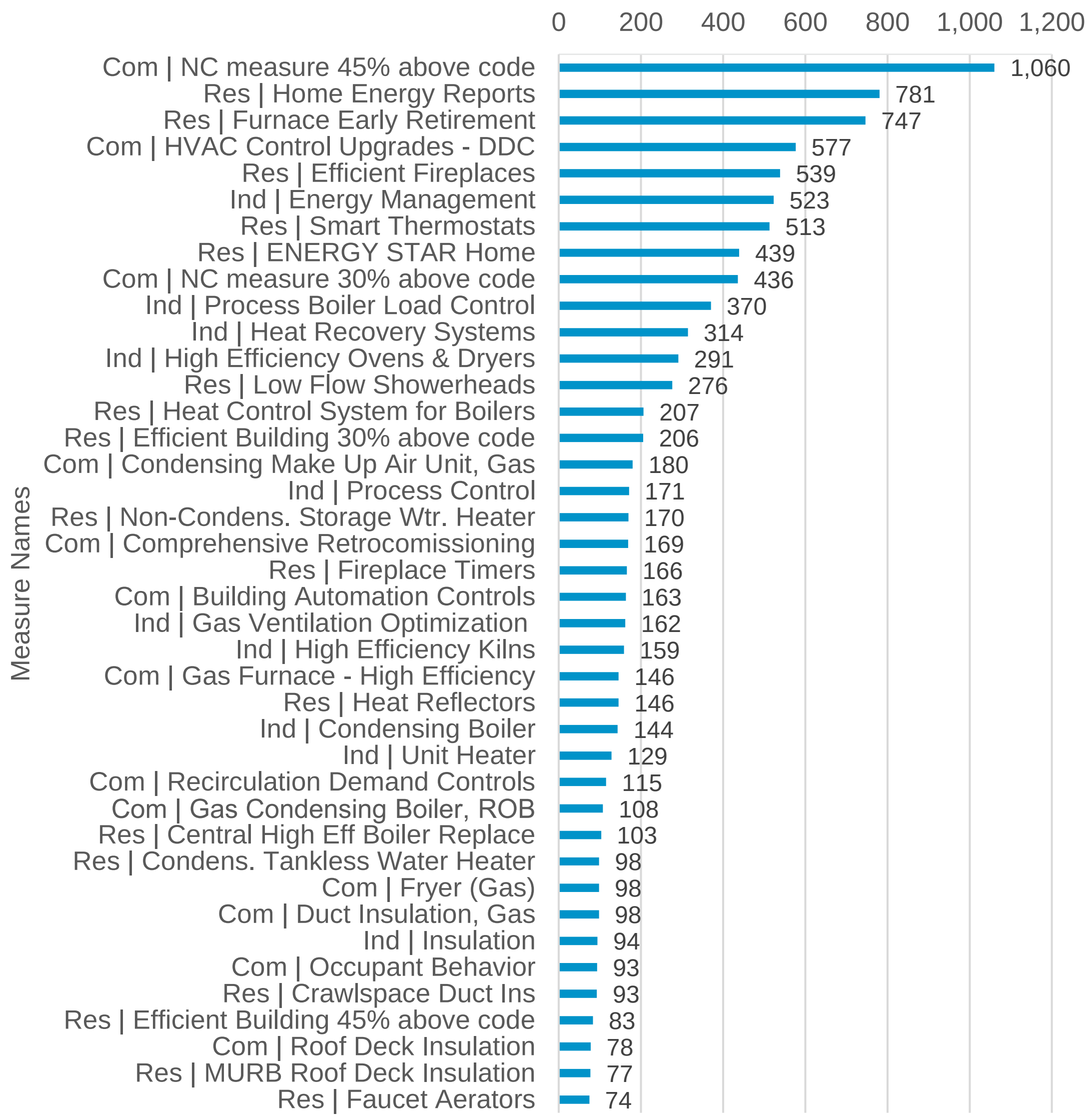
Figure 5-25. mTRC Cumulative Gas Savings Market Potential as Percent of Sector Consumption (%)



Source: Navigant

Figure 5-26 and Table B-16 list the top 40 gas saving measures with the highest market potential. Compared with the TRC market potential results, new construction practices 45% better than code and home energy reports remain as the top two measures. Residential furnace early replacement which is uneconomic using the TRC screen becomes economic and ranks third. Similarly, residential efficient fireplaces increase significantly in market savings using the mTRC and move into the top five measures.

Figure 5-26. mTRC Top 40 Measures for Gas Energy Market Savings Potential in 2025 (TJ/year)



Source: Navigant

5.4.4 mTRC Cost Effectiveness

The following tables present cost effectiveness results for the mTRC case, including the portfolio and sector-level budget estimates and benefit-cost test ratios. Table 5-5 shows the mTRC case's total portfolio budget is $1,388 million over the 2016-2035 timeframe, as compared to $760 million under the TRC case over the same timeframe. Although market potential savings increase by 15% using the mTRC screen instead of the TRC screen, the portfolio budget increased by approximately 85%. This is because the least costly savings are captured using the TRC screen (i.e., the "low hanging fruit"), whereas the measures captured using the mTRC screen are significantly more costly on a $/GJ basis.

The vast majority of the increased budget is from an increase in residential incentive costs. Residential incentives more than triple in magnitude, while commercial and industrial incentives increase by 14% and 34%, respectively.

Table 5-5. Budgets by Sector – mTRC Case (Million $/year)

Sector	Spending Type	2016	2020	2025	2030	2035	2016-2035 Total*
Commercial	Incentives	$13.77	$18.32	$21.65	$23.21	$23.16	$402.89
	Non-Incentives	$1.68	$1.76	$1.93	$1.93	$1.78	$36.33
	Total	$15.44	$20.08	$23.58	$25.14	$24.94	$439.22
Industrial	Incentives	$3.45	$5.70	$9.21	$12.67	$14.32	$187.59
	Non-Incentives	$1.21	$1.78	$2.52	$3.10	$3.36	$49.48
	Total	$4.66	$7.47	$11.73	$15.76	$17.67	$237.06
Residential	Incentives	$26.45	$32.93	$33.64	$31.43	$30.01	$606.37
	Non-Incentives	$5.32	$5.01	$4.71	$5.43	$6.43	$105.38
	Total	$31.78	$37.94	$38.35	$36.86	$36.44	$711.75
Portfolio	Incentives	$43.67	$56.94	$64.50	$67.31	$67.49	$1,196.85
	Non-Incentives	$8.21	$8.55	$9.17	$10.45	$11.57	$191.19
	Total	$51.88	$65.49	$73.67	$77.77	$79.05	$1,388.04

*The 2016-2035 Total column represents the sum of all forecasted years (2016-2035), not just those shown in the table.
Source: Navigant

Given that the change in avoided costs for the mTRC does not apply to the UCT, PCT, or RIM benefit-cost tests, these test ratios are only presented in Section 5.3.

Table 5-6 shows the mTRC benefit-cost test ratios by sector and for the portfolio. Compared with the TRC benefit-cost test ratio, the 2016-2035 portfolio benefit-cost ratio increases from 1.99 to 4.67. The mTRC benefit-cost ratios for the residential, commercial, and industrial sector also have increases of similar magnitude. The increase in benefit-cost ratios is a result of the higher avoided costs used for mTRC test.

Table 5-6. mTRC Benefit-Cost Test Ratios for the Portfolio and by Sector

Sector	Year	Benefit-Cost Ratio
Commercial	2016	6.86
	2020	6.54
	2025	6.32
	2030	5.98
	2035	5.65

Table 5-7 presents the mTRC net benefits by sector and for the portfolio. The net benefits increase from $460 million using the TRC screen to approximately $3,310 million using the mTRC screen. The residential, commercial, and industrial sectors increase in net benefits almost proportionally to the overall portfolio.

Table 5-7. mTRC Net Benefits for the Portfolio and by Sector (Million $/year)

Sector	Year	Net Benefits
Commercial	2016	$137.22
	2020	$165.37
	2025	$184.18
	2030	$183.98
	2035	$171.44
	2016-2035	$1,683.70
Industrial	2016	$34.95
	2020	$61.06
	2025	$100.57
	2030	$130.88
	2035	$141.95
	2016-2035	$832.10
Residential	2016	$48.88
	2020	$74.72
	2025	$82.88
	2030	$103.21
	2035	$126.07
	2016-2035	$801.37
Portfolio	2016	$221.05
	2020	$301.15
	2025	$367.63
	2030	$418.07
	2035	$439.47
	2016-2035	$3,317.18

*Total net benefits for 2016-2035 represent prevent values. Other yearly values represent non-discounted single year net benefits.

5.5 Hybrid mTRC/TRC Results

The “Hybrid” case uses results from the mTRC test for the residential sector and results from the TRC test for the commercial and industrial (C&I) sectors, which is most analogous to FortisBC Gas’s actual DSM program environment. Because sector-level results are identical to the mTRC case’s residential results and the TRC case’s C&I results, the reader can refer to Sections 5.2 and 5.4 for sector-level results. This section focuses exclusively on portfolio-level results, which are a weighted combination of TRC and mTRC results.

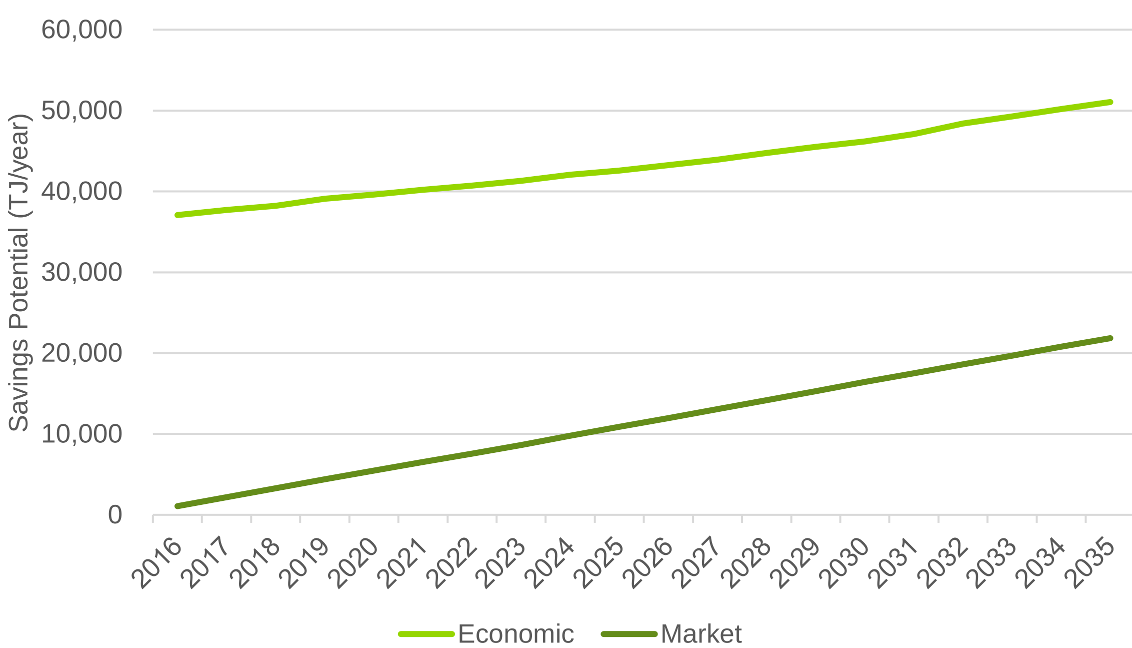
5.5.1 Approach to Estimating Hybrid mTRC/TRC Results

FortisBC Gas uses both the mTRC and TRC tests as cost effectiveness screens for measures within their existing DSM portfolio. As noted in Section 5.1, FortisBC Gas's regulatory environment at the time of this analysis allowed the utility to spend up to 33% of its entire DSM portfolio on measures or programs that require the mTRC to be cost effective. To date, FortisBC Gas's experience is that typically most programs in the residential sector require the mTRC. Since FortisBC Gas uses a combination of TRC and mTRC benefit-costs tests to screen measures and programs within their portfolio, Navigant estimated "Hybrid" market potential using the mTRC test for the residential sector and the TRC test for the C&I sectors to most closely simulate FortisBC Gas's actual DSM portfolio.

5.5.2 Hybrid mTRC/TRC Economic and Market Potential Results

Since the results from the Hybrid case are a weighted combination of the TRC and mTRC results, all results in this section will fall somewhere between the bounds set by those two cases. Figure 5-27 and Table B-17 in Appendix B show the economic and market gas savings potential for the Hybrid case. On average across the study period, the Hybrid case's economic potential is 20% larger than the TRC case and 9% smaller than the mTRC case, while the market potential is 12% larger than the TRC case and 5% smaller than the mTRC case. The Hybrid results more closely resemble the mTRC case because over two-thirds of the increase in market potential between the TRC and mTRC cases occurred in the residential sector, and those residential increases are captured in the Hybrid results.

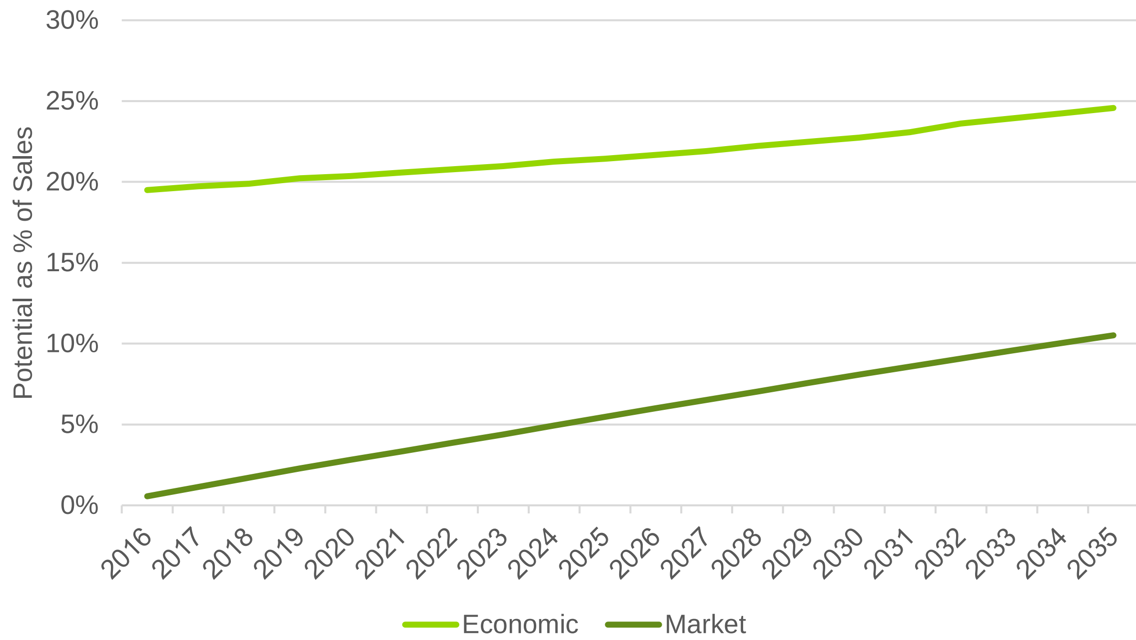
Figure 5-27. Hybrid Cumulative Gas Savings Economic and Market Potential by Sector (TJ/year)



Source: Navigant

Figure 5-28 and Table B-18 present the Hybrid case's economic and market potential as a percentage of total gas consumption. Market potential reaches just over 10% of total gas consumption by 2035, and it captures 43% of the economic potential.

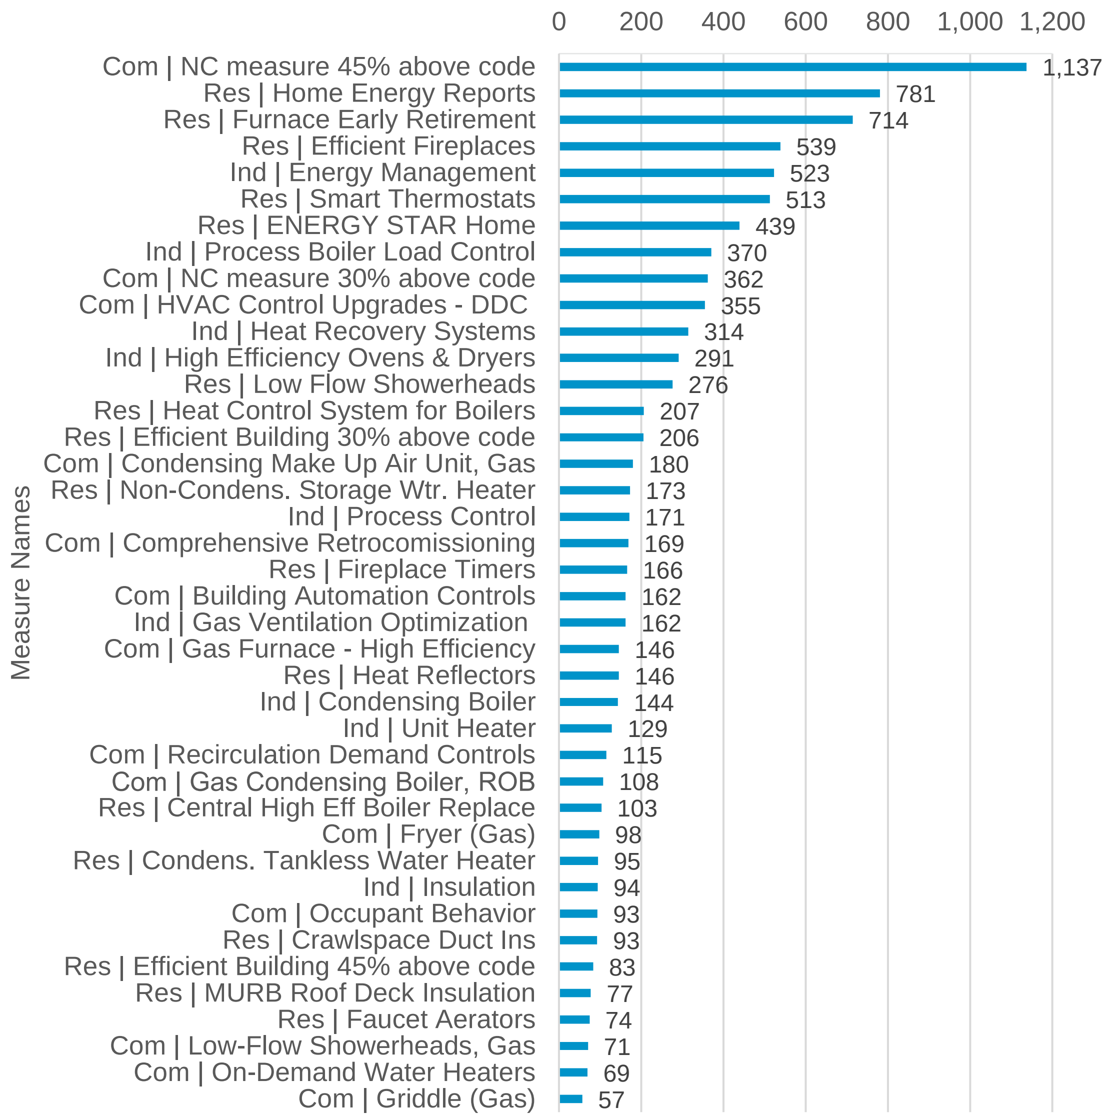
Figure 5-28. Hybrid Cumulative Gas Savings Economic and Market Potential as Percentage of Consumption (%)



Source: Navigant

Figure 5-29 and Table B-19 list the top 40 gas saving measures with the highest market potential for the Hybrid case. This table looks very similar to the TRC case except that residential measures have moved up the ranks. In particular, furnace early retirements and efficient fireplaces appear in the top ten, whereas they do not in the TRC case.

Figure 5-29. Hybrid Top 40 Measures for Gas Energy Market Savings Potential in 2025 (TJ/year)



Source: Navigant

5.5.3 Hybrid mTRC/TRC Cost Effectiveness

The following tables present cost-effectiveness results for the hybrid mTRC/TRC case. Table 5-8 shows that total spending for the Hybrid case begins at just over $46M/year and increases to $74M/year by 2035. The total 20-year spending in the Hybrid case is 71% larger than the TRC case and 8% smaller than the mTRC case. The costs borne by the utility to acquire market savings—on a dollar-per-savings basis—increase 0 to 3 percent per year, on average and in real terms, across the various sectors. This contrasts with recent program experience, where per-unit-of-savings utility costs have shown declining trends (see Section 5.3.2 for a discussion on this difference in cost trends).

Table 5-8. Budget for Portfolio – Hybrid Case (Million $/year)

Sector	Spending Type	2016	2020	2025	2030	2035	2016-2035 Total*
Portfolio	Incentives	$38.30	$51.08	$58.75	$61.91	$62.81	$1,114.66
	Non-Incentives	$7.97	$8.29	$8.92	$10.21	$11.33	$186.88
	Total	$46.27	$59.37	$67.67	$72.12	$74.13	$1,301.53

**The 2016-2035 Total column represents the sum of all forecasted years (2016-2035), not just those shown.*
Source: Navigant

The benefit-cost ratios and net benefits from the Hybrid case, which are presented in Table 5-9, are more similar to the TRC case than the mTRC case. Since the residential sector has lower benefit-cost ratios compared to the other sectors in both the TRC and mTRC cases, using the slightly higher residential results from the mTRC case does not significantly lift the benefit-cost ratios of the Hybrid portfolio. However, the additional net benefits that the residential mTRC case adds to the Hybrid portfolio is approximately $705 million in present value over the study period (expressed in 2016 dollars).

Table 5-9. Hybrid Portfolio Benefit-Cost Test Ratios and Net Benefits (Million $/year)

Sector	Year	Benefit-Cost Ratio	Net Benefits
Portfolio	2016	2.02	$67.04
	2020	2.26	$103.08
	2025	2.43	$125.10
	2030	2.73	$155.67
	2035	3.00	$185.00
	2016-2035*	2.41	$1,162.60

**Total net benefits for 2016-2035 represent present values in 2016 dollars. Other yearly values represent non-discounted, single-year net benefits.*

Appendix C-2

CONSERVATION AND ENERGY MANAGEMENT PROGRAM AREA COST EFFECTIVENESS TEST RESULTS

APPENDIX C-2: CONSERVATION AND ENERGY MANAGEMENT PROGRAM AREA COST EFFECTIVENESS TEST RESULTS

1.1 Background

The base year of the 2017 LTGRP forecast is 2015 but the C&EM analysis does not include data for 2015 and 2016 since these years are in the past already. FEI filed its actual program performance for these years with the Commission in its 2015 and 2016 C&EM Annual Reports.[1,2] FEI does not expect the LTGRP 2017 cost effectiveness test results to match its 2017 C&EM Annual Report because both filings are different in nature and methods and use different years of actuals data (2015 versus 2017, respectively). In particular, the 2017 LTGRP C&EM analysis excludes the items noted in Section 4.2.3.2 of the Application. The C&EM analysis, like the BC CPR, also includes numerous energy efficiency measures which are not included in FEI's current C&EM program portfolio.

All cost effectiveness test results reported below exclude data from behavioural and energy management measures. In alignment with the BC CPR, the 2017 LTGRP C&EM analysis assumes that these measures have negligible incremental costs which cause them to have uncharacteristically high cost effectiveness test results. Excluding data for these measures prevents their results from skewing the aggregate data reported below.

In general, Upper Bound cost effectiveness test ratios are lower than Lower Bound ratios because the low natural gas cost and carbon cost parameters in this scenario depress the avoided cost of gas which reduces the benefits from energy efficiency measures. The Modified Total Resource Cost Test (MTRC) represents an exception to this as this test relies on the Zero Emissions Energy Alternative (ZEEA) for its avoided cost of gas. In the 2017 LTGRP, the ZEEA is not impacted by the natural gas and carbon cost critical uncertainties. In general, cost effectiveness test ratios fall over time as the more easily realized energy savings opportunities (i.e. the low-hanging fruit) are depleted. The 2017 LTGRP C&EM cost effectiveness test results also display the Cost of Conserved Energy (CCE) in dollars per GJ. The CCE is an industry standard method for expressing the Total Resource Cost Test (TRC) results in dollars per GJ. Electric utilities use the CCE to express the net cost of saving one unit of utility-supplied energy. The CCE can be used to express UCT results in dollars per GJ by applying the UCT benefit and

2 Appendix D-28: https://www.fortisbc.com/About/RegulatoryAffairs/GasUtility/NatGasBCUCSubmissions/Documents/170331_FEI_2016_DSM_Annual_Report_FF.PDF.

cost inputs.[3] While Section 4.2.3.3 of the Application outlines cost effectiveness test results for the aggregate C&EM portfolio, the remainder of this appendix provides the same results for each of the program areas within the 2017 LTGRP C&EM analysis.

1.2 Residential Program Area

Table C2-1 below summarizes the Reference Case cost effectiveness test results for the residential program area while Figures C2-1 to C2-4 illustrate how cost effectiveness test results vary across scenarios. The aggregate residential program area TRC ratio is lower and the aggregate Utility Cost Test (UCT) is higher than the corresponding portfolio level results. Aggregate residential CCE results are higher than the corresponding portfolio level results but the annual results drop over time.[4]

Table C2-1: Estimated Reference Case Cost Effectiveness Test Results – Residential Program Area

Year	TRC	MTRC	UCT	CCE ($/GJ)
Aggregate	**1.6**	**7.2**	**2.3**	**6.3**
2017	2.4	9.7	2.9	7.4
2018	2.2	9.0	2.8	7.2
2019	2.1	8.8	2.7	7.0
2020	2.1	8.6	2.7	7.0
2021	1.9	8.2	2.6	6.9
2022	1.9	7.9	2.5	6.8
2023	1.8	7.7	2.4	6.7
2024	1.7	7.3	2.3	6.8
2025	1.6	7.2	2.3	6.7
2026	1.6	7.1	2.3	6.6
2027	1.6	7.0	2.3	6.5
2028	1.5	6.9	2.2	6.4
2029	1.5	6.8	2.2	6.4
2030	1.5	6.7	2.2	6.3
2031	1.5	6.7	2.2	6.2
2032	1.5	6.9	2.2	6.1

[3] In this case, the CCE represents the annualized and, where applicable, discounted UCT costs divided by annual energy savings.

[4] This appears to be due to the relative trajectory of the ZEEA in relation to projected residential energy savings.

Year	TRC	MTRC	UCT	CCE ($/GJ)
2033	1.5	7.1	2.3	6.0
2034	1.6	7.2	2.3	5.9
2035	1.6	7.4	2.4	5.8
2036	1.6	7.6	2.4	5.7

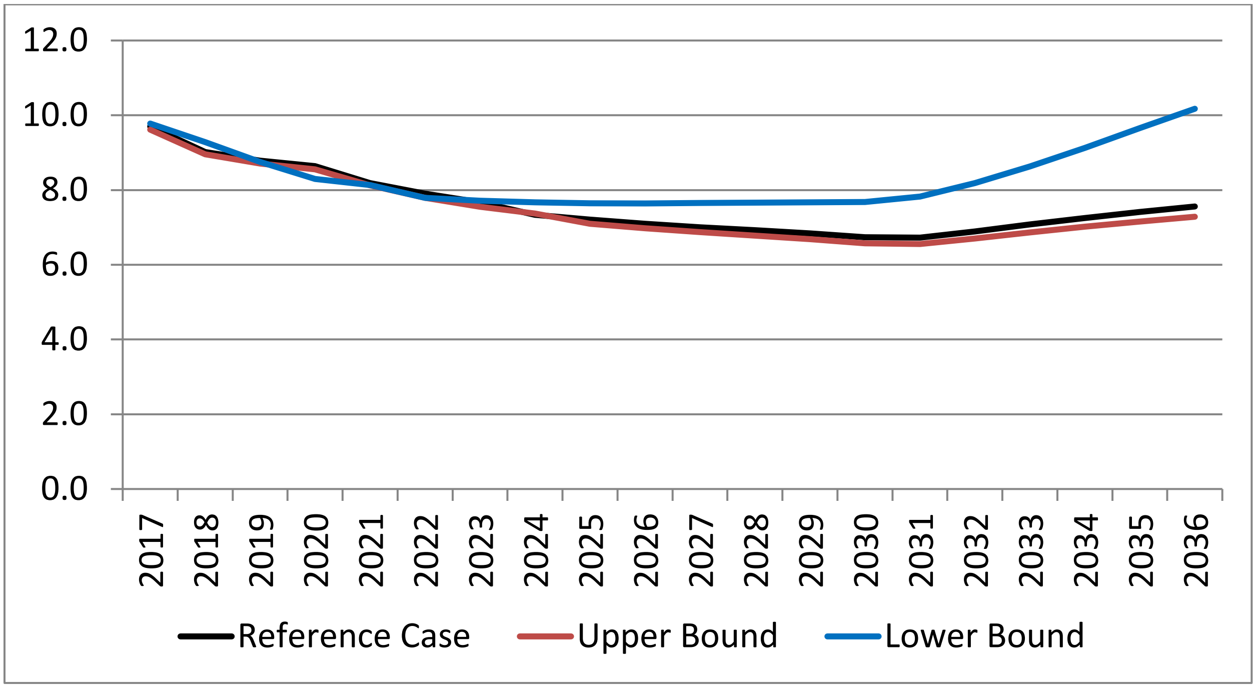

Figure C2-3: Estimated UCT Results by Scenario – Residential Program Area

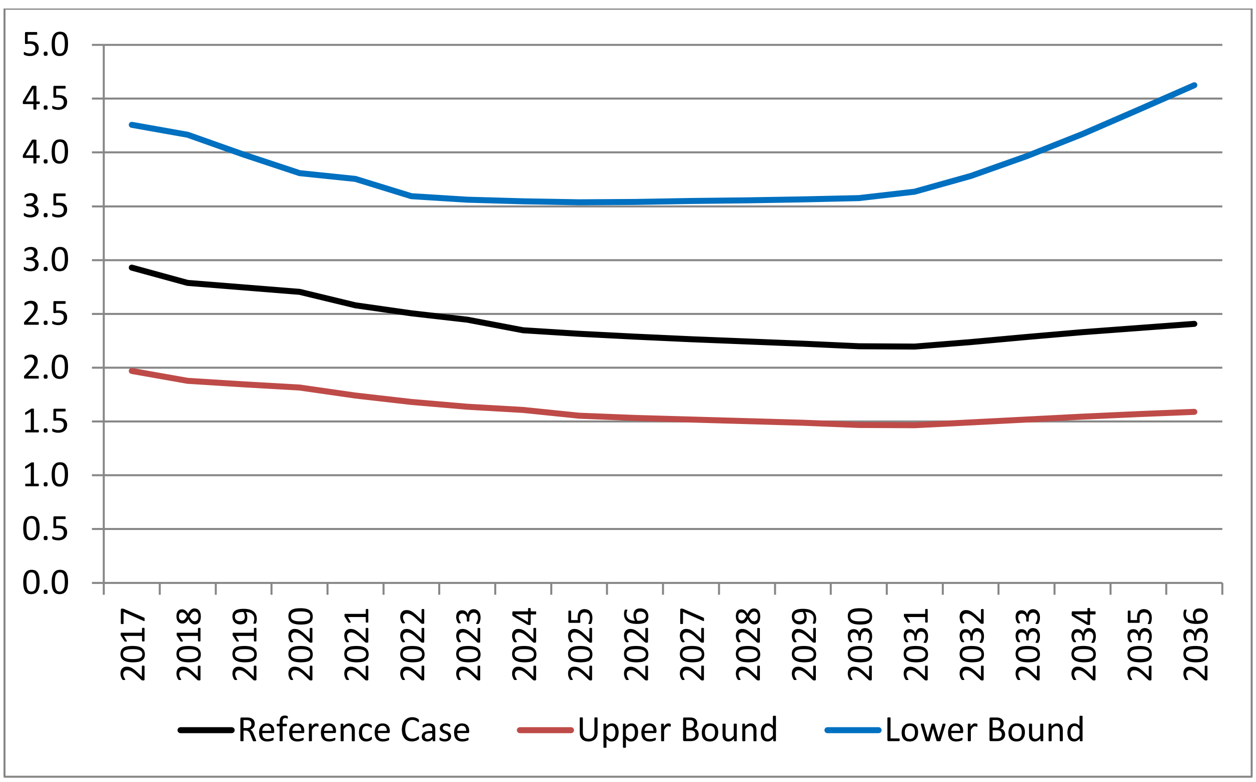

Figure C2-4: Estimated CCE Results by Scenario ($/GJ) – Residential Program Area

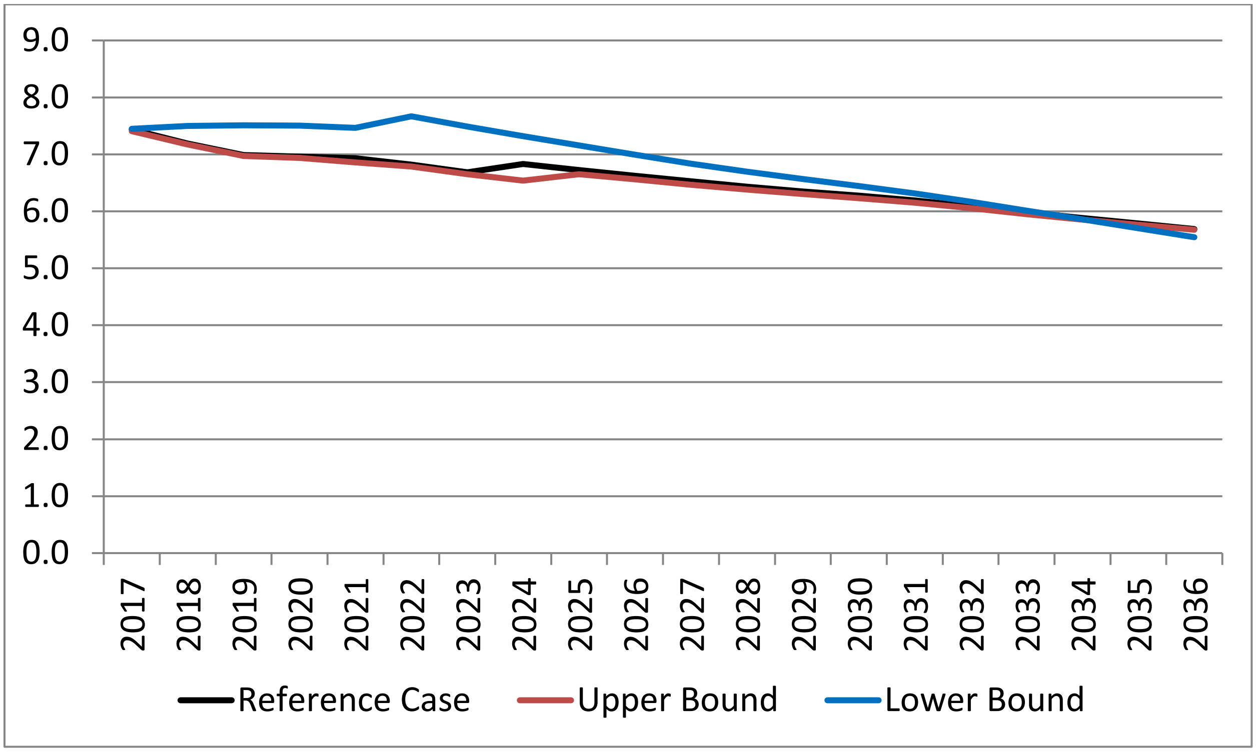

1.3 Commercial Program Area

Table C2-2 below summarizes the Reference Case cost effectiveness test results for the commercial program area while Figures C2-5 to C2-8 illustrate how cost effectiveness test results vary across scenarios. The aggregate commercial program area TRC ratio is higher than and the aggregate UCT is the same as the corresponding portfolio level results. Aggregate commercial CCE results are lower than the corresponding portfolio level results but annual results increase over time.

Table C2-2: Estimated Reference Case Cost Effectiveness Test Results – Commercial Program Area

Year	TRC	MTRC	UCT	CCE ($/GJ)
Aggregate	**2.8**	**14.9**	**2.2**	**4.0**
2017	5.8	31.8	5.0	1.3
2018	5.3	28.5	4.4	1.6
2019	4.5	24.4	3.7	2.2

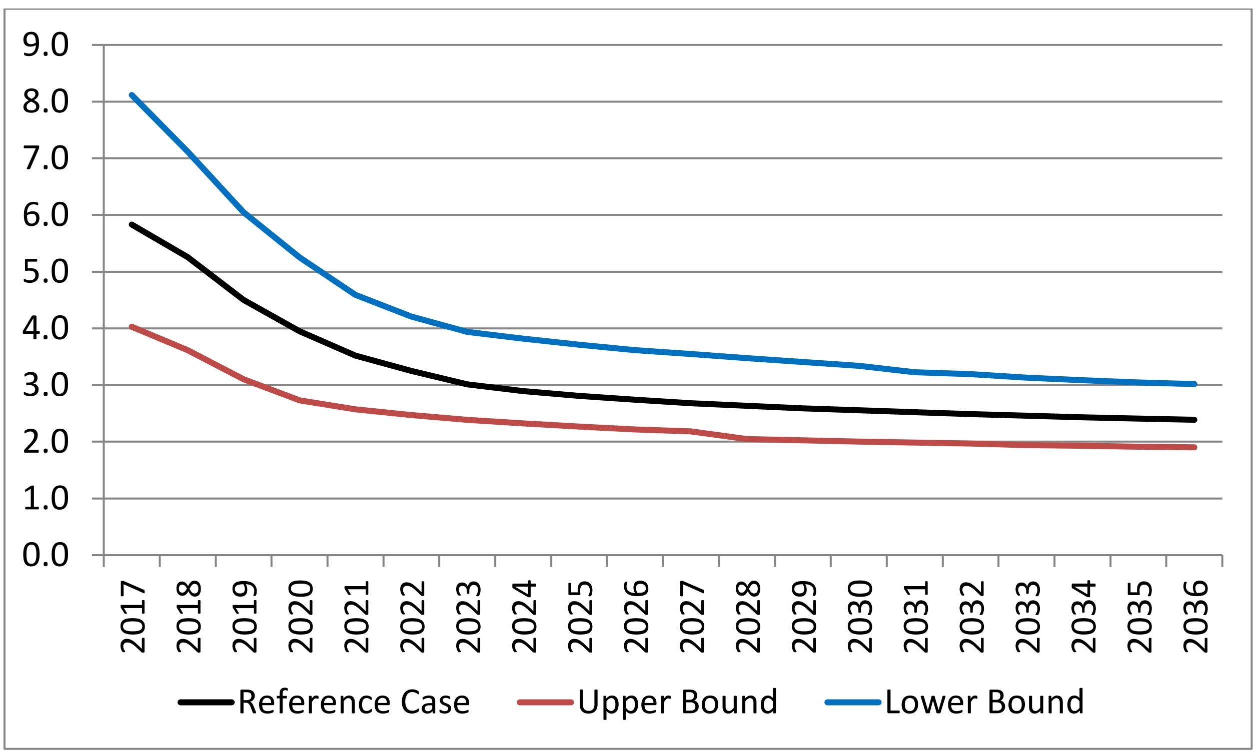

Figure C2-6: Estimated MTRC Results by Scenario – Commercial Program Area

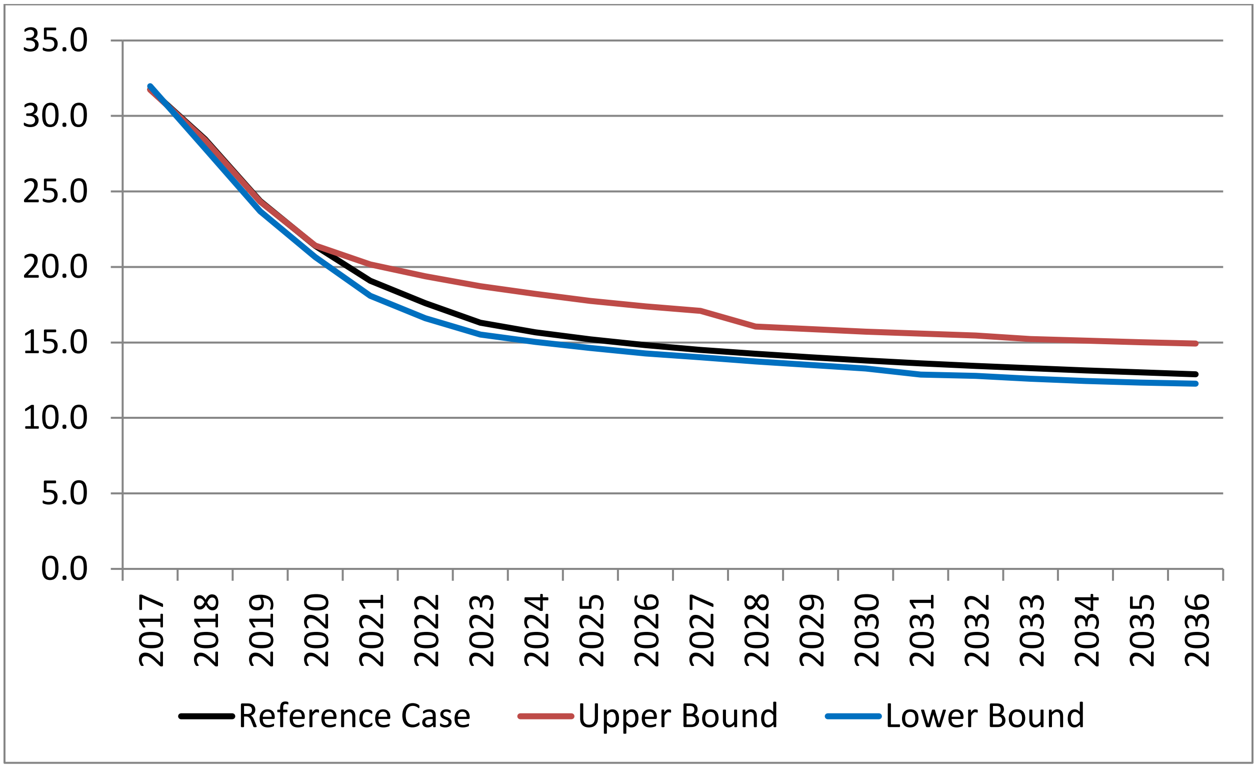

Figure C2-7: Estimated UCT Results by Scenario – Commercial Program Area

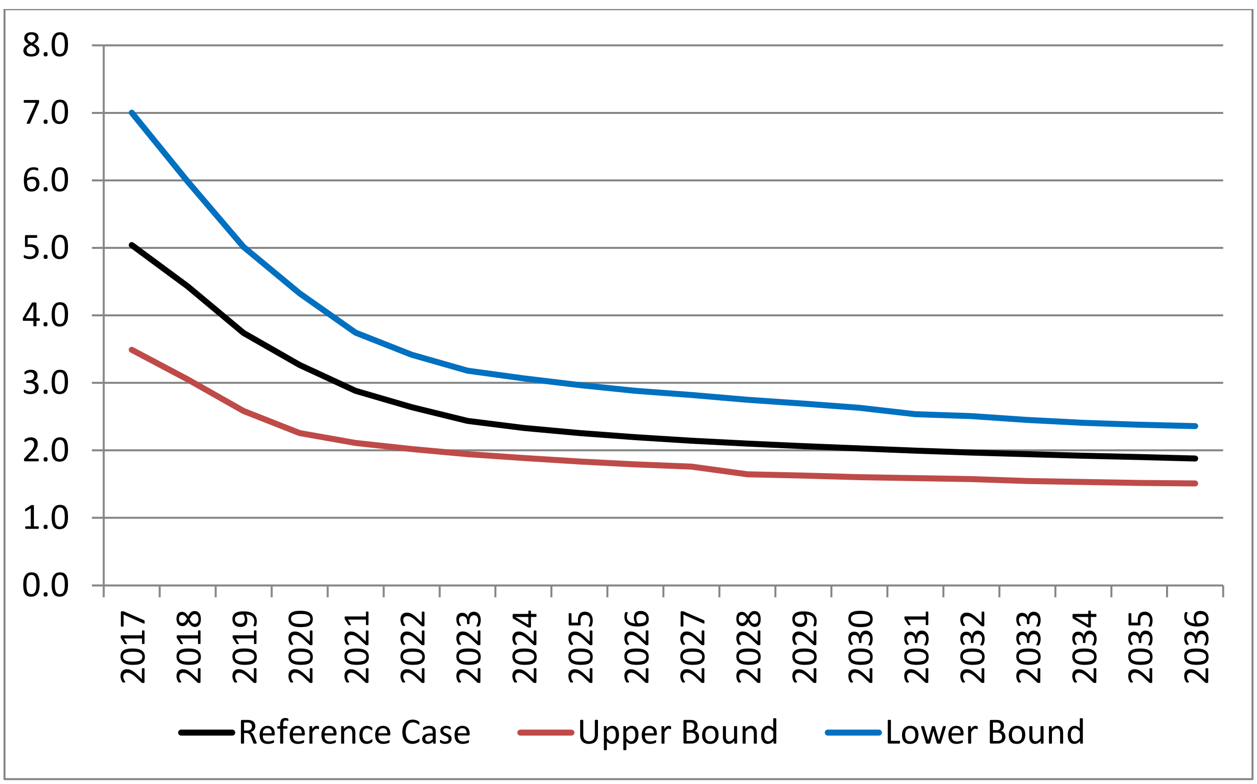

Figure C2-8: Estimated CCE Results by Scenario ($/GJ) – Commercial Program Area

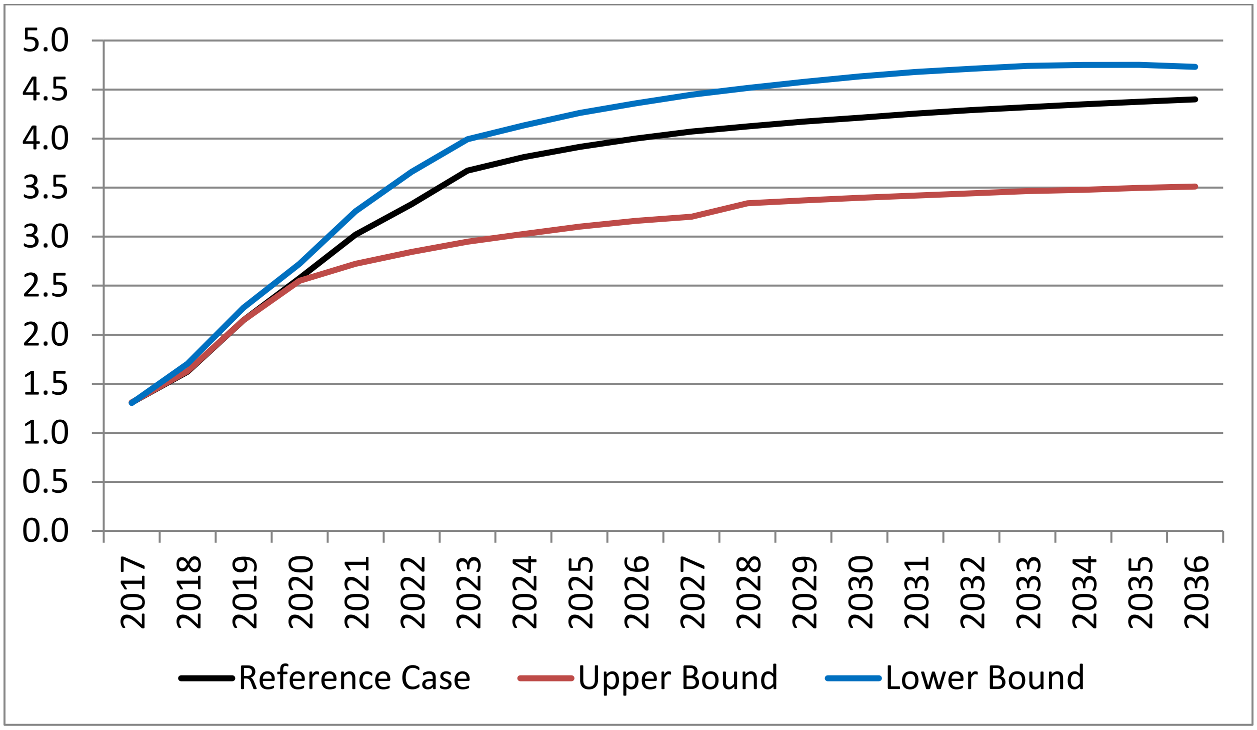

1.4 Industrial Program Area

Table C2-3 below summarizes the Reference Case cost effectiveness test results for the industrial program area while Figures C2-9 to C2-12 illustrate how cost effectiveness test results vary across scenarios. The aggregate industrial program area TRC ratio is higher than and the aggregate UCT is lower than the corresponding portfolio level results. Aggregate industrial CCE results are lower than the corresponding portfolio level results and annual results remain flat over time.

Table C2-3: Estimated Reference Case Cost Effectiveness Test Results – Industrial Program Area

Year	TRC	MTRC	UCT	CCE ($/GJ)
Aggregate	**1.7**	**9.4**	**1.8**	**3.3**

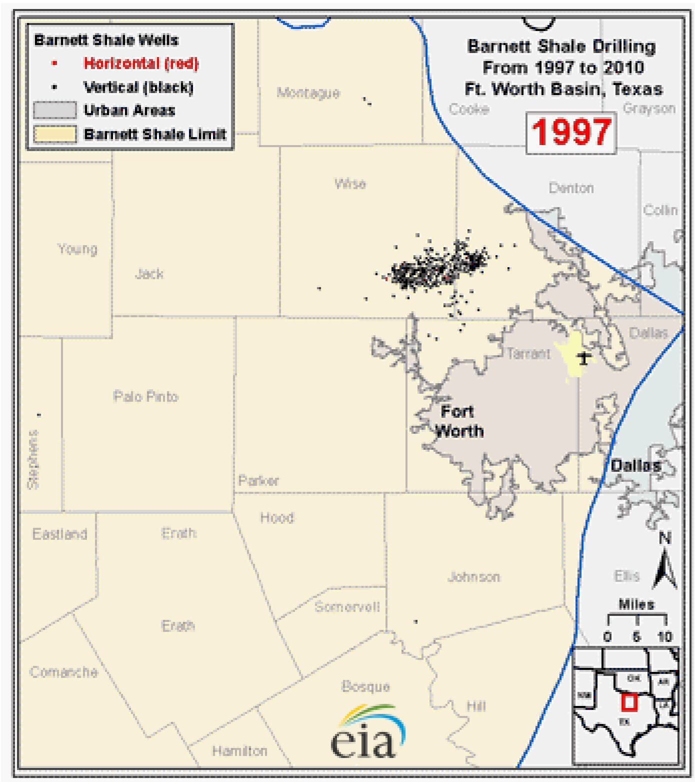
Technology drives natural gas production growth from shale gas formations

Watch Barnett Shale Drilling from 1997 to 2010



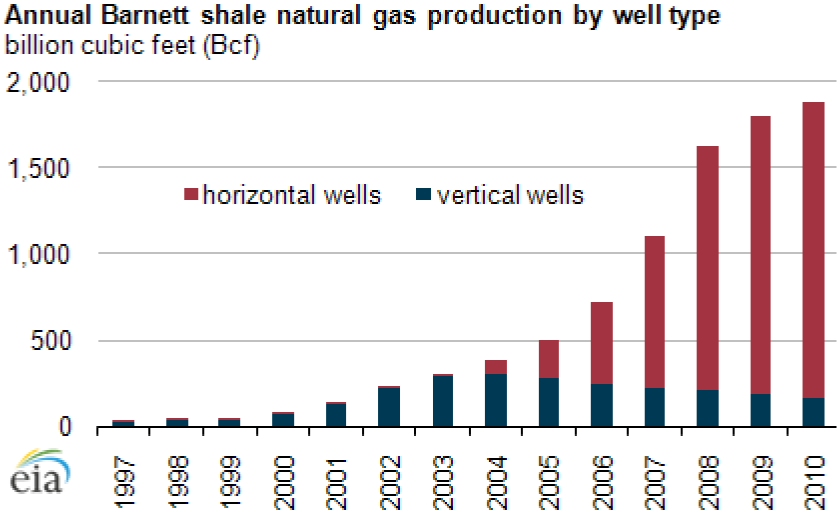
Source: U.S. Energy Information Administration based on HPDI, LLC

Rapid increases in natural gas production from shale gas formations resulted from widespread application of two key technologies, horizontal drilling and hydraulic fracturing. Horizontal drilling lets producers access far more natural gas from relatively thin shale deposits. In Texas' Barnett shale, the Nation's most developed shale play, the number of producing horizontal wells rose from fewer than 400 in 2004 to more than 10,000 during 2010.

Click on the map above to see how horizontal drilling has displaced traditional vertical drilling since 1997 in the Barnett shale.

As the animation shows, producers have drilled some horizontal wells within the city of Fort Worth, and even on the property of the Dallas-Fort Worth airport, where wells began to appear in 2007 (near the end of the animation). The sharpened focus on horizontal drilling has generated steady and significant increases in natural gas production (see chart below). Annual production from horizontal wells exceeded that from vertical wells for the first time in 2006, and presently accounts for about 90% of total Barnett natural gas production.

Starting in the late 1990s, drilling in the Barnett grew rapidly, initially in the form of vertical wells. Since about 2003, however, the number of producing horizontal wells (red dots in the animation) has increased considerably, surpassing vertical wells (black dots) in 2007 and accounting for about 70% of producing wells in the Barnett during 2010.



Source: U.S. Energy Information Administration based on HPDI, LLC

Shale deposits are typically thin layers of rock that cover a wide area. Horizontal drilling lets producers drill through a much greater extent of gas-producing rock in such a formation. Horizontal wells can traverse 5,000 feet or more of a given shale deposit, while a vertical well would simply go through the deposit, tapping only a small vertical layer of shale. When combined with hydraulic fracturing to break apart the relatively impermeable shale, horizontal wells allow considerably greater gas production than vertical wells, more than enough to make up for their greater expense.

Foreword

National Energy Board

The National Energy Board (NEB or Board) is an independent federal regulator established to promote safety and security, environmental protection and economic efficiency in the Canadian public interest within the mandate set by Parliament for the regulation of pipelines, energy development and trade. The Board's main responsibilities include regulating the construction, operation and abandonment of pipelines that cross international borders or provincial/territorial boundaries, as well as the associated pipeline tolls and tariffs, the construction and operation of international power lines and designated interprovincial power lines; and imports of natural gas and exports of crude oil, natural gas liquids (NGL), natural gas, refined petroleum products and electricity.

For oil and natural gas exports, the Board's role is to evaluate whether the oil and natural gas proposed to be exported is surplus to reasonably foreseeable Canadian requirements, having regard to the trends in the discovery of oil or gas in Canada.

If a party wishes to rely on material from this report in any regulatory proceeding before the Board, it may submit the material, just as it may submit any public document. Under these circumstances, the submitting party in effect adopts the material and could be required to answer questions pertaining to its content.

This report does not provide an indication about whether any application will be approved or not. The Board will decide on specific applications based on the material in evidence before it at that time.

The Northwest Territories Geological Survey

The Northwest Territories Geological Survey (NTGS) is a division of the Department of Industry, Tourism and Investment, Government of the Northwest Territories. The NTGS advances geoscience knowledge about the Northwest Territories for the benefit of northerners and all Canadians. The NTGS does this through the delivery of geoscience research, analysis of mineral and petroleum resources, and by offering excellence in digital data management. The NTGS regularly collaborates with its partners and other organizations in support of modern geoscience research, public awareness and education, and informed decision making.

The Yukon Geological Survey

The mandate of the Yukon Geological Survey (YGS) is to be the authority and provider of choice for the geoscience and related technical information required to enable stewardship and sustainable development of the Territory's energy, mineral, and land resources. The YGS generates and compiles information on Yukon's geology, mineral and petroleum resources; works in partnership with other branches of Yukon Government to distribute geoscience maps and publications to exploration companies, First Nations and the public; and through studies such as this assessment, contributes information required to make informed resource management decisions.

British Columbia Oil and Gas Commission

The BC Oil and Gas Commission (Commission) is the provincial regulatory agency with responsibilities for regulating oil and gas activities in British Columbia, including exploration, development, pipeline transportation and reclamation.

The Commission's core services include reviewing and assessing applications for industry activity, consulting with First Nations, cooperating with partner agencies, and ensuring industry complies with provincial legislation and all regulatory requirements. The public interest is protected by ensuring public safety, respecting those affected by oil and gas activities, conserving the environment, and ensuring equitable participation in production.

Responding to the complex and often competing economic, environmental and social priorities driving the oil and gas industry, the Commission maintains a modern regulatory framework and proactively looks for innovative solutions for continued safe and sustainable oil and gas development in the province. In accordance with its mandate, the Commission strives to deliver fair and timely decisions on proposed projects, balancing firm oversight of operational safety and First Nations' rights.

The Commission liaises with other provincial and federal government agencies in ensuring effective delivery of government policy, improved regulatory climate and cohesive application of existing regulations. It is of key importance for the Commission to stay fully apprised of the latest technological breakthroughs, and independent world-wide scientific research pertinent to the industry.

British Columbia Ministry of Natural Gas Development

The role of the British Columbia Ministry of Natural Gas Development is to guide the responsible development and ensure maximum economic benefits to British Columbians from the province's natural gas resources and the province's next new major industrial sector - that of liquefied natural gas (LNG).

Through teamwork and positive working relationships with its clients, the Ministry facilitates B.C.'s thriving, safe, environmentally responsible and competitive natural gas sector to create jobs and economic growth. In developing natural gas policies, legislation and guidelines, the Ministry consults with other ministries and levels of government, energy companies, First Nations, communities, environmental and industry organizations, and the public.

A key component of the Ministry's mandate is to develop tenure, royalty and regulatory policy for British Columbia's natural gas industry, thereby promoting the effective and environmentally responsible management of the province's natural gas resources.

The Ministry provides a range of natural gas related services, including the issuance of Crown subsurface resource rights, royalty programs, public geoscience and policies to address potential future resource opportunities, including unconventional natural gas resource development. The Ministry's LNG Secretariat reports to the new Cabinet Working Group on Liquefied Natural Gas, which will advise on budgets, structure, mandate and service plan goals.

Executive Summary

The marketable, unconventional gas potential of the Exshaw and Patry shales of the Liard Basin's Besa River Formation have been evaluated in a joint assessment by the National Energy Board, the British Columbia Oil and Gas Commission, the British Columbia Ministry of Natural Gas Development, the Northwest Territories Geological Survey, and the Yukon Geological Survey. The thick and geographically extensive Exshaw and Patry shales are expected to contain 6.20 trillion m³ (219 trillion cubic feet) of marketable natural gas.[1]

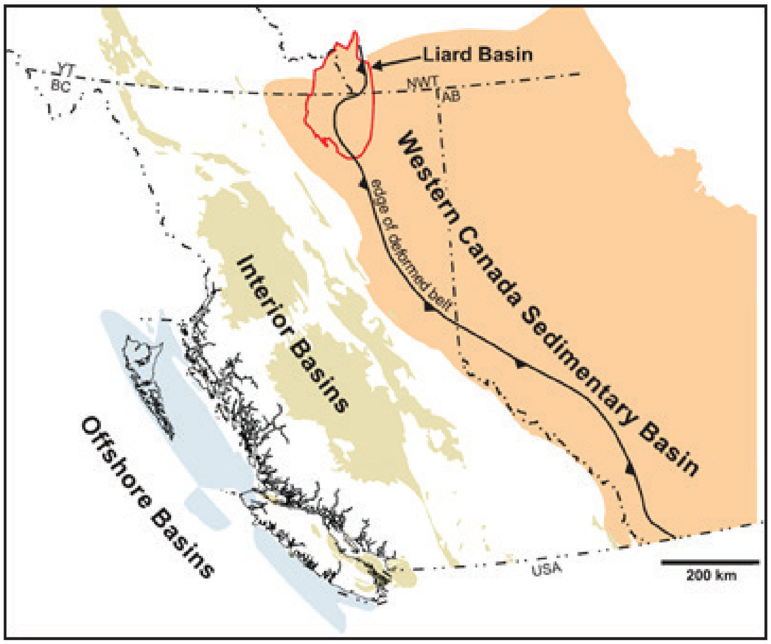

Figure 1. Location of the Liard Basin within the Western Canada Sedimentary Basin. The eastern boundary of the Liard Basin largely coincides with the Bovie Fault (see Figure 2). Modified from Ferri et al. (2015)

Introduction

The Liard Basin is a lightly drilled region at about 60 °N that straddles the boundaries of the Northwest Territories (NWT), Yukon, and the province of British Columbia (B.C.) (Figure 1). It is located at the far northwest corner of the Western Canada Sedimentary Basin (WCSB), Canada's major oil and gas producing area. The Liard Basin's unconventional[2] potential had not been assessed in detail before this study.

While **the Liard Basin's conventional potential was not assessed in this study**, conventional natural gas has been produced in the Liard Basin from the Beaver River Field of B.C. since the late 1960s, the Pointed Mountain Field and other gas fields of NWT since the early 1970s, and the Kotaneelee Field of Yukon since the late 1970s. Conventional gas has also been produced from B.C.'s Maxhamish Field since the late 1990s. Thus, there are already gas pipelines in the Liard Basin in all three jurisdictions.

[1] Marketable natural gas, as used in this report, indicates the volume of gas that is recoverable using existing technology, and is in a condition to be used by the market. While it implies a sense of economic recovery, no economic assessment was performed. The presence of gas pipelines did not affect this analysis.

[2] For this study, unconventional gas in the Liard Basin is considered natural gas that is developed using horizontal drilling and multi-stage hydraulic fracturing.

Geological Description

Sediments were deposited in the Liard Basin from the Cambrian period to the end of the Cretaceous period (from 540 million years (Ma) ago to 65 Ma ago). The central and eastern portions of the Liard Basin are relatively undeformed by faults where the Liard Basin's western and northwestern regions were faulted when the Rocky Mountains and Mackenzie Mountains were uplifted. The Liard Basin's eastern edge is defined by the Bovie Fault, separating it from the Horn River Basin. However, the two basins share many of the same shales, including the Exshaw and Horn River shales (Figure 2).[3] The Horn River Basin's shale gas potential was assessed in 2011.[4]

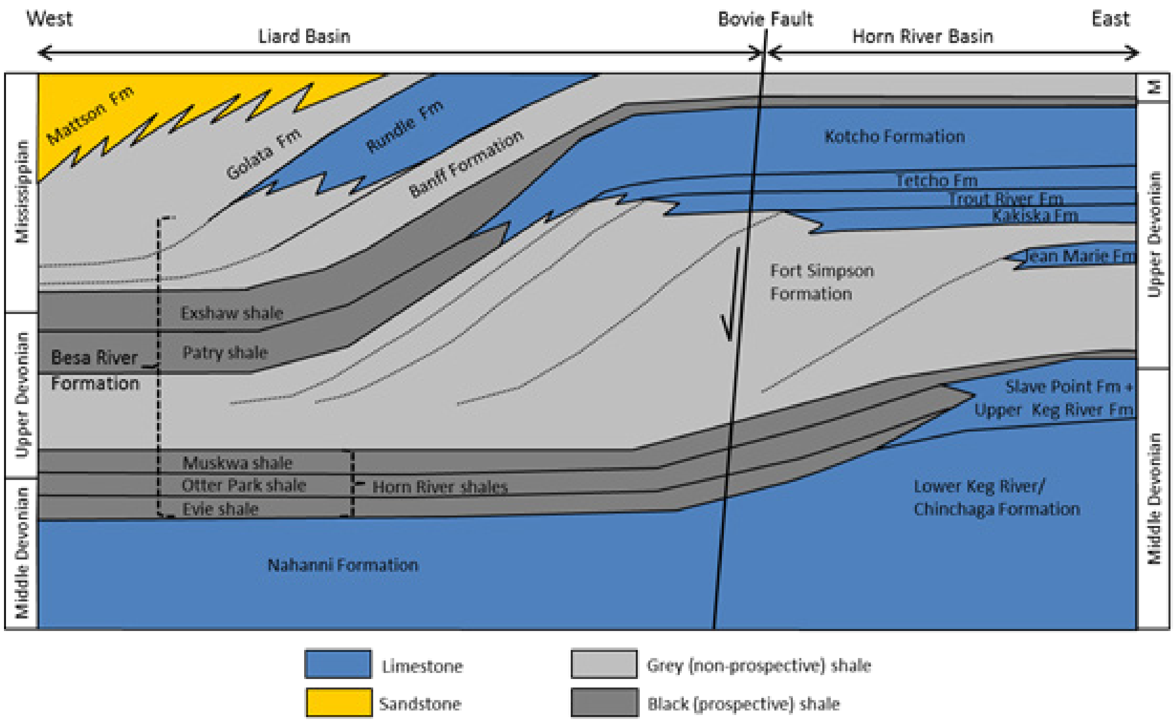

Figure 2. Stratigraphic architecture of the Besa River Formation and related units (not to scale). Vertical displacement on the Bovie Fault is not shown.

The Middle Devonian to Middle Mississippian Besa River Formation (deposited from 385 Ma to 335 Ma ago) is a succession of shales in the Liard Basin (Figure 2). The Besa River Formation ranges from 300 metres (m) thick to the west to over 2 000 m thick near the Bovie Fault to the east.

Straddling the Devonian-Mississippian boundary in the Besa River Formation is the Exshaw shale, which is prospective for shale gas. For most of the Liard Basin, the Patry shale underlies the Exshaw and is also prospective.[5] The Exshaw-Patry shale is in the early stages of exploration and, since 2009, has produced 356.6 million m^3 (12.6 billion cubic feet (Bcf)) of gas from two vertical wells and two horizontal wells in B.C.

The Exshaw-Patry shale's "net pay"[6] ranges from 20 m thick at the Liard Basin's eastern edge to over 200 m in the basin's centre. The Exhsaw-Patry shale is less than 1 kilometre (km) deep at the basin's northern edge to over 4 km deep in the centre of the basin. Total organic carbon (TOC) contents are typically 1.5 to 6 per cent. Silica contents are from 65 to 85 per cent. Porosity is between 4 and 9 per cent and is highest in organic-rich horizons.

---

[3] The hierarchy of stratigraphic units in the Liard Basin has been simplified for this study, because it differs between the three jurisdictions and is being revised with new information.

[4] *Ultimate Potential for Unconventional Natural Gas in Northeastern British Columbia's Horn River Basin*, 2011.

[5] For more details on the characteristics and stratigraphy of the Exshaw-Patry succession in BC, please see Ferri, F, McMechan, M., and Creaser, R., 2015, *The Besa River Formation in Liard Basin, British Columbia,* pp. 1-27.

[6] Not all of a rock section may be prospective for hydrocarbons. "Net pay" is a measurement of a section's prospective thickness.

The Exshaw-Patry shale is also exceptional amongst North American shale gas plays because it is typically very deep, very rich in silica (the reservoir is very brittle and prone to cracking when hydraulic fracturing is applied), and it is 100 per cent over-pressured where tested.[7]

Deeper in the Besa River Formation are the Horn River shales (Figure 2), which extend into the Liard Basin from the Horn River Basin to the east, where they produce shale gas. Little information is available about these deeper shales in the Liard Basin of B.C., while more information is available in NWT and Yukon where the Horn River shales are shallower. In NWT and Yukon, these shales range from less than 1 km deep at the northern edge of the Liard Basin to more than 4 km deep at the territories' southern borders. The net pay ranges from 40 m at its northern edge to almost 300 m around the Pointed Mountain gas field of NWT.

Methods

The original gas-in-place (OGIP) in the Liard Basin was assessed using methods similar to those in a 2013 study that examined B.C.'s Montney Formation[8], where map grids of geological data were connected to free gas and adsorbed gas equations[9] to determine how gas volumes geographically vary. However, unlike the Montney study, this study's marketable gas was determined from the estimated ultimate recovery (EUR) from a hypothetical, index shale gas well as based on an analysis of Liard Basin production data. The EUR from an index tract[10] was then determined from the number of wells assumed to fully develop it. The EURs of other tracts in the Liard Basin were then determined by calibrating them to the index tract through their net pays, TOCs (a proxy for porosity, gas saturation, and adsorbed gas), pressures, and areas.

Statistical distributions were applied to some variables in assessment equations and then Monte Carlo simulations were used to estimate low, expected, and high values.[11] A surface loss to convert raw OGIP to dry OGIP through the removal of gas impurities[12], as well as to convert raw EURs to marketable EURs through the removal of impurities and some fuel gas for gas processing, was also applied.

In B.C. and Yukon, areas of the Liard Basin within the Rocky Mountains, Mackenzie Mountains, and Franklin Mountains were excluded from the assessment except for the outer fringes of the Rocky Mountain and Franklin Mountain foothills, which were considered a deformed play area. In NWT, the Franklin Mountains (including the Liard Range) were included in the assessment and formed NWT's deformed area. Elsewhere, the Liard Basin was considered undeformed.

To simulate reservoir risks in deformed areas where pressures can be naturally drained by faults, a reservoir risk factor was applied to OGIP. Meanwhile, technical risk factors were applied to EURs in deformed areas because of risks associated with drilling such that less gas was considered recoverable in the deformed areas of B.C. and Yukon, while no gas was considered recoverable in the deformed area of NWT except for the Pointed Mountain gas field. It was also assumed that development would not occur where net pay is less than 30 m and where depths are shallower than 1 500 m, because flow rates would be too low to justify drilling.

The Exshaw-Patry shale was assessed in B.C., NWT, and Yukon for both OGIP and marketable gas because prolonged production from the interval indicates that gas is present and recoverable. In contrast, the Horn River shales in the Liard Basin were assessed solely for OGIP and only in NWT and Yukon because the Horn River shales are considered to be too deep in B.C. to be developed. Although a preliminary well test in NWT indicates gas is present in the Horn River shales, there is not enough production data to indicate that gas is recoverable in any meaningful amount. No volumes of natural gas liquids were assessed because gas analyses indicate that the gas is dry.

More details of the assessment's methods are available in Appendix B.

---

[7] Higher than normal gas pressures for that depth. Over-pressured formations can store more natural gas, because the gas is further compressed, and tend to have significant internal "push" to drive the gas out, improving recoveries and making economics better. "Normal" can be generally considered what the pressure would be under a column of water to that depth.

[8] *The Ultimate Potential for Unconventional Petroleum from the Montney Formation of British Columbia and Alberta – Energy Briefing Note.* 2013.

[9] Free gas is gas found in a rock's pore spaces; adsorbed gas is "stuck" to the side of organic matter or clay present in the rock.

[10] For this study, a tract in B.C. is considered to be four units arranged two-by-two (about 2.6 km^2) of the NTS geographic-grid system and one section (about 3.2 km^2) of the NTS-quad geographic-grid system in NWT and Yukon.

[11] A Monte Carlo simulation is a computerized process where random numbers (as determined from a statistical distribution) are picked hundreds to thousands of times to help determine a range of possibilities and uncertainty in an estimate.

[12] Natural gas in the Exshaw-Patry and Horn River shales is about 8 per cent and 15 per cent carbon dioxide, respectively. The carbon dioxide must be removed before it can be considered marketable.

Assessment Results and Observations

The ultimate potential for marketable, unconventional gas in the Liard Basin is estimated to be very large (Table 1), with expected volumes of 6 196 billion m³ (219 Tcf).[13] Uncertainty in the estimates is reflected by the spread between estimated low and high values in Table 1.[14] Most of the marketable gas is located in B.C., though NWT's and Yukon's potentials are still large.

For perspective, the Montney Formation's marketable potential has been estimated to be 12 719 billion m³ (449 Tcf) and the Horn River Basin's 2 198 billion m³ (78 Tcf). Further, total Canadian natural gas demand in 2014 was 89.4 billion m³ (3.2 Tcf)[15], making the Liard Basin gas resource equivalent to 68 years of Canada's 2014 consumption. However, it is too early to know whether the Liard Basin will significantly contribute to Canadian gas production in the near term because gas prices are expected to remain low for the next several years, deterring development. Although additional in-place gas potential is found in the Horn River shales of the Liard Basin (Table 2), it is uncertain whether any is technically recoverable.

By combining this marketable gas estimate with prior assessments, including assessments of conventional natural gas, the total ultimate potential in the WCSB is estimated to be 29 773 billion m³ (1 051 Tcf) (Table 3). Of this, 24 140 billion m³ (853 Tcf) remains after cumulative production to year-end 2014 is subtracted. This total is expected to evolve, likely growing over time as additional potential is estimated in unassessed shales, such as the Duvernay Formation of Alberta. Overall, Canada has a very large remaining natural gas resource base in the WCSB to serve its markets well into the future.

Table 1. Ultimate potential for Liard Basin unconventional gas in the Exshaw-Patry shale.

Shale	Play Area	Volume units	Gas in Place (dry)			Marketable Gas		
			Low	Expected	High	Low	Expected	High
Exshaw-Patry	Total	Billion m³	20 041	**34 365**	54 475	2 419	**6 196**	12 019
		Tcf	708	**1 213**	1 924	86	**219**	425

		Tcf	27	**47**	73	3	**8**	14

Table 2. Unconventional gas resources of the Liard Basin's Horn River shales

Shale	Play Area	Volume units	Gas in Place (dry)			Marketable Gas		
			Low	Expected	High	Low	Expected	High
Horn River	Northwest Territories	Billion m³	2 584	**5 293**	8 983	-	-	-
		Tcf	91	**187**	317	-	-	-
	Yukon	Billion m³	318	**593**	1 024	-	-	-
		Tcf	11	**21**	36	-	-	-

[13] "Tcf" is an abbreviation for trillion cubic feet.

[14] "Low" and "high", as used here, refer to a range where there is reasonably high confidence that the real in-place and eventual produced marketable volumes from the Exshaw-Patry shales will fall inside it. Thus, there is a small chance that real in-place and produced marketable volumes could be lower than the low values or higher than the high values.

Notes:

- Determined from reliable, published assessments by federal and provincial agencies.
- For this table, “unconventional” is defined as natural gas produced from coal (CBM) or by the application of multi-stage hydraulic fracturing to horizontal wells.
- The ultimate potential for natural gas should be considered an estimate that will evolve over time. Additional unconventional potential may be found in unassessed shales, such as the Duvernay Shale of Alberta.

Appendix A – List of Acronyms

B.C.	British Columbia
Bcf	Billion cubic feet
EUR	Estimated ultimate recovery
Ma	Million years
NTS	National topographic system
NWT	Northwest Territories
OGIP	Original gas in place
Tcf	Trillion cubic feet
TOC	Total organic carbon
WCSB	Western Canada Sedimentary Basin

Appendix B – Methods

Key Assumptions

1) The gas resource was considered to be a resource play in all three jurisdictions, where gas is pervasively distributed through the geologically defined area. Thus, the chance of success at discovering gas with a well is 100 per cent.
2) Well EURs are based on existing technology, current trends in development, and limited production. No detailed analyses of technological advancements have been performed for this study. Recoveries and levels of development could be different in the future as technology advances and the play matures.
3) No study has been undertaken to determine the economics for marketable resources and the determination of what can be developed is based on the view of the project agencies.

Stratigraphy and Study Area

Stratigraphic Intervals and Net Pay Determination

The Exshaw-Patry interval (Figure A.1) was treated as a single, radioactive shale whose net pay could be identified using a 10 ohm-m or higher reading on resistivity logs. Net pay in NWT's and Yukon's Horn River shales (Figure A.1) was identified with the same criteria.

Play Areas

The assessed area of the Liard Basin was defined on its eastern side by the Bovie Fault and on its western side by the western limit of Cretaceous outcrop. Thus, in B.C. and Yukon, the assessment area excludes the Rocky Mountains, Mackenzie Mountains, and Franklin Mountains except for the outer fringes of the Rocky Mountain and Franklin Mountain foothills, which form a deformed play area. Meanwhile, the Franklin Mountains (including the Liard Range) of NWT are included in the assessment and considered NWT's deformed area. Elsewhere, the Liard Basin is considered undeformed (Figure A.2). Areas north of 60º 40' N in the NWT were excluded because of proximity to Nahanni National Park.

Tracts

The Liard Basin map area was broken into a grid of small tracts to accommodate the way the reservoir locally changes. In B.C., a tract was considered a grid-spacing unit: four units arranged two-by-two in the National Topographic System (NTS) geographic-grid system, about 2.6 km^2 in size. In NWT and Yukon, a tract was considered a section in the NTS-quad geographic-grid system, about 3.2 km^2 in size.

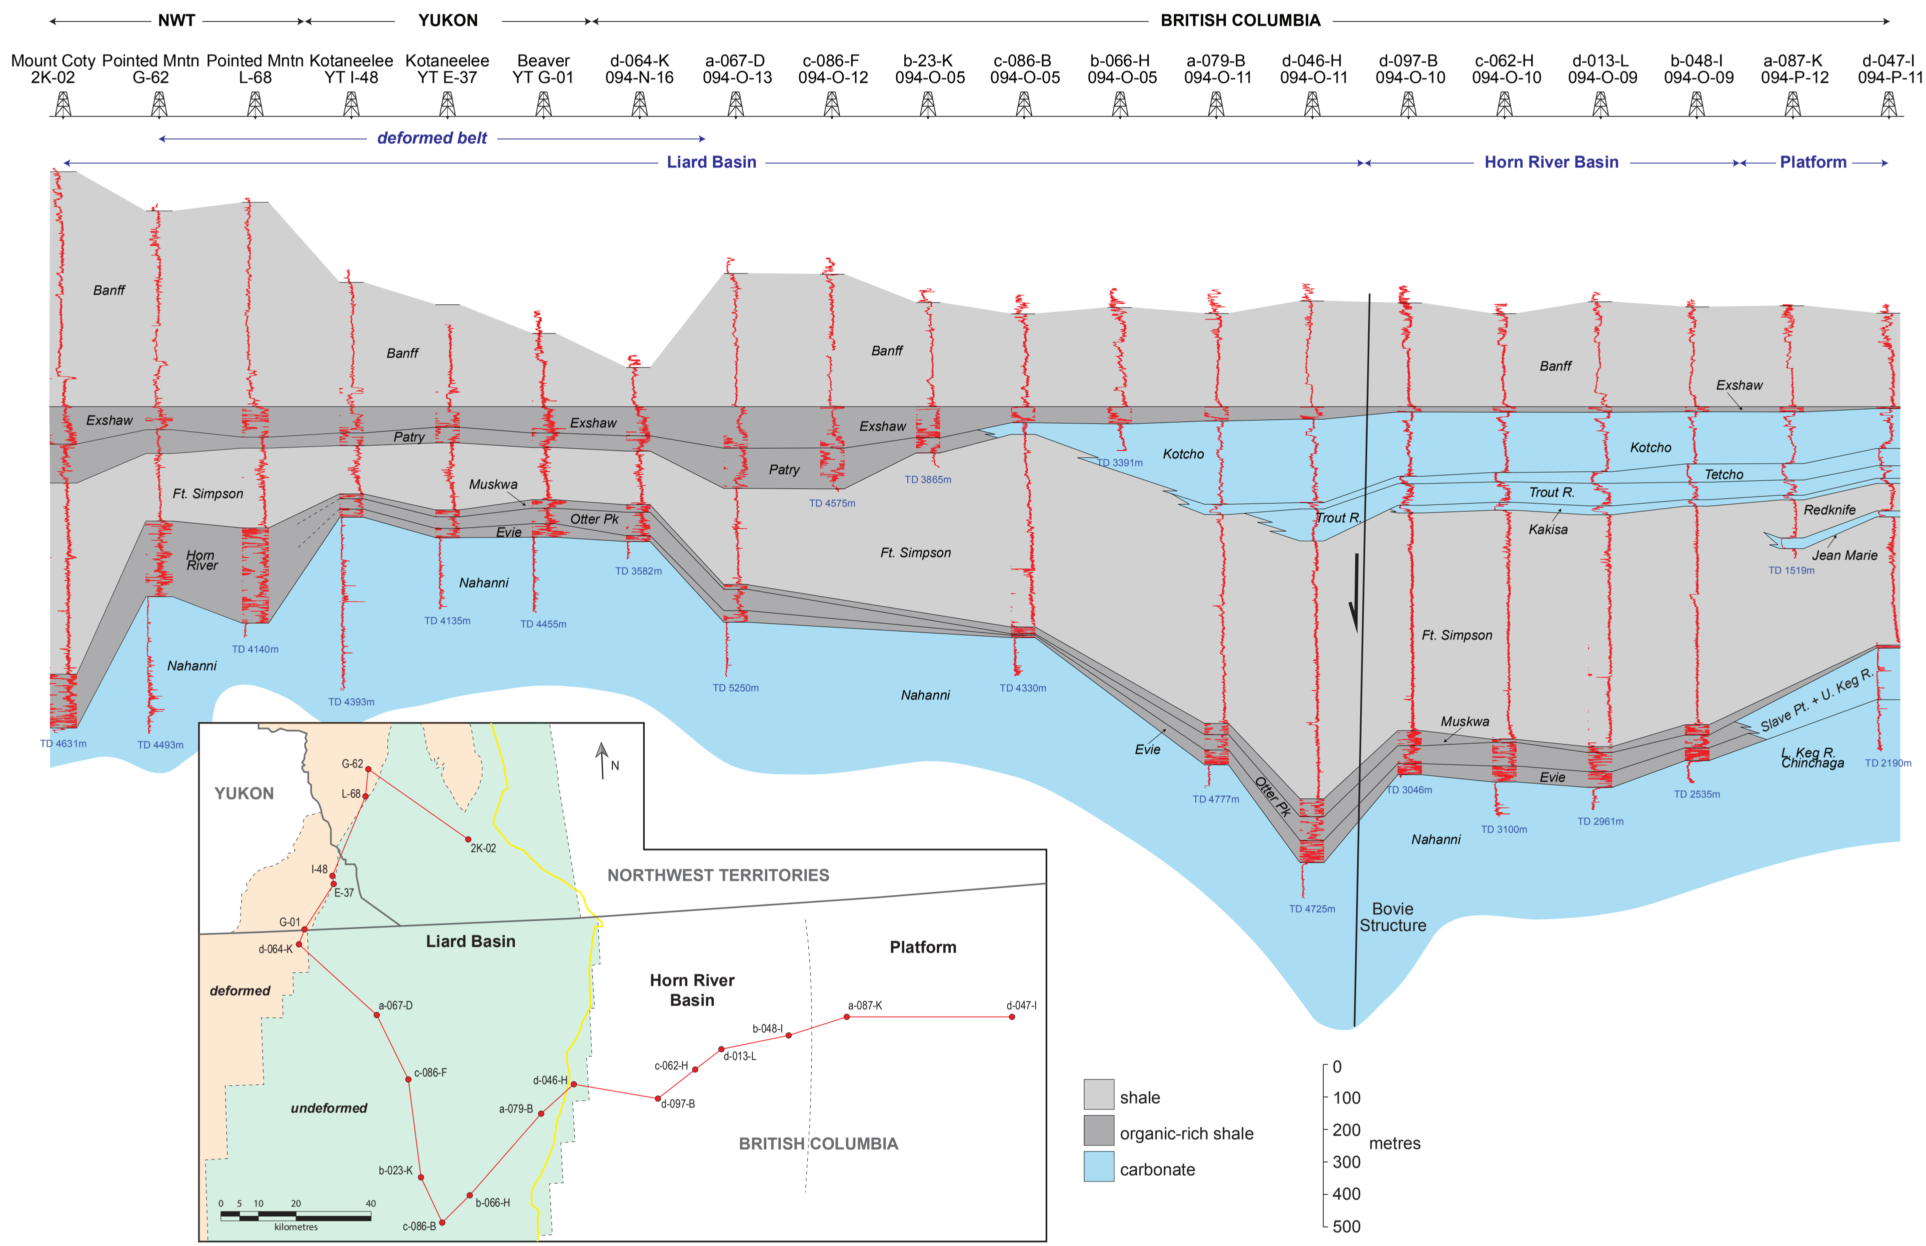

Figure A.1. Cross-section across study area with Exshaw top as datum

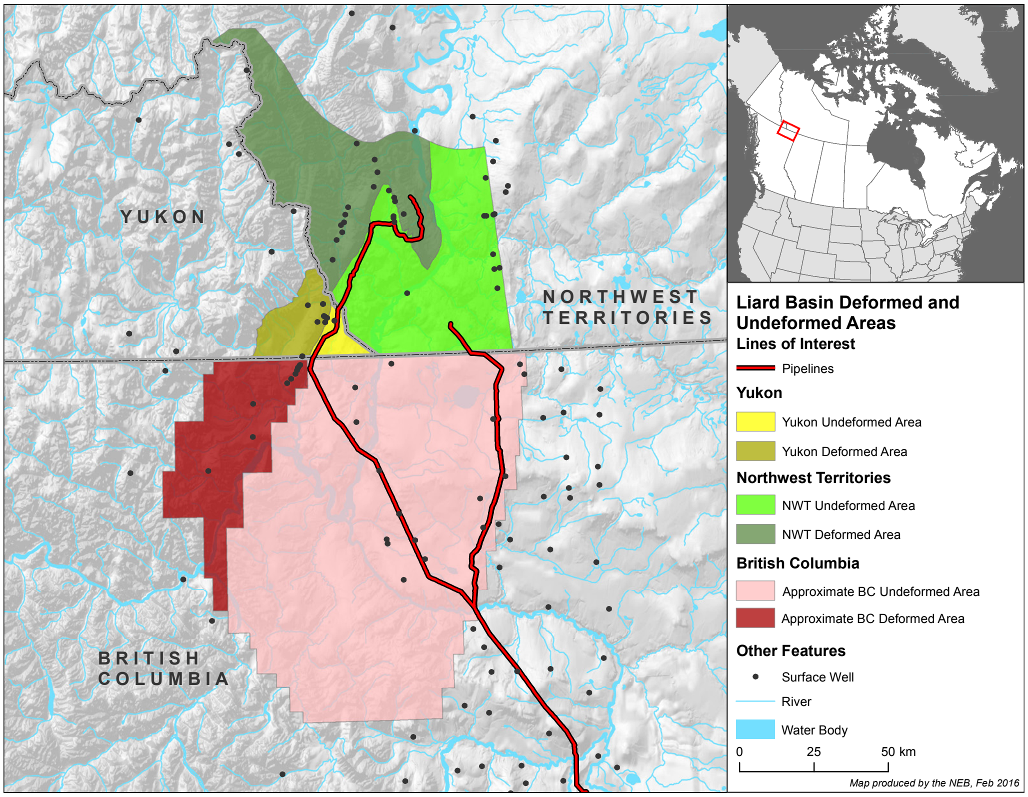

Figure A.2. Assessment play areas

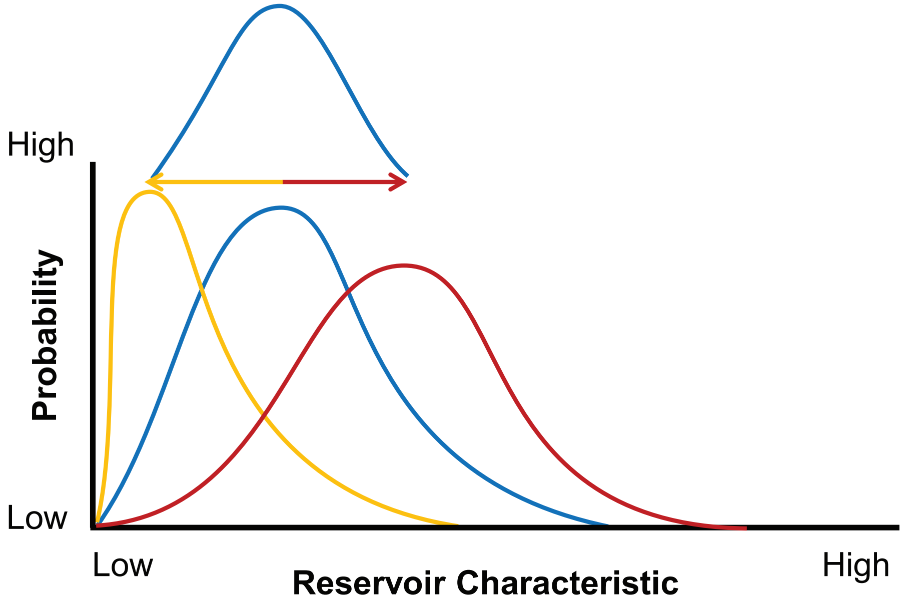

Figure A.3. One distribution applied upon another to create a "distribution of distributions"

Free and Adsorbed Gas Estimations for Estimation of in-place resources

The assessment was done on a map-grid basis where, for each tract, Monte Carlo simulations were run on a series of mathematical equations to determine volumes and the results summed to determine the total. The assessment was also integrated at two levels, i) a tract-by-tract scale, and ii) a basin scale (Figure A.3), to try to incorporate local changes with uncertainties inherent at the basin level.

See Table A.1 for the equation variables based on mapped data as well as the variables (both mapped and unmapped) that had distributions attached to them for the Monte Carlo simulations. Because the evaluated horizons were treated as single units, variables like porosity, water saturation, and TOC were applied as averages over the entire rock section.

To reduce potential skewing of distributions modeled on mapped data, “soft” maximums or minimums for distribution curves were used (i.e., the distribution’s low and high values wandered based on a percentage of the mapped “most likely” values) rather than “hard” maximum or minimums, as long as the soft values did not exceed or fall below impossible values, such as creating negative numbers. For distributions modeled on net pay, TOC, and depth, the uncertainties—the ranges between a tract’s low and high values—were reduced as determined by the number of data points in the surrounding NTS block in the case of B.C. and the surrounding grid area in NWT and Yukon.

In-place Resources Equations

Natural gas in the Liard Basin is present in two main forms: free and adsorbed. Therefore, the total raw natural gas stored in the Liard Basin prior to production can be determined by using the following basic equation at each grid point:

$$RGIP_{total} = RGIP_{free} + RGIP_{adsorbed}$$

Where $RGIP_{total}$ is the total raw gas in place, $RGIP_{free}$ is the free raw gas in place, and $RGIP_{adsorbed}$ is the raw adsorbed gas in place.

Free raw gas in place was estimated with a volumetric equation (all variables for all equations described in Table A.1):

$$RGIP_{free} = A \times H \times Ø \times S_g \times \frac{(D \times PG \times T_s)}{(P_s \times T_f \times Z)} \times RRF$$

Adsorbed raw gas in place was estimated with the equation:

$$RGIP_{adsorbed} = A \times H \times \rho_b \times (1 - Ø) \times \frac{(TOC \times LtO \times D \times PG)}{(P_L \times D \times PG)} \times RRF$$

Raw gas in place was converted to dry gas in place ($DGIP_{total}$) with the equation:

$$DGIP_{total} = RGIP_{total} \text{ X } (1 - SL_{GIP})$$

Reservoir Risk Factors

In B.C. and Yukon, a reservoir risk factor of 0.9 was applied to OGIP in deformed areas (i.e., OGIP would be reduced by 10 per cent) because, while there is some faulting that could drain gas pressures, these areas are largely in a relatively undeformed, broad syncline between the Franklin Mountains and the structurally controlled Beaver River and Kotaneelee gas fields. In NWT, a reservoir risk factor of 0.5 was applied to OGIP in deformed areas (except for the Pointed Mountain gas field, where 0.75 was used) because these are largely within the heavily faulted Franklin Mountains.

Table A.1. Variable descriptions and model inputs used for assessment – Exshaw-Patry succession

Variable	Symbol	Map (Y/N)	Prob. Dist. (Y/N)	Tract Model Inputs (low / most likely/ high)	Basin Model Inputs (low / most likely / high)	Correlations and notes	Data Source

Estimated Exshaw-Patry EURs

B.C.'s c-45-K/94-O-5 horizontal well, which was completed in the Exshaw-Patry interval, was used to create an index well so that recoveries from an index tract could be determined. c-45-K's production was modeled using an early stage of transient flow for the first 84 months of post-peak production followed by a later stage of boundary-dominated flow, which is not yet observed in the historical data in any of the shale-gas wells in the Liard Basin (data up to 53 months). A cutoff of 50 years was applied to cumulative production to determine its EUR. Results were compared to nearby wells to determine whether the estimated EUR was reasonable. A well-quality factor was also applied, which caused the well's EUR to range higher or lower to simulate uncertainty in EUR results (zero as a minimum to twice as high as a maximum).

Transient flow

The modeled transient flow excluded the first month of post-peak data, which did not fit the main trend of historical data on a log-log plot of production vs. time. This early deviation was likely because the well was still flowing back hydraulic fracturing fluids or production was in early bilinear flow before transitioning to linear flow.

Transient flow was modeled by regressing the historical data using the Duong model[16], the Arps hyperbolic model[17] (where Excel's Solver is used to determine initial production, initial decline, and the Arps *b* exponent), and a Long Duration Linear Flow model (which, for this study, is a linear regression of the historical data on a log-log plot of production versus time) (Figure 4).

Boundary-dominated flow

Boundary-dominated flow at the end of transient flow for each of the three, above models was estimated using Arps hyperbolic flow. Because boundary-dominated flow is not yet observed in well data, initial production was assumed to be production at the end of each model's transient flow, the annual initial decline to be 0.1, and the Arps *b* exponent to be 0.5.

Indexing Tracts

The index well (Figure A.4 and Table A.3) was created by: 1) averaging the three estimated EURs; 2) calculating the EUR per 1 km of stimulated horizontal leg in c-45-K; and 3) creating a hypothetical well that would fit along the long axis of a tract while keeping "buffer" space at the well's toe and heel to avoid interfering with any wells that would be drilled in adjacent tracts.

The index tract (Table A.3) was created by estimating the amount of recoverable gas in a tract local to c-45-K as based on the number of index wells expected be drilled in it. Some reservoir characteristics at c-45-K—net pay, pressure, and TOC (which is assumed to be a proxy for porosity, gas saturation, and adsorbed gas concentrations)—were extracted from local tracts to create an index for how production in other tracts might behave where reservoir conditions differ. Because tract sizes change in the NTS grid based on how units and sections change sizes in north-south directions, the index tract was also indexed to tract size at c-45-K to reflect that well spacing or development plans could change where tracts are bigger or smaller.

Figure A.4. Modeled production curves for c-45-K

Limits to Development

For the EUR analysis, it was assumed that no development would occur in areas shallower than 1 500 m or where the net pay was less than 30 m, because flow rates would likely be too low to justify drilling. In B.C. and Yukon, a technical risk factor of 0.75 was applied to tract EURs in deformed areas to simulate technical risks that recoveries may face. In NWT, the Franklin Mountains are heavily faulted and this technical risk factor was decreased to zero except in the Pointed Mountain gas field where it was decreased to 0.6 (i.e., outside the Pointed Mountain gas field, the NWT's deformed area was assumed to have gas in place in the Exshaw-Patry interval, but no recoveries).

Raw Gas to Marketable Gas Conversion

Similar to OGIP estimates, raw EUR was converted to marketable EUR by applying a surface loss based on expected impurity contents as well as fuel needed for gas processing.

Foreword

National Energy Board

The National Energy Board is an independent federal regulator established to promote safety and security, environmental protection and economic interest within the mandate set by Parliament for the regulation of pipelines, energy development and trade. The Board's main responsibilities include regulating the construction and operation of interprovincial and international oil and natural gas pipelines, international power lines, and designated interprovincial power lines.

For oil and natural gas exports, the Board’s role is to evaluate whether the oil and natural gas proposed to be exported is surplus to reasonably foreseeable Canadian requirements, having regard to the trends in the discovery of oil or gas in Canada.

If a party wishes to rely on material from this report in any regulatory proceeding before the Board, it may submit the material, just as it may submit any public document. Under these circumstances, the submitting party in effect adopts the material and could be required to answer questions pertaining to its content. This report does not provide an indication about whether any application will be approved or not. The Board will decide on specific applications based on the material in evidence before it at that time.

British Columbia Oil and Gas Commission

The BC Oil and Gas Commission is the provincial regulatory agency with responsibilities for regulating oil and gas activities in British Columbia, including exploration, development, pipeline transportation and reclamation.

The Commission’s core services include reviewing and assessing applications for industry activity, consulting with First Nations, cooperating with partner agencies, and ensuring industry complies with provincial legislation and all regulatory requirements. The public interest is protected by ensuring public safety, respecting those affected by oil and gas activities, conserving the environment, and ensuring equitable participation in production.

Responding to the complex and often competing economic, environmental and social priorities driving the oil and gas industry, the Commission maintains a modern regulatory framework and proactively looks for innovative solutions for continued safe and sustainable oil and gas development in the province. In accordance with its mandate, the Commission strives to deliver fair and timely decisions on proposed projects, balancing firm oversight of operational safety and First Nations’ rights.

The Commission liaises with other provincial and federal government agencies in ensuring effective delivery of government policy, improved regulatory climate and cohesive application of existing regulations. It is of key importance for the Commission to stay fully apprised of the latest technological breakthroughs, and independent world-wide scientific research pertinent to the industry.

For general information about the Commission, please visit www.bcogc.ca or phone 250-794-5200.

Alberta Energy Regulator

The Alberta Energy Regulator (AER) ensures the safe, efficient, orderly, and environmentally responsible development of hydrocarbon resources over their entire life cycle. This includes allocating and conserving water resources, managing public lands, and protecting the environment while providing economic benefits for all Albertans. The AER succeeds the Energy Resources Conservation Board and takes on regulatory functions from the Ministry of Environment and Sustainable Resource Development that relate to public lands, water, and the environment. In this way, the AER provides full-lifecycle regulatory oversight of energy resource development in Alberta - from application and construction to abandonment and reclamation, and everything in between. The AER is authorized to make decisions on applications for energy development, monitoring for compliance assurance, decommissioning of developments, and all other aspects of energy resource activities (activities that must have an approval under one of the six provincial energy statutes). This authority extends to approvals under the public lands and environment statutes that relate to energy resource activities.

The Energy Resource Appraisal Group (ERA) is part of the Geology, Environment and Reserves Branch of the AER. The ERA generates knowledge and information related to the oil and gas geology and resource endowment of Alberta. Data provided by the AER for this report was data compiled and created by ERA. Much of the data used in this report has been previously published by ERA in AGS Open File Reports.[1]

For general information about the Alberta Energy Regulator, please visit www.aer.ca or phone toll-free 1-855-297-8311.

British Columbia Ministry of Natural Gas Development

The role of the British Columbia Ministry of Natural Gas Development is to guide the responsible development and ensure maximum economic benefits to British Columbians from the province’s natural gas resources and the province’s next new major industrial sector—that of liquefied natural gas (LNG).

Through teamwork and positive working relationships with its clients, the Ministry facilitates B.C.’s thriving, safe, environmentally responsible and competitive natural gas sector to create jobs and economic growth. In developing natural gas policies, legislation and guidelines, the

[1] Available at: www.ags.gov.ab.ca/publications

Ministry consults with other ministries and levels of government, energy companies, First Nations, communities, environmental and industry organizations, and the public.

A key component of the Ministry’s mandate is to develop tenure, royalty and regulatory policy for British Columbia’s natural gas industry, thereby promoting the effective and environmentally responsible management of the province’s natural gas resources.

The Ministry provides a range of natural gas related services, including the issuance of Crown subsurface resource rights, royalty programs, public geoscience and policies to address potential future resource opportunities, such as unconventional natural gas resource development. The Ministry’s LNG Secretariat reports to the new Cabinet Working Group on Liquefied Natural Gas, which will advise on budgets, structure, mandate and service plan goals.

The Ministry is also responsible for the British Columbia Oil and Gas Commission.

Executive Summary

The Montney Formation's marketable, unconventional petroleum potential has been evaluated for the first time in a joint assessment by the National Energy Board, the British Columbia Oil and Gas Commission, the Alberta Energy Regulator, and the British Columbia Ministry of Natural Gas Development. The thick and geographically extensive siltstones of the Montney Formation are expected to contain 12,719 billion m^3 (449 Tcf) of marketable natural gas, 2,308 million m^3 (14,521 million barrels) of marketable NGLs, and 179 million m^3 (1,125 million barrels) of marketable oil.

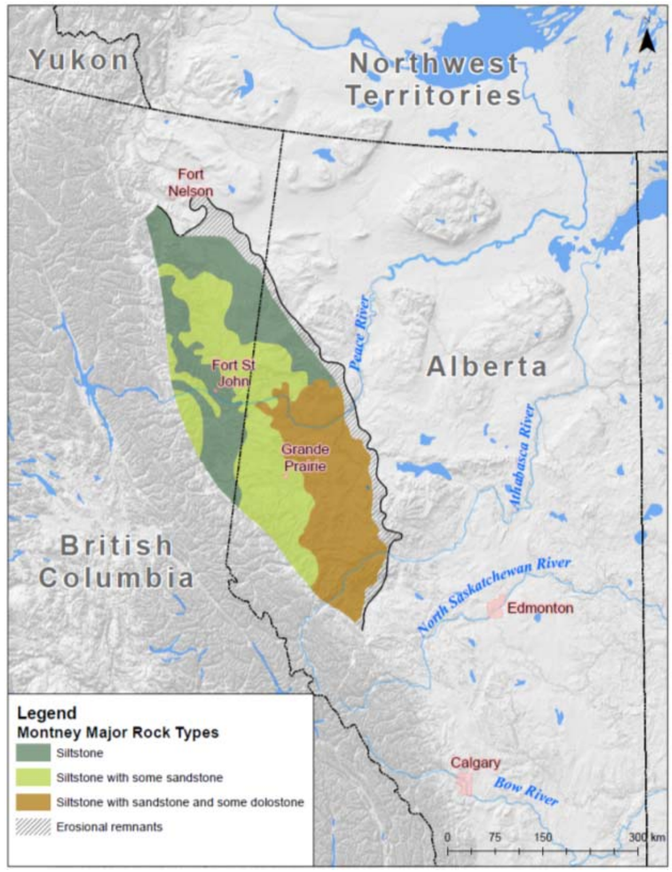

Figure 1. Generalized map showing the location of the Montney Formation in the subsurface of Alberta and British Columbia. Modified from the Geological Atlas of the Western Canada Sedimentary Basin.

Introduction

The Montney Formation of Alberta and British Columbia (Figure 1) has been the target of oil and gas exploration since the 1950s, with industry traditionally focusing on the Montney's conventional sandstone and dolostone reservoirs. These conventional reservoirs are encased in siltstone, which represents a far greater volume of rock within the formation and also contains oil and gas. However, Montney siltstones remained undeveloped until 2005, when advances in horizontal drilling and multi-stage hydraulic fracturing made it possible to economically develop this extensive, unconventional siltstone resource.

For this report, the National Energy Board (NEB), the British Columbia Oil and Gas Commission (BC OGC), the Alberta Energy Regulator (AER), and the British Columbia Ministry of Natural Gas Development (BC MNGD), collectively the Agencies, have jointly assessed the unconventional petroleum resources of the Montney Formation.[2] For British Columbia, both the in-place and marketable[3] petroleum volumes were estimated for the Montney siltstone, which included some thin sandstones that were unlikely to be developed conventionally. For Alberta, only marketable petroleum volumes were estimated because the in-place petroleum of Montney Formation siltstone was already determined in a prior study by the Energy Resources Conservation Board (now the AER). This is the first publicly released study to examine the marketable, unconventional petroleum potential of the Montney Formation in any detail.

---

[2] For the purposes of this assessment, in Alberta, the Montney Formation will include the siltstone at the bottom of the overlying Doig Formation in Alberta. See Appendix A for more details.

[3] "In place" refers to the amount of petroleum originally in the reservoir. "Marketable resources", as used in this report, indicates the volume of in-place petroleum that is recoverable under foreseeable economic and technological conditions and in a condition ready to be used by the market. While it implies a sense of economic recovery, no economic assessment was performed.

Geological Description

The Lower Triassic Montney Formation is aerially extensive, covering approximately 130,000 km^2 (Figure 1). It is also thick, typically ranging from 100 m to 300 m, though thins to zero at its eastern and northeastern edges while increasing to over 300 m on its western side before it begins outcropping in the Rocky Mountains. Most of the formation consists of siltstone containing small amounts of sandstone that originally collected on the bottom of a deep sea, whereas more porous sandstones and shell beds were deposited in shallow water environments to the east. The depth of the formation also increases from northeast to southwest, generally along with increasing reservoir pressures and decreasing natural gas liquid[4] (NGL) and oil content. Thus, reservoir characteristics vary widely across the formation.

For a more detailed description of Montney geology in Alberta, please see *Summary of Alberta's Shale-and Siltstone-Hosted Hydrocarbon Resource Potential*[5] as well as the forthcoming assessment of the lowermost Doig siltstone's resource potential.[6] For more details on Montney geology in British Columbia, please see the *Montney Formation Play Atlas NEBC*.[7] Other details about the Montney Formation are available in Chapter 16 of the *Geological Atlas of the Western Canada Sedimentary Basin*.[8]

Methodology

For British Columbia, the Montney was assessed using a process similar to one used in a 2011 study of the shale gas resources in the Horn River Basin.[9] In the Horn River Basin assessment, the volumes of free gas and adsorbed gas[10] were determined by connecting map grids of geological data to free gas and adsorbed gas equations. This way, gas volumes could be estimated by location and capture how the geological nature of the shales changed from place to place. Statistical distributions were applied to some variables in the equations and then Monte Carlo simulations were used to estimate low, expected, and high values.[11] However, the Montney assessment was expanded to include NGLs and oil, which are not present in the Horn River Basin to any significant degree. Dissolved gas, which is gas that is dissolved in oil deep underground but is liberated at surface under lower pressures, was also estimated for the

[4] For this study, NGLs are defined as ethane, propane, butane, pentane, and heavier hydrocarbons that are produced in the gas stream out of a well.

[10] Free gas is gas found in a rock's pore spaces; adsorbed gas is gas "stuck" to the side of any organic matter or clay present in the rock.

[11] A Monte Carlo simulation is a computerized process where random numbers (as determined from a statistical distribution) are picked hundreds to thousands of times to help determine a range of possibilities and uncertainty in an estimate.

Montney. Altogether, in-place and marketable petroleum resources were determined for dry natural gas[12], NGLs, and oil. Only over-pressured[13] areas were included in the British Columbia analysis, because unconventional development has so far been limited to over-pressured areas.

For the Alberta portion of the Montney, the in-place volumes of dry natural gas, NGLs, and oil have already been estimated as part of Alberta's two resource studies, their methodology described in the publication *Quantification of Uncertainty in Shale Gas Resources*.[14] For this joint study, a marketable resource volume was estimated by applying recovery factors to map grids of Alberta's in-place resource data. Because Montney development is occurring in both over-pressured and under-pressured areas in Alberta, the entire Montney unconventional play was assessed for marketable resources. Full development was assumed to occur in deeper areas (where the Montney mid-point depth was more than 1750 m) as these have a higher chance of being over-pressured according to pressure-depth data. Shallower areas are expected to have only partial development because they are typically under-pressured. Thus, a "development risk" factor was applied to shallower areas, as well as lower recovery factors.

Conventional reservoirs within the Montney section were excluded from this analysis as these have been assessed in prior studies.[15,16] Further, the methods for determining the in-place resources for each province, while similar, did have some significant differences. The geological mapping of the Montney Formation in British Columbia included some thin sandstones unlikely to be developed conventionally, while all sandstone was excluded from the Alberta analyses. No extra Monte Carlo simulations were run when adding British Columbia's and Alberta's low, expected, and high values together. Thus, while the addition between provinces is not statistically rigorous, the total results should still provide a reasonable estimate of total potential. More details on the methodology are available in Appendix A.

Assessment results and observations

The ultimate potential for unconventional petroleum in the Montney Formation is estimated to be very large (Table 1), with expected volumes of 12,719 billion m^3 (449 Tcf) of marketable natural gas, 2,308 million m^3 (14,521 million barrels) of marketable NGLs, and 179 million m^3 (1,125 million barrels) of marketable oil.[17] Uncertainty in the estimates is reflected by the spread between estimated low and high values in Table 1.[18]

[12] "Dry natural gas" is natural gas with the NGL contents and other impurities removed to make the gas ready to be shipped in gas distribution systems and sold to consumers.

[13] Higher than normal oil and gas pressures for that depth. Over-pressured formations can store more natural gas, because the gas is further compressed, and tend to have significant internal "push" to drive the petroleum out, improving recoveries and making economics better. "Normal" can be generally considered what the pressure would be under a column of water to that depth.

[17] Common abbreviations used in this report are cubic metres (m^3), cubic metres per day (m^3/d), billion cubic feet per day (Bcf/d), trillion cubic feet (Tcf), and barrels per day (b/d).

[18] "Low" and "high", as used here, refer to a range where there is reasonably high confidence that the real in-place and eventual produced marketable volumes from the Montney will fall inside it. Thus, there is a small chance that real in-place and produced marketable volumes could be lower than the low values or higher than the high values.

The Montney's marketable unconventional gas resource is one of the largest in the world. While most of it is located in British Columbia (Table 2), Alberta's share is still large (Table 3). To further illustrate the size of the Montney, total Canadian natural gas demand in 2012 was 88 billion m^3 (3.1 Tcf)[19], making the Montney gas resource equivalent to 145 years of Canada's 2012 consumption. In addition, the Montney is already considered one of Canada's most economic gas plays.[20] Even though it is only in the early stages of development, its 2012 production rose to an average of 48.6 million m^3/d (1.7 Bcf/d) out of total Canadian marketable gas production of 392.7 million m^3/d (13.9 Bcf/d). [21] It is expected that Montney gas production will continue to increase and grow its share of Canadian production.[22]

By combining this marketable gas estimate with prior assessments, including the most recent estimates of western Canadian ultimate potential for <u>conventional</u> natural gas, the total ultimate potential in the Western Canada Sedimentary Basin (WCSB) has more than doubled to 23,249 billion m^3 (821 Tcf) (Table 4). Out of this total, 17,898 billion m^3 (632 Tcf) is remaining after cumulative production to year-end 2012 is subtracted. The ultimate potential for natural gas should be considered an estimate that will evolve, likely growing over time as additional unconventional potential can be found in unassessed shales, such as those in the Liard Basin of British Columbia and the Duvernay Formation of Alberta. Overall, Canada has a very large remaining natural gas resource base in the WCSB to serve its markets well into the future.

The marketable unconventional NGL and oil volumes in the Montney Formation are also very large. However, the volume of marketable oil, which is almost entirely found in Alberta, remains highly uncertain, as indicated by the wide spread between its low and high values. This is because the areas that are richest in Montney unconventional oil tend to be in shallower areas, where uncertainty about development is much greater. The Montney unconventional oil resource is only in the initial stages of development, with its 2012 production averaging only 4108 m^3/d (25,845 b/d), a small component of total Canadian 2012 oil production, which averaged 513,960 m^3/d (3.23 million b/d). Alberta's marketable NGL volumes are also highly uncertain, mostly because the in-place volumes are also largely found in shallower areas.

Notes for Table 4:
- Determined from previously published assessments by the National Energy Board and/or provincial agencies; coalbed methane (CBM) ultimate potential based on initial reserves in the AER ST-98 Report (available at: www.aer.ca).
- Cumulative production current to year-end 2012.
- Additional gas potential can be found in other regions of Canada. Please see Tables 2.6A and 2.6B of Saskatchewan's Ultimate Potential for Conventional Natural Gas, available at: www.neb-one.gc.ca
- Values may contain rounding errors when added.

Appendix A - Methodology

Introduction

The methodology for the analysis of the British Columbia portion of the Montney petroleum resource is largely based on a prior study that examined the shale-gas resources in the Horn River Basin[23], although it incorporates some new approaches to reflect geological differences in the reservoirs plus feedback received after the initial study. For the Alberta portion of the Montney petroleum resource, the in-place estimate had already been determined in two Alberta studies[24,25] from which a recoverable estimate was extracted for this study. Please see the two Alberta studies as well as *Quantification of Uncertainty in Shale Gas*[26] for more details on the AER's methodologies and assumptions.

Key Assumptions

1) In British Columbia, the petroleum resource was considered to be a resource play, pervasively distributed through the geologically defined area, though its constituents (oil, gas, and NGLs) could vary depending upon location. Thus, the chance of success at discovering petroleum with a well is 100 per cent. In Alberta's assessments of in-place petroleum potential, the range of water saturations included the possibility of having water-saturated wells, thus the chance of petroleum discovery was not necessarily 100 per cent.
2) In British Columbia, thin sandstones unlikely to be targeted by conventional development were included within the siltstone section. In Alberta, all sandstones were excluded from the in-place evaluations and were therefore excluded from this assessment.
3) No study has been undertaken to determine the economics for marketable resources and the determination of what is economic is based on the view of the Agencies. Prior studies have estimated the supply cost of the Montney gas resource to be one of the lowest cost in western Canada, however.[27]
4) Recovery factors are based on existing technology, current trends in development, and limited production. No detailed analyses of technological advancements have been performed for this study. The recovery factors and levels of development could be different in the future as technology advances and the play matures, in particular in the shallower areas of Alberta and under-pressured areas of British Columbia.

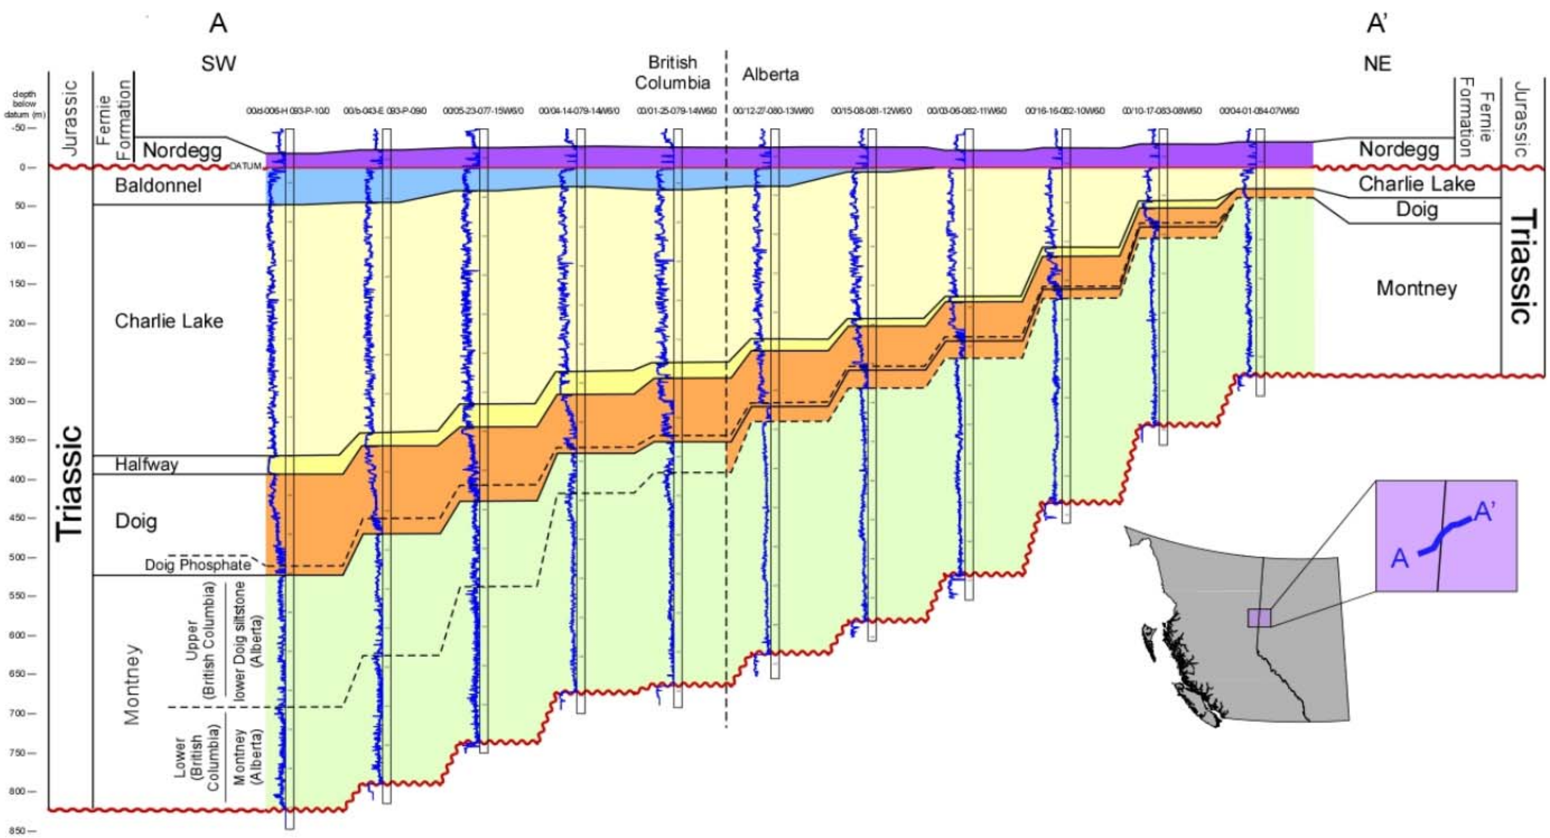
Figure A.1. Cross section of the Montney Formation. Note the siltstone at the bottom of the Doig Formation in Alberta that is equivalent to the Upper Montney in British Columbia.



Stratigraphy and Study Area

Stratigraphic Intervals

In British Columbia, the Lower Triassic Montney Formation was treated as a single unit. In Alberta, a siltstone unit near the bottom of the overlying Doig Formation was included with the Montney because it is stratigraphically equivalent to the Upper Montney in British Columbia (Figure A.1). The two sections of rock in Alberta were then treated as a single unit for the assessment.

Play Area

For British Columbia, the assessment was limited to over-pressured areas due to a lack of unconventional development in under-pressured areas. However, the uncertainty model that was applied to the pressure-gradient map during Monte Carlo simulations could change typically under-pressured areas into over-pressured areas in the case of "high" scenarios, and could change typically over-pressured areas into under-pressured areas in "low" scenarios, thus the boundary between over-pressured areas and under-pressured areas varied by modeled iteration. Over-pressured areas were then assumed to be fully developed in order to determine marketable resources.

In Alberta, the play area was the geographical extent of mapped in-place, siltstone-hosted petroleum resources as determined during Alberta's previous studies. The entire area was assessed for marketable resources because development appears to be occurring in both over-pressured and under-pressured areas; however, the Montney was divided into two different development areas as based on depth. Areas deeper than 1750 m were considered to be more likely developed than shallower areas, as based on current exploration trends.

Tracts

Because of computational limitations, the British Columbia Montney data was aggregated on an NTS (National Topographic System) block basis instead of a smaller grid-spacing unit (GSU) basis, including over the Peace River Block, where values were converted from the DLS (domain land survey) grid to the NTS grid. In Alberta, the Montney data was aggregated on a township basis rather than by section. The equations to determine petroleum volumes were then applied to each NTS and township tract.

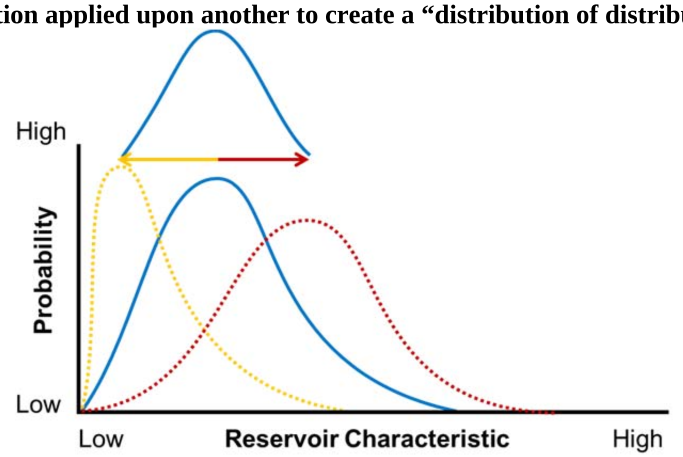
Free, Adsorbed, and Dissolved Hydrocarbon Estimations

British Columbia – Estimation of in-place and marketable resources

Like the Horn River Basin assessment, this assessment was done on a map-grid basis where, at each grid point, Monte Carlo simulations were run on a series of mathematical equations to determine volumes and the results summed to determine the total. Further, the assessment was integrated at two levels: i) a tract-by-tract scale; and ii) a basin scale (Figure A.2) in order to try to incorporate local changes with uncertainties inherent at the basin level. Please see the

“Resource Modeling” section of the 2011 Horn River Basin assessment for more details on this “distribution of distributions” methodology.

Figure A.2. One distribution applied upon another to create a “distribution of distributions”



Most of the maps for the Montney Formation already exist in the *Montney Formation Play Atlas NEBC*[28], such as depth, thickness, and pressure gradient maps. Other maps were constructed solely for this assessment, such as the gas compressibility and “propane plus” molar fraction maps. See Table A.1 for the variables in the assessment based on mapped data as well as the variables (both mapped and unmapped) that had distributions attached to them for the Monte Carlo simulations. Because the Montney Formation was treated as a single unit, variables like porosity, water saturation, and total organic content were applied as averages over the entire rock section.

Unlike the Horn River Basin assessment, no net pay cutoff was used for the Montney in British Columbia. Sandstones, where present within the siltstone within British Columbia, were included in the unconventional play if those sandstones were unlikely to be developed conventionally. Porosities in less prospective areas were assigned lower average porosities than in more prospective areas (i.e., porosities were reduced where depth was greater than 2800 m, or where thickness was greater than 300 m <u>and</u> the tract was on the western half of the British Columbia map). To reduce potential skewing of distributions modeled on mapped data, “soft” maximums or minimums for distribution curves were used (i.e., the distribution’s low and high values wandered based on a percentage of the mapped “most likely” values) rather than “hard” maximum or minimums as long as the soft values did not exceed or fall below impossible values, such as creating negative numbers. Further, when applying the basin-scale distribution to the tract-scale distribution, variables that could have zero as a minimum (such as porosity or water saturation) always had their minimums tied to zero. As a result, not only did the maximums and most likely values vary for those distributions at the tract level, but the shape of the curve could also change. For distributions modeled on the pressure gradient, the range between a tract’s low and high values was reduced as determined by the number of reservoir pressure measurements in it, which increased certainty in the mapped pressures.

Finally, typical solution gas ratios and formation volume factors from Montney and Doig oil pools in British Columbia, as well as gas-to-oil ratios obtained from production data, were

[28] Available at: www.bcogc.ca/montney-formation-play-atlas-nebc.

applied to an emerging oil play in British Columbia to back-calculate local free oil and free gas contents at reservoir conditions.

British Columbia – In-place Resources Equations

Natural gas and NGLs in the Montney Formation are present in three forms: free, adsorbed, and dissolved. Therefore, the total raw natural gas stored in the Montney Formation prior to production can be determined by using the following basic equation at each grid point:

$$RGIP_{total} = RGIP_{free} + RGIP_{adsorbed} + RGIP_{dissolved}$$

Where:

$RGIP_{total}$ = total raw gas in place
$RGIP_{free}$ = free raw in place
$RGIP_{adsorbed}$ = adsorbed raw in place
$RGIP_{dissolved}$ = dissolved raw gas

The assessment of Montney unconventional oil in British Columbia considers only free oil, which comprises a very small component of the total resource. Thus:

$$OIP_{total} = OIP_{free}$$

Where:

OIP_{total} = total oil in place
OIP_{free} = free oil in place

Free raw gas in place was estimated with the volumetric equation (all variables for all equations described in Table A.1):

$$RGIP_{free} = A \times H \times \Phi \times (1 - S_w) \times \left(\frac{D \times PG \times T_S}{P_S \times T_F \times Z} \right) \times (1 - OP_{fraction})$$

Adsorbed raw gas in place was estimated with the equation:

$$RGIP_{adsorbed} = A \times H \times \rho_b \times (1 - \Phi) \times \left(\frac{TOC \times LtO \times D \times PG}{P_L + D \times PG} \right)$$

Dissolved raw gas in place was estimated with the equation:

$$RGIP_{dissolved} = OIP \times GOR_{sol}$$

Raw gas was converted to dry gas with the equation:

$$DGIP_{total} = RGIP_{total} \times (1 - SL - NGL)$$

NGLs in place, in their gaseous form, was estimated with the equation:

$$NGLIP_{total\ gaseous} = RGIP_{total} \times NGL$$

Then converted to their volume in liquid form with the equation:

$$NGLIP_{total} = NGLIP_{tota\lg aeous} \times (C2_{frac} \times C2_{GtL} + C3_{frac} \times C3_{GtL} + ...)$$

Oil in place was estimated with the equation:

$$OIP_{free} = A \times H \times \Phi \times (1 - S_w) \times OP_{fraction} \ / \ FVF$$

But, since the free petroleum in the system is likely a mixture of oil and raw gas, an $OP_{fraction}$ (the fraction of oil in the petroleum in the reservoir) was required:

$$OP_{fraction} = \frac{OIP_{res}}{OIP_{res} + RGIP_{free(res)}}$$

$$= \frac{FVF}{\left[FVF + \dfrac{(GOR_{surface} - GOR_{sol}) \times P_S \times T_F \times Z}{T_S \times D \times PG}\right]}$$

British Columbia – Marketable Resources Equations

Marketable gas resources can be calculated with the following equation:

$$MG_{total} = MG_{free} + MG_{adsorbed} + MG_{dissolved}$$

Where:

MG_{total} = Total marketable dry gas
MG_{free} = Marketable free dry gas
$MG_{adsorbed}$ = Marketable adsorbed dry gas
$MG_{dissolved}$ = Marketable dissolved dry gas

Free marketable dry gas was estimated with the equation:

$$MG_{free} = DGIP_{free} \times RF_{gas}$$

Where RF_{gas} is the recovery factor, the most likely value assumed to be 15 per cent.

Marketable adsorbed dry gas, which is the amount of gas that can desorb from the organic and mineral matter in the formation at well-abandonment pressures and then be recovered by moving through the reservoir to any well, was estimated with the equation:

$$MG_{adsorbed} = RF_{gas} \times \left\{ DGIP_{adsorbed} - (1 - SL - NGL) \times A \times H \times \rho_b \times (1 - \Phi) \times \left(\frac{TOC \times LtO \times P_A}{P_L + P_A} \right) \right\}$$

Dissolved gas was assumed to be extracted with the free gas where present in the same reservoir, as subsurface de-pressurization during free-gas extraction would cause some dissolved gas to come out of solution from the oil. Therefore, the same recovery factor for free gas was applied to the dissolved gas. While this would likely lead to an overestimate of marketable dissolved gas, it forms a very small portion of the overall resource and its impact on the total results is minimal.

$$MG_{dissolved} = DGIP_{dissolved} \times RF_{gas}$$

Marketable NGLs can be estimated with the equation:

$$MNGL_{total} = MNGL_{free} + MNGL_{adsorbed} + MNGL_{dissolved}$$

Where:

$MNGL_{total}$ = Total marketable NGLs
$MNGL_{free}$ = Marketable Free NGLs
$MNGL_{adsorbed}$ = Marketable Adsorbed NGLs
$MNGL_{dissolved}$ = Marketable Dissolved NGLs

Free marketable and dissolved marketable NGLs (with the same potential overestimation of dissolved NGLs as for dissolved dry gas) were estimated with the equations:

$$MNGL_{free} = NGLIP_{free} \times RF_{gas}$$
$$MNGL_{dissolved} = NGLIP_{dissolved} \times RF_{gas}$$

Marketable adsorbed NGLs were estimated slightly differently than marketable dry gas. Since the heavier the hydrocarbon is the more prone it is to adsorption, it was assumed that only ethane and propane would desorb from organic matter during depressurization of the reservoir during production. Further, the amount of ethane desorbed was reduced by 50 per cent and propane by 75 per cent because of their stronger affinities relative to methane. Thus:

$$MNGL_{adsorbed\_gaseous} = NGL_{C2} \times RF_{gas} \times \left\{ RGIP_{adsorbed} - A \times H \times \rho_b \times (1 - \Phi) \times \left(\frac{TOC \times LtO \times P_A}{P_L + P_A} \right) \right\} \times 0.5 +$$
$$NGL_{C3} \times RF_{gas} \times \left\{ RGIP_{adsorbed} - A \times H \times \rho_b \times (1 - \Phi) \times \left(\frac{TOC \times LtO \times P_A}{P_L + P_A} \right) \right\} \times 0.25$$

The marketable adsorbed gas in gaseous form was then converted to liquid form via:

$$MNGL_{adsorbed} = NGLIP_{adsorbed\_gaseous} \times (C2_{frac} \times C2_{GtL} + C3_{frac} \times C3_{GtL})$$

Marketable oil was determined with the equation:

$$MO_{total} = OIP_{total} \times RF_{oil}$$

Where RF_{oil} is the recovery factor for oil, its most likely value assumed to be 1 per cent.

Alberta – Marketable Resources Equations

Because a range of in-place volumes of dry gas, NGLs, and oil for the Alberta Montney play had already been determined, including values for the lowermost Doig siltstone, only the recoverable quantities were estimated for this study. Rather than separately estimating recoverable quantities for each unit, the results of in-place Monte Carlo simulations for the Alberta Montney and lowermost Doig siltstone were added together on a township-by-township and iteration-by-iteration basis. The combined result was then re-simulated by using @Risk software's Resample function, during which recovery factors were applied.

Based on current trends in development, the Montney play in Alberta is largely being developed where the Montney depth is 1750 m or greater, though small developments are occurring in shallower areas. Thus, a development factor was applied to simulate the effects of partial development. The minimum development factor for a township was determined by how many sections in it contained either the surface hole or bottom hole location of existing or licensed horizontal Montney wells. A township where none of its sections had locations was assigned a minimum of 0. The maximum value for a township was then assumed to be 1 and the most likely 0.3 more than the minimum.

Higher recovery factors were applied to the Montney Formation where the formation mid-point was deeper than 1750 m, with the most likely value assumed to be 15 per cent for gas, as in British Columbia, though a 2 per cent most likely value was applied to the deep Montney oil resource given Alberta's more mature development. Lower recovery factors were applied where formation mid-point depths were shallower than 1750 m, the most likely value assumed to be 10 per cent for gas and 1 per cent for oil. Lower recovery factors in shallower areas are supported by available pressure data, which demonstrates that shallower areas in the Alberta Montney have a much greater tendency to be under-pressured. Dissolved gas was not considered to be recoverable, thus the amount of marketable gas in the Alberta Montney siltstone may be somewhat underestimated.

Therefore, marketable Alberta resources were estimated with the equations where *DF* is the development factor:

$$MG_{free} = GIP_{free} \times RF_{gas} \times DF$$
$$MG_{adsorbed} = GIP_{adsorbed} \times RF_{gas} \times DF \times DR$$

$$MG_{total} = MG_{free} + MG_{adsorbed}$$
$$MNGL_{total} = NGLIP_{free} \times RF_{gas} \times DF$$
$$MO_{total} = OIP_{free} \times RF_{oil} \times DF$$

DR is a desorption-reducing factor, because not all adsorbed gas would be able to be desorbed by the time a well was abandoned. This was assumed to be 0.33 as based on the results of the British Columbia analysis.

Table A.1. Variable descriptions and model inputs used for assessment.

Variable	Symbol	Map (Y/N)	Prob. Dist. (Y/N)	Tract Model Inputs (low/most likely/high)	Basin Model Inputs (low/most likely/high)	Correlations and notes	Data Source

GOVERNMENT OF CANADA RESPONSE TO
THE STANDING COMMITTEE ON NATURAL RESOURCES' INTERIM REPORT:

"THE FUTURE OF CANADA'S OIL AND GAS SECTOR: INNOVATION, SUSTAINABLE SOLUTIONS AND ECONOMIC OPPORTUNITIES"

January 19, 2017

INTRODUCTION

The Government of Canada has reviewed the report of the Standing Committee and thanks its members for their efforts in developing this report. The Government also wishes to extend its thanks to the numerous witnesses who provided expert testimony to the Committee, providing the members with a diversity of perspectives on the oil and gas sector.

For Canadians, the oil and gas sector has long been a driver of economic growth, innovation, and prosperity. In 2015, Canada's the oil and gas sector employed more than 190,000 and accounted for 5.3 percent of Canada's total GDP. Capital investment in the oil and gas sector totalled $65 billion, representing 26 percent of total capital investment in Canada.

However, as the Standing Committee's report indicated, the Canadian oil and gas sector now faces considerable challenges. The Standing Committee's expert witnesses drew attention to a number of economic headwinds for the sector, including persistently low commodity prices; the emergence of low-cost competitors; potential constraints on export capacity; and significant declines in investment. Witnesses also called attention to social and environmental concerns affecting development in the sector. The Standing Committee cited a lack of confidence in regulatory approvals among Canadians which stemmed from among other things, insufficient recognition of Indigenous concerns and engagement; broad concerns around the environmental impacts of resource development, and doubts surrounding the need for oil and gas development as technology looks to reduce our reliance on fossil fuels.

Yet, according to the International Energy Agency (IEA), the world will depend on oil and gas as a significant source of energy for years to come. The 2015 IEA World Energy Outlook forecast that global demand for natural gas could increase by 47 percent from 2014 to 2040, while demand for oil could increase by 14 percent over the same period. In time, Canada has risen to become the world's third largest exporter of oil, and fourth largest exporter of gas. While Canadian energy powers the world, we can make investments in clean technology and renewable energy that will position Canada's energy sector for the future.

It is clear to our Government that in order for the energy sector to continue to be a driver of prosperity and play a part in meeting global demand for energy, resource development must go hand in hand with the environmental and social demands of Canadians.

The Government's Response to the specific recommendations made by the Committee follow. Given the linkages between the committee's recommendations, we have grouped the recommendations thematically in order to provide comprehensive responses. We outline our collaboration with governments at home and abroad to establish policies that will help us to meet our energy needs and address the challenges of climate change; the steps being taken to rebuild public trust through transparency, engagement, and improved environmental and regulatory review processes; our efforts to engage with Indigenous communities in a meaningful way; and investments in innovation and clean technologies that will position Canada for a more innovative and sustainable economy.

THEME 1: ESTABLISHING POLICY FRAMEWORKS THROUGH INTERGOVERNMENTAL COLLABORATION AND CO-OPERATION

RECOMMENDATION 5: ***The committee recommends that the Government of Canada continue to work on a National Energy Strategy in collaboration with Indigenous, provincial, territorial, and international partners to ensure that carbon accounting standards and credit transfer practices are considerate of neighbouring jurisdictions and that all carbon accounting standards are transparent and science-based.***

The Government recognizes the importance of collaborating with Indigenous peoples, provinces, territories, and international partners to ensure Canada's energy resources are developed sustainably as we transition to a lower-carbon future. To this end, the Government is actively working with provinces and territories to advance the Canadian Energy Strategy, which provinces and territories see as a critical tool to coordinate climate change-related actions across jurisdictions.

Our Government is building on momentum from the recent ratification of the Paris Agreement, and the commitments and actions already taken by provinces and territories. Through the Vancouver Declaration of 2016, Canada's First Ministers committed to work together under the Pan-Canadian Framework on Clean Growth and Climate Change to meet or exceed Canada's international emissions targets, and transition our country to a stronger, more resilient, low-carbon economy – while also improving our quality of life. We will transition to a low carbon economy by adopting a broad range of domestic measures, including carbon pricing mechanisms, adapted to each province's and territory's specific circumstances, in particular the realities of Canada's Indigenous peoples and Arctic and sub-Arctic regions.

Through collaboration, we are creating the conditions for collective prosperity, competitiveness, health, and security. The Government is committed to continuing to work with provinces and territories towards the development of a Pan-Canadian Framework, and will also continue to work and meet regularly with national Indigenous organizations. The Government has already committed to:

- support climate change mitigation and adaptation through investments in green infrastructure, public transit infrastructure and energy efficient social infrastructure;
- work together with the provinces and territories on how best to lever federal investments in the Low Carbon Economy Fund to realize incremental emission reductions;
- advance the electrification of vehicle transportation, in collaboration with provinces and territories;
- foster dialogue and the development of regional plans for clean electricity transmission to reduce emissions;
- advance efforts to eliminate the dependence on diesel in Indigenous, remote, and Northern communities – and use renewable, clean energy as a replacement; and

- as part of Canada's participation in “Mission Innovation”, double investments in clean energy, research and development over five years, and work with global partners to promote cleaner energy and better environmental outcomes.

With regards to the Government’s perspective on carbon accounting, standard methods of accounting for greenhouse gas emissions have already been established via the 2006 Intergovernmental Panel on Climate Change Guidelines for National Greenhouse Gas Inventories that were prepared in response to an invitation by the Parties to the United Nations Framework Convention on Climate Change (UNFCCC). As signatory to the 2015 Paris Agreement under the UNFCCC, in any potential participation in international credit transfers, Canada would comply with the robust accounting guidance for the use of international transferred mitigation outcomes that is prescribed by the Agreement.

RECOMMENDATION 9: The Committee recommends that the Government of Canada continue to strengthen our North American Energy Strategy and intergovernmental cooperation on energy policies by taking into account federal, provincial, territorial and Indigenous interests, and take measures to improve the quality and availability of national energy data.

The Government of Canada recognizes the importance of cooperation at various levels in relation to energy policies and energy data. Natural Resources Canada is engaged with the United States and Mexico in a variety of bilateral and trilateral collaborative projects which address a range of technology and policy issues pertaining to climate change and energy.

At the 2014 North American Leaders’ Summit, Leaders agreed to have their respective Energy Ministers meet annually to hold a North American Energy Ministerial (NAEM). The first NAEM was held in December, 2014, at which time a Memorandum of Understanding (MOU) Concerning Cooperation on Energy Information was signed.

Over the course of 2015, the three countries collaborated on energy information as well as a number of technical energy projects which included the launch of a web platform featuring new energy maps, which for the first time depict North American energy resources, production and infrastructure in a single place.

At the 2016 NAEM held in Winnipeg, a revised MOU Concerning Collaboration on Climate Change and Energy Collaboration was signed. This agreement will see Canada, Mexico and the United States collaborate and share information on key areas such as low-carbon electricity; clean energy technologies; energy efficiency; carbon capture, use and storage; climate change adaptation; and reducing emissions from the oil and gas sector, including from methane. The three countries will work together to increase alignment and ensure that the North American energy sector is developed responsibly, effectively and efficiently.

With respect to national energy data, Natural Resources Canada and Statistics Canada have worked to establish a framework for Canadian energy statistics, the Canadian Energy Statistics Framework (ESF), published in February 2016. The ESF is based on the United Nations’ International Recommendations on Energy Statistics. Initiatives are already underway to implement changes to improve the quality of energy data, ensuring it is reflective of Canada's modern energy system.

THEME 2: REBUILDING PUBLIC TRUST IN RESOURCE DEVELOPMENT THROUGH TRANSPARENCY, ENGAGEMENT, AND MODERNIZATION

RECOMMENDATIONS 2 and 4: ***The Committee recommends that the Government of Canada work in collaboration with industry and the Indigenous, provincial, territorial, and municipal governments to develop the supporting infrastructure needed to create a favourable environment for natural resource development and transportation, and to deliver oil and gas products to strategic domestic and international markets;***

And,

The Committee recommends that the Government of Canada address the broader issue of public trust in the energy sector, by fostering more transparency and public engagement in resource development decisions, and recognizing Canada's strong environmental regulations and the work of the national regulators.

The Government agrees with the recommendations. Resource industries have, and must continue to make vital contributions to the prosperity of Canadians. Today, Canada is among the world's largest oil and gas producers and exporters and we expect to continue to play a significant role in meeting global demand for energy. Accessing strategic markets ensures Canadians receive full value for our resources; resources which can fund the next generation of renewable energy.

The Government believes that resource development and environmental protections must go hand in hand, and that collaboration with stakeholders is essential to developing resources in a manner that maintains public trust.

Consultation will be at the core of the review of environmental and regulatory processes and is an essential part of ongoing project reviews. The Government is undertaking a review of environmental and regulatory processes so that Canadians may be certain that decisions on major projects will promote a clean environment and drive economic prosperity. The review focuses on: reviewing federal environmental assessment processes; modernizing the National Energy Board (NEB); and restoring lost protections and introducing modern safeguards to the *Fisheries Act* and the *Navigation Protection Act.*

The Government established a 5-member NEB Modernization expert panel to strengthen the organization to better respond to future needs. The panel will examine issues beyond environmental assessment, including the NEB's governance structure, role and mandate, with a focus on enhancing the participation of the public and Indigenous peoples in regulatory reviews. The expert panel has expertise in policy, energy, business, environment, scientific, regional and Indigenous knowledge, and will provide its recommendations on modernizing the

NEB by March 31, 2017.

The Government understands the crucial role the NEB plays. We will continue to rely on the NEB to support critical decisions on key projects while the modernization review is underway, and have put in place interim principles to guide our decisions on major resource project assessments that are already in-progress. These interim principles strengthen the consultation process and instill greater public confidence by ensuring that decisions are based on science, traditional knowledge of Indigenous peoples and other relevant evidence; views of the public and affected communities are considered; Indigenous peoples are meaningfully consulted, and greenhouse gas emissions are fully assessed.

Specific measures have been put in place to foster more transparency and public engagement in NEB reviews. This includes appointment of a Ministerial Panel that engaged people from potentially affected communities close to the proposed Trans Mountain Expansion pipeline and shipping corridors, as well as appointment of temporary members to the NEB, with the expectation that the NEB Chair would direct them to engage communities and Indigenous groups along the Energy East Pipeline route. Consultations with Indigenous people along proposed pipeline routes have been deepened and the views of Canadians on pipeline projects have been sought through online questionnaires.

The issue of broad public confidence was a key issue discussed at the 2016 Energy and Mines Ministers' Conference (EMMC), an annual gathering of federal, provincial and territorial (FPT) ministers responsible for energy and mining portfolios. The 2016 EMMC concluded with FPT ministers agreeing to endorse four common principles: to foster relationships, improve communications, balance community interests with environmental and health impacts, and support science and innovation. Work is underway to develop a joint action plan that proposes concrete actions to strengthen public confidence in each of these areas.

The review of environmental assessment processes builds on Canada's strong environmental regulations; regulations that are important for creating a culture of safety. For example, the *Pipeline Safety Act,* which came into force in June, 2016, enshrines the polluter-pays principle in legislation. Operators' liability will remain unlimited in cases of fault or negligence and increases to $1 billion regardless of fault. The Government is working to establish regulations on financial requirements, to ensure that federally-regulated pipeline companies are prepared to cover response, remediation costs, and liability claims.

The recently announced Oceans Protection Plan ensures that our coasts are maintained in a modern and efficient way that marries commercial use, environmental sustainability and security. It does so by creating a world-leading marine safety system, including new rescue stations; preserving and restoring the marine ecosystem using new environmental assessments and research, as well as taking measures to address abandoned boats and wrecks; enhancing partnerships with Indigenous communities, including emergency response training; and investing in both wildlife research and oil spill response technology to ensure that decisions taken in emergencies are evidence based.

In addition, in June 2016, Environment and Climate Change Canada (ECCC) introduced regulations which include performance standards for certain types of equipment that operate in oil and gas facilities. In early 2017, ECCC plans to propose federal methane regulations for the oil and gas sector, which will reduce emissions of methane – a potent greenhouse gas – by 40 to 45 percent from 2012 levels by 2025. These regulations are designed to deliver on commitments made at the North American Leaders Summit and through the Canada-United States Joint Statement on Climate, Energy and Arctic Leadership.

Taken together, these actions demonstrate that the federal government is actively working to strengthen public confidence.

THEME 3: EARLY AND EFFECTIVE ENGAGEMENT WITH INDIGENOUS PEOPLES IN RESOURCE DEVELOPMENT DECISIONS

RECOMMENDATION 3: ***The Committee recommends that the Government of Canada work to encourage the early engagement of Indigenous peoples in resource development decisions, in full compliance with existing treaty and Indigenous rights to land and resources. Furthermore, the Committee recommends that the government ensure that consultation processes consider the multidimensional impacts of resource development projects on Indigenous peoples, including issues concerning education, health, economic development, infrastructure and the environment.***

The Government agrees that meaningful Aboriginal consultation and Indigenous engagement in resource development decisions is essential for sustainable natural resource development in Canada. The Government also agrees that the multidimensional impacts of resource projects on Indigenous peoples are important considerations in resource development decisions. Accordingly, federal efforts to enhance both Indigenous engagement and Crown consultation have been increasing since the fall of 2015.

With respect to Canada's legal duty to consult, an approach to consultation and accommodation is in place under the *Consultation and Accommodation Guidelines for Federal Officials*, administered by Indigenous and Northern Affairs Canada (INAC). These Guidelines are built on case law and best practices, to enable federal officials to undertake their responsibilities in an effective and meaningful manner. These guidelines were last updated in 2011 and could be subject to further revision to reflect external reports, feedback from Indigenous peoples and other parties, and case law.

The government has advanced efforts to surpass legal requirements and deepen engagement with Indigenous peoples. Key elements of a whole-of-government approach to Indigenous consultation are in place under the Major Projects Management Office (MPMO) Initiative, which integrates consultation into the major project review process, to the extent possible, the provision of dedicated Indigenous participant funding for major project reviews, and consistency to consider and address Indigenous groups' multidimensional concerns.

Building on this initiative, the Major Projects Management Office-West (MPMO-West) was established at Natural Resources Canada to support early engagement on energy infrastructure development on the West Coast. Dedicated to developing trusting relationships with Indigenous communities and serving as a federal single window on energy infrastructure development, MPMO-West has sponsored and participated in multiple community-led events to discuss concerns.

Indigenous peoples are also being engaged regarding reviews of federal regulatory processes like the Environmental Assessment Review and NEB Modernization. Supporting NEB Modernization, officials from Natural Resources Canada are enhancing engagement with Indigenous peoples on other matters related to resource development. For example, officials from Natural Resources Canada are actively engaging on non-major pipeline projects to share information on provisions for pipeline safety and understand Indigenous groups' interests and concerns.

Interim principles that were introduced for major resource projects currently under review ensure that Indigenous peoples are meaningfully consulted, and that traditional knowledge of Indigenous peoples and other relevant evidence are considered. Consultations are being enhanced through the use of extended timelines as needed, more direct consultation on pipeline projects and additional participant funding. For example, the September 2016 decision on the Pacific NorthWest LNG Project involved meaningful consultation with Indigenous peoples, and where appropriate, impacts were accommodated. Consultations with Indigenous communities were extensive, and included funding to support participation. Indigenous groups near the project site will also participate with federal and provincial governments in environmental monitoring, a new approach that is consistent with the Government's reconciliation agenda and its commitment to enhance the capacity of Indigenous groups in reviewing and monitoring major resource development projects.

Each of the above noted activities and priorities are being advanced in a manner that seeks to build and strengthen relationships between Canada and Indigenous peoples. This is being done in a manner that is based on recognition of rights, respect, co-operation, and partnership. This relationship is vitally important – not just to the shared interests between Canada and Indigenous peoples, but to our respective identities as nations.

THEME 4: SUPPORTING INNOVATION AND GLOBAL LEADERSHIP IN CANADIAN OIL AND GAS

RECOMMENDATION 1: The Committee recommends that the Government of Canada continue to promote the benefits of investing in Canada's Natural Resources sectors, including oil and gas, which shall include the continued encouragement of innovation, research and development.

The Government believes that protecting the environment and growing the economy are not incompatible goals; in fact, our future success demands we do both. The Government is taking action on a number of fronts to reduce GHG emissions by advancing clean energy. For example, Budget 2016 provides $2 billion in funding for a Low Carbon Economy Fund which will support provincial and territorial initiatives aimed at reducing greenhouse gas emissions. Moreover, Budget 2016 provides $1 billion to support clean technology.

The Government, through its policy work and funding of research, development and demonstration (RD&D) of innovative technologies, has made significant investments to reduce greenhouse gas emission and other environmental impacts in Canada's natural resources sectors, including oil and gas. A "Strategy for Advancing Clean Technology in the Natural Resource Sectors" is being advanced; in addition, through "Mission Innovation", Canada has joined 20 other nations in pledging to double spending on clean energy R&D by 2021. This commitment to fund energy R&D will help improve Canada's oil and gas sector, making it more environmentally responsible and economically competitive.

The Government also recently launched initiatives under Budget 2016 targeting innovation in the natural resources sectors, including Natural Resources Canada's $50 million Oil & Gas Clean Tech Program to reduce greenhouse gas emissions in the oil and gas sector; along with the $25 million Clean Energy Innovation Program, which funds projects in areas including the reduction of methane and volatile organic compound emissions in the oil & gas sector.

RECOMMENDATIONS 6, 7 and 8: The Committee recommends that the Government of Canada, through Natural Resources Canada, enhance opportunities to connect inventors, researchers and entrepreneurs with the segments of the oil and gas industry that are most applicable to their areas of expertise;

the Committee recommends that the Government of Canada encourage collaboration through clusters and councils among governments, industry, academia, and international experts, with the aim of maximizing the innovative potential of Canada's oil and gas sector; and,

the Committee recommends that the Government of Canada encourage Canadian companies and entrepreneurs to become global leaders in their respective innovations and/or technologies.

The Government recognizes the importance of connecting innovators with industry, and encouraging Canadian companies to become global leaders. Natural Resources Canada is an associate member of the Canada's Oil Sands Innovation Alliance (COSIA), an alliance of leading oil sands companies focused on bringing together leading thinkers from industry, government, academia and the wider public to improve measurement, accountability and environmental performance in the oil sands.

The Government supports the aim of maximizing the innovative potential of Canada's oil and gas sector, and encourages collaboration through many of Natural Resources Canada's undertakings. Natural Resources Canada's Oil & Gas Clean Tech Program and the Clean Energy

Innovation Program both look to support collaborative projects between clean technology producers and industrial end users of technologies, including the oil and gas industry. In addition to its collaborative efforts through COSIA, Natural Resources Canada's CanmetENERGY lab engages with various levels of governments to maximize the innovative potential of Canada's oil and gas sector. Through collaborations such as the Alberta-Canada *"Collaboratory in Cleaner Oil Sands Development*", the Government is able to encourage strategic alignment between jurisdictions, and identify common projects for collaboration related to oil sands innovation areas.

The Government also actively pursues collaborations with the US Department of Energy, and over the years, has worked on harmonizing energy efficiency regulations, RD&D projects targeting the oil and gas sector, and carbon capture and storage.

Finally, the Government of Canada has actively supported Canada businesses in their efforts to access global markets. This has been achieved through various fora including international trade missions, most recently to India where 20 Canadian Companies met with Indian industry to explore opportunities for Canadian products and know-how. In addition, the Government continues to be an active contributor to international development partnerships, such as the Canada-US Clean Energy Dialogue, the Canada-Israel Industrial Research and Development Foundation, and "Mission Innovation".

PAN-CANADIAN FRAMEWORK

on Clean Growth and Climate Change

Canada's Plan to Address Climate Change and Grow the Economy

PAN-CANADIAN FRAMEWORK on Clean Growth and Climate Change

Canada's Plan to Address Climate Change and Grow the Economy

FOREWORD

The Pan-Canadian Framework on Clean Growth and Climate Change presented here is our collective plan to grow our economy while reducing emissions and building resilience to adapt to a changing climate. It will help us transition to a strong, diverse and competitive economy; foster job creation, with new technologies and exports; and provide a healthy environment for our children and grandchildren.

The Pan-Canadian Framework is both a commitment to the world that Canada will do its part on climate change, and a plan to meet the needs of Canadians. We have built on the momentum of the Paris Agreement by developing a concrete plan which, when implemented, will allow us to achieve Canada's international commitments.

When First Ministers met last March in Vancouver, they agreed to take ambitious action in support of meeting or exceeding Canada's 2030 target of a 30 percent reduction below 2005 levels of greenhouse gas (GHG) emissions. First Ministers issued the Vancouver Declaration on Clean Growth and Climate Change and agreed that a collaborative approach between provincial, territorial, and federal governments is important to reduce GHG emissions and to enable sustainable economic growth.

The Pan-Canadian Framework builds on the leadership shown and actions taken individually and collectively by the provinces and territories, including through the Declaration of the Premiers adopted at the Quebec Summit on Climate Change in 2015. To note, the province of Saskatchewan has decided not to adopt the Pan-Canadian Framework at this time. The federal government has committed to ensuring that the provinces and territories have the flexibility to design their own policies and programs to meet emission-reductions targets, supported by federal investments in infrastructure, specific emission-reduction opportunities and clean technologies. This flexibility enables governments to move forward and to collaborate on shared priorities while respecting each jurisdiction's needs and plans, including the need to ensure the continued competitiveness and viability of businesses.

In the Paris Agreement, Parties agreed that they should, when taking action to address climate change, recognize and respect the rights of Indigenous Peoples. As we implement this Framework, we will move forward respecting the rights of Indigenous Peoples, with robust, meaningful engagement drawing on their Traditional Knowledge. We will take into account the unique circumstances and opportunities of Indigenous Peoples and northern, remote, and vulnerable communities. We acknowledge and thank Indigenous Peoples across Canada for their climate leadership long before the Paris Agreement and for being active drivers of positive change.

Pricing carbon pollution is central to this Framework. Carbon pricing will encourage innovation because businesses and households will seek out new ways to increase efficiencies and to pollute less. We will complement carbon pricing with actions to build the foundation of our low-carbon and resilient economy.

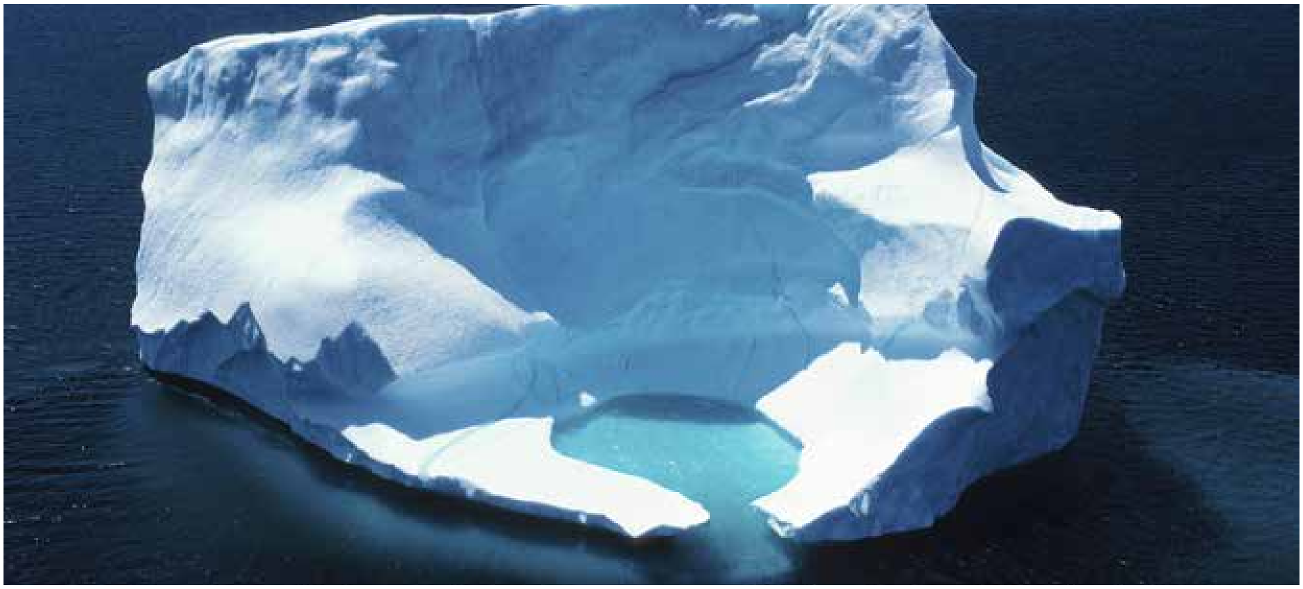
As Canada transitions to a low-carbon future, energy will play an integral role in meeting our collective commitment, given that energy production and use account for over 80 percent of Canada's GHG emissions. This means using clean energy to power our homes, workplaces, vehicles, and industries, and using energy more efficiently. It means convenient transportation systems that run on cleaner fuels, that move more people by public transit and zero-emission vehicles, and that have streamlined trade corridors. It means healthier and more comfortable homes that can generate as much power as they use. It means more resilient infrastructure and ecosystems that can better withstand climatic changes. It means land use and conservation measures that sequester carbon and foster adaptation to climate change. It means new jobs for Canadians across the country and opportunities for growth. It means leveraging technology and innovation to seize export and trade opportunities for Canada, which will allow us to become a leader in the global clean growth economy and will also help bring down the cost of low-emission technologies. It means healthier communities with cleaner air and healthy and diverse ecosystems across the country.

We will maintain a sustained focus on implementation of the Pan-Canadian Framework, consistent with the commitment under the Paris Agreement, to increase the level of ambition over time.

The Pan-Canadian Framework is a historic step in the transition to a clean growth and resilient economy. It is informed by what we have heard from Canadians. We will continue to grow our economy and create good jobs as we take ambitious action on climate change. We will work to ensure that the Pan-Canadian Framework opens new opportunities for Canadian businesses to not only maintain but also enhance their competitiveness. We will continue to engage Canadians to strengthen and deepen our action on clean growth and climate change. And we are committed to transparently assessing and reporting to Canadians on our progress.

Together, we have developed a Pan-Canadian Framework on Clean Growth and Climate Change. This is Canada's plan to address climate change and grow the clean economy.

TABLE OF CONTENTS



INTRODUCTION

In Canada and abroad, the impacts of climate change are becoming evident. Impacts such as coastal erosion; thawing permafrost; increases in heat waves, droughts and flooding; and risks to critical infrastructure and food security are already being felt in Canada. The science is clear that human activities are driving unprecedented changes in the Earth's climate, which pose significant risks to human health, security, and economic growth.

Taking strong action to address climate change is critical and urgent. The cost of inaction is greater than the cost of action: climate change could cost Canada $21-$43 billion per year by 2050, according to 2011 estimates from the National Round Table on the Environment and the Economy. Businesses and markets are increasingly considering climate risks. In recent years, severe weather events have cost Canadians billions of dollars, including in insured losses. Indigenous Peoples, northern and coastal regions and communities in Canada are particularly vulnerable and disproportionately affected. Geographic location, socio-economic challenges, and for Indigenous Peoples, the reliance on wild food sources, often converge with climate change to put pressure on these communities. Much has been done to begin addressing these challenges, including by Indigenous Peoples.

Acting on climate change will reduce risks and create new economic opportunities and good jobs for Canadians. There is already a global market for low-carbon goods and services worth over $5.8 trillion, which is projected to keep growing at a rate of 3 percent per year. Clean growth opportunities will benefit all sectors and regions. Canada will remain globally competitive through innovation, including through the development and promotion of innovative technologies with the potential to address climate change globally. This includes clean technology to enable the sustainable development of Canada's energy and resource sectors, including getting these resources to market, as Canada transitions to a low-carbon economy. Innovation can help further reduce emissions and the cost of taking action at home. Canadian technologies and solutions can also be exported abroad and deployed around the world, creating new markets and partners for Canadian businesses and supporting global action to reduce emissions.

The federal government will continue to work in close collaboration with other countries on climate solutions, including with partners across North America. A number of provinces and territories have already joined or are exploring entry into regional and international efforts to reduce GHG emissions.

Canadian municipalities will also continue to be important partners in developing and implementing climate solutions locally, as well as through international collaboration with other municipalities around the world.

The international community has agreed that tackling climate change is an urgent priority and also an historic opportunity to shift towards a global low-carbon economy. The adoption of the Paris Agreement in December 2015 was the culmination of years of negotiations under the United Nations Framework Convention on Climate Change. The Paris Agreement is a commitment to accelerate and intensify the actions and investments needed for a sustainable low-carbon future, to limit global average temperature rise to well below 2 °C above pre-industrial levels, and to pursue efforts to limit the increase to 1.5 °C. This will require taking action on long-lived GHGs such as carbon dioxide and short-lived climate pollutants such as methane, hydrofluorocarbons and black carbon.

As a first step towards implementing the commitments Canada made under the Paris Agreement, First Ministers released the Vancouver Declaration on Clean Growth and Climate Change on March 3, 2016.

1.1 How we developed the Framework

The development of the Pan-Canadian Framework was informed by input from Canadians across the country, who made it clear that they want to be part of the solution to climate change. Under the Vancouver Declaration, First Ministers asked four federal-provincial-territorial working groups to work with Indigenous Peoples; to consult with the public, businesses and civil society; and to present options to act on climate change and enable clean growth. The working groups heard solutions directly from Canadians, through an interactive website, in-person engagement sessions, and independent town halls.

Representatives of Indigenous Peoples contributed their knowledge and expectations for meaningful engagement in climate action and provided important considerations and recommendations either directly to working groups or to ministers, which helped shape this framework.

Ministers also reached out to Canadians, businesses, non-governmental organizations, and Indigenous Peoples to hear their priorities. In addition, ministerial tables were convened to provide their advice, including the Canadian Council of Ministers of the Environment, Ministers of Innovation, Ministers of Energy, and Ministers of Finance.

ENGAGING CANADIANS:
The Let's Talk Climate Action website was launched on April 22, 2016 to gather ideas and comments from Canadians about how Canada should address climate change. By the submission deadline of September 27, 2016, over 13,000 ideas and comments were received. In addition, consultations by governments and working groups on clean growth and climate change were held across Canada.

1.2 Pillars of the Framework

The Pan-Canadian Framework has four main pillars: pricing carbon pollution; complementary measures to further reduce emissions across the economy; measures to adapt to the impacts of climate change and build resilience; and actions to accelerate innovation, support clean technology, and create jobs. Together, these interrelated pillars form a comprehensive plan.

Pricing carbon pollution is an efficient way to reduce emissions, drive innovation, and encourage people and businesses to pollute less. However, relying on a carbon price alone to achieve Canada's international target would require a very high price.

Complementary climate actions can reduce emissions by addressing market barriers where pricing alone is insufficient or not timely enough to reduce emissions in the pre-2030 timeframe. For instance, tightening energy efficiency standards and codes for vehicles and buildings are common sense actions that reduce emissions, while also helping consumers save money by using less energy.

Canada is experiencing the impacts of climate change, so there is also a need to **adapt and build resilience**. This means making sure that our infrastructure and communities are adequately prepared for climate risks like floods, wildfires, droughts, and extreme weather events, including in particularly vulnerable regions like Indigenous, northern, coastal, and remote communities. This also means adapting to the impacts of changes in temperature, including thawing permafrost.

A low-carbon economy can and will be a strong and thriving economy. Taking action now, to position Canada as a global leader on clean technology innovation, will help ensure that Canada remains internationally competitive and will lead to the creation of new good jobs across the country. Investing in **clean technology, innovation, and jobs** will bring new and in-demand Canadian technologies to expanding global markets. These investments will help improve the efficiency and cost-effectiveness of mitigation and adaptation measures and will equip Canada's workforce with the knowledge and skills to succeed.

In implementing the Pan-Canadian Framework on Clean Growth and Climate Change, federal, provincial and territorial governments will review progress annually to assess the effectiveness of our collective actions and ensure continual improvement. First Ministers commit to **report regularly and transparently** to Canadians on progress towards GHG-reduction targets, on building climate resilience, and on growing a clean economy.

Our governments will continue to recognize, respect and safeguard the **rights of Indigenous Peoples** as we take actions under these pillars.

1.3 Elements of collaboration

The Pan-Canadian Framework reaffirms the principles outlined in the Vancouver Declaration, including

- recognizing the diversity of provincial and territorial economies and the need for fair and flexible approaches to ensure international competitiveness and a business environment that enables firms to capitalize on opportunities related to the transition to a low-carbon economy in each jurisdiction;
- recognizing that growing our economy and achieving our GHG-emissions targets will require an integrated, economy-wide approach that includes all sectors, creates jobs, and promotes innovation;
- recognizing that a collaborative approach between provincial, territorial, and federal governments is important to reduce GHG emissions and enable sustainable economic growth;
- recognizing that provinces and territories have been early leaders in the fight against climate change and have taken proactive steps, such as adopting carbon pricing mechanisms, placing caps on emissions, involvement in international partnerships with other states and regions, closing coal plants, carbon capture and storage projects, renewable energy production (including hydroelectric developments) and targets, and investments in energy efficiency;
- recognizing that the federal government has committed to ensuring that the provinces and territories have the flexibility to design their own policies to meet emission-reductions targets, including their own carbon pricing mechanisms, supported by federal investments in infrastructure, specific emission-reduction opportunities and clean technologies;
- recognizing the commitment of the federal government to work with provinces and territories to complement and support their actions without duplicating them, including by promoting innovation and enabling clean growth across all sectors;
- strengthening the collaboration between our governments and Indigenous Peoples on mitigation and adaptation actions, based on recognition of rights, respect, cooperation, and partnership;
- recognizing the importance of Traditional Knowledge in regard to understanding climate impacts and adaptation measures;

- recognizing that comprehensive adaptation efforts must complement ambitious mitigation measures to address unavoidable climate change impacts; and

- implementing a collaborative, science-based approach to inform Canada's future targets that will increase in stringency as required by the Paris Agreement.

Governments recognize the unique circumstances of the North, including disproportionate impacts from climate change and the associated challenges with food security, emerging economies and the high costs of living and of energy.

Federal, provincial, and territorial governments will work collaboratively to grow the economy, create good-paying and long-term jobs, and reduce GHG emissions in support of meeting or exceeding Canada's 2030 target. These actions will be supported by strong, complementary adaptation policies to build climate resilience. Indigenous Peoples will be important partners in developing real and meaningful outcomes that position them as drivers of climate action in the implementation of the Pan-Canadian Framework. All governments across Canada are committed to ambitious and sustained action on climate change, building on current actions and future opportunities.

THE FEDERAL GOVERNMENT'S RENEWED RELATIONSHIP WITH INDIGENOUS PEOPLES:

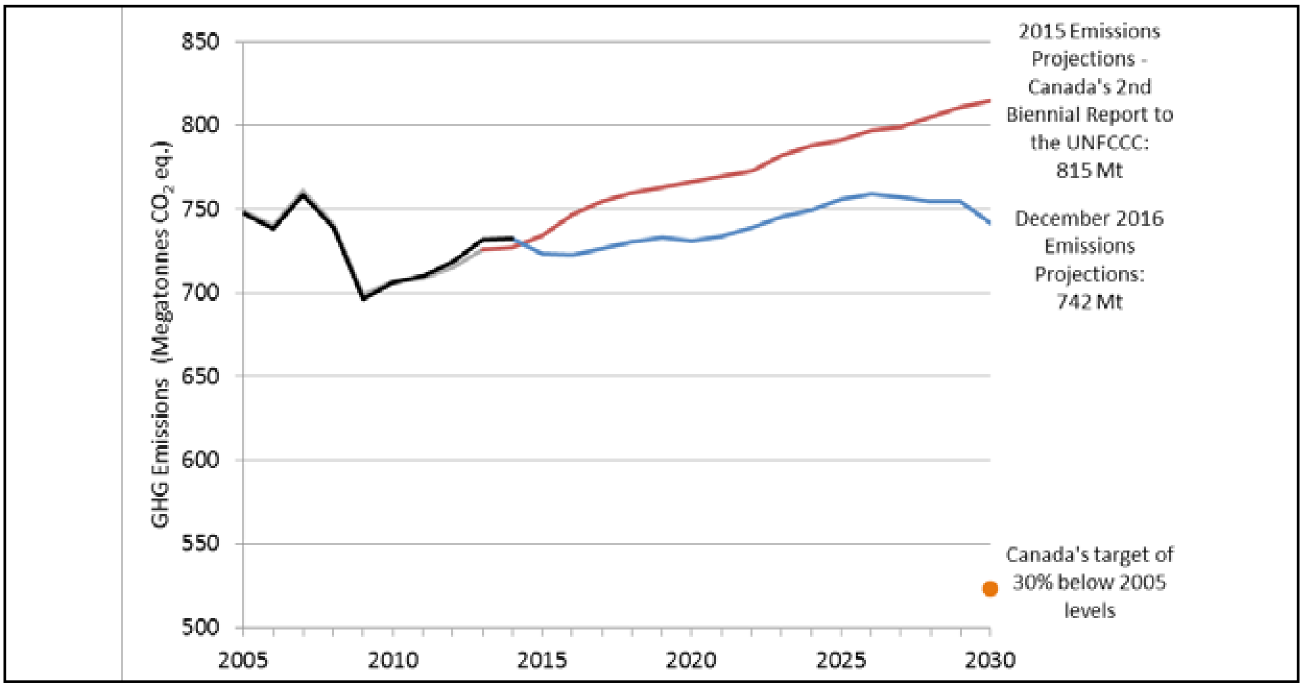
The federal government also reiterates its commitment to renewed nation-to-nation, government-to-government, and Inuit-to-Crown relationships with First Nations, the Métis Nation and Inuit, based on the recognition of rights, respect, cooperation, and partnership, consistent with the Government of Canada's support for the United Nations Declaration on the Rights of Indigenous Peoples, including free, prior and informed consent.

1.4 Emissions trajectory to 2030

The graph below highlights that total Canadian GHG emissions are projected to be 742 megatonnes (Mt) in 2030 under the December 2016 emissions projections (Environment and Climate Change Canada)[1]. Canada's target is 523 Mt.

Projections from the December 2016 emissions projections include revised forecasts for GDP and oil and gas prices and production[2]. Also incorporated are new federal, provincial, and territorial government measures that have legislative or funding certainty as of November 1st, 2016 and were not included in the 2015 emissions projections. These include: federal measures for increasing energy efficiency of equipment in buildings; Ontario's commitment to join the Western Climate Initiative cap-and-trade system; Alberta's coal phase-out, carbon levy, and oil sands emissions cap; Quebec's regulations for new high-rise buildings; and, British Columbia's low carbon fuel standard.

Figure 1: Emissions Projections to 2030



1 Canada's 2016 greenhouse gas emissions projections to 2030 will be released by Environment and Climate Change Canada in December 2016.

2

	Scenarios		
December 2016 Assumptions	**Low**	**Reference**	**High**
Average Annual GDP Growth (2014-2030)	1.0%	1.7%	2.3%
2030 WTI Oil Price (2014 US$/bbl)	42	81	111
2030 Henry Hub Natural Gas Price (2014 US$/GJ)	2.89	3.72	4.62
2030 GHG Emissions (Mt C02eq.)	**697**	**742**	**790**

PRICING CARBON POLLUTION

Overview

Carbon pricing is broadly recognized as one of the most effective, transparent, and efficient policy approaches to reduce GHG emissions. Many Canadian provinces are already leading the way on pricing carbon pollution. British Columbia has a carbon tax, Alberta has a hybrid system that combines a carbon levy with a performance-based system for large industrial emitters, and Quebec and Ontario have cap-and-trade systems. With existing and planned provincial action, broad-based carbon pricing will apply in provinces with nearly 85 per cent of Canada's economy and population by 2017, covering a large part of our emissions.

The federal government outlined a benchmark for pricing carbon pollution by 2018 (see Annex I). The goal of this benchmark is to ensure that carbon pricing applies to a broad set of emission sources throughout Canada and with increasing stringency over time either through a rising price or declining caps. The benchmark outlines that jurisdictions can implement (i) an explicit price-based system (a carbon tax or a carbon levy and performance-based emissions system) or (ii) a cap-and-trade system. Some existing provincial systems already exceeded the benchmark. As affirmed in the Vancouver Declaration, provinces and territories continue to have the flexibility to design their own policies to meet emissions-reduction targets, including carbon pricing, adapted to each province and territory's specific circumstances.

> **"THERE IS A GROWING CONSENSUS AMONG BOTH GOVERNMENTS AND BUSINESSES ON THE FUNDAMENTAL ROLE OF CARBON PRICING IN THE TRANSITION TO A DECARBONIZED ECONOMY."**
>
> World Bank, State and Trends of Carbon Pricing 2015

The following **principles** guide the pan-Canadian approach to pricing carbon pollution, and they are broadly based on those proposed by the Working Group on Carbon Pricing Mechanisms:

- Carbon pricing should be a central component of the Pan-Canadian Framework.

- The approach should be flexible and recognize carbon pricing policies already implemented or in development by provinces and territories.
- Carbon pricing should be applied to a broad set of emission sources across the economy.
- Carbon pricing policies should be introduced in a timely manner to minimize investment into assets that could become stranded and maximize cumulative emission reductions.
- Carbon price increases should occur in a predictable and gradual way to limit economic impacts.
- Reporting on carbon pricing policies should be consistent, regular, transparent, and verifiable.
- Carbon pricing policies should minimize competitiveness impacts and carbon leakage, particularly for emissions-intensive, trade-exposed sectors.
- Carbon pricing policies should include revenue recycling to avoid a disproportionate burden on vulnerable groups and Indigenous Peoples.

NEW ACTIONS

1) Provincial and territorial actions on pricing carbon pollution are described in Annex II.

2) The federal government will work with the territories to find solutions that address their unique circumstances, including high costs of living and of energy, challenges with food security, and emerging economies. The federal government will also engage Indigenous Peoples to find solutions that address their unique circumstances, including high costs of living and of energy, challenges with food security, and emerging economies.

3) The overall approach will be reviewed by 2022 to confirm the path forward.

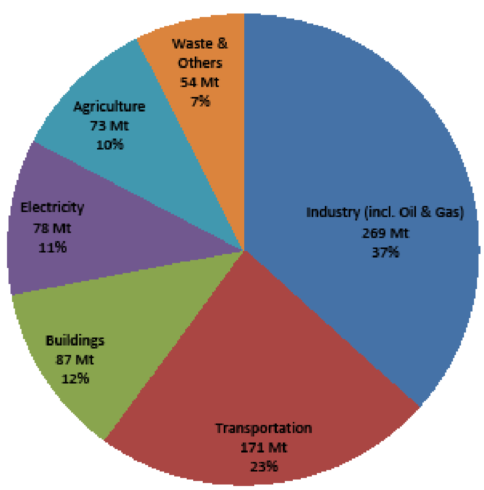
> **"CARBON PRICING IS THE MOST PRACTICAL AND COST-EFFECTIVE WAY TO LOWER GHG EMISSIONS WHILE ENCOURAGING LOW-CARBON INNOVATION."**
>
> Canada's Ecofiscal Commission

COMPLEMENTARY ACTIONS TO REDUCE EMISSIONS

Overview

To reduce emissions, meaningful action will need to be taken across all regions and sectors of the economy. Many of the things that Canadians do every day—like driving cars and heating homes—produce GHG emissions. Many activities that drive economic growth in the country, like extracting natural resources, industrial and manufacturing activities, and transporting goods to customers, also produce emissions. The policies that help drive down emissions can also help the economy to keep growing by cutting costs for Canadians, creating new markets for low-emission goods and services, and helping businesses use cleaner and more efficient technologies that give them a leg up on international competitors.

Emissions by sector in 2014
(megatonnes of CO_2 eq.)



Federal, provincial, and territorial governments will work together to make sure new actions build on and complement existing plans, policies, programs, and regulations and reflect lessons learned from past experience. New policies will be designed to focus on GHG-emission outcomes and will recognize flexibility for regional differences, including through outcomes-based regulatory equivalency agreements. Indigenous Peoples will be involved in defining and developing policies to support clean energy in their communities.

In developing policies, a number of factors will be considered, including:

- economic, environmental, and social impacts and benefits;
- how individual policies will work with carbon pricing;
- the need to consider and mitigate the impacts on emissions-intensive trade exposed sectors (e.g., resource sectors that are price takers on the global market), including the need to avoid carbon leakage;
- co-benefits such as improved health due to air pollutant reductions, and jobs and business growth;
- opportunities to realize near-term climate and health benefits through reducing emissions of short-lived climate pollutants; and,
- benefits for ecosystems and biodiversity.

FALLING COSTS OF RENEWABLE ENERGY:
Between 2010 and 2015, the costs for new utility-scale solar photovoltaic (PV) installations declined by two-thirds, while over the same period the cost of onshore wind fell by an estimated 30 percent on average (IEA, 2016)

Governments will be supporting the actions outlined in the Pan-Canadian Framework through policies and investments. Federal actions are described in Annex I, and provincial and territorial key actions and collaboration opportunities with the Government of Canada are described in Annex II.

3.1 Electricity

Canada already has one of the cleanest electricity systems in the world. About 80 percent of electricity production comes from non-emitting sources, more than any other G7 country. While electricity emissions are going down in large part due to the move away from coal-fired power toward cleaner sources, electricity generation is still Canada's fourth-largest source of GHG emissions.

Clean, non-emitting electricity systems will be the cornerstone of a modern, clean growth economy. Transformations to electricity systems will be supported by federal, provincial, and territorial governments, and, undertaken by utilities, private-sector players, and Indigenous Peoples.

The approach to electricity will include
(1) increasing the amount of electricity generated from renewable and low-emitting sources;
(2) connecting clean power with places that need it;
(3) modernizing electricity systems; and
(4) reducing reliance on diesel working with Indigenous Peoples and northern and remote communities.

Provinces and territories have already taken action on moving from traditional coal-fired generation to clean electricity. Ontario and Manitoba have already phased out their use of coal, Alberta has plans in place to phase out coal-fired electricity by 2030, Nova Scotia has created a regulatory framework to transition from coal to clean electricity generation, and Saskatchewan has a coal-fired generating unit with carbon capture technology, which captures 90 percent of emissions. New capacity will come from non-emitting sources—including hydro, wind, and solar—as well as natural gas. Energy efficiency and conservation will make added contributions to clean electricity systems.

ONTARIO'S COAL PHASE-OUT:
On April 15, 2014, **Ontario** became the first jurisdiction in North America to fully eliminate coal as a source of electricity generation. This action is the single largest GHG-reduction initiative in North America, eliminating more than 30 Mt of annual GHG emissions and equivalent to taking seven million vehicles off the road. On November 23, 2015, Ontario passed the *Ending Coal for Cleaner Air Act*, permanently banning coal-fired electricity generation in the province.

SASKATCHEWAN'S BOUNDARY DAM INTEGRATED CARBON CAPTURE AND STORAGE PROJECT:
is the world's first commercial-scale, coal-fired carbon capture and storage electricity project, and it is able to capture and sequester up to 90 percent of its GHG emissions.

WIND POWER:
Wind capacity in Canada grew 20 times between 2005 and 2015, and there is strong potential for further growth. For example, 4 wind farms in **Prince Edward Island** now generate almost 25 percent of the province's electricity requirements.

ALBERTA'S COAL PHASE-OUT:
Alberta's commitments to end emissions from coal-fired electricity and replace it with 30 percent renewable energy by 2030 are expected to achieve cumulative emission reductions of 67 Mt between now and 2030, and emissions in 2030 will be at least 14 Mt below what is forecast under the status quo. This reduction is the equivalent of taking 2.8 million cars off the road. This move will improve air quality and the health of Albertans and other Canadians. It will also ensure reliability, encourage private investment, and provide price stability for all Albertans.

Connecting clean power across Canada through stronger transmission-line interconnections will help reduce emissions and support the move away from coal. Many provinces already trade electricity across their borders, and there is potential to increase these flows, consistent with market rules and fair competition among electricity producers.

THE CANADIAN ENERGY STRATEGY:
Provinces and territories are already taking a cooperative approach toward sustainable energy development through the Canadian Energy Strategy, which was released by premiers in July 2015. As agreed under the Vancouver Declaration and building on the Quebec Summit on Climate Change in 2015, federal, provincial, and territorial energy ministers are collaborating on specific actions through the Canadian Energy Strategy, to contribute to the Pan-Canadian Framework on Clean Growth and Climate Change. Actions include energy conservation and efficiency, clean energy technology and innovation, and deployment of energy to people and global markets.

Modernizing electricity systems will involve expanding energy storage, updating infrastructure, and deploying smart-grid technologies to improve the reliability and stability of electric grids and to allow more renewable power to be added. As a leader in the development and deployment of innovative energy-storage solutions and smart-grid technology, Canadian clean technology producers stand to benefit from increased investments in our electricity systems.

Many Indigenous Peoples, as well as northern and remote communities in Canada rely on diesel fuel to produce electricity and heat. Opportunities exist for clean electricity infrastructure, distributed energy systems, renewable energy microgrids, as well as grid connections and hybrid systems, which will enhance wellbeing, create local economic opportunities, and contribute to better air quality and a cleaner environment overall. Investing in clean energy solutions will advance the priorities of Indigenous Peoples, as well as northern and remote communities to transition away from diesel.

COLVILLE LAKE SOLAR PROJECT – Colville Lake, Northwest Territories is located north of the Arctic Circle, and it is served with a winter road that is open just a couple of months each year. To reduce diesel use in this remote, off-grid community, a solar/diesel/battery hybrid electricity system has been installed. This system has allowed the diesel generators to be shut down for extended periods in the summer. This innovative energy solution has reduced diesel use and related emissions by 20-25 percent per year.

Taking these actions will have a number of benefits beyond reducing GHG emissions. Phasing out coal and reducing the use of diesel will reduce harmful air pollutants, which have significant implications for human health and associated health-care costs. Designing and building clean-power technologies and transmission lines represents major economic opportunities for Canada. Increasing the amount of clean and renewable electricity sold to the United States could also bring new revenue to utilities and provinces, respecting open-access rules under the authority of the U.S. Federal Energy Regulatory Commission.

THE CANADA INFRASTRUCTURE BANK:
The federal government is creating the Canada Infrastructure Bank, which will work with provinces, territories, and municipalities to further the reach of government funding directed to infrastructure, including clean electricity systems.

COMMUNITY-BASED ENERGY GENERATION:
In May 2015, **New Brunswick** introduced legislation to allow local entities to develop renewable-energy sourced electricity generation in their communities. This legislation will allow universities, non-profit organizations, cooperatives, First Nations, and municipalities to contribute to NB Power's renewable energy requirements.

NEW ACTIONS

1. Increasing renewable and non-emitting energy sources

Federal, provincial, and territorial governments will work together to accelerate the phase out of traditional coal units across Canada, by 2030, as recently announced by the federal government (see Annex I) and to build on provincial and territorial leadership.

The federal government has announced it will set performance standards for natural gas-fired electricity generation, in consultation with provinces, territories, and stakeholders (see Annex I).

Federal, provincial, and territorial governments will work together to facilitate, invest in, and increase the use of clean electricity across Canada, including through additional investments in research, development, and demonstration activities.

2. Connecting clean power with places that need it

Federal, provincial, and territorial governments will work together to help build new and enhanced transmission lines between and within provinces and territories.

3. Modernizing electricity systems

Federal, provincial, and territorial governments will work together to support the demonstration and deployment of smart-grid technologies that help electric systems make better use of renewable energy, facilitate the integration of energy storage for renewables, and help expand renewable power capacity.

4. Reducing reliance on diesel working with Indigenous Peoples and northern and remote communities

Governments are committed to accelerating and intensifying efforts to improve the energy efficiency of diesel generating units, demonstrate and install hybrid or renewable energy systems, and connect communities to electricity grids. This will be done in partnership with Indigenous Peoples and businesses. These actions will have significant benefits for communities, such as improving air quality and energy security, and creating the potential for locally owned and sourced power generation.

RAMEA WIND-HYDROGEN-DIESEL ENERGY PROJECT:
The off-grid community of Ramea in **Newfoundland and Labrador** hosts one of the first projects in the world to integrate generation from wind, hydrogen, and diesel in an isolated electricity system. Since 2010, the Ramea Wind-Hydrogen-Diesel Energy Project has successfully produced approximately 680 000 kilowatt hours of renewable energy.

3.2 Built environment

In Canada, using energy to heat and cool buildings accounted for about 12 percent of national GHG emissions in 2014 or 17 percent if emissions from generating the electricity used in buildings is also included. The emissions in this sector—created by burning fossil fuels and leaks in air conditioning systems—are projected to grow modestly by 2030 unless further action is taken.

In a low-carbon, clean growth economy, buildings and communities will be highly energy efficient, rely on clean electricity and renewable energy, and be smart and sustainable. Making the built environment more energy efficient reduces GHGs, helps make homes and buildings more comfortable and more affordable by lowering energy bills, and can promote innovation and clean job opportunities. Most building owners and architects estimate that retrofitting commercial and institutional buildings pays off in less than ten years, according to data from the Canada Green Building Council. Residential energy efficiency improvements helped Canadians save $12 billion in energy costs in 2013, an average savings of $869 per household.

The approach to the built environment will include (1) making new buildings more energy efficient; (2) retrofitting existing buildings, as well as fuel switching; (3) improving energy efficiency for appliances and equipment; and (4) supporting building codes and energy efficient housing in Indigenous communities.

Advances in clean technologies and building practices can make new buildings "net-zero energy", meaning they require so little energy they could potentially rely on their own renewable energy supplies for all of their energy needs. Through research and development, technology costs continue to fall, and government and industry efforts and investments will accelerate that trend. These advances, supported by a model "net-zero energy ready" building code, will enable all builders to adopt these practices and lower lifecycle costs for homeowners.

EFFICIENCY NOVA SCOTIA:
Canada's first energy efficiency utility—works with more than 100 local partners, and it has helped 225 000 program participants complete energy efficiency projects, saving Nova Scotians $110 million in 2016 alone. For example, the HomeWarming service is funded by the province of Nova Scotia as part of a long-term plan to upgrade all low-income homes in Nova Scotia, over the next 10 years.

At the same time, action is needed on existing buildings, since more than 75 percent of the building stock in 2030 will be composed of buildings already standing today. This can be supported by innovative policies like labelling a building's energy performance, establishing retrofit codes, and offering low-cost financing for retrofits.

Housing for Indigenous communities is particularly pressing. New housing will be built to high-efficiency standards and existing housing will be retrofitted. Indigenous Peoples have also identified the need to incorporate Traditional Knowledge and culture into building designs. Governments will partner with Indigenous Peoples in the design of relevant policies and programs.

Energy efficiency standards for equipment and appliances save consumers and businesses money on energy bills. An early market signal by the government, in the form of an intention to introduce standards by a specific year, can motivate the market to accelerate the uptake of the targeted technologies. Regulations can be supported by actions to educate consumers, to demonstrate benefits, and to overcome market barriers.

Construction in Canada is a $171 billion industry, and it employs well over a million people. New building codes will spur innovation and support Canadian businesses in developing more efficient building techniques and technologies. Investments in retrofits to improve energy efficiency have been shown to be strong job creators, providing direct local benefits, creating local jobs, and reducing energy bills.

NET-ZERO ENERGY BUILDINGS:
Construction costs for net-zero energy buildings have dropped 40 percent in the past decade, and they are continuing to fall. The benefits of net-zero energy buildings are significant. Estimated operating costs for a net-zero energy ready house is 30 percent to 55 percent less than for a typical house, depending on region, fuel type and occupant behaviour. For example, on a -32 °C day, the Riverdale NetZero Project (a semi-detached duplex in Edmonton, Alberta) only needs 6500 W of power for heat—the same amount of heat produced by four toasters.

NEW ACTIONS

1. Making new buildings more energy efficient

Federal, provincial, and territorial governments will work to develop and adopt increasingly stringent model building codes, starting in 2020, with the goal that provinces and territories adopt a "net-zero energy ready" model building code by 2030. These building codes will take regional differences into account. Continued federal investment in research, development, and demonstration, and cooperation with industry will help to reduce technology costs over time.

2. Retrofitting existing buildings

Federal, provincial, and territorial governments will work to develop a model code for existing buildings by 2022, with the goal that provinces and territories adopt the code. This code will help guide energy efficiency improvements that can be made when renovating buildings.

Federal, provincial, and territorial governments will work together with the aim of requiring labelling of building energy use by as early as 2019. Labelling will provide consumers and businesses with transparent information on energy performance.

Provincial and territorial governments will work to sustain and, where possible, expand efforts to retrofit existing buildings by supporting energy efficiency improvements as well as fuel switching, where appropriate, and by accelerating the adoption of high-efficiency equipment while tailoring their programs to regional circumstances. The federal government could support efforts of provinces and territories through the Low Carbon Economy Fund and infrastructure initiatives.

3. Improving energy efficiency for appliances and equipment

The federal government will set new standards for heating equipment and other key technologies to the highest level of efficiency that is economically and technically achievable.

4. Supporting building codes and energy efficient housing in Indigenous communities

Governments will collaborate with Indigenous Peoples as they move towards more efficient building standards and incorporate energy efficiency into their building-renovation programs.

SOCIAL HOUSING RETROFITS:
To help fight climate change, Ontario invested $92 million in 2016 to retrofit social housing buildings to reduce GHG emissions by installing energy efficient boilers, insulating outer walls and mechanical systems, and installing more energy efficient windows and lighting. Ontario's Climate Change Action Plan builds on this initial investment by committing up to $500 million more for social housing retrofits over the next five years.

Aki Energy in **Manitoba** is a non-profit Aboriginal social enterprise that works with First Nations to start green businesses in their communities and to create local jobs and strong local economies. Aki Energy is committed to helping First Nations lower the utility bills to heat buildings, and it has installed over $3 million in cost-effective renewable energy technologies in partnership with Manitoba First Nations.

3.3 Transportation

The transportation sector accounted for about 23 percent of Canada's emissions in 2014, mostly from passenger vehicles and freight trucks. Transportation emissions are projected to decline slightly by 2030 if no further action is taken. Governments are already working to make all modes of transportation more efficient and convenient, but more action is needed.

Low-carbon transportation systems will use cleaner fuels, will have more zero-emission vehicles on the road, will provide convenient and affordable public transit, and will transport people and goods more efficiently.

The approach to transportation will include (1) setting and updating vehicle emissions standards and improving the efficiency of vehicles and transportation systems; (2) expanding the number of zero-emission vehicles on Canadian roads; (3) supporting the shift from higher to lower-emitting types of transportation, including through investing in infrastructure; and (4) using cleaner fuels.

Emissions standards for cars and trucks ensure new engines are more fuel efficient. Retrofitting freight trucks to reduce wind resistance can also cut emissions. And streamlining how goods are transported can improve the overall efficiency of transportation systems.

Zero-emission vehicle technologies include plug-in hybrids, electric vehicles, and hydrogen fuel-cell vehicles. Many of these are becoming increasingly affordable and viable, and governments can help accelerate these trends, including by investing in charging and fueling infrastructure.

ELECTRIFICATION OF TRANSPORTATION:

Québec has committed to take significant action on the electrification of transportation by 2020, including by increasing the number of electric and plug-in hybrid vehicles registered in Québec to 100 000; adding 5000 electric-vehicle jobs and generating $500 million in investments; reducing the amount of fuel used each year in Québec by 66 million liters; and cutting annual GHG emissions from the transportation sector by 150 000 tonnes.

Shifting from higher- to lower-emitting modes of transportation includes things like riding public transit or cycling instead of driving a car, and transporting goods by rail instead of trucks. Improving public transit infrastructure and optimizing freight corridors can help drive these shifts.

Using cleaner fuels such as advanced biofuels can reduce the lifecycle carbon intensities of all fuels across transportation systems, as well as in other sectors like industry and buildings.

Taking these actions will have additional environmental and economic benefits beyond reducing GHG emissions. Efficiency improvements can help Canadians and businesses save money by spending less on fuel and reducing the costs of transporting goods. New, cleaner fuels can create opportunities for resource sectors. Businesses that develop new fuel and vehicle technologies will create jobs, help the economy grow, and give those businesses a competitive edge.

NEW ACTIONS

1. Setting emissions standards and improving efficiency

The federal government will continue its work to implement increasingly stringent standards for emissions from light-duty vehicles, including fuel-efficient tire standards, and to update emissions standards for heavy-duty vehicles.

The federal government will work with provinces, territories, and industry to develop new requirements for heavy-duty trucks to install fuel-saving devices like aerodynamic add-ons.

The federal government will take a number of actions to improve efficiency and support fuel switching in the rail, aviation, marine, and off-road sectors.

2. Putting more zero-emission vehicles on the road

Federal, provincial, and territorial governments will work with industry and other stakeholders to develop a Canada-wide strategy for zero-emission vehicles by 2018.

Federal, provincial, and territorial governments will work together, including with private-sector partners, to accelerate demonstration and deployment of infrastructure to support zero-emission vehicles, such as electric-charging stations.

3. Shifting from higher- to lower-emitting modes and investing in infrastructure

Federal, provincial, and territorial governments will work together to enhance investments in public-transit upgrades and expansions.

Federal, provincial, and territorial governments will invest in building more efficient trade and transportation corridors including investments in transportation hubs and ports.

Federal, provincial, and territorial governments will consider opportunities with the private sector to support refueling stations for alternative fuels for light- and heavy-duty vehicles, including natural gas, electricity, and hydrogen.

4. Using cleaner fuels

The federal government, working with provincial and territorial governments, industry, and other stakeholders, will develop a clean fuel standard to reduce emissions from fuels used in transportation, buildings and industry.

This will take into account the unique circumstances of Indigenous Peoples and northern and remote communities.

3.4 Industry

Canada's industries are the backbone of the economy, but they are also a major source of GHG emissions. In 2014, industrial sectors accounted for about 37 percent of Canada's emissions, the majority of which came from the oil and gas sector. Industrial emissions are projected to grow between now and 2030 as demand grows for Canadian-produced goods, at home and abroad.

A low-carbon industrial sector will rely heavily on clean electricity and lower-carbon fuels, will make more efficient use of energy, and will seize opportunities unlocked by innovative technologies. The province of Alberta has legislated an absolute cap of 100 Mt a year on emissions from the oil sands sector. There are a number of near-term opportunities to reduce industrial emissions while maintaining the competitive position of Canadian firms.

The approach to the industrial sector will include three main areas of action: (1) regulations to reduce methane and hydrofluorocarbon (HFC) emissions; (2) improving industrial energy efficiency; and (3) investing in new technologies to reduce emissions. Together, these actions will help set the path for long-term clean growth and the transition to a low-carbon economy.

Methane and HFCs are potent GHGs, dozens to thousands of times more powerful than carbon dioxide. The oil and gas sector is the largest contributor to methane emissions in Canada. Building on provincial actions and targets, the federal government has committed to reduce methane emissions by 40-45 percent by 2025. Canada joined almost 200 other countries in signing the Kigali Amendment to the Montreal Protocol, which will push the global phase out of HFC emissions. Taking action on HFCs can prevent up to 0.5 °C of global warming due to the potency of these gases, while continuing to protect the ozone layer.

There is significant potential to improve energy efficiency in Canada's industrial sectors. Energy management systems such as ISO 50001, the Superior Energy Performance program (SEP), and the ENERGY STAR for Industry program are useful tools that help businesses track, analyze, and improve their energy efficiency.

Using today's low-emission technologies and switching to clean electricity and lower-carbon fuels are near-term actions industry can take to reduce emissions. Over the longer-term, more dramatic emission reductions will be possible by using new technologies to transform how some industries operate. Investing in promising new technologies is an important area for action. Innovation will help Canadian businesses access global markets and attract foreign investment.

LOWER-CARBON INDUSTRIAL ACTIVITY IN CANADA:
Quebec's aluminum smelters have reduced their emissions by 30 percent since 1990. The modernized world-class aluminum smelter in Kitimat, BC will boost production and reduce emissions by nearly 50 percent. As a result of these investments, Canada's aluminum industry is now the most carbon-efficient producer of aluminum in the world.

OIL SANDS INNOVATION:
COSIA (Canada's Oil Sands Innovation Alliance) is an alliance of 13 oil sands producers, representing 90 percent of production from the Canadian oil sands, who are working together to develop technologies that help reduce the environmental impact of the oil sands, including reducing GHG emissions. Member companies have shared 936 distinct environmental technologies, costing $1.33 billion, since coming together in 2012.

Taking these actions will benefit businesses. Strengthening energy performance is one of the most cost-effective ways for industry to reduce energy use, it generally has quick payback periods, and it will continually generate financial savings. Measures that help cut costs or develop new technologies can improve competitiveness and create jobs and export opportunities for the clean technology sector.

NEW ACTIONS

1. Reducing methane and HFC emissions

The federal government will work with provinces and territories to achieve the objective of reducing methane emissions from the oil and gas sector, including offshore activities, by 40-45 percent by 2025, including through equivalency agreements.

The federal government has introduced proposed regulations to phase down use of HFCs to support Canada's commitment to the Montreal Protocol amendment.

2. Improving industrial energy efficiency

Federal, provincial, and territorial governments will work together to help industries save energy and money, including by supporting them in adopting energy management systems.

3. Investing in technology

Federal, provincial, and territorial governments working with industry will continue to invest in research and development and to promote deployment of new technologies that help reduce emissions.

Federal, provincial, and territorial governments will also work with industry to identify demonstration projects for promising pre-commercial clean energy technologies required to reduce emissions from energy production and use in the Canadian economy, including in the oil and gas sector.

3.5 Forestry, agriculture, and waste

Emissions from agriculture (livestock and crop production) and extraction of forestry resources accounted for about 10 percent of Canada's emissions in 2014, and they are not projected to significantly change by 2030. Municipal waste accounts for a small portion (about 3 percent) of Canada's total GHGs, and these emissions are projected to decline, largely due to increases in landfill gas capture.

Agricultural soils and forests also absorb and store carbon. The emissions or removals from carbon sinks can fluctuate with natural disturbances (e.g. forest fires), but there are still a number of actions that can increase carbon storage and reduce emissions.

Forests, wetlands, and agricultural lands across Canada will play an important natural role in a low-carbon economy by absorbing and storing atmospheric carbon. Actions taken by jurisdictions and woodlot owners to accelerate reforestation, to continuously improve sustainable management practices, and to plant new forests where they do not currently exist will enhance stored carbon. Clean technology, such as lower-carbon bioenergy, and bioproducts that use feedstock from agriculture and forestry waste and dedicated crops to replace higher-carbon fuels can also reduce emissions. Continued innovation and clean technology in agriculture will build on past GHG reduction successes of decreasing emissions per unit of production. The municipal waste sector will also be a key source of cleaner fuels such as renewable natural gas from landfills.

The approach to these sectors will include (1) enhancing carbon storage in forests and agricultural lands; (2) supporting the increased use of wood for construction; (3) generating fuel from bioenergy and bioproducts; and, (4) advancing innovation.

Forests, wetlands, and agricultural lands can be enhanced as “carbon sinks” through actions such as planting more trees, improving forest carbon management practices, minimizing losses from fires and invasive species, restoring forests that have been affected by natural disturbances, and increasing adoption of land management practices like increasing perennial and permanent cover crops and zero-till farming. Protecting and restoring natural areas, including wetlands, can also benefit biodiversity and maintain or enhance carbon storage.

Increasing the use of wood for construction can reduce emissions as the carbon stored in that wood gets locked in for a long period of time. Increasing domestic demand for Canadian wood products will also support the vibrant forest industries across Canada, which have a long history of innovating to develop new products and more efficient and sustainable forest practices.

The **Cheakamus Community Forest** carbon offset project is located adjacent to the Resort Municipality of Whistler, within the traditional territories of the Squamish and Lil'wat Nations. The project retains more carbon in the forest by using ecosystem-based management practices that include increasing protected areas and using lower-impact harvesting techniques.

The forestry, agriculture, and waste sectors also provide biomass for bioproducts that can be used in place of fossil fuels in other sectors. For example, waste products from forestry, agriculture, and landfills can be converted into energy sources such as renewable natural gas. Dedicated crops can be grown as feedstocks for products like bioplastics. Expanding renewable fuel industries represents an opportunity to create new jobs and economic growth across Canada.

BIOMASS-FIRED DISTRICT HEATING:

Prince Edward Island is home to Canada's longest running, biomass-fired district heating system. Operating since the 1980's, the system has expanded to serve over 125 buildings in the downtown core of Charlottetown, including the University of Prince Edward Island and the Queen Elizabeth Hospital, and cleanly burns 66 000 tons of waste materials annually.

Innovative solutions, including clean technologies, are required to reduce emissions from agriculture. Promising new technologies are being developed to reduce emissions from livestock and crop production, including from the use of precision farming and "smart" fertilizers, which time the release to match plant needs, and from feed innovations that reduce methane production in cattle. Actions pertaining to the agriculture sector will be developed collaboratively through Canada's Next Agriculture Policy Framework.

These actions in the forestry, agriculture, and waste sectors, and supporting clean technology businesses, can help to create jobs and build more sustainable communities.

NEW ACTIONS

1. Increasing stored carbon

Federal, provincial, and territorial governments will work together to protect and enhance carbon sinks, including in forests, wetlands, and agricultural lands (e.g. through land-use and conservation measures).

2. Increasing the use of wood for construction

Federal, provincial, and territorial governments will collaborate to encourage the increased use of wood products in construction, including through updated building codes.

3. Generating bioenergy and bioproducts

Federal, provincial, and territorial governments will work together to identify opportunities to produce renewable fuels and bioproducts, for example, generating renewable fuel from waste.

4. Advancing innovation

Federal, provincial, and territorial governments will work together to enhance innovation to advance GHG efficient management practices in forestry and agriculture.

3.6 Government leadership

Governments are directly responsible for a relatively small share of Canada's emissions (about 0.6 percent), but they have an opportunity to lead by example. A number of provinces are already demonstrating leadership, including through carbon neutral policies.

CARBON NEUTRAL GOVERNMENT:
British Columbia's public sector has successfully achieved carbon neutrality each year since 2010. Over the past 6 years, schools, post-secondary institutions, government offices, Crown corporations, and hospitals have reduced a total of 4.3 million tonnes of emissions through improvements to their operations and investments of $51.4 million in offset projects. British Columbia was the first—and continues to be the only—carbon neutral jurisdiction on the continent.

In a low-carbon, clean growth economy, federal, provincial, and territorial governments will be leaders in sustainable, low-emission practices that support the goals of clean growth and address climate change.

Municipalities are also essential partners. How cities develop and operate has an important impact on energy use and therefore GHG emissions.

LEADERSHIP BY CITIES:
The City of Whitehorse's Sustainability Plan outlines 12 community-wide goals in areas such as transportation, buildings, waste, GHG reductions, and resilient, accessible food systems, with associated targets for 2020, 2030, and 2050. For example, Whitehorse has set a target that new buildings will be 30 percent more efficient than the National Energy Code of Canada for Buildings, the National Building Codes, or achievable comparable EnerGuide ratings, while city-owned buildings will be 50 percent more efficient than the National Energy Code.

The public sector can play an important role by setting ambitious emissions reduction targets and by demonstrating the effectiveness of policies to reduce emissions (e.g. from vehicle fleets and buildings).

The approach to government leadership will include (1) setting ambitious targets; (2) cutting emissions from government buildings and fleets; and (3) scaling up clean procurement.

Governments control a significant share of assets like fleets and buildings. By setting targets and implementing policies to make buildings more efficient and to reduce emissions from vehicle fleets, the public sector can help to demonstrate the business case for ambitious action. Governments are also major purchasers and providers of goods and services, and they can help to build demand for low-carbon goods and services through procurement policies. They can also provide a testing ground for new and emerging technologies, creating new opportunities for Canadian firms developing clean technology products, services, and processes.

NEW ACTIONS

1. Setting ambitious targets

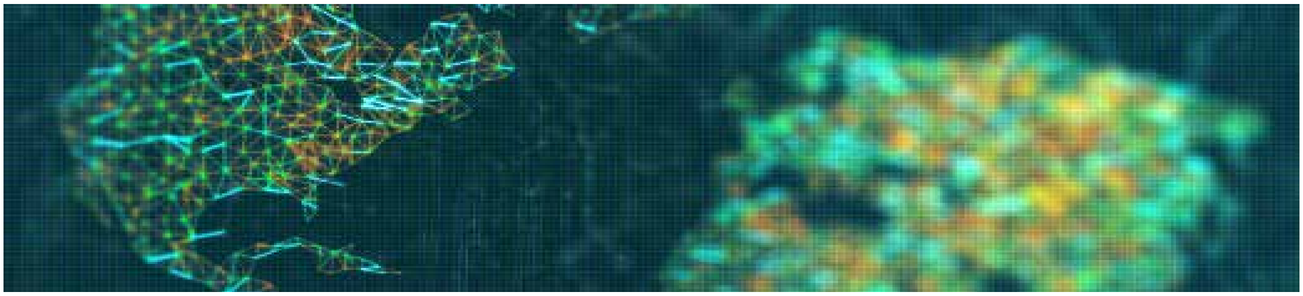
Federal, provincial, and territorial governments will demonstrate leadership through commitments to ambitious targets to reduce emissions from government operations. The federal government is committed to reduce its own GHG emissions to 40 percent below 2005 levels, by 2030 or sooner.

2. Cutting emissions from government buildings and fleets

Federal, provincial, and territorial government will scale up efforts to transition to highly efficient buildings and zero-emission vehicle fleets. The federal government has set a goal of using 100 percent clean power by 2025.

3. Scaling up clean procurement

Federal, provincial, and territorial governments will work together to modernize procurement practices, adopt clean energy and technologies, and prioritize opportunities to help Canadian businesses grow, demonstrate new technologies, and create jobs.



3.7 International leadership

Governments will work with their international partners, including developing countries, to help reduce emissions around the world. The federal government is investing $2.65 billion in climate finance to help developing countries transition to low-carbon economies and build climate resilience.

The priority is to first focus on reduction in emissions within Canada, but part of Canada's approach to climate change could also involve acquiring allowances for emissions reductions in other parts of the world, as a complement to domestic emissions reduction efforts. As recognized under the Paris Agreement (article 6), countries may choose to use emissions reductions that take place outside of their own borders, known as "internationally transferred mitigation outcomes", to meet their targets. Emissions reductions that take place outside of Canada may have lower costs and contribute to investment in sustainable development abroad. Quebec and California already participate in international emissions trading under their linked cap-and-trade system, which Ontario will soon join.

The approach to international leadership will include (1) delivering on Canada's international climate finance commitments; (2) acquiring internationally transferred mitigation outcomes; and (3) engaging in trade and climate policy.

Federal, provincial, and territorial governments will also explore mechanisms and opportunities for provinces and territories to collaborate in international fora, joint missions, and discussions on climate change and energy.

The federal government will continue to engage with and support Indigenous Peoples' action on international climate change issues, including through the United Nations Framework Convention on Climate Change, to formulate a platform for Indigenous Peoples, as agreed to in the Paris decision.

NEW ACTIONS

1. Delivering on Canada's international climate-finance commitments

The federal government will deliver on its historic commitment of $2.65 billion by 2020 to help the poorest and most vulnerable countries mitigate and adapt to the adverse effects of climate change.

2. Acquiring internationally transferred mitigation outcomes

The federal government, in cooperation with provincial and territorial governments and relevant partners, will continue to explore which types of tools related to the acquisition of internationally transferred mitigation outcomes may be beneficial to Canada and will advance a robust approach to the implementation of article 6 of the Paris Agreement. A first priority is ensuring any cross-border transfer of mitigation outcomes is based on rigorous accounting rules, informed by experts, which result in real reductions.

The federal government will work with Ontario, Quebec, and other interested provinces and territories, as well as with international partners, to ensure that allowances acquired through international-emissions trading are counted towards Canada's international target.

3. Engaging in trade and climate policy

The federal government, in cooperation with provincial and territorial governments, will work with its international partners to ensure that trade rules support climate policy.

ADAPTATION AND CLIMATE RESILIENCE

Overview

The impacts of climate change are already being felt across Canada. These changes are being magnified in Canada's Arctic, where average temperature has increased at a rate of nearly three times the global average. They pose significant risks to communities, health and well-being, the economy, and the natural environment, especially in Canada's northern and coastal regions and for Indigenous Peoples. Indigenous Peoples are among the most vulnerable to climate change due to their remote locations and reliance on wild foods. The changes already being experienced are both dramatic and permanent, with significant social, cultural, ecological, and economic implications.

Taking action to adapt to current and future climate impacts will help protect Canadians from climate change risks, build resilience, reduce costs, and ensure that society thrives in a changing climate.

INUIT AND CLIMATE IMPACTS:
Inuit and Inuit Nunangat, the homeland of Inuit in Canada, are experiencing significant climate change impacts, as highlighted in Inuit Tapiriit Kanatami's recent report on Inuit Priorities for Canada's Climate Strategy. More than 70 per cent of Canada's coastline is located in the Arctic and it is defined by ice. Average sea ice thickness is decreasing and sea ice cover is now dominated by younger, thinner ice. Some models are projecting that summer sea ice cover could be almost completely lost before 2050. These changes are already impacting access to wild foods and contributing to hazards and risks on ice.

Developing adaptation expertise and technology can further contribute to clean growth by creating jobs and spurring innovation. Adaptation is a long-term challenge, and it requires ongoing commitment to action, leadership across all governments, strong governance to assess and sustain progress, adequate funding, and meaningful engagement with, and continued leadership by, Indigenous Peoples. Federal investments (see Annex I) will support key adaptation measures.

Federal, provincial, and territorial governments have identified new actions to build resilience to climate change across Canada in the following areas:

1. Translating scientific information and Traditional Knowledge into action
2. Building climate resilience through infrastructure
3. Protecting and improving human health and well-being
4. Supporting particularly vulnerable regions
5. Reducing climate-related hazards and disaster risks

4.1 Translating scientific information and Traditional Knowledge into action

Canadians need authoritative science and information to understand current and expected changes. This includes changing conditions (e.g., rainfall, temperature, and sea ice) and the impacts of climate change across Canada. Long-term monitoring and local observations are also key. Data, tools, and information need to be widely accessible, equitable, and relevant to different types of decision-makers in different settings.

Translating knowledge into action takes leadership, skilled people, and resources. The Government of Canada's Adaptation Platform supports collaboration among governments, industry, and professional organizations on adaptation priorities. Building regional expertise and capacity for adaptation will improve risk management; support land-use planning; help safeguard investments; and strengthen emergency planning, response, and recovery. Decision-making by all governments will be guided by consideration of scientific and Traditional Knowledge.

INFORMATION AND TOOLS FOR ADAPTATION DECISIONS:
Decision-makers in five Quebec coastal municipalities collaborated with researchers, notably from the Université du Quebec à Rimouski and from Ouranos, a regional climate and adaptation consortium, to explore solutions to repeated damage of coastal infrastructure. Projections of future erosion, studies of sea ice and coastal vulnerability due to climate change, and cost-benefit analyses provided the foundation for the municipalities to make decisions on an adaptation solution.

The approach to information, knowledge, and capacity building will include (1) providing authoritative climate information and (2) building regional adaptation capacity and expertise.

Ensuring Canadians across all regions and sectors have the capacity to make informed decisions and to act on them provides the foundation for advancing adaptation in Canada. Indigenous-led community-based initiatives that combine science and Traditional Knowledge can help guide decision making. Including this information in regional and national impacts and adaptation assessments can further advance understanding of climate change across the country.

NEW ACTIONS

1. Providing authoritative climate information

The federal government will establish a Canadian centre for climate services, to improve access to authoritative, foundational climate science and information. This centre will work with provincial and territorial governments, Indigenous Peoples and other partners to support adaptation decision making across the country.

2. Building regional adaptation capacity and expertise

Governments will work with regional partners, including with Indigenous Peoples through community-based initiatives, to build regional capacity, develop adaptation expertise, respectfully incorporate Traditional Knowledge, and mobilize action. Canada's Adaptation Platform and regional consortia and centres support the sharing of expertise and information among governments, Indigenous Peoples and communities, businesses, and professional organizations and support action on joint priorities.

4.2 Building climate resilience through infrastructure

Climate change is already impacting infrastructure, particularly in vulnerable northern and coastal regions, as well as Indigenous Peoples. Climate-related infrastructure failures can threaten health and safety, interrupt essential services, disrupt economic activity, and incur high costs for recovery and replacement.

The approach to building climate resilience through infrastructure will include (1) investing in infrastructure that strengthens resilience and (2) developing climate-resilient codes and standards.

Traditional built infrastructure (e.g. roads, dykes, seawalls, bridges, and measures to address permafrost thaw) can address specific vulnerabilities. Additionally, living natural infrastructure (e.g. constructed/managed wetlands and urban forests) can build the resilience of communities and ecosystems and deliver additional benefits, such as carbon storage and health benefits.

Considering climate change in long-lived infrastructure investments, including retrofits and upgrades, and investing in traditional and natural adaptation solutions can build resilience, reduce disaster risks, and save costs over the long term.

ADAPTATION INFRASTRUCTURE:
The Red River Floodway was originally constructed in 1968 at a total cost of $63 million. It was recently expanded in 2014, at a cost of $627 million. Since 1968, the Floodway has prevented over $40 billion (in 2011 dollars) in flood-related damages for the City of Winnipeg.

NEW ACTIONS

1. Investing in infrastructure to build climate resilience

Federal, provincial, and territorial governments will partner to invest in infrastructure projects that strengthen climate resilience.

2. Developing climate-resilient codes and standards

Federal, provincial, and territorial governments will work collaboratively to integrate climate resilience into building design guides and codes. The development of revised national building codes for residential, institutional, commercial, and industrial facilities and guidance for the design and rehabilitation of climate-resilient public infrastructure by 2020 will be supported by federal investments.

4.3 Protecting and improving human health and well-being

Climate change is increasingly affecting the health and well-being of Canadians (e.g. extreme heat, air pollution, allergens, diseases carried by ticks and insects, and food security). Indigenous Peoples and northern and remote communities in particular are experiencing unique and growing risks to health and vitality.

The approach to protecting and improving human health and well-being will include (1) taking action to address climate change related health risks and (2) supporting healthy Indigenous communities.

Adaptation actions with an inclusive view of well-being (e.g. social and cultural determinants of health and mental health) will keep Canadians healthy and reduce pressures on the health system.

NEW ACTIONS

1. Addressing climate change-related health risks

Governments will collaborate to prevent illness resulting from extreme heat events and to reduce the risks associated with climate-driven infectious diseases, such as Lyme disease. Federal adaptation investments will support actions including surveillance and monitoring, risk assessments, modelling, laboratory diagnostics, as well as health-professional education and public awareness activities. Efforts will also continue to advance the science and understanding of health risks and best practices to adapt.

2. Supporting healthy Indigenous communities

The federal government will increase support for First Nations and Inuit communities to undertake climate-change and health adaptation projects that protect public health.

The federal government will also work with the Métis Nation on addressing the health effects of climate change.

FOOD SECURITY AND SUSTAINABILITY – PLANNING FOR CLIMATE CHANGE IMPACTS IN ARVIAT, NUNAVUT:
With the goal of promoting and providing access to healthy foods, a community-based project in Arviat, **Nunavut** involved researchers and community youth to monitor and collect data on optimal growing conditions in the community greenhouse and to build capacity for its ongoing operation.

4.4 Supporting particularly vulnerable regions

The Indigenous Peoples of Canada, along with coastal and northern regions are particularly vulnerable and disproportionately affected by the impacts of climate change. Unlike rebuilding after an extreme event like a flood or a fire, once permafrost has thawed, coastlines have eroded, or socio-cultural sites and assets have disappeared, they are lost forever.

The approach to supporting vulnerable regions will include (1) investing in resilient infrastructure to protect vulnerable regions; (2) building climate resilience in the North; (3) supporting community-based monitoring in Indigenous communities; and (4) supporting adaptation in coastal areas.

Action taken to support adaptation in vulnerable regions can help communities, traditional ways of life, and economic sectors endure and thrive in a changing climate. The knowledge, expertise, technologies, and lessons from adaptation actions in vulnerable northern and coastal regions can benefit other vulnerable regions and sectors.

COLLABORATING TO ADDRESS CLIMATE IMPACTS IN THE NORTH:
Nunavut, the Northwest Territories, and Yukon hosted the Pan-Territorial Permafrost Workshop in 2013, which brought together front-line decision makers and permafrost researchers from each territory to share knowledge, form connections, and look at possibilities for adaptation in the future.

NEW ACTIONS

1. Investing in resilient infrastructure to protect vulnerable regions

Federal, provincial, and territorial governments will work together to ensure infrastructure investments help build resilience with Indigenous Peoples as well as in vulnerable coastal and northern regions.

2. Building climate resilience in the North

Federal, territorial, and northern governments and Indigenous Peoples will continue working together to develop and implement a Northern Adaptation Strategy to strengthen northern capacity for climate change adaptation. Federal investments to build resilience in the North and northern Indigenous Peoples will support this work.

3. Supporting community-based monitoring by Indigenous Peoples

The federal government will provide support for Indigenous communities to monitor climate change in their communities and to connect Traditional

Knowledge and science to build a better understanding of impacts and inform adaptation actions.

4. Supporting adaptation in coastal regions

Federal, provincial, and territorial governments will support adaptation efforts in vulnerable coastal and marine areas and Arctic ecosystems. Activities will include science, research, and monitoring to identify climate change impacts and vulnerabilities; the development of adaptation tools for coastal regions; and the improvement of ocean forecasting. This knowledge will help inform adaptation decisions related to fisheries and oceans management and coastal infrastructure. Federal adaptation investments will help advance this work.

SUPPORTING VULNERABLE COASTAL COMMUNITIES:
Through the Atlantic Climate Adaptation Solutions Project, **Newfoundland and Labrador, Nova Scotia, Prince Edward Island,** and **New Brunswick** partner together and with Indigenous communities, regional non-profits, and industry to develop practical tools and resources to help vulnerable coastal communities consider climate change in planning, engineering practices, and water and resource management. Examples include land-use planning tools, best practices, and risk assessments.

4.5 Reducing climate-related hazards and disaster risks

Climate change is impacting the intensity and frequency of events such as floods, wildfires, drought, extreme heat, high winds, and winter road failures. Recognizing this reality, Federal-Provincial-Territorial Ministers Responsible for Emergency Management are updating emergency management in Canada including work to mitigate disasters, review the Disaster Financial Assistance Arrangements, develop build-back better strategies, and collaborate on public alerting. Additionally, the Canadian Council of Forest Ministers is working on the establishment of the Canadian Wildland Fire Strategy, with climate change highlighted as a key challenge.

The approach to reducing climate-related hazards and disaster risks will include (1) investing in infrastructure to reduce disaster risks; (2) advancing efforts to protect against floods; and (3) supporting adaptation for Indigenous Peoples.

Disaster risk-reduction efforts and adaptation measures can reduce the negative impacts of these events, some of which have a disproportionate impact on Indigenous Peoples.

NEW ACTIONS

1. Investing in infrastructure to reduce disaster risks

Federal, provincial, and territorial governments will partner to invest in traditional and natural infrastructure that reduces disaster risks and protects Canadian communities from climate-related hazards such as flooding and wildfires.

2. Advancing efforts to protect against floods

Federal, provincial, and territorial governments will work together through the National Disaster Mitigation Program to develop and modernize flood maps and assess and address flood risks.

3. Supporting adaptation in Indigenous Communities

Governments will work in partnership with Indigenous communities to address climate change impacts, including repeated and severe climate impacts related to flooding, forest fires, and failures of winter roads. The federal government will provide support to Indigenous communities for adaptation.

FLOOD AND DROUGHT PROTECTIONS THROUGH WETLANDS RESTORATION:
Alberta's Watershed Resiliency and Restoration Program provided a grant to Ducks Unlimited to restore approximately 558 hectares of wetlands in the South Saskatchewan River basin for the purposes of water storage for flood and drought protection. Using historical imagery and LiDAR data to identify drained wetlands, project leads then work with and compensate landowners to restore wetlands on private land.

CLEAN TECHNOLOGY, INNOVATION, AND JOBS

Overview

Global demand for clean technologies is significant and increasing. Fostering and encouraging investment in clean technology solutions can facilitate economic growth, long-term job creation, and environmental responsibility and sustainability. Taking action on climate change will help to capture new and emerging economic opportunities, including for Indigenous Peoples and northern and remote communities. The window of opportunity exists for Canada to create the conditions for new clean technology investment and exports and seize growing global markets for clean technology goods, services, and processes.

To effectively compete in the global marketplace and capitalize on current and future economic opportunities, Canada needs a step change in clean technology development, commercialization, and adoption across all industrial sectors. Clarity of purpose, investment, and strong coordination that leverages pan-Canadian regional and provincial/territorial strengths are essential to seizing the economic growth and job-creation opportunities of clean technology. International research, development, and demonstration collaboration is also essential. Governments, Indigenous Peoples, industry, and other stakeholders all have a role to play and must be engaged.

5.1 Building early-stage innovation

To become a leader in the development and deployment of clean technologies, Canada needs a strong flow of innovative ideas.

Government investments in clean technology research, development, and demonstration will create the largest benefit where coordinated and focused in areas that will most effectively help Canada to meet its climate change goals, create economic opportunities, and expand global-market opportunities. Efforts to coordinate and focus investment must go beyond governments and involve the collaboration of industry, stakeholders, academia, and Indigenous Peoples in the innovation process. Canada must leverage its domestic strengths, which vary by region. Developing international partnerships will create new economic opportunities, build areas of shared expertise, and foster stronger bilateral relations.

Sustainable Development Technology Canada (SDTC) provides funding support to companies across Canada to develop, demonstrate, and deploy innovative new clean technologies. SDTC has also launched joint funding opportunities in collaboration with Emissions Reduction Alberta and Alberta Innovates and partners with the Ontario Centres of Excellence to enhance Ontario's Greenhouse Gas Innovation Initiative. SDTC estimates its projects have reduced annual emissions by 6.3 Mt of CO_2e, generated $1.4 billion in annual revenue and, in 2015, supported more than 9200 direct and indirect jobs.

Through its participation in Mission Innovation, the federal government has committed to double its investments in clean energy research and technology development over five years, while encouraging greater levels of private sector investment in transformative clean energy technologies. On November 14, 2016, Canada and 21 other Mission Innovation partners launched seven Innovation Challenges aimed at catalyzing global research efforts in areas that could provide significant benefits in reducing GHG emissions, increasing energy security, and creating new opportunities for clean economic growth.

NEW ACTIONS

1. Supporting early-stage technology development

Governments will support new approaches to early-stage technology development, including breakthrough technologies, to advance research in areas that have the potential to substantially reduce GHG emissions and other pollutants. Innovative partnerships with the private sector will make an important contribution to this effort.

2. Mission-oriented research and development

Governments will encourage new "mission-oriented" research approaches to focus RD&D facilities, programs, and supports on clean technology and environmental performance issues.

5.2 Accelerating commercialization and growth

Given Canada's small domestic market, Canadian firms must look to highly competitive international markets to achieve scale. Succeeding in the globally competitive clean technology marketplace requires globally competitive talent, access to the capital and resources needed to demonstrate the commercial viability of products, and strong international networks that facilitate the cross-border flow of clean technology goods and services.

Canadian clean technology producers and researchers are currently confronted by a myriad of programs and services, at the federal, provincial, and territorial level. Streamlining and integrating access to support programs and services is a priority for businesses and essential to building commercial capacity in this area.

Compared with other technology areas, clean technologies face unique challenges and often take longer to get to market, making access to "patient capital" important to successful commercialization. While federal and provincial governments already have a range of supports in place, key needs exist in terms of accessing venture capital as well as working capital and support for first, large-scale commercial projects or deployments.

20/20 Catalysts Program is a mentorship program that matches Indigenous and non-Indigenous project mentors with Indigenous mentees to promote knowledge sharing that will enable Indigenous communities to drive change towards clean technology business and economic development.

Further development of clean technologies could create new opportunities in Canada's resource sectors, increase the productivity and competitiveness of Canadian businesses, and create new employment opportunities, while also improving environmental performance. Canada will need to be able to access the skills and expertise of talented workers from around the world to enable Canadian businesses to succeed in the global marketplace. It will also be important to ensure a commitment to skills and training to provide Canadian workers with a just and fair transition to opportunities in Canada's clean growth economy.

Indigenous Peoples are leaders of change in the transition to a low-carbon economy. Indigenous governments, organizations, and businesses can play a key role in developing pathways for the adoption and adaptation of clean technology solutions for Indigenous Peoples.

Building stronger businesses and commercial capacity in all of Canada's regions is essential to taking advantage of new market opportunities. Support for new technology start-ups, through incubators and accelerators, is important to this effort. A strong, focused Canadian clean technology export strategy is needed to position Canada in growing and emerging global markets.

MaRS Cleantech works closely with entrepreneurs and investors to create solutions in energy, water, agri-tech, advanced materials and manufacturing, and smart cities. Industry looks to MaRS Cleantech to assist with company growth and to remove complex technology-adoption barriers. MaRS supports high-impact businesses by connecting innovators with potential partners, customers, investors, talent, and capital. MaRS strives to build globally competitive companies and to drive clean technology innovation.

NEW ACTIONS

1. Access to government programs

Federal, provincial, and territorial governments will work together to create a coordinated "no-wrong door" approach to supporting Canadian clean technology businesses, ensuring full and effective access to the suite of government programs and services available to support their commercial success.

2. Increasing support to advance and commercialize innovative technologies

Governments will collaborate to enable access to capital for clean technology businesses to bring their products and services to market, including at the commercial-scale demonstration and deployment stages. This will include support for clean technology businesses in the natural resource sectors to improve both competitiveness and environmental performance.

3. Strengthening support for skills development and business leadership

Governments will work together to strengthen skills development and business-leadership capacity in support of the transition to a low-carbon economy.

VENTURE CAPITAL:
BDC Capital is launching a new $135 million venture capital fund to support Canadian energy and clean technology start-up businesses with global potential. The Industrial, Clean and Energy Technology (ICE) Venture Fund II will invest in 15 to 20 new high-impact Canadian start-up firms that demonstrate efficiency and strong scalability and will support the transition to a low-carbon economy. Fund II is a follow-on to BDC Capital's highly successful ICE Venture Fund I, which was launched in 2011 with investments of $287 million now under management.

4. Expedite immigration of highly qualified personnel

Governments will work together to enable expedited processing of visas and work permits for global talent, in particular for high-growth Canadian businesses such as those in the clean technology sector. This will attract top international talent and expand Canada's clean growth capacity.

5. Promoting exports of clean technology goods and services

Federal, provincial, and territorial governments will work collaboratively to strengthen clean technology export potential. This will include targeted export missions and the development of better market intelligence, addressing barriers to markets, support for export financing and marketing, and leveraging Canada's Trade Commissioner services.

6. Standards-setting

Governments will work together to exert a strong leadership role in international standards-setting processes for new clean technologies and to ensure that Canada's clean-technology capacity shapes future international standards.

5.3 Fostering adoption

The adoption of clean technology can create economic opportunities and improve environmental outcomes. Canada's performance on clean technology adoption by industry has significant room for improvement. Even amongst Canadian businesses that regularly adopt advanced technologies, clean technologies are the least likely to be adopted.

SmartICE (Sea-ice Monitoring And Real-Time Information for Coastal Environments) is a partnership with community, academic, government, and industry participation. It is developing an integrated system to provide near-real-time information about coastal sea-ice travel and shipping, improving safety and the ability to adapt to changing climate conditions. The pilot program is preparing to expand across the Arctic through a northern social enterprise.

Pricing carbon pollution will send a market signal that can drive innovation among Canadian businesses and, in return, will make them more competitive, including by opening up access to new markets and reducing costs of deploying clean technologies.

There is significant potential for Canadian governments to "lead by example" as early adopters of clean technology serving an essential role as a first or "reference customer" for Canadian clean technology goods, services, and processes. Having a "first sale" in Canada would boost businesses' chances of securing sales abroad. Beyond direct federal, provincial, and territorial government operations, other bodies, such as municipalities and publicly regulated utilities, could become significant markets for and adopters of clean technology.

Done effectively, the adoption of clean technology could be a mechanism for improving environmental circumstances and creating economic opportunity for Indigenous Peoples and northern and remote communities. Effective engagement and partnership with Indigenous Peoples is essential to this effort.

Encouraging dialogue between regulators and industry could improve certainty in clean technology development and allow for more effective and responsible regulation.

NEW ACTIONS

1. Leading by example

Federal, provincial, and territorial governments will develop action plans for greening government operations and encourage utilities and municipalities and other public sector entities to adopt clean technologies to lead by example.

2. Supporting Indigenous Peoples and northern and remote communities to adopt and adapt clean technologies

Federal, provincial, and territorial governments will support Indigenous Peoples and northern and remote communities in adopting and adapting clean technologies, and ensuring business models support community ownership and operation of clean technology solutions.

3. Consumer and industry adoption

Federal, provincial, and territorial governments will work together to promote and encourage effective working relationships between regulators and industry, providing for early dialogue and effective guidance, which can assist in bringing new clean technologies to market quickly and responsibly.

Governments will also support visible and effective certification programs to ensure consumer and business confidence and support green procurement.

5.4 Strengthening collaboration and metrics for success

An effective approach to clean technology development, commercialization, and adoption in Canada requires coherent, collaborative, and focused approaches. This is true within individual governments and between Canadian jurisdictions. A collaborative approach between governments should take into account regional strategies and jurisdictional responsibilities.

Regular and ongoing discussions between federal, provincial, and territorial governments regarding clean technology and clean growth would help eliminate duplication of efforts and identify gaps in support for clean technology development. Engaging Indigenous Peoples, industry, and stakeholders as a routine component of this process would be important.

There is inadequate data on Canada's clean technology capacity and potential. Building better data, and clear metrics for tracing the impact of government activities, would properly focus these activities and ensure that they achieve intended, meaningful results.

NEW ACTIONS

1. Enhance alignment between federal, provincial, and territorial actions

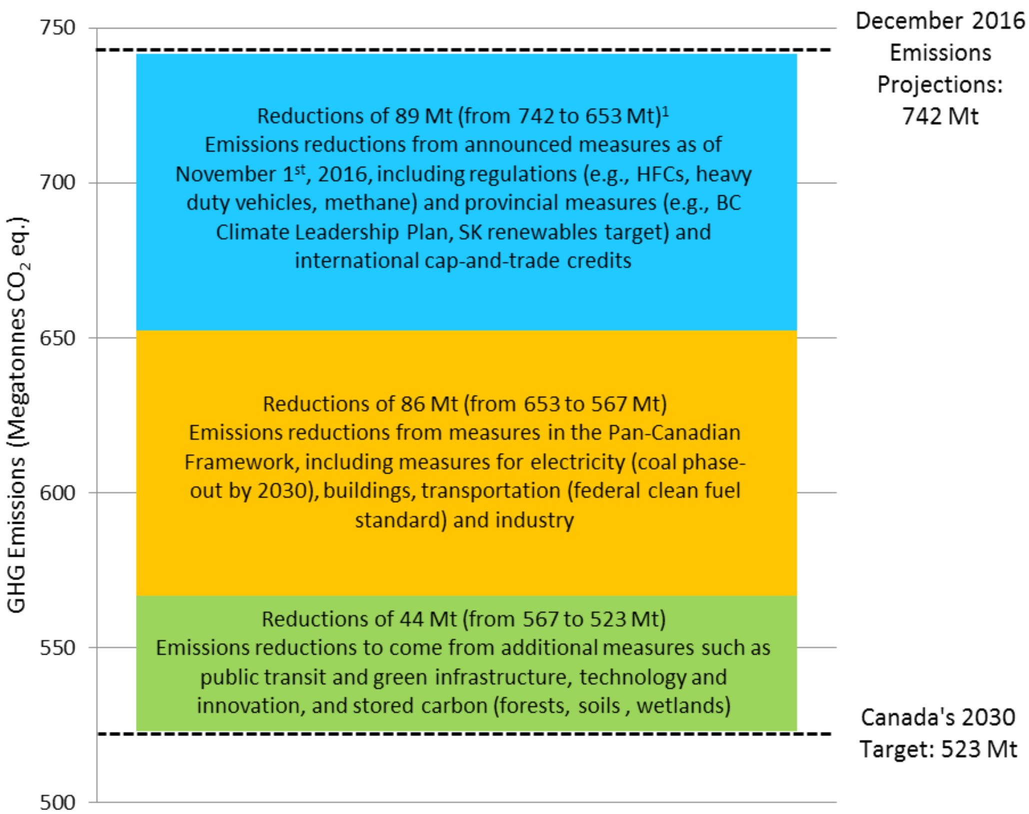
Governments will work together to improve policy and program coordination and sharing of data and best practices, which can sustain intergovernmental momentum and action on clean technology and clean growth. Continued partnership and engagement of Indigenous Peoples, industry, and stakeholders is essential to this effort.

Governments will work together to target and better align clean technology RD&D investments and activities in Canada, including opportunities for co-funding clean technology projects.

2. Establishing a clean technology data strategy

The federal government, working with the provinces and territories, will support the collection and regular publication of comprehensive data on clean technology in Canada to inform future government decision making, to improve knowledge in the private sector and stakeholder community, and to foster innovation.

PATHWAY TO MEETING CANADA'S 2030 TARGET



Note: Reductions from carbon pricing are built into the different elements depending on whether they are implemented, announced, or included in the Pan-Canadian Framework. The path forward on pricing will be determined by the review to be completed by early 2022.

[1] Estimates assume purchase of carbon credits from California by regulated entities under Quebec and Ontario's cap-and-trade system that are or will be linked through the Western Climate Initiative.

REPORTING AND OVERSIGHT

Overview

To help achieve the goals and actions laid out in this Pan-Canadian Framework, the programs and policies put in place will be monitored, results will be measured including impacts on GHG emissions, and actions and performance will be reported on publicly in a way that is transparent and accountable to Canadians. This public reporting will be complemented by ongoing public outreach, including with youth, inviting their contributions to Canada's action on clean growth and climate change. The effectiveness of actions will also be assessed with a view to ensuring continual improvement so as to increase ambition over time, in accordance with the Paris Agreement.

NEW ACTIONS

Measurement and reporting on emissions – Federal, provincial, and territorial governments will continue to collaborate on efforts to track and report GHG emissions in a consistent way across the country, to track progress on the Pan-Canadian Framework, and to support international reporting obligations. This will involve further technical work on measurement to improve emissions inventories and projections, and aligning these where possible. Federal, provincial, and territorial governments will work together through the Canadian Council of Ministers of the Environment (CCME) to examine options for the reporting of emissions and inventories to ensure consistency across provinces and territories, to support Canada's reporting to the UNFCCC, and for a pan-Canadian offset protocol framework and verified carbon credits that can be traded domestically and internationally.

Reporting on implementation – Federal, provincial, and territorial governments will work together to support the coordinated implementation of the Pan-Canadian Framework, engaging with relevant ministerial tables including ministers of environment, energy and mines, transportation, forestry, agriculture, innovation, infrastructure, emergency management, and finance, and with meaningful involvement of Indigenous Peoples. This will include a process to take regular stock of progress achieved, to report to Canadians and, to inform Canada's future national commitments in accordance with the Paris Agreement.

Analysis and advice – Federal, provincial, and territorial governments will engage with external experts to provide informed advice to First Ministers and decision makers; assess the effectiveness of measures, including through the use of modeling; and identify best practices. This will help ensure that actions identified in the Pan-Canadian Framework are open to external, independent review, and are transparent and informed by science and evidence.

Review - Federal, provincial, and territorial governments will work together to establish the approach to the review of carbon pricing, including expert assessment of stringency and effectiveness that compares carbon pricing systems across Canada, which will be completed by early 2022 to provide certainty on the path forward. An interim report will be completed in 2020 which will be reviewed and assessed by First Ministers. As an early deliverable, the review will assess approaches and best practices to address the competitiveness of emissions-intensive trade-exposed sectors.

Federal, provincial, and territorial governments will continue to engage and partner with Indigenous Peoples as actions are implemented and progress is tracked.

LOOKING AHEAD

This Plan provides a foundation for working together to grow the economy, reduce emissions, and strengthen resilience. Ongoing, collaborative action is needed to generate transformational change and to ensure that all Canadians benefit from the transition to a low-carbon economy. First Ministers are tasking their officials to develop an agenda for federal, provincial, and territorial Ministers to implement this Plan. Annual reports to First Ministers will enable governments to take stock of progress and give direction to sustain and enhance efforts.

ANNEX I: FEDERAL INVESTMENTS AND MEASURES TO SUPPORT THE TRANSITION TO A LOW-CARBON ECONOMY

FEDERAL INVESTMENTS

The federal government will help catalyze the transition to a clean growth economy through significant new investments to complement provincial and territorial actions and investments, including investments in infrastructure, the Low-Carbon Economy Fund, and clean technology funding.

- Budget 2016 outlined a number of new federal investments that will support a transition to a low-carbon economy. Some of these investments include
  - » $62.5 million to support the deployment of infrastructure for alternative transportation fuels, including charging infrastructure for electric vehicles and natural gas and hydrogen refueling stations as well as demonstration of next generation recharging technologies;
  - » $50 million over two years to invest in technologies that will reduce GHG emissions from the oil and gas sector;
  - » $82.5 million over two years to support research, development, and demonstration of clean energy technologies with the greatest potential to reduce GHG emissions;
  - » $100 million per year from the Regional Development Agencies to support clean technology, representing a doubling of thei existing annual aggregate support;
  - » $50 million over four years to Sustainable Development Technology Canada (SDTC) for the SD Tech Fund. These resources will enable SDTC to announce new clean technology projects in 2016 that support the development and demonstration of new technologies that address climate change, air quality, clean water, and clean soil;

THE FEDERAL GOVERNMENT HAS COLLABORATED WITH THE FEDERATION OF CANADIAN MUNICIPALITIES ON THE GREEN MUNICIPAL FUND (GMF) SINCE 2000.

- Budget 2016 provided an additional $125 million over two years including for projects that reduce GHG emissions.
- Recently announced projects under the GMF include a $31.5 million investment for 20 new sustainable municipal projects, such as Canada's first net-zero municipal library and Halifax's ground-breaking Solar City project.

» $40 million over five years to integrate climate resilience into building design guides and codes. The funding will support revised national building codes by 2020 for residential, institutional, commercial, and industrial facilities;

» $129.5 million to implement programming focused on building the science base to inform decision making, protecting the health and well-being of Canadians, building resilience in the North and Indigenous communities, and enhancing competitiveness in key economic sectors; and

» $10.7 million over two years to implement renewable energy projects in off-grid Indigenous and northern communities that rely on diesel and other fossil fuels to generate heat and power.

- Building on the infrastructure investments outlined in Budget 2016, the federal government has announced an additional $81 billion over 11 years for investments in public transit, social infrastructure, transportation that supports trade, Canada's rural and northern communities, smart cities, and green infrastructure.
- Green infrastructure funding will support projects that reduce GHG emissions, enable greater climate change adaptation and resilience, and ensure that more communities can provide clean air and safe drinking water for their citizens. Specific projects could include interprovincial transmission lines that reduce reliance on coal, the development of new low-carbon/renewable power projects, and the expansion of smart grids to make more efficient use of existing power supplies.
- The federal government is proposing the creation of the Canada Infrastructure Bank that will work with provinces, territories, and municipalities to further the reach of government funding directed to infrastructure. The Canada Infrastructure Bank will be responsible for investing at least $35 billion on a cash basis from the federal government into large infrastructure projects that contribute to economic growth through direct investments, loans, loan guarantees, and equity investments.
- Funding under the $2 billion Low Carbon Economy Fund will begin in 2017. This Fund will support new provincial and territorial actions to reduce emissions between now and 2030. Projects will focus on concrete measures that generate new, incremental reductions, while considering cost-effectiveness.
- The Government has also committed more than $1 billion, over four years, to support clean technology including in the forestry, fisheries, mining, energy and agriculture sectors.

FEDERAL CARBON PRICING BENCHMARK

The federal government outlined a benchmark for carbon pricing that reflects the principles proposed by the Working Group on Carbon Pricing Mechanisms and the Vancouver Declaration. Its goal is to ensure that carbon pricing applies to a broad set of emission sources throughout Canada with increasing stringency over time to reduce GHG emissions at lowest cost to business and consumers and to support innovation and clean growth.

The benchmark includes the following elements:

1. Timely introduction.

All jurisdictions will have carbon pricing by 2018.

2. Common scope.

Pricing will be based on GHG emissions and applied to a common and broad set of sources to ensure effectiveness and minimize interprovincial competitiveness impacts. At a minimum, carbon pricing should apply to substantively the same sources as British Columbia's carbon tax.

3. Two systems.

Jurisdictions can implement (i) an explicit price-based system (a carbon tax like British Columbia's or a carbon levy and performance-based emissions system like in Alberta) or (ii) a cap-and-trade system (e.g. Ontario and Quebec).

4. Legislated increases in stringency, based on modelling, to contribute to our national target and provide market certainty.

For jurisdictions with an explicit price-based system, the carbon price should start at a minimum of $10 per tonne in 2018 and rise by $10 per year to $50 per tonne in 2022.

Provinces with cap-and-trade need (i) a 2030 emissions-reduction target equal to or greater than Canada's 30 percent reduction target and (ii) declining (more stringent) annual caps to at least 2022 that correspond, at a minimum, to the projected emissions reductions resulting from the carbon price that year in price-based systems.

5. Revenues remain in the jurisdiction of origin.

Each jurisdiction can use carbon-pricing revenues according to their needs, including to address impacts on vulnerable populations and sectors and to support climate change and clean growth goals.

6. Federal backstop.

The federal government will introduce an explicit price-based carbon pricing system that will apply in jurisdictions that do not meet the benchmark. The federal system will be consistent with the principles and will return revenues to the jurisdiction of origin.

7. Five-year review.

The overall approach will be reviewed by early 2022 to confirm the path forward, including continued increases in stringency. The review will account for progress and for the actions of other countries in response to carbon pricing, as well as recognition of permits or credits imported from other countries.

8. Reporting.

Jurisdictions should provide regular, transparent, and verifiable reports on the outcomes and impacts of carbon pricing policies.

The federal government will work with the territories to address their unique circumstances, including high costs of living, challenges with food security, and emerging economies.

OTHER RECENT FEDERAL MEASURES

The federal government has also recently announced new federal measures, including

- During the North American Leaders Summit in June 2016, the federal government made joint commitments with the United States and Mexico to
  - phase out fossil fuel subsidies by 2025. The commitment was reaffirmed by G-20 countries in September 2016.
  - reduce methane emissions from the oil and gas sector by 40 to 45 percent below 2012 levels by 2025.
- On October 15, 2016, Canada signed onto the Kigali Amendment to the Montreal Protocol and committed to propose new regulations to significantly reduce HFC consumption and prohibit the manufacture and import into Canada of certain products containing HFCs. These proposed regulations were published on November 26, 2016. This is additional to measures already introduced to increase the recovery, recycling, and destruction of HFCs in refrigeration and air conditioning equipment and to established regulatory provisions for an HFC reporting system.
- On November 17, 2016, Canada released its Mid-Century Long-Term Low-Greenhouse Gas Development Strategy. The mid-century strategy describes various pathways for innovative and creative solutions. Canada's mid-century strategy is not a blueprint for action nor is it policy prescriptive. It is based on modelling of different scenarios and looks beyond 2030 to start a conversation on the ways we can reduce emissions for a cleaner, more sustainable future by 2050. As a result, it will be a living document.
- On November 21, 2016, the federal government announced that it would be amending its existing coal-fired electricity regulations to accelerate the phase out of traditional coal-fired electricity by 2030. The federal government also announced that, to support the transition away from coal towards cleaner sources of generation, performance standards for natural gas-fired electricity are also being developed.
- On November 25, 2016, the federal government announced that it will consult with provinces and territories, Indigenous Peoples, industries, and non-governmental organizations to develop a clean fuel standard. It is expected that once developed, a clean fuel standard would promote the use of clean technology and lower carbon fuels, and promote alternatives such as electricity, biogas, and hydrogen.

ANNEX II: PROVINCIAL AND TERRITORIAL KEY ACTIONS AND COLLABORATION OPPORTUNITIES WITH THE GOVERNMENT OF CANADA

INTRODUCTION

The Paris Agreement and the Vancouver Declaration have set an ambitious course for low carbon growth and climate action in Canada. The Pan-Canadian Framework on Clean Growth and Climate Change will build on the leadership shown and actions taken by the provinces and territories as well as new policies announced by the federal government.

This annex outlines provincial and territorial accomplishments in reducing greenhouse gas emissions and accelerating clean growth, and presents steps that each jurisdiction has taken or is taking to implement carbon pricing.

The annex also outlines areas where the federal government and each provincial and territorial government will work together to implement the Pan-Canadian Framework in order to spur growth and jobs for Canadians, reduce our emissions and adapt to climate change.

Each province and territory is unique and is responding to the urgency of climate change and the opportunity offered by clean growth in its own way. Effective action will require close collaboration between governments. Each provincial and territorial government has identified multiple areas for potential partnerships with the federal government, adapted to their own priorities, circumstances and strengths. Governments are committed to working together on these priorities to support the implementation of the Pan-Canadian Framework. Governments will also engage the contributions of Indigenous Peoples in advancing shared goals.

This work will be supported by significant new federal investments to drive the transition to a clean growth economy, as outlined in Budget 2016 and the 2016 Fall Economic Statement, including public transit and Green Infrastructure, the Canada Infrastructure Bank, the Low-Carbon Economy Fund, and funding for clean technology and innovation. Federal investments are intended to supplement and accelerate investments by provinces and territories, and will follow applicable program criteria.

BRITISH COLUMBIA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in British Columbia include:

British Columbia's Climate Leadership Plan

B.C. has proven that it is possible to reduce emissions while growing the economy and creating jobs and it's important that this balance be maintained. With this in mind, B.C. released its Climate Leadership Plan in the summer of 2016.

Building on the comprehensive foundation established in 2008, the plan lays out a series of targeted, sector-specific actions that will reduce emissions by 25 million tonnes (Mt) of carbon dioxide equivalent (CO_2e) and create 66,000 jobs. The plan will be further strengthened in the months and years ahead, as B.C. continues to work with First Nations, the federal government, communities, industry and others. B.C. is committed to reducing GHG emissions by 80% below 2007 levels by 2050. To read B.C.'s Climate Leadership Plan, visit: http://climate.gov.bc.ca/

Revenue-Neutral Carbon Tax

B.C. has the highest broad-based carbon tax in North America. The carbon tax sets a transparent and predictable price on carbon while returning all revenue to B.C. individuals and businesses. The price signal creates a real incentive to reduce emissions across the economy and is the backbone of B.C.'s approach to climate action.

Forestry

B.C.'s forests offer potential for storing carbon, so the Province is taking further action to rehabilitate up to 300,000 hectares of Mountain Pine Beetle and wildfire impacted forests over the first five years of the program; recover more wood fibre; and avoid emissions from burning slash.

Clean LNG

B.C. has an abundance of natural gas, which is a lower carbon fuel that will play a critical role in transitioning the world economy off of high carbon fuels such as coal. B.C. is developing the resource responsibly, and provincial legislation will make the emerging LNG sector the cleanest in the world. B.C. is also electrifying upstream development of natural gas and will require a 45% reduction in methane emissions by 2025.

100% Clean Electricity

Thanks to significant historical investments, B.C.'s electricity is already 98% clean or renewable and British Columbians have the third-lowest residential rates in North America. Going forward under the Climate Leadership Plan, 100% of the supply of electricity acquired by BC Hydro for the integrated grid must be from clean or renewable sources. The $8.3 billion Site C Clean Energy Project is a major part of B.C.'s clean energy future and will create enough electricity to power 450,000 homes.

Clean Transportation

B.C. is taking real action to reduce emissions from the transportation sector and help British Columbians make greener choices—initiatives include Zero Emissions Vehicles rebates and funding for more charging stations (which have helped BC become the Canadian leader in clean energy vehicle sales per capita); a scrap-it program; low carbon and renewable fuel standards; and historic investments in transit. B.C.'s actions in the transportation sector have already reduced annual emissions by an estimated 2.5 Mt and combined with the new actions, will reduce annual emissions by up to a further 3.4 Mt by 2050.

Adaptation

In 2010, the Province created a comprehensive strategy to address the changes we will see as a result of climate change. It is based on three key strategies: build a strong foundation of knowledge and tools; make adaptation a part of government business; and assess risks and implement priority adaptation actions in key climate sensitive sectors. The Province is now working with the federal government and other Canadian jurisdictions to further improve the management of the risks associated with a changing climate.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

B.C.'s revenue-neutral carbon tax has been in place since 2008. It is set at $30/tonne and covers approximately 75% of the province's economy. All revenues generated will be returned to tax payers. B.C. will assess the interim study in 2020 and determine a path forward to meet climate change objectives.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

British Columbia and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Growing our forests; reducing our emissions

Forests present a unique opportunity to address climate change because trees absorb CO_2 when they grow. British Columbia, the Government of Canada and First Nations will work together to reduce GHG emissions through forestry activities, including reforestation, enhanced silviculture techniques, and the salvaging of unmerchantable trees for processing into dimensional lumber and bioenergy. The initiative is expected to reduce emissions by 12 Mt in 2050 and create 20,000 jobs.

Preparing for and adapting to climate change

British Columbia and the Government of Canada will support projects across the province to make infrastructure more resilient to a changing climate, and to help communities adapt to a changing climate. Flood mitigation will be an area of focus.

Reduce Emissions from Natural Gas Activities

British Columbia and the Government of Canada will work together to bring clean grid electricity to natural gas operations in northeast B.C. They will co-fund the construction of new transmission lines and other public electrification infrastructure that could serve up to 760 megawatts of upstream natural gas processing load and avoid up to 4 Mt of emissions per year.

Electricity Grid Interconnection

British Columbia and the Governments of Canada and Alberta will work together to restore the capability of the existing high-voltage electricity grid interconnection with Alberta. This project will improve access to clean electricity in Alberta and will result in lower GHG emissions and air pollution, and improved grid reliability in both provinces.

Clean Technology Innovation

British Columbia and the Government of Canada will work together to spur the development and commercialization of new technologies that will reduce emissions and create jobs for Canadians.

ALBERTA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Alberta include:

Climate Leadership Plan

The Climate Leadership Plan is a made-in-Alberta climate change strategy, specifically designed for Alberta's unique economy. While details of the final strategy are still being developed, the Alberta government has moved forward on a number of key areas.

Clean Electricity

Alberta will phase-out GHGs from coal-fired power plants and achieve 30% renewable energy by 2030.

Alberta will add 5,000 megawatts of renewable energy capacity by 2030 through the Renewable Electricity Program. To meet this target, investment in Alberta's electricity system will be solicited through a competitive and transparent bidding process, while ensuring projects come online in a way that does not impact grid reliability and is delivered at the lowest possible cost to consumers.

A new provincial agency, Energy Efficiency Alberta, has been created to promote and support energy efficiency and community energy systems for homes, businesses and communities.

Capping Oil Sands Emissions

A legislated maximum emissions limit of 100 Mt in any year, with provisions for cogeneration and new upgrading capacity, will help drive technological progress.

Reducing Methane Emissions

Alberta will reduce methane gas emissions from oil and gas operations by 45% by 2025.

Innovation and Technology

Alberta is investing in innovation and technology to reduce GHGs, encourage a more diversified economy and energy industry, and create new jobs, while improving opportunities to get the province's energy products to new markets. Alberta has created a task force that will make recommendations on a Climate Change Innovation and Technology Framework.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

A carbon levy to be included in the price of all fuels that emit greenhouse gases when combusted, including transportation and heating fuels such as diesel, gasoline, natural gas and propane. The levy will be applied at a rate of $20/tonne on January 1, 2017 and will increase to $30/tonne one year later.

The Climate Leadership Plan is designed for Alberta's economy. The economic impact of carbon pricing is expected to be small, and every dollar will be reinvested back into the local economy. Reinvesting carbon revenue in our economy will diversify our energy industry by investing in large scale renewable energy, bioenergy initiatives, and transformative innovation and technology. Over the next 5 years:

$6.2 billion will help diversify our energy industry and create new jobs:

- $3.4 billion for large scale renewable energy, bioenergy and technology

- $2.2 billion for green infrastructure like transit
- $645 million for Energy Efficiency Alberta

$3.4 billion will help households, businesses and communities adjust to the carbon levy:

- $2.3 billion for carbon rebates to help low- and middle-income families
- $865 million to pay for a cut in the small business tax rate from 3% to 2%
- $195 million to assist coal communities, Indigenous communities and others with adjustment

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Alberta and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Clean Electricity

Alberta and the federal government will to work together to advance renewable energy, coal to natural gas conversion, and potential hydroelectric projects, including pump storage projects. Alberta is committed to developing incentives for renewable generation in a manner that is compatible with Alberta's unique electricity market.

B.C. – Alberta Intertie

Alberta is working with British Columbia and the federal government to explore new and enhanced interties. The Alberta Electric System Operator is currently working with BC Hydro and industry on a key project, the restoration of the B.C.-Alberta 950 MW intertie to its full path rating (expected completion is in 2020). This restoration would allow imports of 1200 MW on the BC-AB intertie.

.

Innovation and Technology

Alberta is focused on the opportunity to leverage environmental policies and programs into new manufacturing, innovation, and clean technology businesses. Current opportunities include superclusters, advanced sensor technology for environmental applications including methane monitoring and reductions, and municipal waste diversion. Innovative solutions will result in meaningful GHG reductions across Canada and the export of solutions to promote a lower carbon world.

Disaster Mitigation / Infrastructure

Alberta is undertaking targeted work to address the hazards to which Albertans are vulnerable, including flood, wildfire, heat, drought, landslides, and wind.

While hazards and disaster risks have always been a concern, climate change is driving the need to adapt to more intense and frequent events. Federal support for wildfire mitigation infrastructure will reduce the risk of wildland fires. In addition, flood risk requires immediate mitigation infrastructure such as dykes and dams. Federal partnership on these initiatives will support risk management.

ONTARIO

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Ontario include:

Permanent Closure of Coal-fired Electricity Generating Stations

On April 15, 2014, Ontario became the first jurisdiction in North America to fully eliminate coal as a source of electricity generation. This action is the single largest GHG reduction initiative in North America. On November 23, 2015, Ontario passed the *Ending Coal for Cleaner Air Act*, permanently banning coal-fired electricity generation in the province.

Ontario's Climate Change Strategy and Action Plan

On November 24, 2015, Ontario released its Climate Change Strategy setting the framework for the province to meet its long-term 2050 GHG emissions reduction target. The Strategy highlights five key objectives for transformation:

1. A prosperous low-carbon economy with world-leading innovation, science and technology
2. Government collaboration and leadership
3. A resource-efficient, high-productivity society
4. Reducing GHG emissions across sectors
5. Adapting and thriving in a changing climate

On June 8, 2016, Ontario released its Climate Change Action Plan to implement the strategy over the next five years and put Ontario on the path to achieve its longer term objectives. Policies and programs identified in the Action Plan include:

- Transforming how ultra-low and carbon-free energy technologies are deployed in our homes and workplaces, and how we move people and goods
- Halting rising building-related emissions, with a focus on helping homeowners and small businesses move to low- and zero-carbon energy
- Making available funding for industries and manufacturers proposing to transform their operations and move off carbon-based fuels and peak electricity
- Aligning Ontario's R&D and innovation funding to place a greater emphasis on climate change science and technologies, with a view to making the discoveries that could lead to breakthroughs in zero-carbon technology

Ontario has made measurable progress in reducing GHGs. According to Environment and Climate Change Canada's 2016 National Inventory Report, from 2005 to 2014, Ontario's emissions decreased by 41 Mt (-19%), over the same period, Canada-wide emissions fell by 15 Mt (-2%).

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

On May 18, 2016, Ontario passed its landmark *Climate Change Mitigation and Low-carbon Economy Act,* which creates a long term framework for climate action. The Act creates a robust framework for cap and trade program, ensures transparency and accountability on how any proceeds collected under the program are used and enshrines emission reduction targets in legislation.

Ontario's approach, including its cap and trade program and associated emissions reduction targets, will exceed the standards of the federal carbon pricing benchmark. Ontario's targets are:

- 15% below 1990 levels by 2020;
- 37% below 1990 levels by 2030; and
- 80% below 1990 levels by 2050.

Ontario is a founding member of the Western Climate Initiative (WCI), a not-for-profit organization established in 2008 to help member states and provinces execute their cap and trade programs. In 2017, Ontario will link its cap and trade system with those of WCI members Quebec and California to create the largest cap and trade system in North America.

Ontario will set a cap on total emissions from the covered sectors in 2017 based on the forecast emissions for large final emitters, electricity generation and transportation and heating fuels. Allowances will then be created in an amount equal to the cap and either sold or provided free-of-charge to Ontario emitters.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Ontario and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Invest in Zero Emission Transportation and Infrastructure

Ontario is committed to increase uptake of zero emission passenger and commercial vehicles, both by providing purchasing incentives and by expanding the EV charging network across Ontario. In its 2016 budget, the federal government committed to support the deployment of alternative transportation fuel infrastructure, including electric charging stations. Ontario and the Government of Canada will work together to support the deployment of EV vehicles through enabling infrastructure.

Invest in Other Zero Emission Transportation

Ontario seeks a partnership with the Government of Canada to support enabling infrastructure that will increase the availability and use of lower carbon fuels, including LNG, increase the use of low carbon trucks and buses and increase the availability of LNG fueling infrastructure. Ontario is dedicating significant resources for these additional transportation initiatives. Expected emissions reductions in the transportation sector overall are 2.45 Mt in 2020.

Assist with Building Retrofits, Energy Audits and Technology Deployment

Ontario seeks a partnership with the Government of Canada as the province develops programs for fuel switching and energy efficiency, such as retrofits for existing residential buildings (including targeted initiatives for low-income households), and clean technologies for industries and small and medium enterprises. Partnership would increase investment in this area, allowing acceleration and scaling up of progress.

Ontario Climate Modelling Services Consortium

Ontario seeks a partnership with the Government of Canada to build regional capacity and support adaptation actions. Ontario plans to establish an Ontario Climate Modelling Services Consortium, which would act as a one window source of data to help the public and private sectors make evidence-based decisions.

The Consortium would operate at arm's length from government. Ontario would seek partnerships with other governments, non-governmental organizations and the private sector to ensure the organization's effectiveness and long term success. The Consortium would also be expected to develop service fee revenue streams to contribute to the organization's fiscal sustainability.

Electricity Transmission

Ontario, in collaboration with the Government of Canada, will work with its regional partners to advance opportunities to expand and upgrade electricity transmission infrastructure to support clean hydroelectric power to displace the production of electricity from fossil fuels.

Ontario will also collaborate with the Government of Canada to accelerate access to clean electricity in remote Indigenous communities. This will lessen dependence on expensive diesel fuel and reduce greenhouse gas emissions and air pollution.

QUÉBEC

KEY ACTIONS TO DATE

Some of the key measures taken to date by Québec, which has the lowest greenhouse gas emissions per capita between the provinces in Canada, include:

2013-2020 Action Plan on Climate Change (PACC 2013-2020)

PACC 2013-2020 will reduce GHG emissions by 20% below the 1990 level by 2020. Among its other measures, the action plan offers financial help to the different stakeholders of Québec society so they can reduce their energy consumption, improve their practices, innovate and adjust. The work surrounding the development of the actions of Québec after the 2020 period is underway, in particular to reduce GHG emissions of the province by 37.5 % below the 1990 level by 2030.

2016-2030 Energy Policy

The Energy Policy will favour a transition to a low carbon footprint economy, chiefly by improving energy efficiency by 15%, by reducing petroleum consumption by 40%, and by increasing the production of renewable energies by 25%. Québec is one of the world's main producers of renewable energy, which represents 99.8% of its total electricity production.

2013-2020 Governmental Climate Change Adjustment Strategy

The Strategy will mitigate the impact of climate change on the environment, the economy and the communities, and will strengthen the resiliency of Québec society. The government of Québec has, notably, invested in the Ouranos consortium in order to get a better understanding of the impact of climate change on its territory, and to better inform the decision-making process and the development of solutions.

2015-2020 Transport Electrification Plan

Québec targets 100,000 electric vehicles on the road in 2020 and one million in 2030. The zero-emission vehicle (ZEV) standard adopted in October 2016 will encourage automotive manufacturers to improve their offer of ZEV, and the investments in electrification will allow Québec to build up its available renewable energies, its expertise and its world-class know-how.

These measures represent a major contribution at the Pan-Canadian level.

ACTION ON PRICING CARBON POLLUTION

Pioneer in the use of cap-and-trade systems for greenhouse gas emissions allowances, Québec`s system has been linked to California's since 2014, and will soon be linked to that of Ontario. It represents the largest carbon market in North America, and is often referred to as an example of performance and rigour. Because it is based on hard caps to reduce GHG emissions, it is a robust and efficient tool to achieve the ambitious mitigation goals Québec has set for itself for 2020 and 2030.

Furthermore, auction revenues from its cap-and-trade system are entirely reinvested in measures that will spur the transition of Québec's economy to a more resilient and low-carbon one. This comprehensive approach, tailored to the needs and specificities of Québec, allows Québec to fulfill its leadership role in the fight against climate change in North America and internationally.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The governments of Québec and Canada intend to collaborate in the following priority areas in order to fight climate change and allow clean economic growth:

Electric and Public Transport

Support the development of the offer and infrastructure of electric and public transport, by completing various projects such as the Metropolitan Electric Network (MEN), the implementation of bus rapid transit (BRT) systems between Montreal and Laval, the extension of the BRT in Gatineau, and the implementation of a BRT in Québec.

Energy Efficiency and Conversion

Speed up the reduction of GHG emissions in Northern communities, as well as on the Lower North Shore and Magdalen Islands, by replacing diesel with renewable energy sources for the electricity supply of their free-standing network.

Promote the implementation of energy performance and efficiency standards for new buildings, as well as for the renovation of existing buildings. Invest in the industrial sector to improve the energy performance of fixed production processes, by providing innovative technologies and reducing the use of gases with high warming potential such as hydrofluorocarbons, which Québec will continue to prioritize.

Recognition of the International Trade of Emission Rights

Contribute to the implementation of Articles 6 and 13 of the Paris Accord, to which the accounting and disclosure principles of the Western Climate Initiative (WCI) can contribute, as well as within a possible agreement between Canada and the United States regarding the accounting and attribution of "internationally transferred mitigation outcomes" as part of the contributions determined at national level (CDN).

Québec will also share with the government of Canada a detailed methodology, developed in collaboration with California and soon Ontario, in order to tabulate in its international reports the emission reductions achieved by Québec thanks to the carbon market.

Innovation and Adjustment to Climate Change

Promote innovation in green technology and GHG emission reduction, and collaborate on increasing the resiliency of the communities affected by climate change, by assessing the vulnerabilities and risks, adjusting land planning and use, and designing sustainable projects.

Québec will provide its expertise to the initiatives of the government of Canada, focusing in particular on joint financing of prevention and protection infrastructure against certain natural disasters linked to climate change.

NEW BRUNSWICK

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in New Brunswick include:

Transitioning to a Low-Carbon Economy: New Brunswick's Climate Change Action Plan

The Climate Change Action Plan outlines a bold vision for New Brunswick and sets renewed GHG reduction targets: 2030 target of 35% below 1990 levels; and 80% below 2001 levels by 2050. The plan also address other commitments, such as the Canadian Energy Strategy, released by the Council of the Federation in 2015, and contains a Climate Change Adaptation Strategy supported by actions to build resilience into New Brunswick communities, businesses, infrastructures and natural resources.

The Action Plan provides a clear path forward to reduce GHG emissions while promoting economic growth and enhancing current efforts to adapt to the effects of climate change.

Locally-owned Renewable Energy Projects that are Small Scale (LORESS)

In May 2015, the province introduced legislation to allow local entities to develop renewable energy sourced electricity generation in their communities. This will enable universities, non-profit organizations, co-operatives, First Nations and municipalities to contribute to NB Power's renewable energy requirements.

Shifting to renewables in electricity generation

Two fossil fuelled power plants were closed in recent years – one coal and one heavy oil. Also, 300 megawatts of wind energy was installed in the province and biomass fuel use in industry was expanded to displace oil. Solid waste landfills are capturing biogas and some are generating electricity.

These actions are allowing NB Power to achieve the regulated Renewable Portfolio Standard of 40% of in-province sales from renewable energy sources by 2020. This translates to approximately 75% non-emitting by 2020 including nuclear.

Adaptation

The province has developed a progressive Climate Change Adaptation Program including assembling future climate projections, and supporting climate impact vulnerability assessments in communities and for infrastructure. Adaptation projects also focus on solutions building and advanced planning to help reduce or avoid the costs of impacts such as more severe and frequent flooding, coastal erosion and storm events and disease and pest migration.

Several projects are carried out in collaboration with other Atlantic provinces, notably under the Regional Adaptation Collaborative (RAC), which involves federal support, as well as with the Gulf of Maine Council and US partners.

These actions provide a strong contribution to a comprehensive Pan-Canadian Framework.

ACTION ON PRICING CARBON POLLUTION

The province will implement a made-in-New Brunswick carbon pricing mechanism that addresses the requirements of the federal government for implementing a price on carbon emissions by 2018 and that at the same time recognizes New Brunswick's unique economic and social circumstances. The provincial government will take into consideration the impacts on low-income families, trade-exposed and energy-intensive industries, and consumers and businesses, when developing the specific mechanisms and implementation details, including how to reinvest proceeds.

Any carbon pricing policy will strive to maintain competitiveness and minimize carbon leakage (i.e., investments moving to other jurisdictions). Proceeds from carbon emissions pricing will be directed to a dedicated climate change fund.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The Government of New Brunswick and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Enhanced Electricity Generation and Transmission System

New Brunswick will work with the other Atlantic provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region. This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity.

This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

Energy Efficiency

The Government of New Brunswick, in partnership with the Government of Canada, will seek to enhance energy efficiency programs by targeting GHG emission reduction opportunities across sectors and fuels.

Examples of possible targeted interventions include programs that help: trucking fleets add aerodynamic and other efficiency measures to existing equipment; small- to medium-size industry improve their compressed air systems, boilers and lighting; commercial and institutional facilities invest in heating, lighting and other retrofits; and families retrofitting their homes to reduce energy costs, with special treatment for low- and fixed-income families.

Industrial Emissions Reductions

The Government of New Brunswick and the Government of Canada will work to support industrial emission reduction initiatives through technology and energy efficiency improvements while maintaining productivity. For example, there are significant opportunities to reduce emissions resulting from industrial production in the Belledune area of New Brunswick.

NOVA SCOTIA

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Nova Scotia include:

The Environmental Goals and Sustainable Prosperity Act (2007)

In 2007, Nova Scotia passed legislation outlining principles for sustainable economic growth, including a requirement to reduce GHG emissions in the province to 10% below 1990 levels by 2020. The development and implementation of the Nova Scotia Climate Action Plan led to early action on the electricity sector, the largest source of emissions in the province. As a result, Nova Scotia has not only achieved its target six years early, it has also already met the Canadian 2030 target of 30% below 2005 levels, and is on a track to continue reducing emissions.

Nova Scotia's Greenhouse Gas Emissions Regulations

Nova Scotia was the first province in Canada to place a hard cap on GHG emissions from the electricity sector. These regulations, created in 2009 and enhanced in 2013, required the utility to reduce GHG emissions by 25% by 2020, and 55% by 2030. This is a measured and flexible approach which will enable a transition from coal to clean energy in the province.

Nova Scotia's Renewable Energy Regulations

In addition to the hard cap on GHG emissions, Nova Scotia also has a renewable energy standard for the electricity sector. This standard established requirements for 25% of electricity to be sourced from renewable energy by 2015, and 40% by 2020.

Energy Efficiency

Nova Scotia has Canada's first energy efficiency utility, Efficiency Nova Scotia. This independent organization has achieved an annual reduction in electricity demand of over 1% since its creation. It also administers comprehensive energy efficiency programs for low income and First Nations Nova Scotians. These efforts reduce GHG emissions while supporting the growth of the low carbon economy.

Tidal Energy

The Bay of Fundy and Minas Basin are home to the highest tides in the world- every day, more water flows into this bay than the output from all the rivers in the world combined. Nova Scotia has been supporting the development of these tides as a source of clean, predictable and reliable energy for Nova Scotians and as a clean technology export. The Fundy Ocean Research Centre for Energy (FORCE) now has a grid connected 2MW tidal turbine with plans to install more in the coming years.

Waste Management

Nova Scotia is also making efforts to reduce GHG emissions by diverting organic waste from landfills, recycling and creating a circular economy. Progress on waste diversion is reflected in a 30% reduction in greenhouse emissions from the waste sector since 2002.

These actions are just a snapshot of what Nova Scotians are doing to reduce GHG emissions and provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

As part of the pan-Canadian benchmark for carbon pricing, Nova Scotia has committed to implement a cap and trade program in the province that builds on our early action in the electricity sector.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The Government of Nova Scotia and the Government of Canada intend to collaborate in the following priority domains to address climate change and advance clean growth:

Energy Efficiency

Nova Scotia and the Government of Canada are committed to partnering to enhance the existing provincial energy efficiency programs for homes and businesses with the objective of reducing energy use and saving energy costs. This could include expanded energy efficiency programs, efforts to accelerate the electrification of homes and businesses through heat pumps and smart meters, district energy systems, as well as electric vehicle infrastructure.

Renewable Energy Generation, Transmission and Storage

Nova Scotia, in partnership with the Government of Canada, will work together to advance opportunities for renewable energy generated from sources such as wind, tidal and solar, as well as the enabling transmission and storage infrastructure to ensure growth beyond current technical limits. Research and development capacity will continue to be strengthened.

Planning and Implementing Adaptation Infrastructure

Nova Scotia and the Government of Canada will work together and invest in projects to make infrastructure more resilient to a changing climate, and to help communities increase their capacity to adapt to a changing climate.

Regional Electricity Grid Connections

Nova Scotia will work with the other Atlantic provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity. This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

PRINCE EDWARD ISLAND

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Prince Edward Island include:

Climate Change Policy Framework

Prince Edward Island's primary areas of strategic focus for climate change fall into the themes of built environment, transportation, agriculture, conservation and adaptation. Prince Edward Island is in the process of developing new climate change strategies that will result in further actions and initiatives to reduce GHG emissions across the province, increase our resilience to a changing climate, and advance measures to strengthen and grow a prosperous green economy in the province.

Prince Edward Island does not have a legislated provincial emissions reduction target but does contribute to the regional target set by the Conference of the New England Governors and Eastern Canadian Premiers (NEG-ECP). The targets are 10% reductions from 1990 by 2020, 35% - 45% below 1990 levels by 2030, and 75-85% reduction from 2001 levels by 2050. PEI has realized a 9% reduction in GHG emissions since 2005.

PEI Wind Energy

Prince Edward Island is a world leader in producing clean electricity from wind. Prince Edward Island boasts the highest penetration of wind in Canada and 2nd highest in the world next to Denmark. The Government of Prince Edward Island has demonstrated a long-term commitment and investments of $119 million to wind energy.

The first commercial wind farm in Atlantic Canada was developed by the PEI Energy Corporation at North Cape in 2001. North Cape was expanded in 2003, doubling in size.

In January 2007, the PEI Energy Corporation commissioned its second wind farm at East Point. In 2014, the Island's newest wind farm was commissioned at Hermanville/ Clearspring. As a result, Prince Edward Island now has a total installed wind capacity of 78% of peak load, which supplies almost 25% of the province's total electricity requirements.

Biomass

Prince Edward Island is home to Canada's longest-running, biomass-fired district heating system. Operating since the 1980s, the system has expanded to serve over 125 buildings in the downtown core of Charlottetown, including the University of Prince Edward Island and the Queen Elizabeth Hospital. It has contributed to the establishment of a local waste-wood fuel-supply market. The system burns approximately 66,000 tons of waste materials annually.

Coastal Erosion

Prince Edward Island has partnered with the University of Prince Edward Island (UPEI) Climate Research Lab to study coastal vulnerability, including the award-winning Coastal Impacts Visualization Environment (CLIVE). CLIVE is an innovative 3D platform for visualizing the potential future impacts of coastal erosion and coastal flooding at local community scales, on PEI and elsewhere, using past data and Intergovernmental Panel on Climate Change models.

The province has also invested in UPEI in its development of an expansive, cutting-edge coastal erosion monitoring network. This research includes the use of drone and GIS technology to quantify and assess erosion volume of shoreline disappearance along Prince Edward Island's coastline.

Environmental Awareness in Agriculture

As a key industry for Prince Edward Island, agriculture is of particular consequence for climate change and green growth. In recent years, PEI farmers, watershed groups and the fertilizer industry have been implementing a 4R Nutrient Stewardship program to encourage the efficient use of fertilizer and help reduce related emissions.

Island farmers have been making advances in crop diversification, including testing potato varieties that require less fertilizer and adding nitrogen-fixing pulse crops which improve the environmental sustainability of annual cropping systems. The further use of robotics in dairy farming and food additives in livestock production is being employed to reduce methane emissions.

Prince Edward Island is also the first and only jurisdiction in Canada with a provincially-supported Alternative Land Use Services program. Currently, the program has converted almost 4,000 hectares of marginal land from annual crop production to perennial or permanent cover.

These actions provide a strong contribution to a comprehensive pan-Canadian framework and are helping facilitate the transition to a low-carbon economy.

ACTION ON PRICING CARBON POLLUTION

Prince Edward Island will introduce a made-in-PEI approach to carbon pricing which positively contributes to climate change action while benefitting Prince Edward Islanders and ensures optimal conditions for continued growth of the provincial economy. Prince Edward Island will focus on measures that will meaningfully decrease our GHG emissions and recognize the particular elements of our economy.

Our approach will ensure consistent and competitive alignment with efforts being made across the country, including mitigation and price initiatives in all provinces, especially those in our region. PEI is committed to an approach that will directly enhance provincial adaptation and mitigation efforts.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Prince Edward Island and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Energy Efficiency

Prince Edward Island, in partnership with the Government of Canada, will pursue improved energy efficiency for all sectors in the province as outlined in the 2016 PEI Energy Strategy. The Strategy and forthcoming Climate Change Action Plan are key policy tools in reducing GHGs, driving economic growth and creating jobs locally and in the region.

Prince Edward Island is committed to engaging in incremental actions through solutions for the built environment, including businesses and homes, as well as in new building construction. It has been clearly illustrated by research in the region that investing in efficiency is one of the most effective means of delivering jobs and economic growth widely – across sectors and regions – while reducing emissions and providing savings to consumers.

With a predominantly rural population and some of the highest electricity rates in the country, particular consideration will be given to low-income Island families, and sectors that may find the transition to a lower-carbon environment challenging.

Clean Energy

Energy resilience and security and a move to greater electrification are key priorities for the province. Prince Edward Island, in partnership with the Government of Canada, will work to expand its world-class wind resource, invest in solar, and enable greater integration of renewable energy through storage. Prince Edward Island will work with the other Atlantic Provinces and the Government of Canada to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, consistent with fair market principles, help provinces access export markets for clean, non-emitting electricity. This will contribute to both the Atlantic Growth Strategy and Canadian Energy Strategy and will build on existing regional coordination efforts leading to an integrated regional electricity strategy.

Adaptation

With its 1100 km of coastline, Prince Edward Island is uniquely vulnerable to climate impacts and is positioned to advance innovative solutions to make infrastructure more resilient to a changing climate.

Prince Edward Island and the Government of Canada will work together to act on findings from disaster risk reduction planning and coastal infrastructure assessment, and to improve decision-making capacity to adapt to climate change through planning, training and monitoring.

Research and Development

Prince Edward Island and the Government of Canada will work together to support research and development on promising practices and innovation in the areas of agriculture, marine industries, and smart grid and micro-grid/ storage. Prince Edward Island provides an ideal demonstration site for development in these areas.

This research will advance better understanding of influences on emissions and opportunities for clean growth in key sectors of the Prince Edward Island economy.

Transportation

Prince Edward Island relies on exports for continued economic growth. The Prince Edward Island economy is heavily reliant on ground transportation for the movement of goods to markets across Canada and around the world, and the movement of people across the province. The province has no rail system, large container ports, or robust public transit. As the most rural province in Canada, mitigation in transportation is a difficult challenge.

Prince Edward Island and the Government of Canada will work together on methods to support an eventual move to greater electrification in transportation, including corresponding work with other jurisdictions in Canada. Proposed specific areas of work include installation of public charging infrastructure across the province and in collaboration regionally where possible.

NEWFOUNDLAND & LABRADOR

KEY ACTIONS TO DATE

Newfoundland and Labrador is making significant investments to increase the use of clean and renewable hydroelectric power in the province. The Muskrat Falls hydroelectric development, with capital costs of over $9 billion, will result in 98% of electricity consumed in the province coming from renewable sources by 2020.

Muskrat Falls will facilitate advancing by more than a decade the decommissioning of the largest thermal oil-fired electricity generation facility in the province, reducing greenhouse gas (GHG) emissions by about 1.2 Mt annually (equivalent to more than 10% of the province's total emissions in 2015), and assisting other jurisdictions to meet their GHG reduction targets.

To focus the province's efforts to tackle climate change, Newfoundland and Labrador has adopted GHG emission reduction targets of 10% below 1990 levels by 2020 and 75-85% below 2001 levels by 2050, and has endorsed, on a regional basis, the Conference of New England Governors and Eastern Canadian Premiers' reduction marker range of at least 35-45% below 1990 levels by 2030.

To make progress towards these targets Newfoundland and Labrador released a Climate Change Action Plan in 2011 identifying 75 actions to reduce GHG emissions and adapt to the adverse impacts of climate change. Building on this work, Newfoundland and Labrador passed the *Management of Greenhouse Gas Act* in June 2016, creating a legislative framework for reducing GHGs from large industry, and has completed public consultations to inform new provincial actions on climate change.

These actions provide a strong contribution to a comprehensive Pan-Canadian Framework.

ACTION ON PRICING CARBON POLLUTION

The Government of Newfoundland and Labrador and the Government of Canada continue to collaborate to ensure that Newfoundland and Labrador's climate change plan, including carbon pricing, is consistent with the goals in the Pan-Canadian Framework to reduce GHG emissions, improves resilience to climate impacts, and accelerates innovation and job creation.

This made-in-Newfoundland and Labrador plan will address the province's particular social, economic, and fiscal realities. This includes sensitivity to the particular circumstances facing Labrador communities, and the need to consider impacts on all remote and isolated communities, vulnerable populations, consumers and trade-exposed industries, as well as the need to take account of the province's reliance on marine transportation and the absence of lower carbon alternatives.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Newfoundland and Labrador and the Government of Canada intend to explore collaboration in the following priority domains to address climate change and advance clean growth:

Renewable Energy

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to develop renewable energy, including such actions as enhancing hydroelectric capacity, increasing transmission infrastructure, and offsetting diesel use in small-scale off-grid electricity systems.

These efforts will also seek to maximize collaboration with other Atlantic provinces in the electricity sector, contributing to both the Atlantic Growth Strategy and Canadian Energy Strategy, and will build on existing regional coordination efforts, leading to an integrated regional electricity strategy.

Transportation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to reduce GHG emissions in all parts of the transportation sector, including electric vehicles and associated infrastructure, on- and off-road freight and industrial transportation, marine vessels, and public transit.

Energy Efficiency

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to develop energy efficiency programming, improve energy codes, and support fuel switching in all sectors reliant on fossil fuels.

Adaptation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities to expand climate monitoring and adaptation product and information development, as well as best management practices.

Green Innovation

Newfoundland and Labrador and the Government of Canada intend to jointly explore opportunities in research and development in green technology, including fostering innovation networks and initiation of pilot projects.

YUKON

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Yukon include:

Yukon Government Climate Change Action Plan

The Yukon government *Climate Change Action Plan* has four goals: reducing GHG emissions; addressing the impacts of climate change; leading Yukon action on climate change; and enhancing our knowledge and understanding of climate change.

KEY ACTIONS

Work to date in achieving *Climate Change Action Plan* goals includes:

Reducing GHG emissions (mitigation)

- Setting nine sector-specific targets in the areas of transportation, heating buildings, electricity, and industrial operations.
- Completing a study of Yukon's transportation sector, and launching a Ride Share program in partnership with the City of Whitehorse.
- Supporting Yukon homeowners with the Good Energy Residential Incentives Program, which provides incentives to purchase high efficiency wood stoves, boilers and pellet stoves.
- Carrying out detailed energy audits of seven high-consumption Yukon government buildings.
- A Yukon Biomass Strategy to guide the development of a biomass energy sector in the territory.

Addressing the impacts of climate change (adaptation)

- Completing ten adaptation projects in the areas of permafrost impacts to highways, buildings, hydrological responses, and agricultural capacity; flood risk mapping; forestry implications including the encroachment of mountain pine beetle in lodgepole pine forests; and bioclimate shifts.
- With the Pan-Territorial Adaptation Strategy, territorial governments are collaborating on practical adaptation measures for the north. Permafrost thaw has been a key focus.

Leading Yukon action on climate change

- Participating in international and national climate change efforts that impact Yukon, such as the United Nations Framework Convention on Climate Change Conference of the Parties (COP) meetings, including a developmental opportunity for a Yukon youth ambassador.
- Currently supporting the Yukon College to develop a climate change policy course to be offered by Yukon College.

Enhance our knowledge and understanding of climate change

- Supporting development of the Climate Change Indicators and Key Findings report, an important source of independent information that will guide action and research on climate change in Yukon.
- Provide ongoing funding for the Northern Climate Exchange at Yukon College.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

The Government of Yukon recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change.

Given Yukon's particular circumstances, the Government of Canada and the Government of Yukon will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The Government of Yukon and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in Yukon. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by Yukon. Yukon government will distribute these revenues back to individual Yukoners and businesses through a rebate.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Yukon and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Advancing Renewable Energy

Yukon government and the Government of Canada will partner in advancing renewable energy projects in Yukon. This will improve the energy infrastructure in Yukon, including developing new renewable energy sources to provide clean energy for current and future electricity needs.

It will also support remote communities in diminishing their reliance on diesel for electricity and will support the expanded use of biomass as a cleaner option for heating in Yukon.

Energy Efficiency

Yukon government, in partnership with the Government of Canada, will support energy efficiency through the retrofitting of existing buildings. Sound investments in retrofits and new energy efficiency projects will be supported by expanding the capacity for collecting, analyzing, and reporting emissions data that will help identify the areas of greatest opportunity for reducing emissions.

Adaptation: Building Resilient Yukon Communities

Canada's Northern jurisdictions and the Government of Canada are working together to develop the Northern Adaptation Strategy. The Government of Canada will partner with Yukon to help build climate-resilient Yukon communities.

Research collaboration will build the knowledge necessary for evidence-based decision-making in community planning. Investments in infrastructure will address known risks such as infrastructure built on thawing permafrost.

Green Innovation and Technology

Yukon government and the Government of Canada will partner on new research and pilot projects that will explore promising areas for climate action in the north, such as seasonal energy storage, cleaner transportation options, and community-level renewable energy generation.

NORTHWEST TERRITORIES

KEY ACTIONS TO DATE

NWT Climate Change Strategic Framework

The Government of the Northwest Territories (GNWT) has committed to develop a climate change strategy that takes northern energy demands and the cost of living into account. It will reflect commitments to reduce greenhouse gas emissions, explore carbon pricing systems and how to develop local alternatives such as hydro, biomass, wind and solar.

NWT Energy Strategy

The GNWT is currently working on a new 10 year Energy Strategy. The Energy Strategy will focus on the affordability, reliability and environmental impacts of energy in the NWT and will promote energy efficiency, renewable and alternative energy in the electricity, heating and transportation sectors.

The GNWT continues to take the following territorial adaptation actions:

- Support adaptation decision-making with knowledge, information collection and sharing
- Build capacity to translate adaptation knowledge into action
- Build climate-resilience through investments in infrastructure
- Invest in land use planning, management plans and building adaptation capacity and expertise
- Support most vulnerable regions, conducting risk assessments and completing hazard mapping
- Reduce climate-related hazards and disaster by developing disaster risk management plans
- Adapt renewable energy options and solutions for cold regions

The GNWT continues to take the following territorial emissions mitigation actions:

- Work with our federal, provincial indigenous partners and others to find solutions to address diesel use in remote off-grid communities including to develop the NWT's hydroelectricity potential to reduce GHG emissions in the electricity sector.
- Implement policies to support the adoption of lower carbon and energy efficient technologies.
- Implement policies to support industry and large emitters in the adoption of lower carbon and energy efficient technologies.
- Continue biomass initiatives and work towards the development of a local forest and wood product industry and develop local wood pellet manufacturing as an alternate local fuel source.
- Addressing energy use and GHG emissions in government buildings and operations.

These actions provide a strong contribution to a comprehensive pan-Canadian framework.

ACTION ON PRICING CARBON POLLUTION

Through the Climate Change Strategic Framework, the GNWT is exploring potential impacts and opportunities that may arise from pursuing different carbon pricing systems in the territory.

The GNWT recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change. Given the NWT's particular circumstances, the Government of Canada and the GNWT will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The GNWT and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in the NWT. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by the NWT.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

The NWT will work with the Government of Canada, in collaboration with regional partners, to advance opportunities for clean electricity generation, transmission, storage and demand management linkages across the region.

This will: improve access to non-emitting electricity; support the phase-out of coal-fired electricity generation; improve grid reliability and energy security; and, subject to fair market principles, help the region access export markets for clean, non-emitting electricity.

The NWT and the Government of Canada intend to collaborate in the following priority areas to address climate change and advance clean growth:

Taltson Hydro Expansion and Transmission Links

The proposed Taltson hydro expansion is a small scale run of river hydro project that could be developed with little environmental impact next to the existing power plant, on an already developed river, and combined with a transmission link to provide a green energy corridor to our southern neighbours.

The expansion of the Taltson hydro facility would help reduce Canada's GHG emissions by 360,000 tonnes annually for 50-plus years.

The 60 MW expansion of the Taltson hydro facility could be built in partnership with NWT Indigenous governments, creating economic opportunities for Indigenous-owned businesses across the North. The NWT and Government of Canada will undertake technical and feasibility studies as a first step, including the NWT launching the environment assessment process.

Renewable Solutions for Off-Grid Diesel Communities

The Government of Canada and the GNWT will explore opportunities for reducing reliance on diesel in off-grid communities. For example, the Inuvik Wind Project could produce between 2 and 4 megawatts of wind energy for the Town of Inuvik. The project would reduce GHG emissions by 4,300 tonnes per year and eliminate the need for 1.3 million litres of diesel annually in the largest diesel community in the NWT, and help reduce the cost of living for residents.

For other off-grid diesel powered communities of the NWT, a suite of renewable solutions such as solar and wind in combination with energy storage systems and variable generators could reduce diesel use and emissions by 25 percent, an annual GHG elimination of nearly 3000 tonnes.

All-Weather Road Infrastructure for Adapting to Climate Impacts

The safety and reliability of winter roads is being impacted by climate change. Construction of the Mackenzie Valley Highway from Wrigley to Norman Wells would provide safe, secure, and reliable access into the Sahtu region, helping decrease the high cost of living in communities and support the development of resources in the region.

The Great Bear River is a priority as the seasonal ice crossing is increasingly vulnerable to impacts of climate change. Climate change is also limiting access to existing diamond mining operations in the Slave Geological Province.

Construction of an all-weather Slave Geological Province Access Corridor would reduce costs for industry exploration and development in a region that holds world-class deposits of natural resources and continues to be a major contributor to the Canadian and NWT economy.

NUNAVUT

KEY ACTIONS TO DATE

Some of the key actions taken to date or under development in Nunavut include:

Energy efficiency upgrades

The Nunavut Energy Retrofit Program was piloted in Iqaluit in 2007, and addressed all of the government of Nunavut's Iqaluit Government of Nunavut-owned buildings. The one-time project investment of $12.8 million has led to annual savings in excess of $1.6 million and 1,594 tonnes of GHG reductions.

In combination with the conversion of three of our facilities to residual heat, our GHG reduction is approximately 4,100 tonnes, which is roughly 20% of those buildings' total emissions.

Development of a Climate Change and Adaptation strategy

Upagiaqtavut was developed in 2011 and serves as a guiding document for the impacts of climate change in Nunavut (http://climatechangenunavut.ca/sites/default/files/3154-315_climate_english_reduced_size_1_0.pdf).

Climate change databank

The Government of Nunavut is developing and uses information technology to centralize and increase the access to climate change information, such as permafrost data and landscape hazards maps. The information is used to improve infrastructure planning and help mitigate the effects of climate change across Nunavut.

Climate Change Secretariat

The Government of Nunavut is establishing a Climate Change Secretariat (CCS), which will be the central point within the government to address both climate change adaptation and mitigation issues.

ACTION ON PRICING CARBON POLLUTION

The Government of Nunavut recognizes the role of carbon pricing in the pan-Canadian Framework for Clean Growth and Climate Change. Given Nunavut's particular circumstances, the Government of Canada and the Government of Nunavut will work together to assess the implications of carbon pricing in the territory for its economy, communities and people including energy costs, and to develop solutions together.

The Government of Nunavut and the Government of Canada will also work together to assess the implications of carbon pricing in Canada on the cost of living in Nunavut. This will be an important consideration for future policy development.

As outlined in the federal government's benchmark, 100% of the revenues from carbon pricing will be retained by Nunavut.

COLLABORATION PARTNERSHIP OPPORTUNITIES FOR CLEAN GROWTH AND CLIMATE CHANGE

Nunavut and the Government of Canada intend to collaborate in the following domains of priority to address climate change and advance clean growth:

Nunavut and the Government of Canada will assess the economic and technical feasibility of electrification through hybrid power generation in Nunavut's communities. Hybrid power generation would significantly reduce emissions while at the same time ensure that Nunavut's isolated communities have reliable power.

Nunavut and the Government of Canada will work together to develop a retrofit program to increase the energy efficiency of public and private housing. Investment in safe and energy efficient housing is a key component of building strong resilient communities in the Arctic.

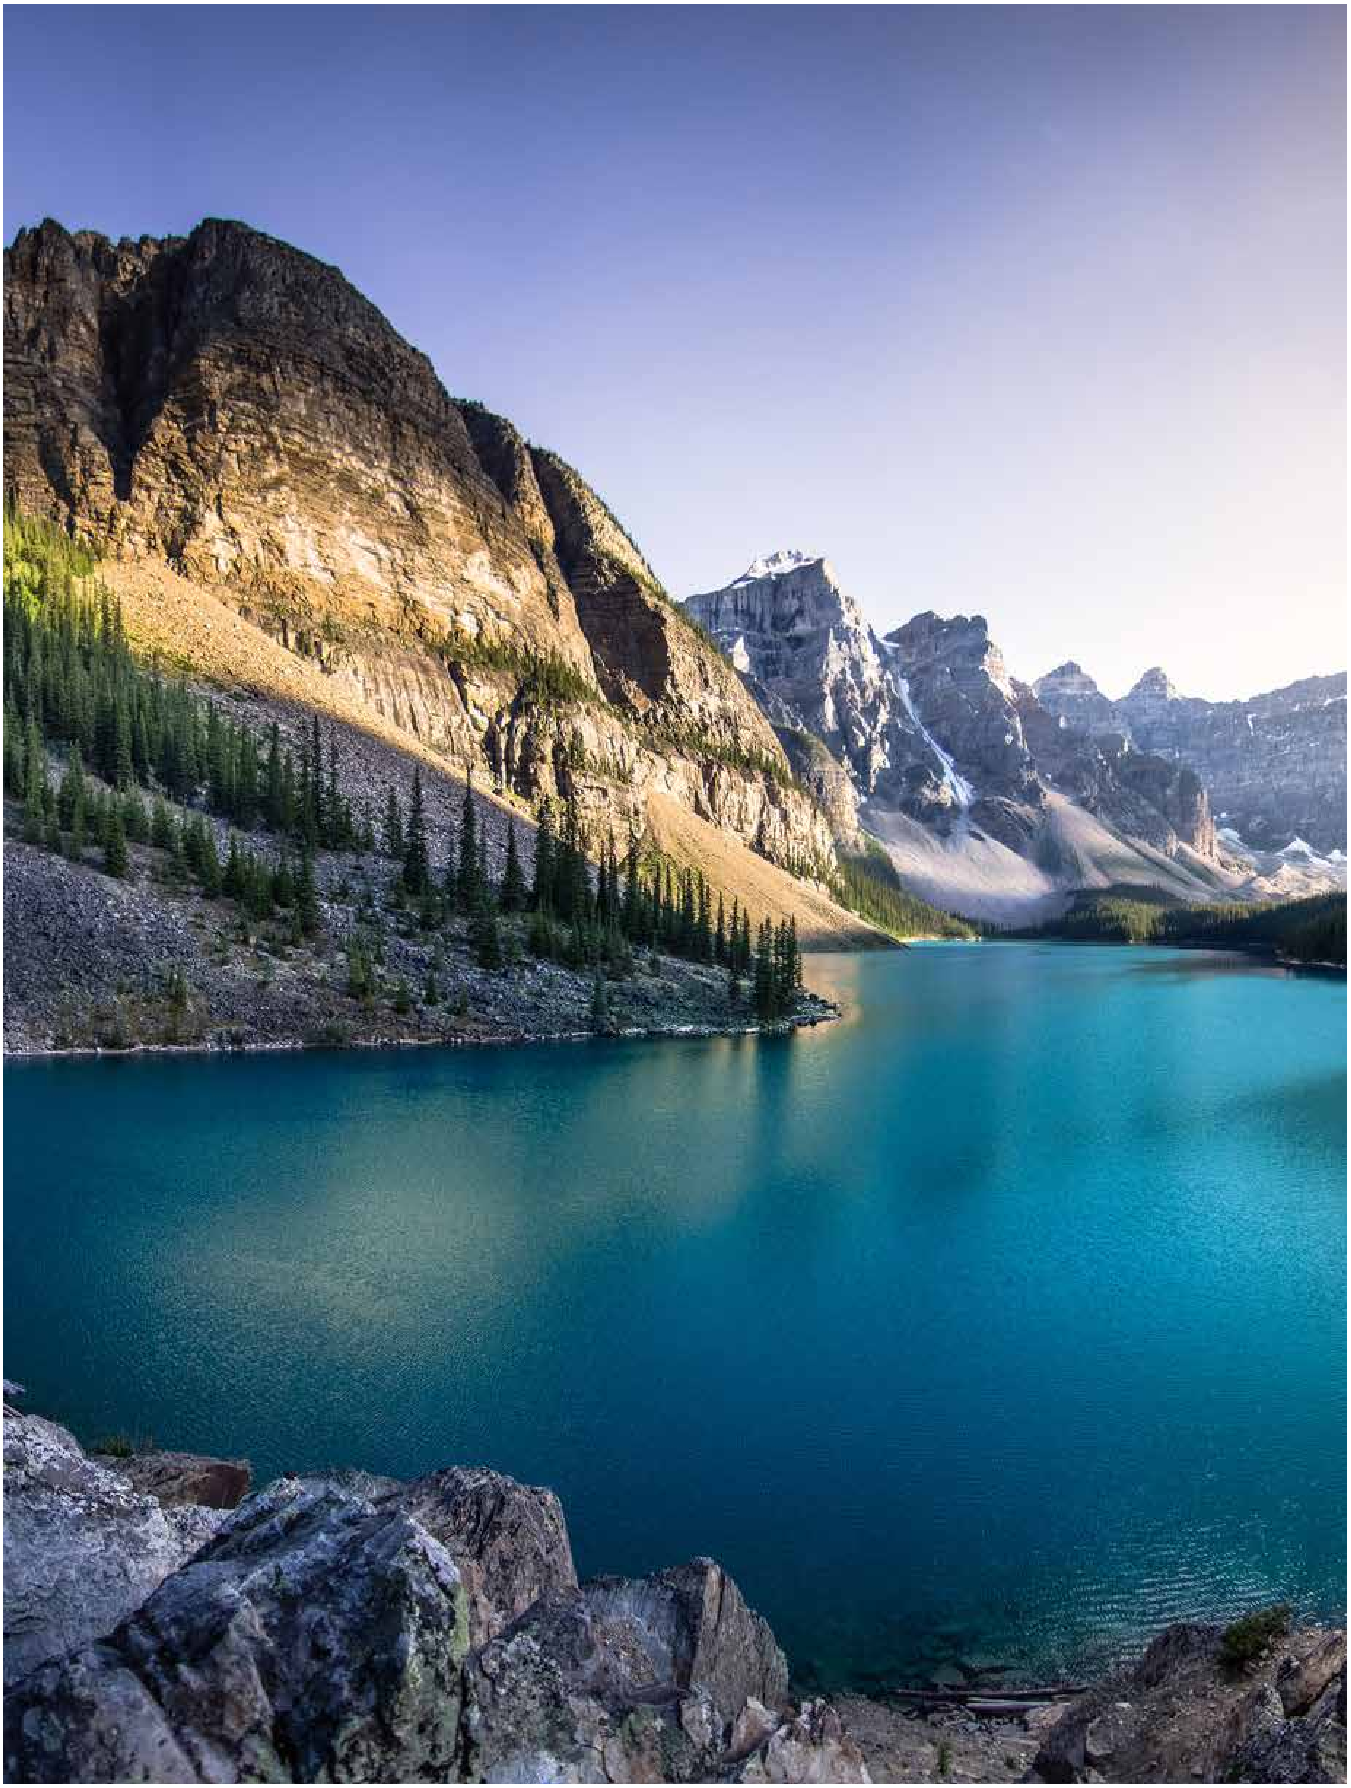
Contents

Foreword

Canada views this initial Mid-Century Strategy report as an opportunity to begin the conversation about what a long-term low-greenhouse gas emission society would entail. The report provides a basic framework regarding what challenges and opportunities have currently been identified in academic literature and expert based analyses regarding deep emissions reductions in the mid to long-term.

Canada submits this strategy to the *United Nations Framework Convention on Climate Change* (UNFCCC) under the premise that the content of the report will continue to be updated and adjusted as Canada advances on the implementation of its low-carbon development pathway. As such, Canada's position is that the Mid-Century Strategies should be submitted in an iterative or cyclical process, where Parties provide regular updates as low-GHG technologies and national circumstances continue to evolve.

This iterative process will allow the Canadian public, experts, and stakeholder communities, to provide substance to this framework as Canada moves towards a common global objective of reducing greenhouse gas emissions.



Executive Summary

Canada is committed to creating a cleaner, more innovative economy that reduces emissions and protects the environment, while creating well-paying jobs and promoting robust economic growth.

A low-greenhouse gas future represents an opportunity to increase prosperity and the well-being of Canadians, to improve the livability of the built environment, modernise transportation, and enhance the natural environment.

Canada's actions on climate change will help communities in Canada in tangible and meaningful ways, since clean growth is not just good for the planet — it's also good for the economy. The benefits include: reducing air pollution and congestion, modernising infrastructure to provide more inclusive and sustainable cities, creating cleaner and more modern communities, growing Canada's clean technology sector, increasing economic productivity and efficiency, saving energy and reducing energy costs, and enhancing resilience to the impacts of climate change.

Addressing climate change paves the way towards innovation and jobs in the clean energy and technology sectors. This represents an opportunity to adopt innovations that can enhance quality of life. Canada is investing in a cleaner future for our children and grandchildren, and creating the right conditions for communities everywhere to create good jobs in a modern, clean global economy.

For the purpose of the Mid-Century Strategy, Canada examines an emissions abatement pathway consistent with net emissions falling by 80% in 2050 from 2005 levels. This is consistent with the Paris Agreement's 2°C to 1.5°C temperature goal.

The Paris Agreement, adopted at the 21st Conference of the Parties (COP21) to the *United Nations Framework Convention on Climate Change (UNFCCC)*, represents the first time in history that virtually all of the world's nations agreed to pursue their highest possible ambition to combat climate change under a common framework. Through the Paris Agreement over 195 countries representing 97% of global GHG emissions agreed to strengthen the global response to the threat of climate change, including by holding the increase in the global average temperature to well below 2°C above pre-industrial levels and pursuing efforts to limit the temperature increase to 1.5°C above pre-industrial levels.

Building on analyses from the Intergovernmental Panel on Climate Change (IPCC) Fifth Assessment Report, the United Nations Environment Programme (UNEP) states that GHG emission reductions in the order of 70 to 95% below 2010 levels would be required by 2050 to remain on a pathway consistent with a >50% likelihood of limiting average global temperature rise to 1.5°C. Achieving this temperature goal is only possible through actions on carbon dioxide and short-lived climate pollutants (SLCPs) together. For the purpose of the *Mid-Century Strategy*, Canada examines an emissions abatement pathway consistent with net emissions falling by 80% from 2005 levels.

Reducing greenhouse gas emissions to levels consistent with the reasonable probability of maintaining this temperature goal will not be easy. It will require substantial effort on the part of all Canadians, with a fundamental restructuring of multiple sectors of the economy. Cost-effective abatement opportunities will need to be realised from virtually every greenhouse gas emissions source and activity. In the energy sector, this will include enhanced energy efficiency and conservation, finding cleaner ways to produce and store electricity, and switching towards non-emitting electricity or other low-GHG alternatives.

Although this will require thoughtful and significant effort on the part of all Canadians (including robust government policy such as carbon pricing, regulatory measures, and support for technology development), the cost of inaction poses a dire risk that cannot be ignored. This risk is threefold:

- Ongoing emissions of anthropogenic GHGs will cause atmospheric concentrations to continue to rise, leading to higher global average temperatures and a cascade of related impacts, including increases in severe weather, and rising sea level.
- Failure to act now means that costs will likely rise in the future as the required pace of decarbonisation increases. This raises the probability of misallocation of investment and infrastructure, as well as stranded assets.
- As the world moves to address climate change, Canada should not be left behind in the emerging global markets for clean energy and related goods and services.

A global clean growth economy offers considerable economic opportunities and co-benefits such as growing Canada's clean technology sector, using more efficient technology globally, mitigating other types of pollutants, improving health and air quality, and increasing productivity through more efficient life cycle production.

Responding to climate change presents an opportunity for Canada to discover and adopt new and innovative ways to enhance our quality of life, while ensuring that this prosperity is sustainable given finite natural resources and environmental concerns. For example, designing low-carbon buildings can save on energy requirements and heating, cooling, and electricity costs, while increasing natural light and airflow. As another example, reducing traffic congestion through more sustainable movement of people and goods would reduce GHG emissions as well as air and noise pollution, save travel time, and lead to healthier and more productive cities. Often through analysing supply chains, or life-cycle assessments of final products, solutions can be found that are environmentally, socially, as well as economically preferable.

Finding low-GHG solutions will also provide Canada with opportunities to help other countries that are also pursuing low-GHG objectives. Canada's clean technology sector has grown substantially over the last few years, and there continues to be considerable prospects for continued growth in the sector. Further investments in research, development and deployment (RD&D) of clean technology, will support Canada's competitiveness in the short and long term, both in emerging and traditional market, creating higher paying jobs, and stimulating exports.

Through "Mission Innovation", Canada along with 20 governments and the European Union, have agreed to double their respective investments in transformative, clean energy research and development over five years, encourage private sector investment in clean energy technology, and increase collaboration among participating countries. Canada is making key investments in clean energy and emissions-reducing technology to accelerate domestic adoption and to deploy our energy know-how and technology to markets around the world. Adopting innovative technologies in the natural resources sectors (energy, mining, forestry, agriculture, and fisheries) will promote Canada's international leadership in sustainable resource development, providing prosperity to Canadians.

While today's technologies and knowledge can significantly reduce emissions, the transition to a low-carbon economy can be eased through innovation, a scale up of RD&D investment, and private sector investment.

Most international and Canadian greenhouse gas mid-century abatement analyses note that deep cuts in emissions are possible with today's technology, although mitigation costs remain high in certain areas. For example, an assessment from the Council of Canadian Academies published in 2015, suggests that Canada can significantly reduce GHG emissions by using commercially available technologies in key sectors of the economy. Studies consistently point to currently deployed technologies as being essential components to the climate change solution, such as expanding the use of non-emitting electricity across end-use sectors, increasing the use of alternative fuels, and improving energy conservation and efficiency.

Many studies also note that new and emerging technologies can help to smooth our transition to a low GHG economy. For example, the International Energy Agency (IEA) demonstrates that a sustainable energy transition is possible with currently deployed or near-commercial technologies, but that the long-term transition will be eased (in terms of investment requirements and timing) with the near-term acceleration of deployment of clean energy options, or the development of more innovative technologies. The IEA highlights that current global RD&D investments are well below what is required to achieve our international climate goals.

Likewise, substantial financial investments are needed from the private sector to move towards a low-GHG future, and related risks and opportunities associated with these investments should be identified early. Carbon pricing can provide the market signal required for private sector investment and innovation. Technology developers and users are best positioned to bring forward new technologies that will ultimately succeed. Innovation in clean technologies, whether it is a breakthrough technology or one that improves the efficiency of an existing process, can lead to significant GHG abatement internationally as the new technology becomes utilised globally.

Canada's mid-century and long-term objectives will be ultimately realized though short-term concrete action.

Canada's Mid-Century Strategy is not a blueprint for action, and it is not policy prescriptive. Rather, the report is meant to inform the conversation about how Canada can achieve a low-carbon economy. This includes describing modelling analyses that illustrate various scenarios towards deep emissions reductions. Canada's Mid-Century Strategy outlines potential GHG abatement opportunities, emerging key technologies, and identifies areas where emissions reductions will be more challenging and require policy focus in the context of a low carbon economy by 2050.

To deliver on Canada's short term action, the Government of Canada is working closely with provinces and territories, and with National Indigenous Organizations to finalize a pan-Canadian framework for clean growth and climate change, which will include actions to reduce emissions, build resilience, and spur innovation and create jobs.

This will develop Canada's plan for meeting the 2030 target of reducing GHG emissions to 30% below 2005 levels, and also includes a carbon pricing framework. The pan-Canadian framework will pave the way towards innovation and jobs in the clean energy sector, and help Canadians manage the effects of climate change, by building capacity for adaptation and strengthening resilience.

On March 3, 2016, Canada's First Ministers and Indigenous Leaders met in Vancouver and committed to developing a concrete plan to achieve Canada's international greenhouse gas reduction commitments through a pan-Canadian framework for clean growth and climate change. Canada's First Ministers released the Vancouver Declaration in which they agreed to build on commitments and actions already taken by provinces and territories in order to meet or exceed Canada's GHG emissions targets. They highlighted the need to foster investment to promote clean economic growth and create jobs that support the transition to a low-carbon economy, while benefitting individual Canadians and addressing competitiveness impacts on businesses. They committed to deliver mitigation actions by adopting a broad range of domestic measures, including carbon pricing mechanisms, adapted to each jurisdiction's specific circumstances. Commitments were also made to develop and implement strong, complementary adaptation policies and action on climate resilience to address climate risks facing our populations, infrastructure, economies and ecosystems, and Canada's northern regions in particular.

The Mid-Century Strategy will help inform the pan-Canadian framework, while long term planning is essential to infrastructure and energy investments, setting the course for a low-carbon future.

The development of a Mid-Century Strategy is an essential step to set the course towards a low-carbon economy as it will inform longer term planning and investment. Long-term planning is fundamental for creating and managing robust energy systems, and careful and far-sighted policy making is essential to combat climate change in an economically efficient, socially acceptable, and effective manner. Because of the long-lived nature of some energy supply and demand equipment, investments and policy decisions made today will affect the level of greenhouse gases in 2050. For example, many of the buildings and electricity generating facilities built today will continue to be operational in 2050. Once these assets are locked-in, replacing them with cleaner alternatives will impose additional costs and complexity. Likewise, government policies should be designed with both a shorter term as well as longer-term focus, ensuring that greenhouse gas emissions will continue to decline towards a low-GHG future.

By aligning its goals to the UNFCCC temperature goals, Canada now has an opportunity to integrate climate change objectives into its long term planning processes. Although this report does not propose specific policies, it identifies key options for Canada's low-GHG development. For example, the anticipation of significant growth in Canadian electricity demand should underpin mid-century investment and planning. Planners should keep in mind that this increased demand will stem from both Canadian applications as they switch away from more carbon intensive energy sources, as well as potentially supplying clean electricity to our continental neighbours. As another example, planners should note that regional differences will be a key consideration due to the variation in electricity generating portfolios, and technical capacities from one jurisdiction to another.

All regions and sectors must act to reduce emissions, but specific abatement pathways could differ from one jurisdiction to another. Regional cooperation will be key to our success.

The Strategy that we present constitutes a growing consensus over possible avenues for low-carbon development informed by independent expert analysis.

This Strategy identifies key objectives and building blocks that could underlie our transition to a low-GHG economy. These building blocks frame the foundation of Canada's long term climate change mitigation strategy:

- Electrification has been identified as an essential step in all deep GHG mitigation analyses. The electrification of end use applications that are currently using fossil fuels is fundamental, for example, using electricity to power certain cars, trucks, building appliances and heating systems, and energy requirements for some industries.
- Concurrent trends towards decarbonisation of the electricity generating sector are needed. Electricity generation in Canada is already more than 80% non-emitting, with a trend towards non-emitting generation expected to continue, including through increased government action.
- The significant increase in electricity demand resulting from electrification policies (e.g., doubling or more by 2050), and electricity exports, should be satisfied through low-carbon sources.
- Canada, and North America's, electricity future will be shaped by interprovincial and intercontinental cooperation. Enhanced interjurisdictional electricity transmission interties could allow areas with hydropower, or other forms of non-emitting generation, to sell electricity to other provinces or U.S. States that rely on fossil fuels.
- Energy efficiency and demand side management are key to achieving deep GHG reductions. For example, the International Energy Agency (IEA) estimates that 38% of the required global emissions reductions associated with a 2°C pathway could be met through energy efficiency improvements. Efficiency gains are also key enablers of electrification technologies and consumer savings.

- Some sectors such as heavy industries, marine transportation, some heavy freight transportation, and aviation could move to lower or low-carbon fuels such as second generation biofuels or hydrogen. Alternatively, new and emerging technologies in synthetic hydrocarbons or energy storage would be needed.
- Abatement of non-carbon dioxide greenhouse gases, such as methane and hydrofluorocarbons, is a priority given their high global warming potentials. Reductions of these pollutants can often help slow the rate of near-term warming and contribute to achievement of the global temperature goal. Although black carbon is not classified as a greenhouse gas, it has strong global warming effects that must also be addressed.
- Behavioural changes will also contribute to a low-GHG economy. For example, innovative approaches to moving people and freight are likely to become more widely adopted over the next 35 years, as well as changes in the way people live, work, and consume.
- Cities are home to 70% of the world's energy-related carbon dioxide emissions. Canadian cities host 80% of the national population, compared to 62% sixty years ago. With a continuing trend in urbanization for the upcoming decades, cities across Canada cannot afford to wait to increase climate change mitigation and adaptation efforts.
- Canada's forests and lands will continue to play an important role in sequestering substantial amounts of carbon dioxide from the atmosphere. This sequestration can be augmented through policies and measures that better manage our forests and forest products. Without consideration of the global land sector, the 1.5 to 2°C temperature goal will be very hard to achieve.
- Innovation will also be crucial. A sustainable energy transition is possible with currently deployed or near-commercial technologies, but the long-term transition will be eased with the near-term accelerated deployment of clean energy options, or the development of more innovative technologies. The private sector has an important role to play in this respect including spurring investment and innovation towards low GHG alternatives. Carbon pricing will be an important element to achieving this objective.
- Collaboration with provinces and territories, Indigenous peoples, municipalities, business and other stakeholders will be essential to Canada's long-term success in enabling clean growth, reducing emissions and seizing the opportunities of the low-carbon global economy.

1 Context

KEY MESSAGES:

- Most Canadians recognise the need to mitigate climate change and limit the increase in the global average temperature, but the magnitude of the challenge is less well understood, with a requirement for very deep emissions cuts from every sector by mid-century.
- Mitigating greenhouse gas emissions is necessary to avoid the increasing threat presented by climate change. Benefits of action to reduce climate risk will outweigh costs and the international community is moving towards low-greenhouse gas economies. A particular focus on short-lived climate pollutants is also required if we are to stay below the 1.5°C - 2°C temperature goal.
- Canada has worked closely with the United States and Mexico in the development of this report. Our continental partners have also described ambitious mitigation action by 2050 in their respective strategies.
- Encouraging international efforts, including reducing emissions in other countries will be key to the global response.
- Working collaboratively with Indigenous peoples by supporting their on-going implementation of climate change initiatives will be key. Consultations with Indigenous communities must respect the constitutional, legal, and international obligations that Canada has for its Indigenous peoples.
- The Mid-Century Strategy will help inform the pan-Canadian framework (PCF) for clean growth and climate change.

1.1 Most Canadians recognise the need to mitigate climate change and limit the increase in the global average temperature, but the magnitude of the challenge is less well understood, with a requirement for very deep emissions cuts from every sector by mid-century.

Canada played a leadership role in advancing the adoption of the Paris Agreement and supporting the global temperature goal of holding the increase in the global average temperature to well below 2°C and pursue efforts to limit the temperature increase to 1.5°C above pre-industrial levels. Ensuring that the global temperature remains well below 2°C will require global greenhouse gas emissions to peak as soon as possible with a rapid decline in emissions thereafter. It will also require fast concurrent actions on short-lived climate pollutants (SLCPs) (see chapter 5).

The latest assessment report from the Intergovernmental Panel on Climate Change (IPCC) relied on a range of models to examine feasible scenarios for global emissions trajectories consistent with limiting global warming to less than 2°C. Building from this analysis, a recent study from the United Nations Environment Programme (2015)[1] found that scenarios consistent with limiting warming to 2°C, with a >66% chance, reach net zero global anthropogenic carbon dioxide emissions by about 2070, while those consistent with limiting warming to 1.5°C with a > 50% chance reach net zero carbon dioxide emissions by about 2050.

1 United Nations Environment Programme, *Emissions Gap Report 2015.*

Net "*negative*" carbon dioxide emissions (i.e., more emissions are sequestered through anthropogenic means than released to the atmosphere) would then be required later in the century to meet the temperature goal. Negative carbon dioxide emissions may be achieved, for example, with large-scale afforestation or bioenergy with carbon capture and storage. Negative CO_2 emissions are required in these scenarios to offset hard-to-mitigate non-CO_2 emissions (e.g., methane and nitrous oxide emissions associated with food production), in order to achieve net zero global anthropogenic GHG emissions.

In terms of total greenhouse gas emissions, according to the IPCC's Fifth Assessment Report, a limited number of studies provide scenarios that are more likely than not to limit warming to 1.5°C by 2100; these scenarios are characterized by GHG concentrations below 430 ppm CO_2-eq by 2100 and 2050 emission reduction between 70% and 95% below 2010.[2]

In this context, the United States noted that its Intended Nationally Determined Contribution target is consistent with a straight line emission reduction pathway from 2020 to deep, economy-wide emission reductions of 80% or more by 2050. Other jurisdictions such as Japan and the EU have adopted similar goals. For the purpose of the *Mid-Century Strategy*, Canada examines an emissions abatement pathway consistent with net emissions falling by 80% from 2005 levels.

1.2 Mitigating greenhouse gas emissions is necessary to avoid the increasing threat presented by climate change. Benefits of action to reduce climate risk will outweigh costs and the international community is moving towards low-greenhouse gas economies. A particular focus on short-lived climate pollutants is also required if we are to stay below the 1.5°C - 2°C temperature goal.

The consequences of inaction to reach the temperature goals are severe, and will have an impact on the global environment, health, and quality of life. The global average temperature is projected to continue to increase well beyond 2°C over the 21st century if no further action is taken. With some regions of the world experiencing severe effects earlier than others, including in some of the most vulnerable areas.

The IPCC concluded that global climate change risks are high to very high with global mean temperature increases of 4°C or more above preindustrial levels, consistent with expected levels by 2100 under a business-as-usual scenario. These risks include substantial species extinction, large risks to global and regional food security, and compromised normal human activities such as growing food or working outdoors due to the combination of high temperature and humidity. These risks are reduced substantially under scenarios which limit global warming to 2°C or lower.[3]

Several studies have shown that the cost to address climate change decreases if early action is taken. For example, in 2014, the White House's Council of Economic Advisers published a report stating that for the same level of temperature stabilisation, each decade of delayed mitigation effort leads to a 40% increase in net mitigation costs.[4] A 2012 Navius Research report, which considered the implications of policy delay in the context of an aggressive 2050 target, suggested that a delay in domestic GHG policy action from 2012 to 2020 could cost Canada an additional $87 billion over the 2020 to 2050 period, which represents an increase of about 27% in the cost of abatement.[5]

In addition, several studies suggest that the benefits of mitigation action can often outweigh the cost over the long run in terms of energy and fuel savings though resource efficiency gains. For example, a recent New Climate Economy Report shows that cities globally could save $16.6 trillion over the 2015-2050 period through investments in projects such as mass transit and energy efficient buildings.[6] Although there is inherent uncertainty around predicting far into the future, the agreement in the literature reinforces the point that early action on climate change is crucial to reducing the overall cost of climate change over time.

1.3 Canada has worked closely with the United States and Mexico in the development of this report. Our continental partners have also described ambitious mitigation action by 2050 in their respective strategies.

As described in the *Leaders' Statement on a North American Climate, Clean Energy, and Environment*

5 Navius Research Inc., *Investment and Lock-In Analysis for Canada: Low Carbon Scenarios to 2050.*

6 Global Commission on the Economy and Climate, *The Sustainable Infrastructure Imperative: Financing for Better Growth and Development.*

Partnership, North America has the capacity, resources, and the moral imperative to show strong leadership building on the Paris Agreement, which entered into force on November 4, 2016. We recognize that our highly integrated economies and energy systems afford a tremendous opportunity to harness growth in our continuing transition to a clean energy economy. Our actions to align climate and energy policies will protect human health and help level the playing field for our businesses, households, and workers.

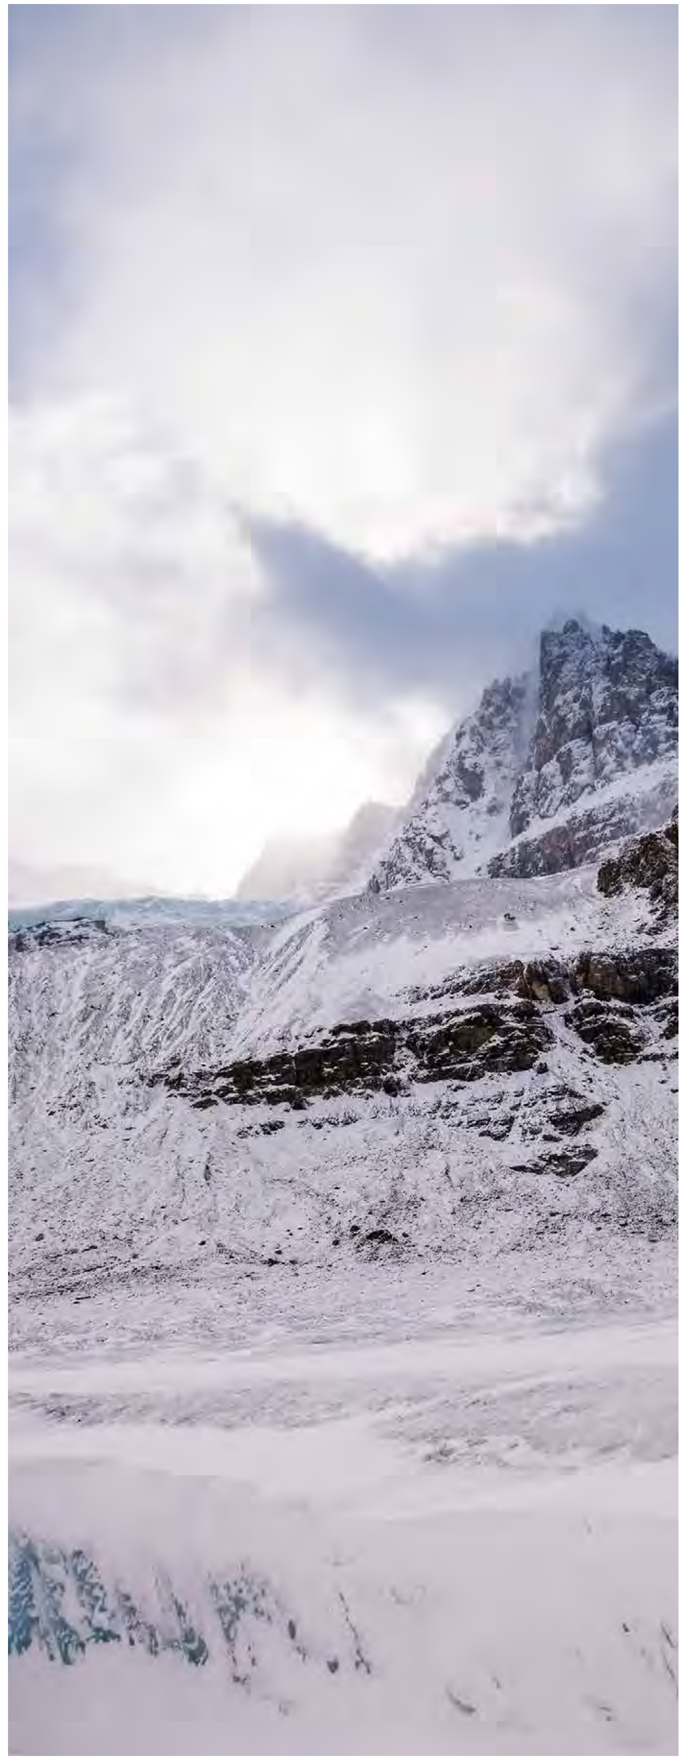
In recognition of our close ties and shared vision, Canada has worked closely with the U.S. and Mexico in the development of this report, including sharing analyses and key insights. Our partners' respective *Mid-Century Low-GHG Emissions Development Strategies* outline ambitious mitigation action by 2050.

1.4 Encouraging international efforts, including reducing emissions in other countries will be key to the global response.

The Paris Agreement recognises that addressing climate change through adaptation, technology, and capacity building will require significant international cooperation and finance, especially in the context of sustainable development. International collaboration is also fundamental to building an innovation and knowledge based economy.

Collaboration on technology innovation will underpin successful global efforts. The Carbon Trust, a global leading think tank on GHG emissions and energy technologies, was commissioned by the United Kingdom to analyse the benefits of energy technology innovation. Their paper *United Innovations* concludes that through collaborative energy technology innovation, "the world could save US$550 billion on the cost of deploying clean energy technologies over the next decade".

International cooperation to mitigate greenhouse gas emissions will be fundamental to limiting temperature rise. This is because GHG abatement costs differ substantially from sector to sector and jurisdiction to jurisdiction, but the environmental benefits of reducing a given amount of emissions are always the same. Cooperating to mitigate emissions in the most cost effective areas will ensure that financial resources are used in the most efficient way, resulting in larger reductions in emissions per unit of capital investment.



Article 6 of the *Paris Agreement* recognises that countries may choose to use internationally transferred mitigation outcomes, including emissions trading, to help access more cost effective abatement opportunities, as well as to help other countries mitigate emissions and promote sustainable development. International market-based approaches to reduce emissions (e.g., linked cap-and-trade programs; bilateral cooperative approaches; etc.) can stimulate cost effective and economically efficient greenhouse gas mitigation. Some regions of the world, including subnational governments, are already working cooperatively, or link carbon markets. These "bottom-up" type approaches could continue to develop and grow moving forward. For example, the province of Quebec has linked its emission trading system to California's through the *Western Climate Initiative*, with other subnational regions planning or considering doing the same. By 2050, it is hoped that there will be an international emissions trading system in place that would ensure robust environmental integrity and transparency at a global level.

In Canada, there are challenges to reducing greenhouse gas emissions from emissions-intensive heavy industry, primary extraction, and certain applications in the transportation sector. In the short-to-medium term, there may be more cost effective GHG reduction opportunities in other sectors or regions, where abatement technologies are more effective or lower-GHG alternatives exist. Emissions trading, or accessing internationally transferred mitigation outcomes, can provide a lower cost method of reducing GHG emissions, allowing more time for GHG intensive capital stock to turn over and allow low-carbon alternatives to be introduced without stranding assets. Canada recognises that sustainable development is a key principle pertinent to this type of cooperation. Canada will consider internationally transferred mitigation outcomes as a short-to-medium term complement to reducing emissions at home. Likewise, Canada intends to take into account internationally transferred mitigation outcomes arising from cross-border subnational emission trading as part of its international contribution to addressing climate change.

1.5 Working collaboratively with Indigenous peoples by supporting their on-going implementation of climate change initiatives will be key. Consultations with Indigenous communities must respect the constitutional, legal, and international obligations that Canada has for its Indigenous peoples.

There are a number of statements and agreements[7] that highlight Canada's commitment to consult, collaborate, and engage Indigenous peoples. Work to address climate change and related interactions with Indigenous peoples, must be consistent with Canada's approach to implementing the United Nations Declaration on the Rights of Indigenous peoples, in accordance with Canada's constitution.

This is especially relevant given the disproportionate challenges that First Nations, Inuit, and Métis communities face because of climate change. Despite the changes that are facing both traditional resources and the land, indigenous citizens and communities alike are taking tangible steps to become active drivers of change. For them, building resilience in the face of climate change is fundamentally about food, water, and energy independence, where Indigenous communities are self-sufficient.

Indigenous peoples, communities, and organisations across Canada are implementing a range of climate change initiatives.[8] Above and beyond renewable energy projects, Indigenous peoples are implementing ground-breaking initiatives on sustainable land use management, food security, and education informed by traditional values. Advancing cross-cultural learning on climate change mitigation and adaptation is one step in the journey towards reconciliation in Canada.

In order to move forward, Canada will encourage the development of green infrastructure in northern and remote Indigenous communities. It is also important for municipalities, provinces and territories to promote energy security for Indigenous peoples. For example, through its Feed-in Tariff program, Ontario has been able to set aside 10% for community and Indigenous engagement in renewable energy projects, with many Indigenous communities as partners or owners in renewable energy systems as a result.[9]

7 For example: the United Nations Framework Convention on Climate Change's Paris Agreement; the Vancouver Declaration; the Leader's Statement on a North American Climate, Clean Energy, and Environment Partnership.

1.6 The Mid-Century Strategy will help inform the pan-Canadian framework (PCF) for clean growth and climate change.

On March 3, 2016, Canada's First Ministers and Indigenous Leaders met in Vancouver and committed to developing a concrete plan to achieve Canada's international greenhouse gas reduction commitments through a pan-Canadian framework for clean growth and climate change. Canada's First Ministers released the Vancouver Declaration in which they agreed to build on commitments and actions already taken by provinces and territories in order to meet or exceed Canada's GHG emissions target for 2030. They highlighted the need to foster investment to promote clean economic growth and create jobs that support the transition to a low-carbon economy, while benefitting individual Canadians and addressing competitiveness impacts on businesses. They committed to deliver mitigation actions by adopting a broad range of domestic measures, including carbon pricing mechanisms, adapted to each jurisdiction's specific circumstances. Commitments were also made to develop and implement strong, complementary adaptation policies and action on climate resilience to address climate risks facing our populations, infrastructure, economies and ecosystems, and Canada's northern regions in particular.

Canada's *Mid-Century Strategy* will help inform the pan-Canadian framework for Clean Growth and Climate Change, but does not outline any further specific policies. Instead, Canada's Mid-Century Strategy outlines potential GHG abatement opportunities, emerging key technologies, and identifies areas where emissions reductions will be more challenging and require policy focus – in the context of achieving very low greenhouse gas objectives by 2050. The strategy also outlines the importance of addressing other pollutants, such as black carbon, that are significant climate warmers.

2 Existing Analyses on Decarbonisation

The study and analysis of what low-carbon futures might look like and the pathways for how we might achieve them is relatively recent. There is, however, a rapidly growing body of international research on low-carbon futures, including a few analyses that have focused on Canada. From this work, a number of common themes and conclusions have emerged that inform the development of this report. This work involves examining various pathways that Canada can take to achieve a low-carbon economy in 2050 and identifying associated opportunities and challenges. The studies also highlight Canada's achievements in decreasing GHG emissions to-date, provide wide-ranging insights on potential transformational low-emitting GHG technologies, and point to policies and measures that could be implemented to achieve deep reductions in GHG emissions and the necessary innovation required to ease this transition.

This literature review aims to highlight the principle themes and key messages from relevant research in order to inform the development of Canada's Mid-Century Low GHG Strategy. The review focuses on Canada-wide approaches and does not consider provincial-level pathway assessments.

KEY MESSAGES:

- Substantial decarbonisation by mid-century is possible with current technologies.
- Decarbonisation presents opportunities to improve social welfare and economic productivity.
- Challenging areas for abatement require increased policy focus, research and development, and investment.
- Decarbonisation objectives should underlie long-term, coordinated planning in key areas such as investments towards new infrastructure and clean technologies.

2.1 Substantial decarbonisation by mid-century is possible with current technologies.

Canada has already started to decarbonise and can do even more with currently available technologies. In its *Canada 2015 review*, the International Energy Agency (IEA) mentions that Canada has achieved important reductions to date through federal and provincial/territorial initiatives. The report underlines that in 2013, more than 75% of Canada's current electricity generation mix is non-emitting due to significant production from hydro and nuclear and that, over the past decade, Canada has decreased its energy intensity by 20%. It also mentions the progress made in the industrial sector with four carbon and capture storage projects, including the Boundary Dam CCS project, which is the world's first commercial application of CCS to a coal-fired power plant.[10]

An assessment from the *Council of Canadian Academies* published in 2015 suggests that Canada can significantly reduce GHG emissions by using commercially available technologies in key sectors of the economy.[11] The assessment identifies many existing

10 International Energy Agency, *Energy Policies of IEA Countries: Canada 2015 Review, p. 10.*
11 Council of Canadian Academies, *Technology and Policy Options for a Low-Emission Energy System in Canada.*

technologies that are able to achieve further energy efficiency improvements and increase production of non-emitting electricity. These technologies are commercially available, can deepen current energy efficiency improvements, and further decarbonise the electricity generation sector. The report also highlights the opportunity to stimulate the low carbon transition at the time of infrastructure renewal.

The *Deep Decarbonization Pathways Project*[12] is a global initiative of 16 countries covering 74% of energy emissions that aims at providing country specific pathways to meet a mitigation goal consistent with limiting global temperatures to 2°C above pre-industrial levels. The project suggests that current and developing technologies can achieve decarbonisation if sufficiently broad, wide, and nationally appropriate climate policy is imposed. The Canadian study published in 2015 provides six decarbonisation pathways, several of which rely on pushing deployment of currently available technologies. The results suggest that Canada can make significant progress through the decarbonisation of the electricity grid using mainly renewable energy sources (e.g., hydro, wind, solar), some fossil fuels with CCS, and replacement of combustion-based energy sources with electricity in many sectors (including the transportation, buildings, manufacturing, and heavy industry sectors). The study employed a highly detailed, behaviourally realistic technology stock turnover model (CIMS) to capture changes in energy, process an fugitive emissions, linked to regionally and sectorally disaggregated macroeconomic model (RGEEM) to capture changes in GDP, economic structure, employment and trade. Emissions reductions in both models were driven by a policy package of performance based technology regulations and hybrid (i.e., general tax and cap and trade) carbon pricing.

The *Trottier Energy Futures Project* looks at 11 different scenarios for Canada to achieve different levels of GHG reductions by 2050 using one optimisation model and one simulation model that integrate energy and economic systems with different sets of strategies to achieve reductions at a minimum cost. The projections presented in the report provide detailed information on Canada's sectoral energy consumption and production for each scenario and take into account specific regional circumstances. The report states that "for most scenarios, the approach was based on currently deployed technologies with plausible extrapolations for future improvements and cost reductions".[13] These include expanding the use of non-emitting electricity across end-use sectors, increasing the use of biofuels in the transportation sector, and improving energy conservation and efficiency. The report also noted that further research is needed on ways to achieve net-negative GHG emissions, including through bioenergy with carbon capture and storage (BECCS), increased use of wood products for carbon retention in buildings, and carbon sequestration through afforestation and reforestation.

The Canadian study *Acting on Climate Change: Solutions from Canadian Scholars* also provides an insight into how current technologies and appropriate policy options are sufficient to decarbonise the Canadian economy. A concerted effort of sixty Canadian scholars, the report suggests that Canada can rely 100% on low-carbon electricity production by 2035, due to the availability of renewable energy sources in the country, making it possible to achieve an 80% reduction in GHG emissions by 2050. In addition, an evolving smart urban design, drastic changes in the transportation sector and a broader sustainability agenda are all fundamental factors that will help change energy consumption in Canada. To this end the authors suggest numerous policies, such as east-west interprovincial electricity trade, and emphasise the benefit of a carbon pricing policy.

2.2 Decarbonisation presents opportunities to improve social welfare and economic productivity.

The Smart Prosperity roadmap, *New thinking*, provides a vision of Canada's potential low-carbon future with healthy, vibrant, and green communities. The Canadian think tank proposes a future Canadian society in which smart cities and towns provide sustainable means of living in communities with hyper-efficient insulated buildings with roof tiles made of solar panels, plenty of public parks and community gardens, and streets and sidewalks filled with electric plug-in stations for next-generation electric cars. In this green economy, clean innovation would provide many job opportunities using human ingenuity to efficiently produce goods and services while continuously seeking new ways to reduce greenhouse gas emissions. Smart grid systems endowed with advanced technologies would allow home appliances, such as water heaters, to act as electric batteries and transportation modes

12 Bataille, C. et al., *Pathways to Deep Decarbonization in Canada.*

13 Trottier Energy Futures Project, *Canada's Challenge & Opportunity, p. 6.*

to recharge and start their duties at inexpensive, low-peak load times. Under this vision, connected communities could become more efficient by sharing resources and knowledge. The roadmap states that Canada's future prosperity depends on the investment choices we make today and that the development of clean infrastructures will "offer substantial economic opportunities for Canadian companies, many of which are already among the leaders in energy technology, water infrastructure, and transportation innovation".[14]

A transition to a low-carbon economy could present significant benefits beyond GHG abatement that could improve Canadian's well-being by producing jobs in the clean technology industry and improving productivity in other sectors. The International Energy Agency (IEA) report *Energy Technology Perspectives (ETP) 2016* underscores Canadian success stories.[15] For example, in Alberta, the Drake Landing Solar Community (DLSC) integrates solar thermal energy to its district system to store significant amount energy underground during the summer so it can be used in the winter for space heating. According to the DLSC, each of the single family homes reduces about 5 tonnes of GHG per year and is 30% more efficient than conventionally built homes.[16] Another success story relates to the use of applications for traffic signals (e.g., communications systems, adaptive control systems, traffic-responsible, real-time data collection and analysis, maintenance management systems) in British Columbia to allow motorists to turn off their engines while they wait at the Peace Arch Border Crossing. The system reduces GHG emissions by 45% while decreasing levels of air pollution which result in improvements in human health. Vehicle users also incur fuel savings.[17]

Data analysed in the *2016 Canadian Clean Technology Industry Report*, published by Analytica Advisors, suggests that the Canadian clean technology sector has grown considerably over the last decade and that a pathway toward decarbonisation would further stimulate the sector by increasing domestic demand for clean technologies, thereby developing domestic knowledge and innovation. The report mentions that the Canadian clean technology sector delivers "high-skill, high-wage, knowledge-based jobs"[18] and that it continues to out-perform other industries on that aspect. Clean technologies can also increase the productivity and efficiency of other sectors of the economy, including traditional industries, and make them more competitive. Nevertheless, the report also highlights that these same Canadian companies are losing market share world-wide, and that moving swiftly towards decarbonisation could provide significant opportunities to the sector.

The *Trottier Energy Futures Project* also points to other kind of economic opportunities, such as taking advantage of potential mutual benefits from a greater integration of the electricity network and trade between the U.S. and Canada. More specifically, Quebec could increase exports of zero-emitting electricity to the U.S. North East region, and Manitoba could do the same with the U.S. Mid-West region. The benefits include higher electricity sale revenues for Quebec and Manitoba and lower cost electricity supply for American States, opportunities for optimal integrated system dispatch

18 International Energy Agency, *Energy Technology Perspectives 2016*, p. XXII.

which could generate revenue through trading of energy, minimised overall cost of system supply (complementing Canadian hydro production with U.S. low cost nuclear and thermal baseload), the sharing of emergency reserve, and a more stable system. The report also mentions that there may be further opportunities for reducing overall electricity costs since the peak demands in Canada and the U.S. occur at different periods of the year (most of Canadian provinces' peak periods are in the winter, while U.S. peak period is in the summer), and for complementing the baseload with more intermittent renewables.[19]

2.3 Challenging areas for abatement require increased policy focus, research and development, and investment.

Decarbonisation pathways also present challenges which require effective and flexible policies that encourage innovation. The academic literature stresses the need for Canada to capitalise on its vast knowledge and expertise to spur innovation and develop clean technologies to cost-effectively reduce emissions in some areas, particularly industrial process emissions and freight transportation. In order to succeed in making major scientific breakthroughs and ensuring clean reliable energy systems, the literature emphasises the need for private and public actors to strengthen research, development and deployment (RD&D) in all sectors of the economy, and continuously engage with the international community. In their 2015 report, the *Council of Canadian Academies* provides an overview of the key challenges faced by industries. These are mainly associated with the lack of cost-effective, low emission-intensive ways to produce high levels of heat, and that energy-related emissions are scattered across many different processes and applications. The report points to R&D, technological development, and flexible policies as key solutions to reduce the costs and encourage commercialisation of low-emitting technologies.

The *National Round Table on the Environment and the Economy* (NRTEE) provided their recommendations in a report titled *Getting to 2050: Canada's Transition to a Low-emission Future*. The report established many "enabling conditions" which would guide Canada in formulating a long-term strategy to achieve its long-term GHG emission and air pollution targets. The report pointed out that long term policy certainty is central to provide predictability to attract new durable investments in clean technology and innovation. The report proposed to establish an economy wide price signal, through a market-based policy. The NRTEE also highlights the need to create a level playing field for energy investments with the goal of enhancing Canadian firms' access to fast-growing low-carbon markets and mobilising investments in low-carbon infrastructure and technology.

Mark Jacobson from Stanford University and other researchers have also looked at energy roadmaps to convert 139 countries to 100% clean and renewable energy use. The roadmaps represent pathways for converting the energy systems of these countries to ones powered by wind, water, and sunlight (WWS). The roadmaps are based on IEA energy consumption data projected to a 2050 BAU scenario. They rely on existing WWS electricity generation technologies and exclude nuclear, CCS, biofuels or natural gas, and do not include the construction of new hydropower dams.

In the wake of the COP21 Conference, the Royal Dutch Shell company published the report *A Healthy Planet: Pathways to Net-Zero Emissions: A New Lens Scenarios Supplement*. The report highlights current societal challenges in achieving a net zero GHG world. The report recognises the important role of renewable energy in decarbonising the energy system but points out other challenges that many industrial sectors are facing (e.g., iron and steel, cement manufacturing, heavy freight and air transportation, chemical and fertilizers). To make progress on reducing these emission sources, the report suggests mass deployment of carbon capture and storage technologies combined with sustainable biomass use. The report also recommends policies to accelerate the world's transition to a low-carbon economy including economy-wide carbon pricing and financial investment for research and development in low-carbon technologies.

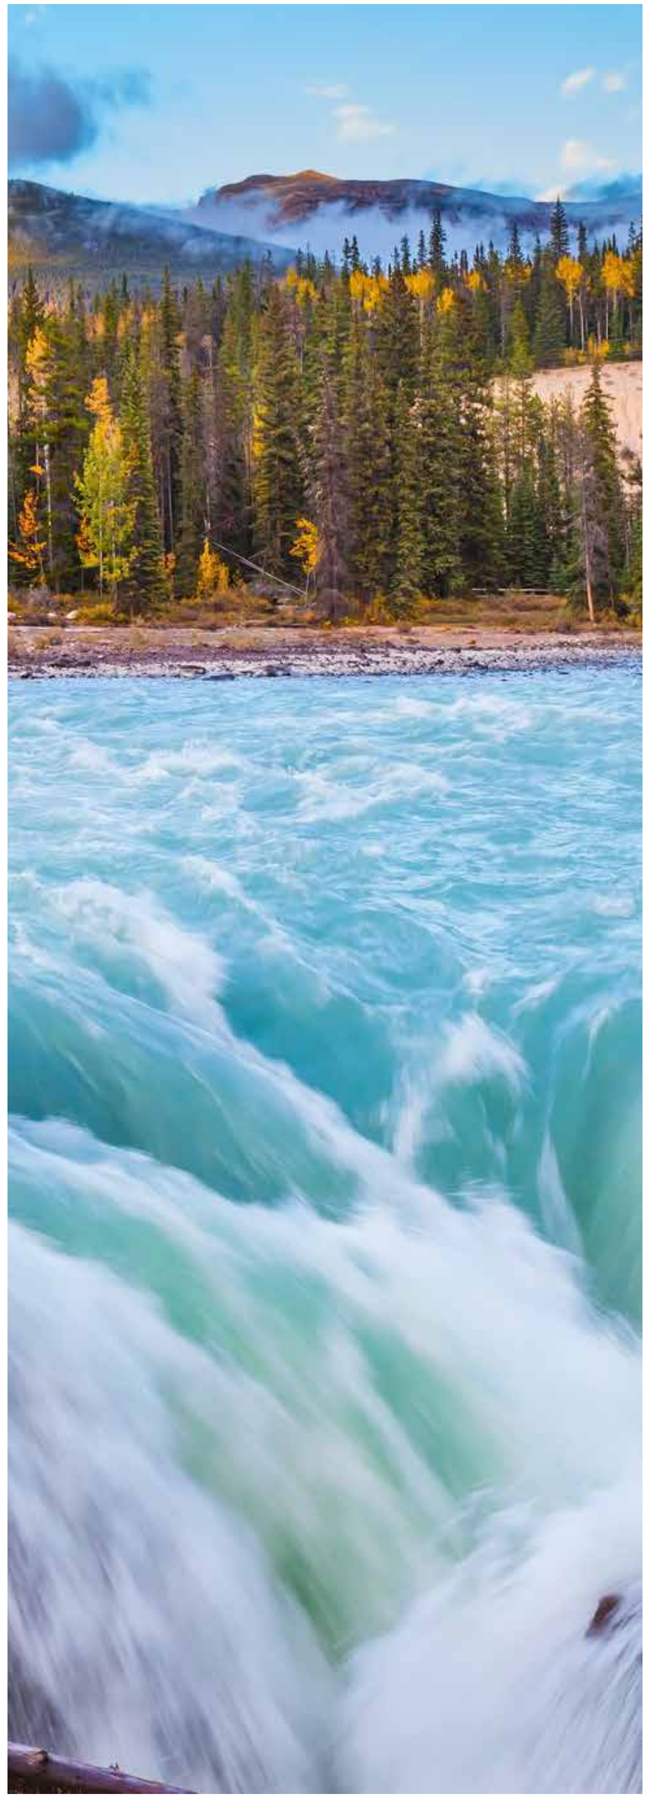
19 Trottier Energy Futures Project, *Canada's Challenge & Opportunity*, pp. 217-224.

2.4 Decarbonisation objectives should underlie long-term, coordinated planning in key areas such as investments towards new infrastructure and clean technologies.

Smart Prosperity's roadmap stresses the importance of building smart infrastructure to facilitate the penetration of clean transportation modes and non-emitting energy. The roadmap also points to municipal governments having a key role in planning zoning and permitting in order to favour clean development of cities. This vision will require strong coordination from federal and provincial governments, National Indigenous Organisations across the country, municipalities, and the public.

As cities are becoming the heart of economic development and strategic centres for innovation in clean technologies, they offer significant opportunities to contribute to reducing GHG emissions. IEA's *Energy Technology Perspectives (ETP) 2016* presents an extensive modelling exercise including projections of three pathways using four interlinked models of the energy supply, and the buildings, industry, and transport sectors. The results present the structural changes required to shift the world toward clean energy and transform cities into innovation powerhouses. The report also highlights the role cities play in driving energy demand and the solutions they may offer to lower the carbon content of the world's energy systems. According to the report, increasing energy demand from urban economic and population growth will need to go hand in hand with innovation and massive deployment of clean technologies and significant behavioral changes. It also emphasises the role of cities in supporting higher efficiency transport and buildings, with dense urban development being a structural prerequisite. Increased demands in space heating and cooling could be decoupled by connecting households to district energy networks. Sustainable land-use planning, the implementation and electrification of transportation modes, and the installation of rooftop solar photovoltaics present attractive solutions to propel cities toward a low-carbon pathway. All of these solutions will require careful planning of today's investments in infrastructure by all levels of government.

The report from the *Council of Canadian Academies* also mentions that many investment decisions such as transmission and distribution systems and strategic planning of urban, land-use and infrastructure developments will allow for a better integration of low-emitting electricity use.



3 Decarbonisation and Expansion of Canada's Electricity System

KEY MESSAGES:

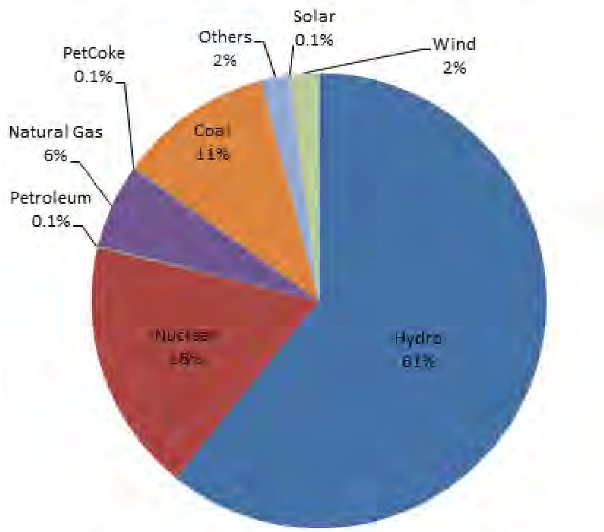
- Canada's electricity generating portfolio is already more than 80% non-GHG emitting, with the trend towards cleaner generation expected to continue. This provides Canada with an international comparative advantage relative to countries seeking to decarbonise their fossil fuel dominated portfolios.
- A low carbon electricity system will allow for GHG emissions reductions in other sectors (e.g., transportation, buildings, industrial processes) through electrification. The anticipation of significant growth in electricity demand should underpin long term investment and planning.
- Further decarbonisation of the electricity sector will facilitate the transition to a low-GHG future. Non-emitting sources will need to be considered for all new and existing needs, but generating portfolios will differ from one jurisdiction to another. Regional differences will need to be a key consideration for electricity climate change policies.
- Interprovincial, interjurisidictional, and intercontinental cooperation will enhance integration of clean electricity generation to satisfy growing demand. Canada's contribution towards global GHG abatement could include providing clean power to our continental neighbours, as well as clean power services to the international community.
- Energy conservation and energy efficiency measures should increase and be implemented alongside efforts to reduce emissions from electricity generation. Electricity savings should underlie decarbonisation pathways: demand side management and reducing equipment and transmission losses makes electrification far more effective and feasible

3.1 Canada's electricity generating portfolio is already more than 80% non-GHG emitting, with the trend towards cleaner generation expected to continue. This provides Canada with an international comparative advantage relative to countries seeking to decarbonise their fossil fuel based portfolios

Canada already has one of the cleanest electricity systems in the world, with more than 80% of electricity generated from sources that do not produce greenhouse gas emissions such as hydro, wind, solar, and nuclear power. Canadian rivers provide immense hydroelectric generating capability, and Canada is second largest producer of hydroelectricity globally. In 2014, Canada produced 379 terawatt hours (TWh) of hydroelectricity, representing 9.8% of global production[20] with further capacity remaining untapped. There is also significant potential for the development of other renewable energy sources across Canada.

20 National Energy Board, *Canada's Energy Future 2016: Energy Supply and Demand Projections to 2040.*

Figure 1: Canadian Utility by Source (2014)



Source: CANSIM Tables 127-0006 for fossil fuel sources and 127-0007 for other sources. Total generation data is extracted from CANSIM 127-0007.

In 2014, nuclear power provided 18% of Canada's electricity generation from electric utilities (63% of Ontario's generation and 34% of New Brunswick's generation). Canada is the world's second-largest producer and exporter of uranium—representing over 20% of world production—and ranks fourth globally in identified resources of uranium. There are 4 operating nuclear power stations in Canada—3 in Ontario and 1 in New Brunswick, with a combined total of 19 reactors. In Ontario, planned investments of $25 billion over the next 15 years will extend the life of 10 nuclear reactors for another 25 to 30 years.

Electricity-related emissions have been declining in Canada due to a return to service of a number of nuclear units, fuel switching from coal to natural gas, and government policies to phase out coal-fired electricity. This trend is expected to continue as hydropower generation and electricity generation from renewables, such as wind and solar, are expected to increase throughout Canada.

Although electricity generation is already moving in a positive direction with respect to a low-GHG future, government policy and long-term planning can help accelerate this trend. For example, as Canadian provinces continue to move away from coal-fired electricity, they will face decisions regarding what type of fuel should replace and augment generating capacity. Natural gas might provide a lower-GHG option than coal in the short run, but its place in a decarbonised system is less clear over a longer-term horizon.

As the global community moves to reduce greenhouse gas emissions, many countries will face challenges with regard to the decarbonisation of their electricity generating sectors. In this respect, Canada is already ahead of many of its peers. Currently, Canada is the second largest producer of hydropower after China, fourth globally for generation from a combination of hydro, wind, solar and biomass,[21] and sixth for generation from nuclear energy.[22] Given this comparative advantage, Canada has the opportunity to increase its clean electricity exports, as well as leverage its expertise in current and emerging technologies (e.g., electrification technologies; smart grids for intermittent sources) that could help other countries reduce their emissions.

3.2 A low-carbon electricity system will allow for GHG emissions reductions in other sectors (e.g., transportation, buildings, and industrial processes) through electrification. The anticipation of significant growth in electricity demand should underpin long term investment and planning

Although electricity generation only accounted for 11% of Canada's emissions in 2014, continuing to move towards a non-emitting electricity generating sector would help decarbonise other sectors, such as, transportation and buildings. Increasing the share of non-emitting electricity generation is fundamental to Canada's low-carbon future.

A near decarbonisation of the electricity sector is underscored in most of the deep-decarbonisation literature, both nationally and internationally. For example, in the IEA Energy Technology Perspective 2016, the global electricity power sector is almost completely decarbonised by 2050 under a scenario consistent with the global 2°C temperature goal. Domestically, virtually all of the academic and expert analysis on deep decarbonisation in Canada point to non-emitting electricity and the electrification of buildings and passenger vehicles as fundamental aspects to a low-carbon future given current technologies. For example, the *Trottier Energy Futures Project* shows that one of the lowest cost options to decarbonise Canada is to move the electricity generation sector toward a zero-emitting transition by expanding renewables, especially hydro, and other non-emitting sources.

21 International Energy Association, *IEA's Electricity Information Report.*

22 Nuclear Energy Institute, *Top 10 Nuclear Generating Countries.*

The near term focus on mitigation in this sector also reflects the technological availability of abatement options including the ability to tackle large point sources of emissions over a shorter time period. From an investment perspective, Canada is at a point in time where its traditional coal-fired generating sources are facing closures or refurbishments with carbon capture and storage, primarily due to government policies; therefore, there is an opportunity to transition to a decarbonised system at more limited incremental cost.

Meanwhile, the price of renewable electricity such as wind and solar continues to decline dramatically, making these options increasingly economically attractive. Recent *Bloomberg New Energy Finance* analysis projects the levelised cost of electricity for onshore wind and photovoltaics solar to decrease by 41% and 59%, respectively, from 2016 to 2040.[23] The levelised cost of electricity (LCOE) is an economic assessment of the average total cost to build and operate a power-generating asset over its lifetime divided by the total energy output of the asset over that lifetime. It can also be regarded as the minimum cost at which electricity must be sold in order to break-even over the lifetime of the project.

The U.S. Energy Information Agency (EIA) describes the average levelised costs for plants entering service in 2022 and 2040 in the U.S. (see Table 1). The EIA notes that some renewables such as wind power are expected to be cheaper than fossil-fuel based forms of generation within the U.S by 2022. These costs take into account building and operating a plant over its lifetime, fuel costs (where appropriate) and the federal tax burden, but do not include regional factors or utilisation rates. Government subsidies are not included in the estimates but would decrease the costs even further.[24] It should be emphasized that these are future costs in the United States and cannot be directly compared to Canada.

In Canada, the Canadian Council on Renewable Electricity (CanCORE)[25] states that hydropower and wind are already cost-competitive. Solar energy is quickly catching up and is on track to be the least-cost generation technology in most countries around the world by 2030.

Table 1: Average Levelised Costs of Electricity (2015 $/MWh) for Plants Entering Service in 2022 & 2040; United States[26]

Energy Source	2022	2040
Wind	64.5	58.8
Wind Offshore	158.1	133.7
Natural Gas-fired Conventional Combined Cycle	58.1	57.6
Hydroelectric	67.8	65.3
Advanced Nuclear	102.8	93
Biomass	96.1	78.7
Geothermal	45.0	57.0
Solar Photovoltaics	84.7	71.2
Coal with CCS	139.5	125.8

3.3 Further decarbonisation of the electricity sector will facilitate the transition to a low GHG future. Non-emitting sources will need to be considered for all new and existing needs, but generating portfolios will differ from one jurisdiction to another. Regional differences will need to be a key consideration for electricity climate change policies.

Modeling analyses that examine deep aggregate cuts to GHG emissions in Canada by mid-century indicate that Canada's future non-emitting electricity portfolio could take various forms, and different non-emitting options exist for each Canadian jurisdiction. The following section outlines the various scenarios developed around non-emitting electricity generation scenarios for Canada and explains the modelling results of each scenario.

MODEL AND SCENARIO DESCRIPTION

Deep Decarbonisation Pathways Project – High Ambition (DDPP):

Ambition:

The DDPP modelled its scenarios in line with achieving 89% GHG emission reductions from overall emission levels projected for 2050, excluding agriculture, which corresponds to an emissions reduction of 88% from 2015 levels by 2050 (78Mt CO_2e).

Model Description:

The DDPP uses an energy and economic model to forecast demand for GHG-intensive goods and services, energy balances, technology and ultimately emissions (CIMS model). CIMS is a bottom-up technology-focused model that competes and selects technology market shares based on firm and household responses to the DDPP policy package, including carbon pricing and technology regulations. To forecast GDP, employment, economic structure and trade, a macroeconomic regionally and sectorally disaggregated Computable General Equilibrium (CGE) model called GEEM, is used.

Scenario Description:

- This modelling work assumes GDP growth ranging from 2% to 2.2% per year from 2015 to 2050.
- The scenario discussed here is based on oil prices of $80 ($US2014) per barrel in 2050.

Trottier Energy Futures Project:

Ambition:

The Trottier Energy Futures Project modelled its scenarios based on achieving a 60% GHG emission reduction target from the 1990 levels in combustion emissions. This corresponds to a 65% reduction from 2015 combustion emission levels. This analysis excludes process emissions. Scenarios 3 (Current Tech Trottier) and 8 (New Tech Trottier) of the report are shown in this section.

Model Description:

The Trottier Energy Futures Project uses two models to develop its scenarios, the North American TIMES Energy Model (NATEM) and CanESS models. Both models include separate representations of the sectors in Canada's economy, split for all provinces and territories.

Scenario Description:

- Scenarios 3 (Current Tech Trottier) and 8 (New Tech Trottier) of the report are shown, both of which aim to achieve a 60% GHG emission reduction target from the 1990 levels in the energy sector.
- This work relies on the National Energy Board's GDP per capita growth rate from 2010 to 2035, which is 1.9%, with somewhat slower growth after 2035.
- This modelling exercise assumes an oil price of about $135 ($2011) per barrel in 2050.

Environment and Climate Change Canada: Global Change Assessment Model (GCAM) – High Non-Emitting:

Ambition:

This modelling work was based on a net 80% GHG emission reduction from 2005 levels. This is modelled as a combination of full reductions achieved in the combustion and non-combustion sectors, as well as the addition of scenarios representing a 65% reduction in Canadian economy emissions, with a 15% achievement through Internationally Transferable Mitigation Outcomes and Land sector credits.

Model Description:

GCAM is a dynamic-recursive model with technology-rich representations of the economy, energy sector, land use and water linked to a climate model. GCAM is a Representative Concentration Pathway class model that can be used to simulate scenarios, policies, and emission targets from various sources.

Scenario Description:

The first scenario (High Nuclear) is heavily dependent on nuclear electricity production, while the second scenario (High Hydro) relies on a mix of hydro and wind to produce a majority of its electricity generation.

- This modelling work was based on a 65% and net 80% GHG emission reduction from 2005 levels.

<u>Environment and Climate Change Canada: Computable General Equilibrium Model (CGE) – High Demand Response:</u>

Ambition:

- This modelling work was based on a net 80% GHG emission reduction from 2005 levels. This is modelled as a combination of full reductions achieved in the combustion and non-combustion sectors, as well as the addition of scenarios representing a 65% reduction in Canadian economy emissions, with a 15% achievement through with the addition of scenarios including Internationally Transferable Mitigation Outcomes and Land sector credits.

Model Description:

- This is a multi-sector, multi-regional open-economy recursive-dynamic computable general equilibrium model of the global economy. The model captures characteristics of country-specific or regional production and consumption patterns through a detailed input-output table and links countries/regions via bilateral trade. The model incorporates rich detail in energy use and greenhouse gas emissions related to the combustion of fossil fuels and tracks non-energy related greenhouse gas emissions. Economic activities in regions involve 28 industrial sectors, final consumption by the household, the governments and investment.

In the figure below, results from these scenarios are presented with respect to electricity generation. Comparing results across models, or across modelled scenarios, provides us with overarching high-level messages and key takeaways for Canada's decarbonised electricity sector. The graph depicts various electricity generating portfolios in the year 2050 from the four different models, and compares these to the current generating mix (2014), labelled as "Historical" in the graph.

In all of the scenarios, Canadian electricity generation will increase substantially to fulfill end-use electrification requirements. Essentially, additional electricity is required to power cars, light trucks, buildings, and industrial production processes that are switching away from fossil fuel generation to electricity to power their needs. In the ECCC analyses, total electricity generation increases by 113 to 189% between 2013 and 2050, whereas it increases by 184 to 295% in the Trottier analyses and by 160% in the DDPP analyses.

Depending on the modelling scenario, there is a huge variation in potential electricity demand growth. This is dependent on the level of energy efficiency/consumption changes emerging from the modelling results. However, in all of the low GHG economy modelling analyses, non-emitting sources such as hydro, nuclear, wind, and solar replace fossil fuel generation well before mid-century.

All scenarios demonstrate growth in hydropower electricity generation between 2013 and 2050. The ECCC High Hydro scenario illustrates a 172% increase in hydropower generation. In the DDPP analyses, hydro increases by 120%, whereas in the Trottier analyses it increases by 134% in both scenarios.

Figure 2: Scenarios of Canada's Non-Emitting Electricity Generating Supply

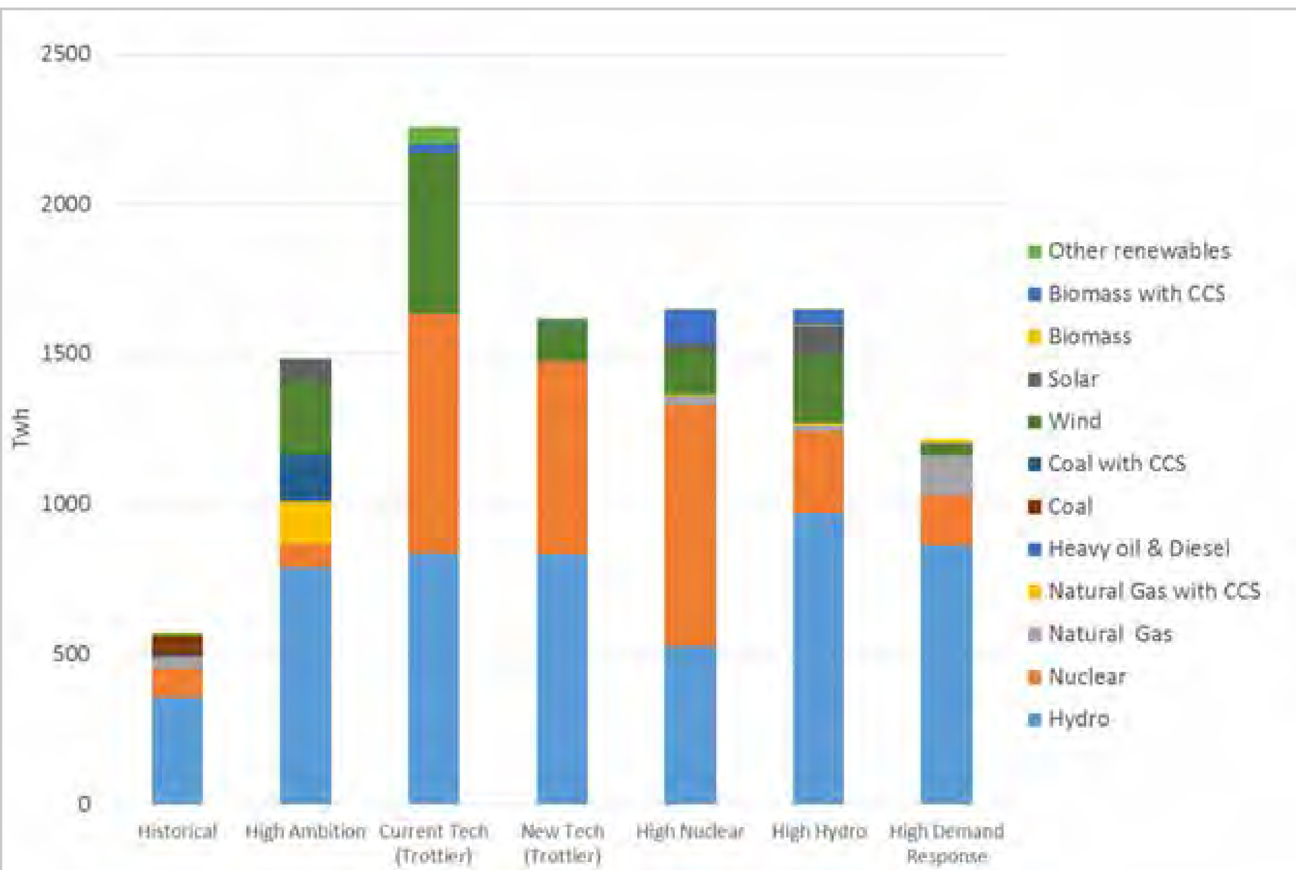

Figure 3: Canada's installed hydro power capacity against theoretical technical potential (MW), and installed wind power: by province and territory in 2014;

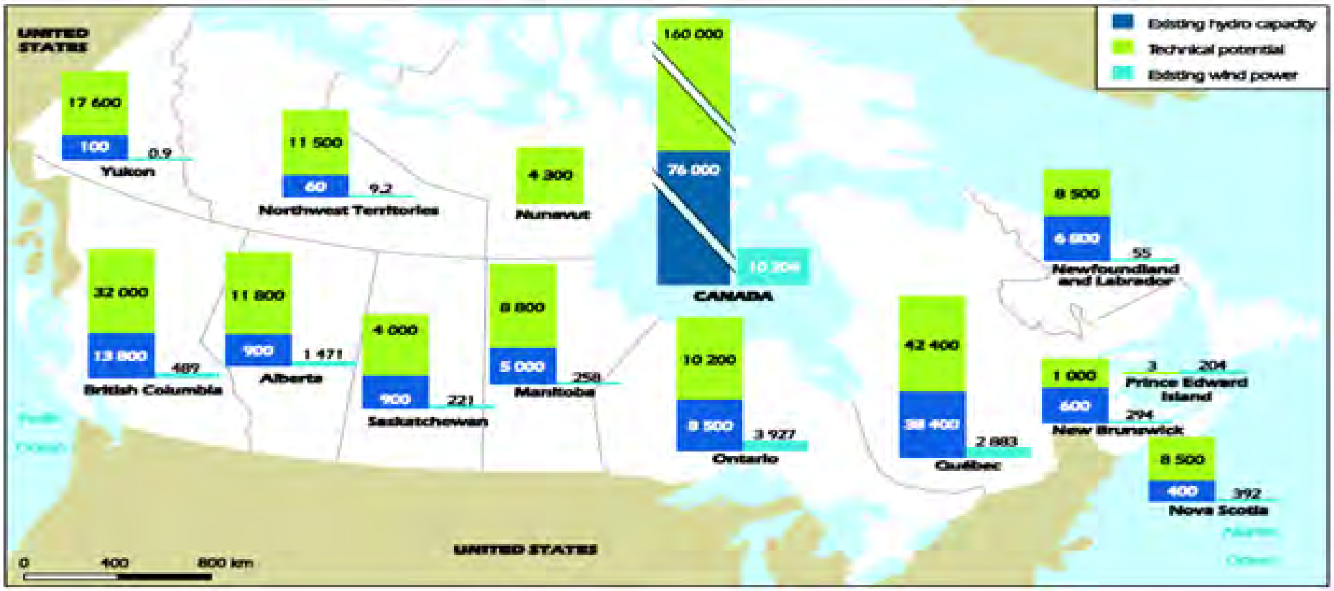

Source: International Energy Agency[28]

The different scenarios correspond to different levels of additional hydro capacity that needs to be built by 2050 to reach the greenhouse gas mitigation objectives. The DDPP scenario requires about 101,500 MW of additional capacity, while the Trottier scenarios require about 111,000 MW of additional capacity. ECCC's High Nuclear scenario would require 36,000 MW of capacity to be built, while the High Hydro scenario would require 130,000 MW to be built. Finally, ECCC's High Demand Response modelling run indicates that 108,000 MW of additional capacity would need to be built.

Although this is a significant increase in hydropower capacity, a study conducted for the Canadian Hydropower Association shows that in 2006 Canada had 160 GW of hydro potential, a large portion of which is economically viable. Canadian rivers provide close to 7% of the world's renewable water supply and this resource provides tremendous hydroelectric generating capability.[27] Currently, over 10 GW of hydro capacity have been proposed or planned in Canada, tapping the Churchill, Nelson, Slave, Athabasca, and Peace river systems. Over 3500 MW of this capacity is already under construction in Canada.

Figure 3 depicts the theoretical technical potential for hydro power generation by province. The above scenarios are all below the technical potential of hydro power capacity, indicating that this type of generation could be possible. The DDPP modelling exercise is 29% below technical potential, whereas both Trottier scenarios are 25% under this threshold. The High Nuclear scenario is 52% under technical potential, while the High Hydro scenario is closer, at 13%. Finally, ECCC's high Demand Response scenario is 22% below the technical potential of hydro power.

Hydro power also provides a good "coupling" to intermittent sources generated by renewables such as wind and solar power. Since renewable electricity is generated at intervals when the wind is blowing or the sun is shining, a high degree of coverage of electricity demand by wind or solar is possible only with access to energy storage or an adequate complementary form of electricity that can be ramped-up during periods of low generation. Fortunately, hydroelectric plants are well suited for this in Canada, and can store water in hydroelectric reservoirs that could be used when solar or wind generation is not available.

Hydro power may have negative implications, mainly based on the impact of dams on fisheries and water flows since dam reservoirs have an impact on flows, temperatures, and silt loads of rivers and streams. There have been examples of large dams blocking migrating fish from reaching their spawning grounds. For these reasons, the construction of future large hydro projects will require careful consultation processes.

27 National Energy Board, Canada's Energy Future 2016: Energy Supply and Demand Projections to 2040

28 International Energy Agency, Energy Policies of IEA Countries: 2015 Canadian Review.

Generally, further innovation will be required if hydro power is to increase substantially in Canada.[29] However, much of this increase in hydropower generation can be accomplished without building new dams. Many technologies allow for an increase in electricity generation from existing hydro dams, such as through increased efficiency turbines, at a relatively low cost.

While hydro power increases in all scenarios, nuclear energy varies depending on the modelling assumptions. The ECCC High Hydro scenario, assumes that nuclear power generation is maintained at today's levels, with the addition of expected refurbishments. The DDPP assumes that existing nuclear power is maintained, but no new capacity is added out to 2050. In comparison, under the Trottier analyses as well as the second ECCC GCAM analyses (High Nuclear) the model chooses a significant increase in nuclear power between now and 2050. Scenarios from the Trottier analyses show nuclear growing to about the same level as ECCC's High Nuclear scenario, although it grows slightly less for the New Technologies scenario, which assumes less electricity generation needs based on energy efficiency technologies.

The amount of nuclear capacity from the ECCC High Nuclear scenario, as well as the Current Tech Trottier scenario, corresponds to 797 TWh of generation per year in 2050, which is much higher than the current share of nuclear in the electricity mix, which corresponds to about 98 TWh of generation. There are significant challenges to building sizeable infrastructure projects like these, mainly because of high capital costs, delays in construction, and other potential issues. However, benefits to nuclear power include emissions free generations, reliable baseload capabilities, and a lower levelised cost of electricity. As such, new and emerging nuclear technologies could become an increasingly attractive option for a

29 Potvin, C. et al., *Acting on Climate Change: Extending the Dialogue Among Canadians: Some reflections on Climate Change Response Policy.*

POTENTIAL INNOVATIVE NUCLEAR TECHNOLOGIES

In the short term, Canadian Deuterium-Uranium (CANDU) reactors enable the use of alternative fuels in current nuclear generation. Canadian industry is currently working with China to run CANDU reactors on depleted uranium by-products and spent fuel recycled from other reactors.

Canadian and international developers are working on Small Modular Reactors (SMRs), which are compact nuclear reactors that can be scaled to generate power to communities ranging from several hundred people up to 300,000 homes. Compared with conventional nuclear power plants, SMRs require lower capital investment and offer scalability, siting flexibility, and enhanced safety features—including passive features that could prevent meltdowns even in the absence of power. SMRs are seen as a potential replacement for coal-fired power plants, or as a complement to intermittent renewables in transitioning remote communities off of diesel generation.

A transition from uranium to thorium-based fuels is possible over the longer term. Thorium is three to four times as abundant as uranium, and thorium-based fuels could reduce the amount of nuclear waste produced by reactors. Advanced nuclear reactors, including those using thorium-based fuels, could also achieve higher efficiencies than existing nuclear plants. China is investing heavily into thorium technologies, including the potential for CANDU reactors—which can support thorium fuel cycles more readily than other currently-available reactor types—and development of an advanced thorium reactor it hopes to demonstrate within the next decade.

Nuclear fusion represents a potentially game-changing technology for clean energy. Fusion differs widely from fission, the process used in conventional nuclear power generation. A Canadian company is developing a novel fusion reactor that could unlock large amounts of energy from hydrogen, a near-infinitely abundant resource on earth, in a process that would not generate any long-lived radioactive waste and entails no risk of a meltdown. For these reasons, nuclear fusion is a potentially transformative technology. While it still has hurdles to pass before making it to market, if it were to succeed, it would alter the landscape of clean energy permanently.

GHG-constrained energy system by 2050 (*see feature box on Potential Innovative Nuclear Technologies*).

Both ECCC High Non-Emitting scenarios point to a higher penetration of wind energy. Wind energy generation in 2050 represents 154 TWh, 9% of total generation, in Scenario 1, and 228 TWh, 14% of total generation, in Scenario 2. In comparison, wind energy increases to 17% of the generating mix in the DDPP analysis, whereas it increases to 24% in the Current Tech Trottier scenario and 8% in the New Tech Trottier scenario. Although these scenarios represent sizeable figures, a Pan-Canadian Wind Integration study[30] has demonstrated that Canada can reliably and cost-effectively integrate enough wind energy to meet 35% of Canada's electricity demand.

In both High Non-Emitting scenarios, solar power generation increases significantly reaching levels of 18 TWh, 1% of total generation, and 99 TWh, 6% of total generation in 2050. In comparison, solar energy increases to 5% of the generating mix in the DDPP analysis, and is only part of the solution for Alberta and Saskatchewan in select Trottier scenarios. The Trottier project notes that when deriving minimum cost solutions for electricity generation in Canada, solar did not compete well with wind.

However, the National Energy Board notes that Canada has a strong solar photovoltaic (PV) potential that is largely unexploited and that certain prairie cities including Regina, Calgary and Winnipeg have well above-average solar potential. Furthermore, it noted that in much of Canada, solar potential is higher than in Germany, the country with the most installed solar PV capacity in the world in 2014.[31]

In order to fully exploit Canada's solar potential, solar PV generation must reach competitive delivery costs to stimulate the large scale investments needed for significant deployment. Incentive programs such as Ontario's Feed-in-Tariff and microFIT programs may determine the pace of growth of solar generation across Canada in the near term. Household production of solar electricity through rooftop solar panels can also be beneficial and could provide more electricity than the household uses, providing an opportunity to sell electricity back to the grid. Fully realising the potential of distributed PV will likely require utility investments to upgrade existing distribution networks to handle two-way power flow. The NEB also highlights potential technological breakthroughs, such as utility-scale electricity storage options, which could provide a boost to the solar industry in Canada (*see box on energy storage*).

In the Deep Decarbonisation Pathways Project analyses, natural gas and coal with carbon capture and storage (CCS) technology is apparent throughout the projection period. In Saskatchewan, CCS was retrofitted to the Boundary Dam coal-fired electricity-generation plant in 2014 and is expected to generate reductions of up to 1 megatonne CO_2 per year. The project, implemented by SaskPower, shows that generating reliable, low-emitting electricity using coal is feasible. The project is key to better understanding the technical, economic, and environmental performance of CCS technology and could produce worldwide spillover effects if other countries choose to implement similar projects. The DDPP analysis also features natural gas generation with CCS as a significant proportion of electricity generation in 2050. Although no large scale demonstration projects have gone forward with this technology, it has the benefit of allowing CCS technology developed for coal electricity generation plants to extend to natural gas generation, which provides more flexibility to utilities in reducing emissions from their generation. Furthermore natural gas with CCS is estimated to be generally cheaper than using coal with CCS because of the lower capital cost of natural gas plants and their lower GHG intensity.[32]

Current Tech Trottier (in figure 2) models Canada's electricity generation with current technologies, a better interconnection between provinces, and allows the use of lowest cost electricity technologies available anywhere in Canada. In comparison, New Tech Trottier models the same GHG reduction target with a set of new technologies reaching market, including CCS and energy efficiency technologies. This technology application results in energy efficiency measures in end-use applications, reducing required electricity demand from 2,257 to 1,622 TWh between the two scenarios.

Other renewable energies offer potential in the mid-to-long term. For example, generating zero-emitting electricity with geothermal power is possible using hot subsurface water or steam coming from underneath the earth's surface. Standard well drilling technology can provide access to high temperature sources and power to turbines that offer reliable electricity.

Tidal energy is a type of renewable energy produced from ocean currents. Since tides are predictable, the generation potential of tidal energy is more

INDIGENOUS RENEWABLE ENERGY INITIATIVES

Indigenous peoples, communities and organisations across Canada are implementing a range of climate change initiatives.[33] A database compiling Indigenous climate change initiatives has so far identified 79 renewable energy initiatives with a web-based presence, 16 of which are presented on the Nations' or communities' websites.[34] Renewable energy initiatives can yield multiple benefits, such as protection of the land, air and water, while creating much-needed employment.

The T'Sou-ke Nation of Vancouver Island in British Columbia, dubbed Canada's first Aboriginal Solar Community, developed three community-owned solar demonstration projects. These include a stand-alone system with battery storage on a community office building, a grid-connected solar PV system that can be used as a backup power source, which that can sell surplus power back to the grid for communities that wish to have net-zero energy use, and a kilowatt grid-connected, net-metered solar PV system on the community canoe shed, which powers its administration buildings. Surplus energy created in summer is sold to the grid and bought back in winter.

Additionally, the T'Sou-ke have installed solar hot water on 42 of the 86 private residences in the community, begun a comprehensive energy conservation program for all houses, and installed two solar-powered electric car charging points. The Government of Canada has just announced funding for a partnership between T'Sou-ke Nation and Schneider Electric to develop energy storage for a worldwide market. In Quebec, the First Nation's political and administrative organisations of Mashteuiatsh, Pekuakamiulnuatsh Takuhikan, and the Regional County Municipalities of Maria-Chapdelaine and Domaine-du-Roy in Saguenay-Lac-Saint-Jean have formed a non-profit 100% regional partnership to identify and develop renewable energy projects using a sustainable development approach. Since its creation, the partnership has contributed to the development of two mini hydro projects. Company profits are transferred to the communities.

Many power project developments occur in the traditional territories of Indigenous Peoples and many in remote areas. By proactively partnering in power developments, Indigenous Peoples can create long-term sustainable value for their members through investment, employment, infrastructure and new business opportunities. By working with the power developers at the earliest stages of project planning, indigenous communities have input into the design to meet local needs which include reducing environmental impacts. For example, "First Nations Power Authority" was mandated to facilitate the development of First Nations-led power projects and promote indigenous participation in procurement opportunities with the crown utility in Saskatchewan, SaskPower.[35]

predictable than that of wind and solar sources. These water flows can turn underwater turbines without the use of dams or reservoirs. Similarly, wave energy is generated by harnessing the motion of waves. Canada has significant tidal and wave energy resources, which can, in the future, contribute to emission free electricity generation. These technologies are currently at the demonstration stage and it is therefore too early to consider modelling their potential contribution to Canada's energy mix.

Additionally, as an alternative to fossil fuels, biomass can be used to generate renewable and sustainable energy. While trees and other plants grow, they absorb carbon from the atmosphere. Over time, the carbon dioxide sequestration from growing trees and plants will offset the short-term carbon dioxide emission from bioenergy, and could deliver substantial carbon savings when compared to fossil fuel use over time (*see more on biomass in Chapter 6*).

34 Sustainable Canadian Dialogues, *Acting on Climate Change: Indigenous Innovation.*
35 First Nations Power Authority; *About First Nations Power Authority.*

As mentioned, wind, solar, and run of river (or low-head hydro) only produce electricity when their resource is available (e.g., when the wind is blowing). For this reason, it is necessary to pair these technologies with hydro or other firm power sources, or with grid interties or management operations (*see box on energy storage*). Energy storage, grid interconnects, and smart grids could improve grid-stabilisation and buffer peak electricity demands, which could in-turn, support a larger share of renewables in the electricity grid.[36]

Storage technologies and smart grids may also be particularly useful in incorporating renewable technologies in remote and off-grid communities, since they have the potential to reduce or eliminate transmission costs. Between today and 2050, it is likely that significant developments will occur in storage technology with the potential to transform the energy system.

36 National Energy Board, *Canada's Energy Future 2016: Energy Supply and Demand Projections to 2040.*

37 International Energy Agency, *Energy Policies of IEA Countries, 2015 Canada Review.*

3.4 Interprovincial, interjurisidictional, and intercontinental cooperation will enhance integration of clean electricity generation to satisfy growing demand. Canada's contribution towards global GHG abatement could include providing clean power to our continental neighbours, as well as clean power services to the international community.

Canada, and North America's, electricity future will be shaped by interprovincial, interjurisdictional, and intracontinental cooperation. Since Canadian provinces and territories have purview over energy decisions within their jurisdictions, they have traditionally designed electricity infrastructure with consideration towards meeting their own energy demands. However, interprovincial electricity trade is becoming an important component of many provinces' supply and demand considerations. This type of cooperation becomes more important when considering climate change objectives, including maximising use of non-emitting sources (e.g., hydro), as well as when increasing the amount of intermittent electricity sources in the grid (e.g., solar, wind, tidal, wave). The recent Ontario-Quebec Trade and Cooperation Agreement provides a good example of interprovincial electricity trade.

Figure 4: Electricity exports and imports between Canada and the U.S., by province, 2014[38]

Expansion of electricity grid interties could allow more areas with surplus hydropower, or other forms of non-emitting generation, to sell electricity to other provinces or U.S. States that rely on fossil fuels. The integration of electricity markets between Canada and the U.S. includes 35 physical interconnections crossing the border and over $2.3 billion in Canada-U.S. electricity trade revenue.[38] In August 2015, the U.S. Environmental Protection Agency released the final version of the *Clean Power Plan* which could reduce GHG emissions from the U.S. power sector by 32% from 2005 levels. Under certain conditions, U.S. states can help meet their emissions reductions targets through imported clean electricity from Canada.

This is expected to create a significant new market opportunity for Canadian electricity exports and increase the profitability of various clean electricity projects, such as large hydroelectric facilities.

It will be important to maximise the benefits from this trade from both an economic as well as a global greenhouse gas standpoint. Under the North American Leaders' Statement on Climate, Clean Energy, and Environment Partnership, leaders announced a goal for North America to strive to achieve 50% clean power generation by 2025, which will require further cross-border transmission projects, including for renewable energy.

REDUCING CANADIAN NORTHERN, REMOTE AND INDIGENOUS COMMUNITIES' RELIANCE ON FOSSIL-FUEL GENERATED ENERGY

According to the Remote Communities Energy Database, there are 288 remote and off-grid communities in Canada, 190 of which rely on diesel fuel for their electricity needs, either completely or partially.[39] Most of these communities also rely on diesel fuel for home heating.[40] In addition to remote communities, a number of governmental and private buildings also rely on diesel fuel for electricity and heating. Sixty percent of Canada's remote and off-grid communities are First Nations, Inuit, or Métis communities. In many cases the diesel must be flown in at great expense.

There are various environmental and human health concerns associated with the transportation, storage and combustion of diesel fuel. Further, high fuel costs associated with diesel generation and power plants already operating at capacity represent barriers to improving living conditions and facilitating economic development. The cost of producing off-grid electricity from diesel generators in Canada's northern and remote communities can be up to 10 times higher than electricity generated on the main grid, and can significantly add to the cost of living for northern and remote communities.[41]

Circumstances of specific communities will affect the costs and viability of options to increase the share of non-emitting electricity generation. While connecting small and distant communities to existing grid infrastructure is not economically feasible, in some cases, hybrid wind/solar-diesel generation systems could be deployed in communities to decrease reliance on diesel fuel. Other potential non-emitting energy alternatives to diesel generation include hydro, tidal, geothermal, small modular nuclear reactors, and biomass. Diesel is also used to provide home heating in northern and remote communities. There may be opportunities to further displace diesel with lower emitting technologies.

A number of renewable energy projects have already been deployed to displace diesel in northern and remote communities. In many circumstances, diesel infrastructure is reaching the end of its life providing an opportunity to shift to cleaner technologies. Although the upfront capital costs to building non-emitting supply are high, these may be partially offset by lower operating/fuel costs. Long-term planning and investment is pertinent to the success of this transition.

40 Carleton School of Public Policy and Administration, *Report of the State of Alternative Energy in the Arctic.*

41 Government of Canada, *Status of Remote/Off-Grid Communities in Canada.*

Moreover, non-emitting electricity infrastructure investments can help address issues of energy security for Indigenous communities and help set the conditions required for stable, and favorable policy climates for establishing mini and micro grids for rural and remote electrification, including those that are First Nation community or family owned.

Currently, the electricity sector requires major investments in new infrastructure, as many facilities are about to be retired or refurbished. The majority of investments in the sector will be in electricity generation; however, transmission and distribution will also see significant investments. There are estimated investment requirements of as much as $350 billion in electricity infrastructure in Canada between now and 2030.[42] The Deep Decarbonisation Pathways Project estimates that $16 billion in additional annual investments will be necessary to achieve Canada's low-carbon future, of which 87% ($13.5B) will be required in the electricity sector.[43] As conventional new sources of low-carbon electricity become less viable, or available (e.g., hydro), new investments in emerging technologies will become increasingly targeted.

Given the long-term nature of electricity related infrastructure, planning and investment decisions will need to be made in the near term to have the desired effect on the 2050 time horizon. For example, infrastructure spending, loan guarantees, and low-interest loans could potentially help fund new hydro projects and transmission lines to facilitate clean electricity projects.

3.5 Energy conservation and energy efficiency measures should increase and be implemented alongside efforts to reduce emissions from electricity generation. Electricity savings should underlie decarbonisation pathways: demand side management and reducing equipment and transmission losses makes electrification far more effective and feasible.

Improvements in energy efficiency and demand side management are core elements of a long-term low-GHG strategy and present economic opportunities. In many cases, energy efficiency is a cost-effective way to reduce GHG emissions as it provides substantial monetary savings for residential consumers and businesses through lower electricity bills, as well as other benefits such as reduced maintenance and improved durability. In addition, several commercialisation opportunities exist; for example the International Energy Agency (IEA) estimates the global energy efficiency market at $221 billion in 2015. The IEA also notes that efficiency investments helped drive a global energy intensity improvement of 1.8% in 2015 however "the intensity improvement needs to immediately step up to 2.6% per year from now until 2030 to get on a 2°C pathway".[44]

The IEA argues that energy efficiency is key to reaching global emissions levels consistent with the 2°C temperature goals. They estimate that electricity savings, through efficiency measures, could avoid 5,100 GW of new capacity by 2050. Likewise, Torrie Smith Associates notes that low-carbon future analysis typically include per capita levels of fuel and electricity use that are about half the current Canadian average, and energy productivity (GDP/energy) four times higher than current Canadian levels.[45] Energy efficiency trends are already positive in Canada as energy efficiency improved from 1990 to 2013 by 24%.[46] The National Energy Board projects that total end-use energy demand will increase at an average annual rate of 0.7% from 2014 to 2040, almost half the rate of increase from 1990 to 2013.

Higher electricity efficiency can be achieved with targeted demand-side management measures and technological improvements. Changes in behaviours such as consuming electricity during low-demand periods could reduce peak power demand which could contribute to reduce GHG emissions from load generation.[47] Energy efficiency can also defer transportation and distribution investments, reduce line losses and avoid capacity reserve requirements. As technology develops, further electricity productivity gains should be realised with devices like smart meters helping to reduce and optimise end-use.

46 Natural Resources Canada, *Improving energy efficiency in Canada.*

47 Energy efficiency can also defer transport and distribution (T&D) investments, reduce line losses and avoid capacity reserve requirements (IEA 2016)

Modernizing the electricity grid could also contribute to improved electricity efficiency by reducing losses when electricity is generated and transmitted. Grids generally follow north-south orientations since most of Canada's population live in southern jurisdictions along the international border with the United States, while the largest hydroelectric projects are located in scarcely inhabited areas to the north. Since the Canadian transmission networks extend over 160,000 km, losses are significant between generation and end-use sources. However, by 2050, it is highly probable that distributed generation will play a bigger role, reducing the requirement for electricity to travel long distances from point of generation to end use.

ENERGY STORAGE

The principal challenge with variable renewable energy such as wind or solar is that they are intermittent, meaning that power is not available when the wind is not blowing or the sun is not shining. As such, improvements in energy storage would make these intermittent sources much more attractive to grid operators, ensuring that power is available to meet demand cycles. Additionally, increase in energy density and charging rates for battery energy storage technologies can provide the improvements in the transport sector that will be required for a widespread adoption of electric means of transportation.

Incorporating intermittent power flows to existing grids requires added flexibility elsewhere on the grid, which can increase system costs. However, such costs could be offset by the adoption of technologies that can store excess power for weather conditions that are unfavorable to power generation and support the grid during peak demand time. Storage technologies could also allow households to rely on their own energy production, thus increasing the growth of local energy production, potential of smart grid systems, and energy availability for remote communities.

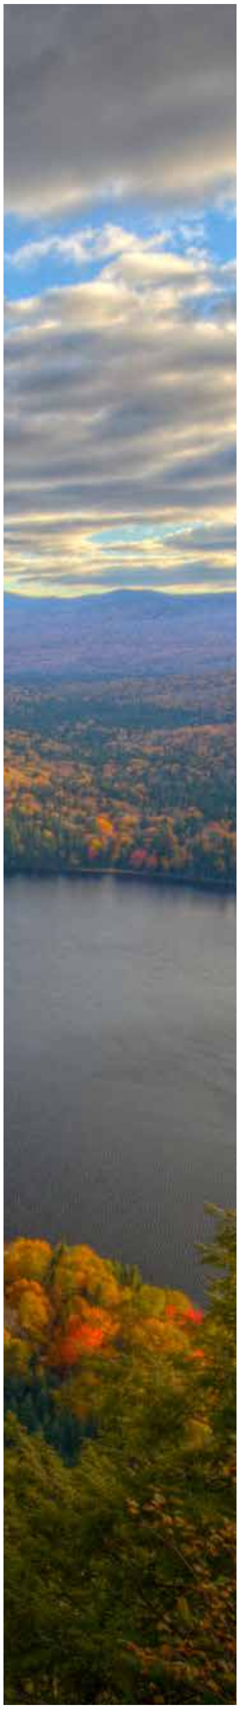
Figure 5 : Technology Roadmap : Energy Storage

Source: International Energy Agency, 2014. Technology Roadmap: Energy Storage

The private sector has been a major leader in energy storage research. Specifically, battery storage technologies for cellphones, computers and electric vehicles, have seen tremendous growth in recent years. Already, the costs of lithium ion batteries are being significantly reduced by the production of electric transportation companies, such as Tesla Motors. Moreover, other cheaper and more efficient options are being developed, with possibilities for the entire energy sector. For example, sulfur-based and graphene-based battery technologies offer tremendous potential for cheaper and more powerful battery storage. Other energy storage options are available, with some of them already adopted by Canadian electricity providers. Recently, the Toronto Hydro Company's compressed air energy storage pilot project was deployed in Lake Ontario and now provides 1 MW of storage capacity that can be sent to the city grid during peak demand times. Thermal energy storage is also being used in the community of Okotoks, Alberta. Nevertheless, the most promising option for some Canadian provinces is likely to be pumped storage hydropower (PSH). The technology is readily available, has low operation and maintenance costs, and is not limited by cycling degradation.

Although recent improvements achieved by the private sector are encouraging, much more innovation is needed to allow for widespread renewable energy production by 2050. Consequently, due to the essential role of energy storage technologies in the electrification of numerous processes, including transportation, it is fundamental that energy storage technologies continue to improve over time. In order to accomplish this, governments and private actors have a shared responsibility to scale up investments throughout the innovation chain in order to allow breakthrough technologies as well as incremental improvements to be brought to market.

4 Energy Consumption in End Use Applications



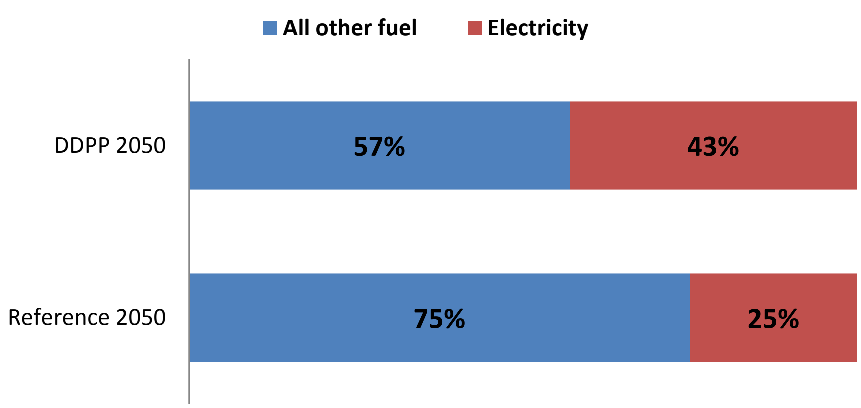
Under a low-carbon future, Canada's electricity demand is expected to increase substantially by 2050, partly as a result of traditional pressures such as population and industrial growth, but also because of the electrification of end use applications that currently use other forms of energy. Many applications (e.g., cars, trucks, boilers, heaters) can use clean electricity to fulfil their power requirements, reducing emissions by switching away from refined petroleum products, natural gas, and other fossil fuels. This greater use of electric power is often accompanied by important efficiency gains, especially in the transportation sector, leading to an expected reduction in overall energy demand under low GHG scenarios. Maximising the abatement potential from electrification requires the simultaneous near decarbonisation of existing electricity generation and the large expansion of new zero or low emissions electricity sources, as discussed in the previous chapter.

All academic and expert analyses that pertain to low-GHG pathways show an increase in electricity supply and greater proportion of electricity in total energy demand. For example, the *Deep Decarbonization Pathways Project* shows electricity rising to 43% of total energy by 2050 compared to 25% currently, more than doubling the current supply between now and 2050. Moreover, the *Trottier Energy Futures Project* shows electricity generation more than tripling between now and 2050.

Given Canada's relatively cheap and clean electricity generating portfolio, implicit carbon costs for electric power are lower than in many other countries. This means that clean electricity is a comparative advantage for Canada. It will be important to examine any change or rise in electricity costs associated with the new demand requirements, and ensure that Canada continues to have access to affordable and reliable electricity going forward.

Apart from electrification technologies, renewable and low carbon fuels are low or non-emitting options to fulfil many of Canada's energy requirements. These fuels will be particularly important in areas where electrification is not currently possible or too costly, such as aviation and marine transport, some heavy freight transportation, and many industrial activities. Likewise, renewable or low carbon fuels can often be used in existing cars and trucks or building furnaces in higher blends, without affecting equipment performance, safety or warranties.

Figure 6: Electricity as a share of National energy consumption



Source: Bataille, *C. et al. Pathways to deep decarbonization in Canada.*

It is important to recognize that all energy related emissions reduction activities work best when paired with increasing energy efficiency. For example, increasing the number of homes heated by clean electricity will be much more viable when building envelopes are designed to minimise heat loss. Importantly, a reduction in demand through energy efficiency, conservation, and demand side savings will partially offset the increased Canadian electricity requirements from the electrification of end use applications.

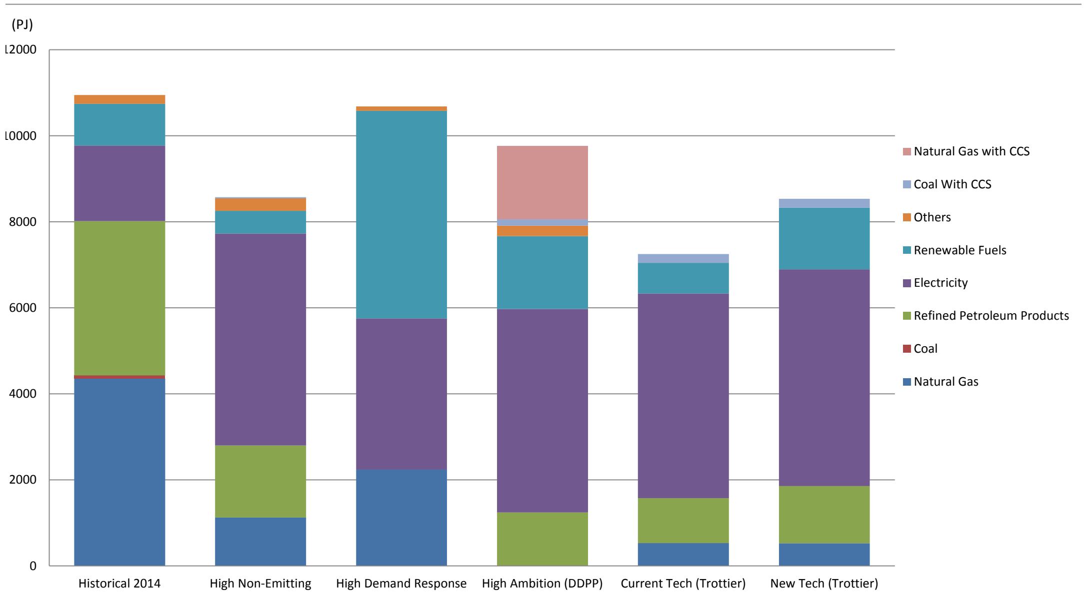
Figure 7 presents several analyses of total energy use in Canada by 2050 under low-GHG scenarios. The current energy use (2014) is presented, as well as DDPP and Trottier Institute 2050 results. While there is population and economic growth during the period, even stronger energy efficiency gains allow for decreases in total energy consumption in most analyses. For example, total energy consumption decreases from 10 950 PJ in 2014 to 7971 PJ on 2050 (ECCC GCAM scenario, labelled "High Non-Emitting") or even 7 251 PJ in 2050 (New Tech Trottier). The central role of energy efficiency gains in the projections is consistent with Chapter 2 that depicted energy conservation as the "first fuel", the foremost criteria to meet the 2050 GHG emissions reduction levels.

Apart from a reduction in total energy consumption, the switch from fossil fuels use to electricity and renewable fuels alternatives is another cross cutting theme of all scenarios presented. Clean electricity production across the country, achieved before 2050 in all scenarios, allows for deep GHG emission reductions from the electrification of end uses and industrial processes. Electricity use in 2050 is predicted to reach between 40 to 72% of total energy consumption, up from 16% in 2014.

Renewable fuels provide the last alternative in most scenarios to decarbonise the intensive GHG sectors of the economy. In key sectors, notably in heavy industry and freight transport, renewable fuels replace conventional petroleum and natural gas usage. Those alternative fuels are essential to attain deep GHG emissions reductions, since it is not likely that technological advances will allow electrification of all sectors of the economy by 2050.

Specifically, ECCC presents two scenarios where electricity generates either 33% (High Demand Response) or 57% (High Non-Emitting) and renewable fuels supply either 45% (High Demand Response) or 6% (High Non-Emitting) of total energy consumption in Canada by 2050. ECCC's High Non-Emitting projection estimate refined petroleum products will still account for around 20% of total energy consumption by 2050, with natural gas generating 13%. ECCC's High Demand Response scenario projects a use of natural gas falling to 21% of total energy consumption by 2050, and no future use of refined petroleum products. In contrast, the DDPP estimates that electricity will generate 48% of total energy consumption in Canada by 2050, with 17% supplied by renewable fuels, 17% by natural gas (with Carbon Capture Storage Technologies [CCS]), 2% by coal (with CCS) and 13% by refined petroleum products. Trottier estimates electricity to take between 59-66% of total energy consumption in Canada, with renewable fuels supplying either 9 and 17%, refined petroleum products supplying between 14-16%, natural gas 6-7%, coal 2-3% (retrofitted with CCS).

Figure 7: 2050 Projections of Total Energy Consumption by End Use Fuel



4.1 Transportation

KEY MESSAGES:

- Electrification of the transportation sector presents the potential for significant emission reductions; for personal vehicles, electric vehicle technology is commercially available and continues to improve.
- Greater uptake and broad use of electric vehicles will require more widespread acceptance of the technology supported by information and understanding around: cost of ownership and performance, charging availability and times, and range expectations. All of which are expected to improved significantly over the coming years.
- Low-carbon and renewable fuels are consistent with low-GHG scenarios, particularly in areas that face challenges with electrification.
- Freight transport is a challenging sector, but there are a number of solutions that show potential towards deeper emissions reductions.
- Emerging technologies such as energy storage or advanced lightweight materials will increase energy efficiency and decrease emissions; innovative approaches to moving people and freight are likely to become more widely adopted by mid-century.
- Modal shifts, such as moving passengers and freight to less GHG intensive modes, could offer notable emissions reductions, which would be further strengthened through clean technology deployment, such as electrified passenger rail.
- 62% of Canada's black carbon emissions arise from the Transportation sector. In addition to being linked to climate warming, black carbon emissions are also a public health concern. Canada continues to take complementary action to reduce black carbon emissions.

4.1.1 Electrification of the transportation sector presents the potential for significant emission reductions; for personal vehicles, electric vehicle technology is commercially available and continues to improve.

The transportation sector plays a vital role in the lives of Canadians and in the Canadian economy. Almost 82% of Canadians live in urban areas and 80% of commuters drive to work in their own vehicles. Canada's transportation system moved over $1 trillion worth of goods to international markets and employed 896,000 Canadians (5% of total employment) in 2014. Compared to other countries, Canada depends heavily on cars for urban mobility, and has a relatively high share of large cars. Canada has large distances between its cities, increasing intercity travel emissions.

Currently, the transportation sector is a major contributor to Canadian GHG emissions. Roughly one quarter (28%) of Canada's GHG emissions come from the transportation sector, such as from cars, buses, trucks, motorcycles and recreational vehicles.[48] About 57% of these emissions come from passenger transport, while heavier freight transport accounts for 37% of transport emissions.[49] However, given increasing efficiency improvements in passenger vehicles (mainly driven by federal regulations) and challenges in achieving efficiency improvements in freight, the share (and net amount) of GHG emissions from freight transportation is expected to increase into the future.

Road transportation activity can be broken down into two components: how people and freight travel (mode choice) and how far they travel (activity level).[50] Emissions reductions could result from a greater market penetration of alternative vehicle technologies and modal shifts (e.g., away from single-occupancy vehicles). Activity level changes could be achieved through consumption patterns shifting with technological advances (e.g., teleworking) or urban densification. Canada will continue to encourage cities to improve public transit and bike lanes, and design urban spaces that reduce the need for vehicle transportation.

Battery electric vehicles provide the opportunity to emit zero GHG emissions when renewable or

48 Environment and Climate Change Canada, *National Inventory Report 1990-2014: Greenhouse Gas Sources and Sinks in Canada.*

49 Based on Canada's *Emission Trends Report 2014.*

50 Conference Board of Canada, *A Long, Hard Road: Reducing GHG Emissions in Canada's Road Transportation Sector by 2050.*

clean electricity is used. In addition, electric vehicles reduce local air pollutant emissions. Electric vehicle technology is well known, proven, and available for purchase in Canada with increasing variation and choice: in total, there are 22 different plug-in models on the road in Canada, made by 12 different manufacturers.[51] Alternatively, plug-in hybrid vehicles offer increased driving range by switching to fossil fuels when the electric battery charge diminishes. While these vehicles still use fuel, most of them are used in a way that relies solely on electricity about 90% of the time. [52]

4.1.2 Greater uptake and broad use of electric vehicles will require more widespread acceptance of the technology supported by information and understanding around: cost of ownership and performance, charging availability and times, and range expectations. All of which are expected to improved significantly over the coming years.

51 CAA, *Electric Vehicles: What You Need to Know.*
52 EVObsession, *Best Electric Car for the Average American.*

In spite of Canada's ambitious mitigation objectives and clean electricity portfolio, we lag behind many of our peer countries with respect to electric vehicle penetration. For example, Norway reached annual sales of almost 40,000 fully electric vehicles in 2015, reaching a market share of 23% of passenger vehicles sold. China has grown its electric vehicle fleet by 207,000 passenger vehicles in 2015, with an additional 123,700 electric buses and commercial trucks on the road.[53] Meanwhile, there are now more than 40,000 electric vehicle charging stations in Japan, including in personal homes and commercial buildings. Charging stations are now more common than the roughly 35,000 gas stations in the country.[54]

Although only about 24,000 plug-in vehicles have been sold in Canada thus far, sales increased by 32% between 2014 and 2015, and are projected to continue to increase as prices converge with those of conventional vehicles, charging infrastructure is built out, and more vehicle selection becomes available.[55] For example, out of the roughly 400,000 reservations

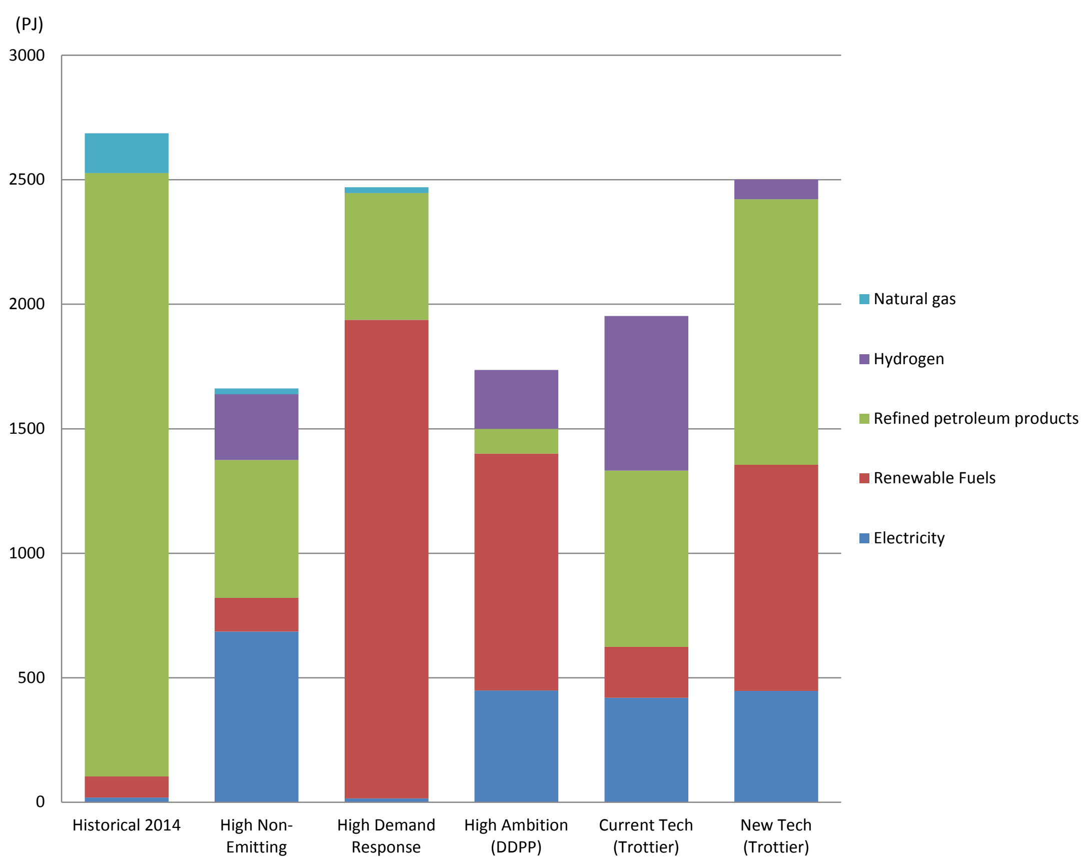
Figure 8: 2050 Transportation Sector Energy Use Projections (PJ)



of the upcoming Tesla Model 3 electric vehicle, an estimated 36,000 have been made in Canada.[56]

While the production costs of electric vehicles remain higher than traditional gasoline vehicles, a more significant challenge limiting electric vehicle adoption is consumer concerns regarding the range of the battery charge. Charging speeds and battery range currently do not allow for comparable refueling times when benchmarked against traditional gasoline vehicles. In some circumstances, cold weather can also reduce electric vehicle driving range. However, studies have found that the current battery range for electric vehicles is sufficient to satisfy close to 90% of personal vehicle use. For example, a study from the Massachusetts Institute of Technology used GPS data to estimate the energy requirements of personal vehicles across the United States, determining that 87% of requirements could be met with current electric vehicles.[57]

In addition, there are significant efforts put in place to increase fast charging infrastructure in some Canadian jurisdictions, which can allow the average electric car to charge 80% of its battery capacity in 30 minutes. Although needs for infrastructure investments will be important in the coming years, it is important to note that chargers will not need to be as abundant as fuel dispensers are today, as more than 95% of charging is done at home, and public charging stations generally only need to be used when motorists travel long distances.

4.1.3 Low-carbon and renewable fuels are consistent with low-GHG scenarios, particularly in areas that face challenges with electrification.

Low-carbon, renewable fuels, and hydrogen are of particular importance for areas that are hard to electrify. A number of renewable fuels are already commercially available such as ethanol, biodiesel or biofuels. Fuel blends contain varying renewable content, and environmental benefits expand when second-generation biofuels are used. Unlike other modes of transportation, the aviation industry has few options available for reducing GHG emissions. Improved technological and operational measures will have their role, but only low-carbon alternative fuels (biojet) have the potential to offer significant life-cycle GHG emission reductions.

Renewable natural gas offers the potential to achieve considerably greater emissions reductions than natural gas. Biogas, generated from biomass from landfill sites, agriculture, wastewater, or other sources is upgraded to natural gas quality. It can then be directed to the grid for use in buildings or transportation applications in the form of compressed natural gas (CNG) or liquefied natural gas (LNG).

Natural gas vehicles are used in several fleets around the world. Up to a 25% reduction in carbon dioxide equivalent emissions can be achieved on a well-to-wheel basis when replacing gasoline with compressed natural gas in light-duty vehicles. Natural gas can be an effective solution for transportation that is harder to electrify such as on-road freight, marine shipping and rail, featuring relatively quick refueling times and long ranges. As such, it has been a key area for research and development for these modes. Natural gas also has the advantage of significantly improving air quality and reducing noise when compared to diesel.

Hydrogen fuel cell technology can also help decarbonise the transportation sector. The process of producing electricity with a fuel cell involves hydrogen and oxygen as inputs, and produces water vapor and heat at the tailpipe, therefore emitting no GHG emissions. However, hydrogen production currently either requires significant amounts of electricity to be produced through electrolysis, or can be produced with methane reforming, which is an emitting process.

Hydrogen fuel cell vehicles provide the benefit of having similar refueling times when compared with internal combustion engine vehicles, but they also face important barriers such as the cost of fuel cells, cost and energy intensity of hydrogen production, and the need for new infrastructure for hydrogen refueling stations. Nonetheless, hydrogen is a key component of several modelling exercises including the IEA and Deep Decarbonization Pathways Project. For example, the IEA has modelled different levels of Fuel Cell Electric Vehicle adoption. So far, Toyota and Hyundai have commercialised fuel cell electric vehicles in Europe, South Korea, California, Vancouver and Japan and further investments could help to accelerate infrastructure deployment. For example, there are already several hydrogen stations and buses in Whistler, British Columbia. Hydrogen is used widely in industry for ammonia production and refining, and can be used for storing the energy in excess renewable electricity. Canada is well placed in the development of hydrogen and alternative fuels with companies such as Westport innovations and Ballard, developing and exporting these low carbon technologies.

56 Model 3 Tracker, *Known Sport of Model 3 Vehicles by Status.*
57 Needell, Z., *Potential for Widespread Electrification of Personal Vehicle for Travel in the United States.*

Modelling results from very low greenhouse gas scenarios for 2050 point to various avenues to power Canada's transportation sector (*see description of models and scenarios in Modelling and Scenario Box in Chapter 2*). Currently, refined petroleum products (e.g., gasoline, diesel) power over 90% of Canada's transportation energy requirements. Under scenarios where aggregate Canadian emissions decline dramatically in 2050, the energy portfolio of the transportation sector shifts considerably (*see Figure 8).*

Under ECCC's first High Non-Emitting scenario, electricity powers 41% of transportation energy requirements in 2050, whereas renewable low-carbon fuels account for 8%. The remaining requirements are met with hydrogen (16%) and natural gas (1%), although refined petroleum products continue to power 33% of the vehicle fleets including air and marine transportation. In comparison, ECCC's High Demand Response model points to renewable and low-carbon fuels dominating the transportation energy portfolio (78%). In this modelling scenario, electric vehicles do not penetrate the market.

The Deep Decarbonization Pathway Project also points to a high penetration of renewable and low-carbon fuel powered vehicles (55%). Electricity makes up 26% of the power requirements from the transportation sector, whereas hydrogen accounts for 14%. Under the Trottier analyses scenarios, renewable or alternative fuels power 10-18% of the transportation requirements in 2050. Electricity powers 18-21% and hydrogen powers 3-32%. Refined petroleum products continue to power 36-43% of the sectors energy requirements.

4.1.4 Freight transport is a challenging sector, but there are a number of solutions that show potential towards deeper emissions reductions.

Freight transportation, *such as heavy duty on road vehicles, aviation and marine is a challenging area for GHG mitigation*. Improving the fuel efficiency of freight transportation is essential to reducing greenhouse gas emissions from this subsector. Moreover, alternatives to conventional internal combustion engines exist including vehicles that run on fuels such as biofuel blends, liquefied petroleum gases, or natural gas. The use of these fuels can reduce the GHG intensity of road transportation, sometimes significantly.

Electrification of freight transport is currently limited due to technological constraints such as insufficient range for long-haul shipping, long charging times for delivery requirements, as well as the significant energy requirements and engine sizes required to transport heavy loads. However, some companies have revealed plans to develop electric freight transport in the coming years. For example, last July

CANADIAN BUSINESSES ADOPTING LIGHT FREIGHT ELECTRIFICATION

A number of Canadian companies, and companies operating in Canada, have opted to green their fleet through the use of hybrid-electric vehicles or fully electric vehicles. For couriers and other shipping companies, fleet management and fuel use has a major impact on operating costs, and is constantly being reviewed to minimise costs and increase performance. Some companies have opted for electric vehicle technology for both economic and environmental benefits.

As a few examples, Canada Post, Purolator, the United Postal Service, Fedex, and Novex have moved towards more sustainable transportation solutions for shipping. Other initiatives, such as a fully electrified taxi company, have been developed, for example in Montréal by Téo Taxi. Although information gaps appear to be an important barrier to adoption of electric vehicles by small and medium enterprises, several companies are providing support services to demonstrate the business case for greening vehicle fleets. This involves procedures such as calculating expenditure impacts, renting out vehicles to allow for trials, and providing technical support for charging infrastructure management.

Another company, Communauto, North America's oldest and largest car-sharing company, has recently announced its purchase of 600 hybrid-electric or fully electric vehicles. Among these vehicles, 515 are destined to the Québec market, while the remainder will be distributed to Communauto's European market. Ride-sharing services also displace a significant amount of personal vehicle requirements, thereby reducing GHG emissions further.

Mercedes-Benz unveiled its latest electric prototype, the Urban eTruck, conceived for dense urban areas. The fully electric vehicle has two electric motors, can hold 3 batteries, and will be able to support up to 26 tons. Conceived for short distances (200 kilometers) and use in heavy traffic, Mercedes-Benz expects to commercialise the vehicle by 2020.[58]

Despite continuous progress, there are some challenges associated with reducing emissions from freight transportation. Finding economical means of producing biofuels and alternative means of transporting merchandise will be key.

Figure 9: An Urban eTruck[59]

A large deployment of heavy electric trucks may take longer than cars since the turnover rate of heavy trucks is significantly lower than for cars (30 years for trucks compared to 20 years for cars). Emissions from aviation, marine, and rail transport are also challenging to reduce due to the high energy density of fuel required with these modes. Despite these challenges, the energy intensity of the freight transportation sector decreased from 1.38 MJ/Tkm in 2011 to 1.30 MJ/Tkm in 2013. A recent report from the Conference Board of Canada suggests that much greater performance and efficiency improvements will be needed to help bring Canada to deep decarbonisation in the transportation sector.[60]

In 2013, new federal regulations imposing GHG emission standards for new on-road heavy-duty vehicles and engines were implemented to align with U.S. national standards and move the Canadian heavy truck fleet toward more fuel efficient vehicles. In the marine and rail sectors, where fuel represents a significant share of overall costs, operators are actively seeking improvements in fuel efficiency and GHG performance through new technologies, designs and system efficiencies, and are exploring a shift to low-carbon fuels. For marine shipping, mandatory technical and operational emissions reduction measures established by the International Maritime Organization (IMO) are also driving efficiency improvements. However, significant emissions reductions will take time as the existing stock of ships and locomotives turn over. Electric and alternative fuel solutions can also achieve meaningful reductions from port and cargo handling equipment at transportation hubs.

4.1.5 Emerging technologies such as energy storage or advanced lightweight materials will increase energy efficiency and decrease emissions; innovative approaches to moving people and freight are likely to become more widely adopted by mid-century.

Looking forward, improvements in energy storage technology will facilitate the adoption of electric vehicles. The most anticipated technological development related to battery storage is the use of graphene in batteries, which would allow for a significantly higher energy density (battery capacity per unit of weight), significantly faster recharging times, and lower costs. Graphene is abundantly available and the emergence of graphene batteries could be a tipping point where electric vehicles will become more affordable and convenient, broadening adoption.

Connected and automated vehicles, combined with smart infrastructure, are expected to be increasingly deployed by automakers, and have the potential to not only make driving more convenient, but considerably safer, and more efficient, which can lead to improved environmental outcomes. While not as significant as the impact of electrifying transportation, efficiency improvements from autonomous driving could be important. With quicker reaction times than humans, connected and autonomous vehicles can circulate with less distance between cars, allowing for much more efficient traffic movement (e.g., reduced idling, smoother acceleration), and perfectly safe slipstreaming (i.e., cars avoiding wind resistance by following others closely), resulting in less energy wasted. The expected safety improvements and reduced congestion could add up to large fuel savings, with significant co-benefits for the economy and the environment.

Finally, advanced lightweight materials and manufacturing methods will need to be integrated

ELECTRIFIED PUBLIC TRANSPORT AND SMART URBAN PLANNING

In the transition to a low-carbon economy, public transportation provides significant GHG emission reductions as compared with personal vehicles, but diesel buses still emit a sizeable amount. More recently, advances in the development of batteries for electric vehicles have spilled over to city buses. For example, the city of Gothenburg has been using three electric buses on one line of its public transport service, and has been using seven hybrid electric buses. Although the buses are significantly more expensive than diesel buses upon purchase, the fuel savings rapidly compensate this difference. The buses are charged for six minutes between trips, allowing for more than enough range for the route they serve, while providing outlets to charge phones and providing Wi-Fi to users inside the buses.[61] Similar projects are under way in Montreal, starting with hybrid-electric buses.[62]

Another important consideration in transitioning to a low carbon economy is how to plan and design cities in order to support low-emission technologies and lifestyles, and correct for the traffic congestion levels that are seen in large Canadian cities. Congestion is an important cost to the economy, evaluated in 2008 as costing the regional economy of the Greater Toronto and Hamilton Area, directly and indirectly, $6 billion annually.[63] This kind of structural change will take time to realise, but governments can start building momentum in the short-term by deciding to take a holistic approach to development through integrating land use, transportation, energy production and community planning.

More and more, cities are looking into innovative solutions to reduce congestion on their roadways. For example, the city of Edmonton is one of two Canadian cities taking part in a North American program aimed at developing Connected Vehicle Technology.[64]

This technology can improve many elements of transportation in cities, by preventing collisions between cars, by guiding drivers through detours when there is a slowdown or an accident on the road, and even adjusting traffic lights along the detour routes to minimise congestion. Other technological advances are leading to autonomous vehicles and greater use of vehicle sharing, which stand to have important impacts of the future movement of people within cities. Technological advances also help pave the way for new management approach by cities and governments, such as the use of efficient pricing of tolling mechanisms. For example, High Occupancy Tolls Lanes allow for both vehicles with enough passengers and permit holders to drive in these lanes, allowing for reduced congestion and revenues that can be invested into public transit.

across all modes of transportation to increase efficiency, from on-road electric vehicles to aviation. Other considerations to reduce transportation emissions include: retrofit of heavy-duty vehicles including tractors with GHG-reducing technologies (aerodynamics, auxiliary power units) and the scrappage of less efficient vehicles.

64 City of Edmonton, *On the Front Edge of Smart Vehicle Technology.*

4.1.6 Modal shifts, such as moving passengers and freight to less GHG intensive modes, could offer notable emissions reductions, which would be further strengthened through clean technology deployment, such as electrified passenger rail.

Given the emissions profile and current limitations in electrifying freight transportation, a shift towards rail transit for a majority of freight could reduce the amount of energy needed to move goods around the country. Although rail transportation entails issues such as longer shipping times, and less flexibility in terms of routing of goods, it has the potential to reduce emissions per unit of goods moved by about 75% compared with on-road vehicles for the same distance travelled.[65] As for passenger transportation,

65 Association of American Railroads, *Freight Railroads Help Reduce Greenhouse Gas Emissions.*

rail offers another potential avenue for intercity travel, which could reduce emissions compared to personal vehicles or bus transportation. Other benefits to shifts toward rail transportation include reduced wear and tear on roads and reduced road congestion.

In addition to being less GHG-intensive than on-road modes of transportation, there may be an opportunity to reduce emissions even further through electrification of Canada's passenger rail systems moving on dedicated tracks. Heavily populated corridors, such as the Windsor-Quebec axis, represent prime areas for such a system. Although this type of project requires significant capital expenditures, important savings can be realised through reduced energy costs, increased performance allowing better optimisation (e.g., allowing more units to be attached to the same locomotive), and reduced maintenance costs.[66] Electrification of trains also provides other benefits in the form of smoother rides, reduced power load at higher altitudes compared with diesel, and service to underground locations (which is not possible for diesel given emissions of pollutants).

Electric light-rail trains represent an interesting mode of transportation for public transit, as it is up to 10 times cheaper than underground metro systems for the same distance covered.[67] At this cheaper cost per kilometer, light-rail trains become particularly appealing for bringing commuters from suburban areas into cities faster, while reducing the amount of vehicles in downtown areas. Light-rail trains are also easier to electrify than buses, which makes it a less GHG-intensive transit option than buses, while also reducing the cost of electrification.

4.1.7 62% of Canada's black carbon emissions arise from the Transportation sector. In addition to being linked to climate warming, black carbon emissions are also a public health concern. Canada continues to take complementary action to reduce black carbon emissions.

The transportation sector emits significant amounts of black carbon mostly through diesel engines and vehicles. Canada continues to take regulatory action to address air pollutant emissions from transportation, which also reduces black carbon, including regulations for on- and off-road diesel vehicles and engines manufactured or imported for sale in Canada. Regulations to implement the North American Emissions Control Area to reduce emissions from shipping also reduce black carbon emissions.

In addition to being linked to climate warming, black carbon emissions are also a public health concern. As a component of $PM_{2.5}$, black carbon particles are small enough to be inhaled and absorbed into the lungs and bloodstream. Reductions in black carbon emissions from the transportation sector have important co-benefits for the health of Canadians.

4.2 Buildings

KEY MESSAGES:

- Over one third of Canadian homes are already heated and cooled with clean electricity; emerging technologies will make this option increasingly economically attractive.
- Natural gas continues to play an important role in heating and power requirements. Renewable Natural Gas is a small but growing part of the supply mix meeting those energy needs.
- The electrification of the building sector should be matched with a scale-up of energy efficiency measures.
- District heating for residential and commercial buildings could help lower GHG emissions since heat is generated in a centralised location with non-emitting fuel options.
- Life cycle assessment quantifies holistic environmental impacts of buildings, enabling optimal decisions in sustainable design.
- Retrofitting existing buildings will be necessary to address the inefficient building stock that could otherwise stand well beyond mid-century.
- Smarter, more sustainable cities are key to a prosperous future.

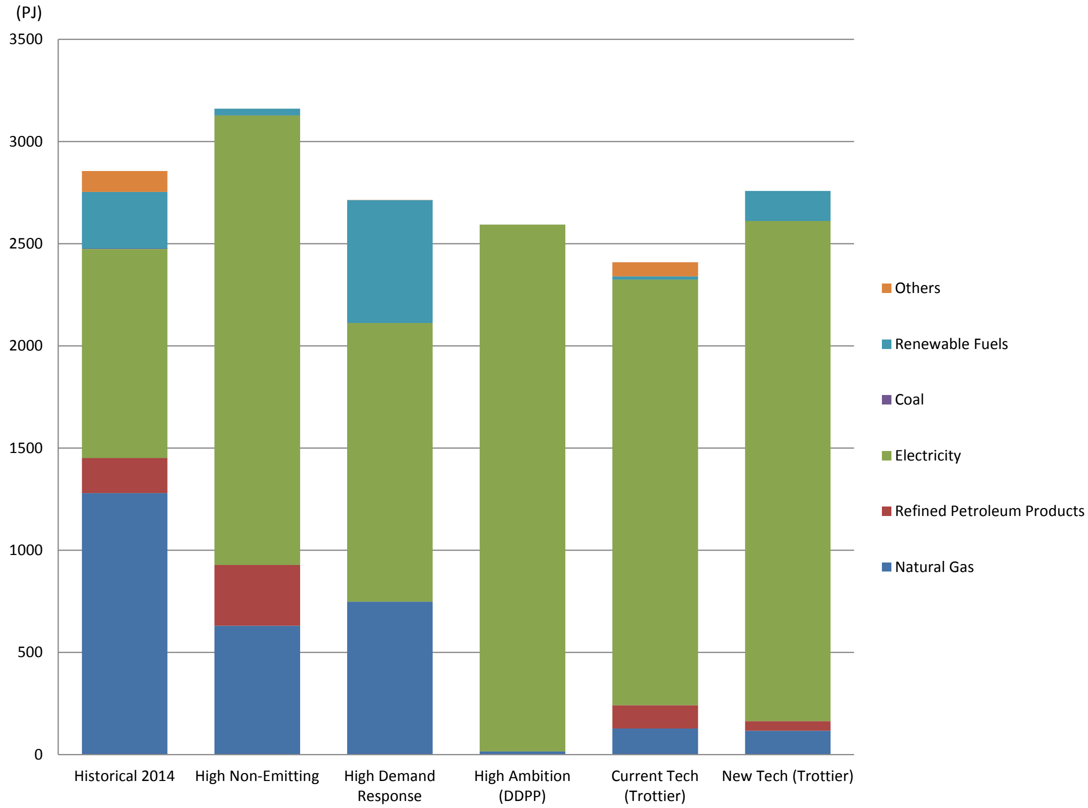
Figure 10: 2050 Building Sector Energy Use Projections



4.2.1 Over one third of Canadian homes are already heated and cooled with clean electricity; emerging technologies will make this option increasingly economically attractive.

Emissions from the buildings sector arise from residential, commercial, and institutional buildings, as well as the equipment in them. The building sector is currently one of the most GHG-intensive in Canada and is the third largest emitting sector representing 12% of Canada's emissions - with emissions currently projected to grow through 2030. However, a number of measures can help to achieve reductions in the sector including fuel-switching and energy efficiency.

Some Canadian homes and commercial buildings already rely on clean electricity to power their heating, cooling, lighting and appliances. Current technology such as electric boilers, electric baseboards, space heaters, and heat pumps can be used instead of fossil fuels, resulting in zero greenhouse gas emissions when combined with a non-emitting electricity portfolio. In 2011, 39% of Canadians households used electricity for their heating equipment. Electricity was the predominant energy sources for heating in Quebec (66%), Newfoundland and Labrador (56%) and New Brunswick (48%). [68]

Current technologies that may become more cost effective in the future include electrically driven geothermal and air source heat pumps, and increased use of ambient solar heating. Air-source heat pumps can draw heat from the air and transfer warm air inside during the winter or outside during the summer.[69] Ground-source heat pumps, also called earth-energy systems, can use energy from the ground to produce heating and cooling and are being increasingly used across Canada. Due to their high efficiency, ground-source heat pumps can yield energy savings of up to 40% higher than an air-source pump but require higher up-front installation costs.

Solar energy for homes also offers many advantages and helps lower grid-related energy requirements. New technologies are emerging to better generate photovoltaic energy for homes such as: solar roadways, solar shingles, solar panels installed on the sides of buildings, and thin solar films that can be applied to any metal roofing.

68 Statistics Canada, *Households and the Environment: Energy Use (11-526-S)*
69 Natural Resources Canada, *Coming to Terms with Heat Pumps*

Figure 10 illustrates the current use of energy in the building sector as comprising of natural gas (45%), electricity (36%), renewable fuels (10%) and refined petroleum products (6%). Modelling projections for a low GHG economy in 2050 take into account a variety of factors such as potential provincial energy codes amendments, regulations on new buildings requirements and technological costs. Note that the projections do not take into account a potential increase in the use of clean district heating systems in Canada.

In all of the low-GHG analyses, the share of energy met through clean electricity increases from today's levels. The first ECCC low-GHG analyses (High Non-Emitting) illustrates electricity at 70% of the energy use of the building sector by 2050, while the second projection (High Demand Response) estimates electricity to be 50% of energy use in the sector (renewable fuels represent 22%).

The DDPP scenario demonstrates that electricity increases to fulfill 99% of the building sector's energy requirements in 2050 (with 1% remaining for natural gas). The Trottier Institute, demonstrates two scenarios where the share of electricity increases to 86-89% of total energy use in the sector by 2050, where the remaining requirement is fulfilled through natural gas (4-5%), renewable fuels (4-5%) and refined petroleum products (2-5%).

4.2.2 Natural gas continues to play an important role in heating and power requirements. Renewable Natural Gas is a small but growing part of the supply mix meeting those energy needs.

Across most scenarios, natural gas, a relatively lower emitting fossil fuel, continues to power some heating and other requirements in the building sector. Natural gas can also be substituted for Renewable Natural Gas where desirable, without replacing capital or infrastructure, such as natural gas home furnaces. Generally, Renewable Natural Gas is fully interchangeable with conventional natural gas.

Methane that is released from sources such as landfills, agricultural residues, livestock production, sewage treatment plants, and forestry waste can be recovered, cleaned, and can be directly substituted for conventional natural gas.

4.2.3 The electrification of the building sector should be matched with a scale-up of energy efficiency measures.

Increasing energy efficiency is particularly important in the Canadian building sector, as Canadian households consume an average of 11,000 KWh of electricity per year (2010). By comparison, this is just under the U.S. average (12,960 KWh), and well above Australia (7,350 KWh) and EU countries' average such as France (5,760 KWh), the United Kingdom (4,510 KWh) or Germany (3,515 KWh).[70] This is generally attributable to Canada's cold climate and relatively large sizing in residential housing.

Energy efficiency improvements can be realised either through the design of a building's system, including air sealing, better construction materials, passive heating, insulation, white roofs, triple pane windows; or more energy efficient equipment and appliances including heat pumps, condensing boilers, high efficiency cooling, energy-efficient lighting and appliances, and energy management control systems. Development of highly efficient heating and cooling technologies, such as energy management systems and smart thermostats, can reduce costs and improve performance of heating, ventilation, and air conditioning.

In Canada, provincial and municipal building energy codes and federal energy-efficiency standards are important tools for driving energy productivity improvements. Future policies will need to ensure that energy efficiency programs and energy supply fuel-switching both correspond to low-GHG objectives.

Energy efficiency in the buildings sector has numerous co-benefits such as infrastructure resilience and lower operating and maintenance costs, as well as positive effects on national income and employment. Moreover, several studies have pointed to increased health benefits from better designed buildings in terms of lower risks of respiratory and cardiovascular conditions, rheumatism, arthritis or allergies. Lastly, energy efficiency savings can be beneficial for lower income Canadians.

4.2.4 District heating for residential and commercial buildings could help lower GHG emissions since heat is generated in a centralised location with non-emitting fuel options.

District heating (also known as heat networks or teleheating) is a system for distributing heat

70 World Energy Council Indicators, *Average electricity consumption per electrified household,*

generated in a centralised location for residential and commercial heating requirements such as space heating and water heating. These systems have the potential to help reduce GHG emissions, by utilising low-carbon fuel options such as waste heat or biofuel.

District heating is the dominant heating system in Nordic countries (except for Norway). In those countries, biomass, natural gas, and municipal solid waste biogas are commonly used as energy sources for district heating. Specifically, biomass is used as fuel for 60% of district heating system in the Swedish building sector, 40% in Denmark, and 70% in Finland. Canada has similar geographical and climatic conditions and has thus a vast and untapped potential for extensive district heating systems.[71]

4.2.5 Life cycle assessment quantifies holistic environmental impacts of buildings, enabling optimal decisions in sustainable design.

Life cycle assessment (LCA) is a scientific method for measuring the environmental footprint of materials, products and services over their entire lifetime. Applied to a building, LCA measures environmental impacts like energy consumption and greenhouse gas emissions at every stage of a building's life. It includes raw resource extraction, product manufacturing and transportation, building construction, operation and repair, and demolition.

LCA helps building designers consider the total environmental impact of material choices and other design decisions. Designers use LCA to examine trade-offs and alternatives, for the lowest possible lifetime environmental footprint of the building. This data-driven process allows building designers to test and validate their sustainability decisions.[72]

4.2.6 Retrofitting existing buildings will be necessary to address the inefficient building stock that could otherwise stand well beyond mid-century.

According to the *Canadian Housing and Mortgage Corporation*, Canadian residential construction has grown at an average rate of 1.5% in the past five years.[73] At this rate, the built residential environment would double in Canada in approximately 50 years from today, well past mid-century. New construction has been addressed in the previous sections, but the dominating remaining building stock could mostly remain standing in 2050. According to the IEA, close to 75% of the OECD countries building stock from 2010 will still be standing in 2050.

Therefore, new building energy code regulations on their own will not be enough to achieve significant GHG emissions reductions from by 2050 and additional efforts will be needed to address existing buildings. The same is true in the industrial and commercial building subsectors.

Making existing buildings more energy-efficient through retrofitting is an important step towards reducing GHG emissions reductions in Canada. Retrofitting requires investments, especially in the case of deep retrofits where significant parts of the building must be refurbished. Different retrofit rates are found around the world depending on type of buildings, climate and costs. For example, EU member countries have an energy savings retrofit target rate of 3%/year for government owned buildings.[74] Similarly, Germany has a target of thermal retrofitting 2% of total residential buildings per year.[75]

Energy management practices, including energy benchmarking, audits, and on-going building optimisation can help generate better understanding of buildings energy usage and costs, identify areas of opportunities, and make improvements where and when necessary. They can also provide green solutions for systems that are embedded in the building and may be harder or more costly to replace.[76]

4.2.7 Smarter, more sustainable cities are key to a prosperous future

Urban planning and design will be key to making building sites and designs work together to enable lower GHG solutions. In a low-GHG economy, for example, communities should be making effective use of local energy sources ranging from on-site renewable energy to waste heat and organic waste, allowing optimal use of clean energy grids. District energy networks will distribute thermal energy for

LOW EMISSIONS OPERATIONS AND GOVERNMENT PROCUREMENT

Governments have an important leadership role to play in the transition to a low-carbon economy given the size of their operations. By implementing ambitious policies, federal, provincial and territorial governments can lead by example on many aspects of the low-carbon transition. Canada's Federal Sustainable Development Strategy has developed objectives for greening government operations.[77] The federal government has adopted a target to reduce emissions by 40% from 2005 levels by 2030, with the aspiration to achieve it earlier, potentially by 2025. Furthermore, the government has committed for all operations run by Public Services and Procurement Canada to use 100% of their electricity purchased from clean power, and to significantly increase the energy efficiency of federal buildings, with the goal of cutting emissions almost in half. Several provinces, such as British Columbia, Quebec, and Ontario, have also adopted targets to reduce emissions or to achieve carbon neutral operations.

Governments can lead the way in many areas, such as green procurement, green buildings, energy efficiency measures, and other green investments. New government buildings could require a certain type of environmental certification, as green buildings are generally recognised to have a positive effect on the asset value.[78] For older buildings, the use of deep retrofits would help to substantially reduce energy costs and GHG emissions. The use of energy performance measurement could help to better understand and improve energy use. Governments could also encourage the use of public and active transportation as well as flexible working arrangements such as telework.

Green procurement is one way in which the government can reduce its environmental footprint and increase domestic demand for clean technologies and other environmentally preferable goods and services. For example, the federal government's Policy on Green Procurement targets specific environmental outcomes where procurement can effectively be used to mitigate the impact of environmental issues, such as climate change. Allowing climate considerations to be streamlined into the procurement process, such as the disclosure of climate performance, could more accurately benchmark and compare different product and services. The purchasing power of governments could also be used to support the development of green technologies. Governments could also help to accelerate the adoption of certain green products such as electric vehicles with charging stations at work locations.

In some sectors, there are opportunities to take a more important role in greening their operations. The defense sector is increasingly recognising the strategic importance of having alternative sources of power and the potential cost savings. The Pentagon has become the second largest purchaser of long-term renewable electricity contracts in the U.S., according to Bloomberg data.[79] Low-carbon opportunities exist for Department of National Defense and other government departments that have large fleets.

It is important that governments explore best practices on greening government operations by learning from other jurisdictions. This is important for developing knowledge and raising ambition over time in order to be innovative and creative in finding solutions.

heating and cooling, while smart electrical grids manage local energy supply and demand. Energy storage systems could help to balance variations in supply and demand for heating, cooling and power while local industrial, commercial, and agricultural enterprises approach energy in an integrated way. Finally, businesses could take advantage of waste heat, use renewable fuels, and capitalise on opportunities as energy producers.

AN ELECTRIFICATION SUCCESS STORY

Mining vehicles typically require energy-dense fuels to move and lift heavy loads. However, in 2008, SBC Case Industries, PapaBravo's parent company, initiated an R&D project to develop electric vehicles for use in potash mines. Later, PapaBravo developed a business plan based on R&D technology with the support of the National Research Council's Industrial Research Assistance Program. The company was able to develop many vehicles such as the Marmot-EV and a second-generation truck able to function in environments other than potash mines. The vehicles have a range of about 120 kilometres and can recharge in less than an hour. The Saskatoon firm PM&P which acquired PapaBravo in 2015 is now a global competitor in electric mining vehicles and is doing business in Canada, South Africa, Australia, and New Zealand.[80]

4.3 Industry

KEY MESSAGES:

- National circumstances represent challenges for the decarbonisation of Canadian industrial sectors.
- Electrification of industrial operations offers emissions reduction potential.
- Cogeneration reduces waste heat and generates thermal and electric energy, thereby producing environmental and economic benefits.
- Other improvements in energy efficiency through innovative ways of optimising energy production and consumption will be essential.
- Carbon capture and storage, fuel switching to non-emitting fuels, and recycling can also reduce emissions. These technologies continue to improve.
- Nevertheless, there remain challenges in reducing emissions from some sectors, for which innovation and research and development will be necessary.

4.3.1 National circumstances challenge the decarbonisation of Canadian industrial sectors

Historically, Canada has benefited from an internationally competitive economy based on low-cost natural resources and accompanying industrial activities. These activities face significant challenges to decarbonisation:

- Canada's energy sector is an important driver of the Canadian economy. Canada's exports of energy, extracted resources, and agricultural commodities are significant contributors to the gross domestic product. Also, Canada is a net energy exporter. It is the world's fourth largest exporter of crude oil and fifth largest exporter of natural gas.
- Canada's oil and gas sector is GHG intensive due to the energy required in the primary extraction of fossil fuel and other natural resources.
- Industries are concentrated in particular areas of the country, making distributional impacts of abatement policies a particular concern. Regional cooperation and progressive mitigation policies will be key to ensure that decarbonisation efforts do not disproportionally affect certain regions.
- Over 75% of Canada's total industrial energy use is consumed in the mining, pulp and paper, iron and steel, cement, smelting and refining,

80 National Research Council Canada, Revolutionizing Canada's Mining Industry with Electric Vehicles.

chemicals, and petroleum refining sectors. The greatest portion of energy (about 70%) is used for heating purposes such as thermal treatment (mainly in heaters and furnaces), drying, and steam generation. These emissions are more challenging to reduce than in other sectors due to the high heat requirements of certain processes. Technology solutions exist, often with deep GHG reduction potential, however market barriers to adoption are such that significant investments may be required to achieve large-scale commercial uptake.

4.3.2 Electrification of industrial operations offers emissions reduction potential

Many Canadian industries are already electrifying their operations or discovering other innovative ways to lower GHG emissions. For example, motor systems such as pumps, fans, conveyers, and compressors are almost entirely powered by electricity in some sectors. Electrified operations can be set for production during off-peak electricity periods to benefit from lower electricity prices. Specific sub-sectors, such as the aluminium industry, where smelting processes are highly energy intensive, are already relying on non-emitting electricity to fulfil their power demands. The energy intensity of aluminium plants has also decreased over time, leading to reduced electricity demand per unit of output.

In the iron and steel sector, some Canadian plants operate with electric arc furnaces that produce steel from recycled metal and require significantly less energy compared to conventional processes using ore. In the glass industry, electric glass melting tanks can be used, while in the pulp and paper industry, electricity can be used for mechanical pulping. In the mining sector, hybrid diesel-electric equipment could be used in underground mines and fully electric vehicles could further reduce emissions and diminish needs for ventilation.

In Canada's oil sands, extracting and upgrading bitumen is an energy-intensive process where large amounts of thermal energy and electricity are used. Further electrification of processes, including the electrification of heat (for example electro-thermal or radio frequency electromagnetic heating), provides an avenue to decarbonisation, but requires a clean electricity source.

The adoption of electric steam generators to replace natural-gas fired steam generators could reduce direct emissions. Electric steam generators use electric resistance elements to produce steam and heat, and the conversion of electricity into thermal energy is very efficient. It is technically possible for the separation of bitumen, hydrogen production for upgrading, and refining and pipelining operations to use electricity instead of natural gas.

A study by the Canadian Energy Research Institute has looked at scenarios for the electrification of oil sands production using hydropower and increased electricity transmission capacity. Overall, the study finds that the use of hydropower could potentially reduce the GHG emissions of oil sands operations by 13-16%. Reductions are possible from a range of technologies that could require significant investment in infrastructure as well as the application of new technologies. The potential for reductions could be even higher with the development of in-situ extraction using electricity for heating purposes, but many of these technologies are still under development.

In general, several options exist to decarbonise heavy industry, but significant R&D, piloting, and commercialisation support are required to allow their penetration.

4.3.3 Cogeneration reduces waste heat and generates thermal and electric energy, thereby producing environmental and economic benefits.

Cogeneration, also called combined heat and power (CHP), produces electrical and thermal energy simultaneously by using a single fuel for heating or cooling applications. Cogeneration allows for gains in energy efficiency as it can use waste from one process as an energy input into another. The main types of cogeneration systems include steam turbines, gas turbines, reciprocating engines, microturbines, combined cycle gas turbines and organic rankine cycles. Cogeneration requires maximizing electricity production, while matching thermal load requirements to the extent possible in terms of quantity and energy quality.[81] The energy savings from cogeneration relative to standalone generation range from 5% to 35%.

In Canada, about 7% of electricity generation is produced from cogeneration. Most energy generated from cogeneration (both electric and thermal) is from the utility, paper and wood products, and oil and gas extraction sectors. Growth in cogeneration occurred during two periods. In the

81 Canadian Industrial Energy End-Use Data and Analysis Centre, Cogeneration Facilities in Canada 2014, p. 7.

1970s cogeneration capacity increased in response to a significant increase in energy prices. The second period of growth occurred in the 1990s as a response to many socio-economic factors including increasing cost-effectiveness and full retail access to the electricity grid in Alberta. Cogeneration has the potential to achieve significant energy savings, particularly in the oil sands sector, as the extraction and upgrading processes require large amounts of heat and steam.

In order to fully maximise the potential of cogeneration to reduce GHG emissions, the adoption of certain technologies may be necessary, including those that optimise load matching, improve operations in harsh environments, and allow for biomass gasification, advanced power cycles, and high-penetration of renewables into fossil thermal cycles (e.g., solar thermal pre-heating of the inlet air to gas turbines).

4.3.4 Other improvements in energy efficiency through innovative ways of optimising energy production and consumption will be essential

Energy efficiency measures that improve processes and reduce heat loss can be implemented across sectors using current best available technologies. Heat management practices can improve heat production and heat transfer to and within process users. Innovative waste heat recovery technologies can help reduce energy consumption, production costs, and emissions in industrial facilities.

Energy efficiency measures include process optimisation; operation and control improvement; waste heat recovery and upgrading for heat, cold, or power production; and new technology and process development. Examples of process optimisation include adopting proper motor sizes to optimise power use, and using adjustable-speed drives. Frequent and proper maintenance and repair can also improve energy efficiency of equipment. In some industries, there are potential solutions which involve entirely changing production processes to reduce energy requirements. For example, the pulp and paper industry can use chemical additives to reduce the heat required to dry paper.[82]

For the oil and gas sector, energy efficiency and energy use optimisation can amplify the emissions abatement potential of electrification and other options. For example, deploying energy management systems to oil and gas facilities and improving energy efficiency through programs and standards could help drive significant reductions in the demand for energy. Although electrification is key, the recovery and use of waste heat should be pursued across subsectors concurrently. Other innovative ideas that could support energy use optimisation include the development of industrial eco-parks which facilitate the exchange of excess energy and industrial by-products, and minimise transportation requirements between facilities.

In oil sands operations, the adoption of innovative low-carbon extraction processes offers potential GHG emission reductions. Advanced technologies, such as solvent and electrothermal-based extraction methods for in situ, or direct contact steam generation, are at a stage of development whereby they offer a substantial opportunity to reduce emissions. These innovations could offer up to 50% GHG emissions reductions per barrel produced and could prove pivotal in delivering economically and environmentally competitive fossil fuel supplies to a decarbonising global market. Vacuum-insulated tubes can also be used to save heat in the process of moving the steam down the well and could accelerate the pre-heating process of the well significantly.[83] Further, some of these innovative extraction techniques leave the heavier contents of the bitumen in the reservoir, meaning less diluent is needed in pipelines. Not having to store these heavier contents, for which there are fewer markets, also reduces operating costs and GHG emissions.

In the mining industry, ventilation-on-demand can be adopted to reduce the energy consumption required to ventilate underground metal mines. For example, a medium-size nickel mine with diesel equipment and 10 operating levels emits about 10,000 tonnes of CO_2 annually. Estimated energy cost savings from the adoption of ventilation on demand technology can reach 50% depending on the size of the mine.

4.3.5 Carbon capture and storage, fuel switching to non-emitting fuels, and recycling can also reduce emissions. These technologies continue to improve

Beyond the electricity sector, carbon capture and storage (CCS) also has potential in the oil and gas, iron and steel, pulp and paper, chemical, and cement sectors. CCS is currently being used to capture emissions from steam methane reformers. The Shell Quest Project, which has been in operation since November 2015, captures and

82 Energy Economics, Optimizing the Energy Efficiency of Conventional Multi-Cylinder Dryers in the Paper Industry, p.35.

83 Council of Canadian Academies, Technology and Policy Options for a Low-Emission Energy System in Canada, p. 92.

THE USE OF BIOMASS FOR CEMENT MANUFACTURING

Bioenergy as a replacement for fossil fuels in cement making is currently at the commercial demonstration phase in Canada. For example, the Lafarge plant in Bath, Ontario, was funded under the ecoENERGY Innovation Initiative to demonstrate a 10% coal-to-biomass fuel switching project. This includes processing the raw materials into a useful form, developing and installing an injection system, running fuel trials, and compiling the results of the carbon savings resulting from this process. The results of these trials will inform the permanent use of low-carbon fuels at the Bath plant and could be used by other companies in the cement industry.[84]

sequesters 1 million tonnes of CO_2 per year from the Shell Scotford steam methane reformers. The Alberta Carbon Trunk Line (ACTL), a project under development, is a 240 km pipeline that will capture and use CO_2 emissions for enhanced oil recovery from the facilities in the Alberta Industrial Heartland. The initial industrial facilities that will capture and supply CO_2 are Agrium Inc. and the Sturgeon Refinery. The ACTL will have the capacity to permanently store about 14.6 million tonnes of CO_2 annually as of 2017.

Some barriers for deployment of CCS technology in these sectors remain, such as lack of economic capture technology and infrastructure to connect carbon source with sequestration formations. This will require significant investments and pipeline network construction. In the upstream oil and gas sector, relevant carbon capture technology for in-situ boilers and cogeneration units could be available within a 10 to 15 year timeframe. However, more technological advances would be required to make CCS economic. With the knowledge and technological advancements spurred from projects currently underway, the cost of CCS could go down in the future and be applied in other industrial sectors.

Fuel-switching options are also available to industrial sectors. As mentioned previously, the oil and gas sector can use solvents instead of natural gas in SAGD applications, despite being relatively expensive at the moment. Using electricity instead of fossil fuels is also a possibility. Finally, biomass waste can be used by many sectors, including oil and gas and cement, to replace more carbon intensive energies.

The recycling of materials in many industrial sectors is another option to reduce GHG emissions as it reduces needs for energy, raw materials, and landfill space. For example, in the pulp and paper sector, recovered paper can be recycled through chemical pulping instead of producing paper from new feedstocks.

84 Natural Resources Canada, Low Carbon Fuel Demonstration Pilot Plant.

Another example is the reuse of recycled plastic in the chemical and petrochemical sector as a substitute to polymer based inputs. Plastic waste that cannot be recycled can be used as an energy input - In the iron and steel sector it can be burned as a replacement for coal or coke – or as a feedstock in other sectors. The use of recycled scrap metal materials to produce iron and steel can also lead to emission reductions as producing iron and steel from iron ore requires more energy than from scrap.[85]

Figure 11 (below) illustrates the world GHG reduction potential estimated by the IEA from four types of industrial GHG emissions reductions technologies for IEA's low-demand and high-demand scenarios. According to the IEA, energy efficiency improvements, switching to low-carbon fuels, increased recycling, and new innovative processes such as CCS will all be needed to decarbonise large industrial emitters.

4.3.6 Nevertheless, there remain challenges in reducing emissions from some sectors, for which innovation and research and development will be necessary

Emissions-intensive industrial sectors often face challenges in reducing GHG emissions as many of their emission sources are difficult to address through cost-effective electrification, energy efficiency, or fuel-switching. These challenges are compounded as many industries also face competitive pressures due to their exposure to international trade competition, and their low profit margins. Bargaining power of suppliers and buyers, the threat of substitutes and new entrants, and the level of rivalry between competitors are some of the factors that determine how competitive industries are in global markets. Many companies face global prices for their outputs, meaning that they must contain their production costs in order to remain competitive. Canadian oil producers operate in a global market and they are essentially price takers for their outputs, which requires them to look at ways of reducing their production and transportation costs in order to remain competitive. Moreover, these companies may face additional challenges associated with decreasing global demand for their goods in the future as governments act to mitigate GHG emissions. Canadian natural gas producers are currently competing in a continental market. In the future, with additional liquefied natural gas plants expected to come online, the global natural gas market is expected to be increasingly integrated.

Innovation in these sectors is likely to yield significant benefits to companies that can improve processes and technologies to reduce emissions. Government and private sector funding will be required for further research and development to promote technology innovations in many strategic areas pertaining to industrial emissions. These include CCS technologies to reduce costs and improve efficiency, industrial efficiency improvements, fuel switching to bioenergy and the conversion of biomass into bio-based products and bioenergy, technologies to address process emissions, and enhanced recycling capabilities.

5 Non-Carbon Dioxide Emissions

KEY MESSAGES:

- Non-carbon dioxide climate warming emissions include short-lived climate pollutants (SLCPs) and nitrous oxide, a long-lived GHG. Non-carbon dioxide emissions have significantly greater warming effects per tonne than carbon dioxide.
- The only way to meet the 1.5 to 2°C temperature goal encompassed in the Paris Agreement is to take early global action on carbon dioxide and short-lived non-carbon dioxide emissions together.
- Reducing short lived climate pollutants has considerable benefits beyond those that are climate related, such as improving air quality, human health, and environmental and ecosystem outcomes.
- Current technology and know-how has the potential to significantly reduce non-carbon dioxide emissions, often helping to slow the rate of near-term warming.

5.1 Non-carbon dioxide climate warming emissions include emissions of short-lived climate pollutants (SLCPs) and nitrous oxide, a long-lived GHG. Non-carbon dioxide emissions have significantly greater warming effects per tonne than carbon dioxide.

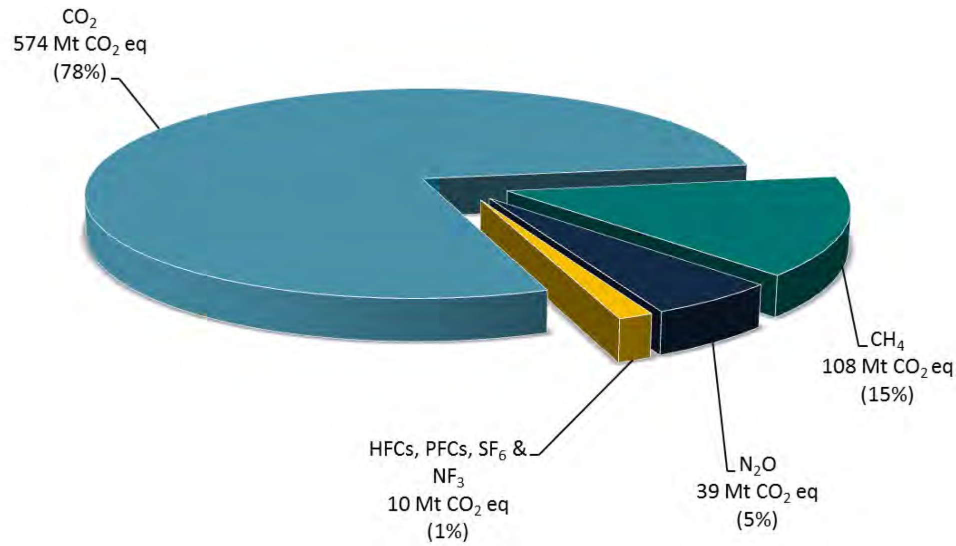
Short-lived climate pollutants (SLCPs) are potent greenhouse gases (GHGs) and air pollutants. They have relatively short atmospheric lifetimes compared to longer-lived GHGs such as carbon dioxide (CO_2), and have a warming impact on the climate. SLCPs include methane, hydrofluorocarbons (HFCs), and ground-level ozone, as well as black carbon, a component of particulate matter. Black carbon is also an air pollutant, resulting from the incomplete combustion of fossil fuels and biomass. Ground-level ozone is also an air pollutant and key contributor to smog, which is associated with adverse impacts on human and ecosystem health. Nitrous oxide is a long-lived GHG.

Figure 12 below illustrates Canada's greenhouse gas emissions in terms of CO_2 equivalency where non- CO_2 emissions account for around 21% of total emissions. Methane and nitrous oxide are the two main non-CO_2 GHGs emitted and originate mostly from fossil fuel related activities, livestock farming, and industrial processes. Although HFC emissions are not currently a significant contributor to total GHG emissions in Canada, in the absence of the recent phase-down amendment to the Montreal Protocol, they were projected to more than triple between 2013 and 2030.

Methane emissions, which account for 15% of total GHG emissions in Canada,[86] are significant contributors to climate impacts. In addition, methane contributes to the formation of ground-level ozone. The oil and gas sector accounted for 44% of Canada's methane emissions in 2014, largely from oil and natural gas fugitive sources, including venting . The remainder of Canada's methane emissions arises largely from agriculture and solid waste disposal.

86 The GHG estimate of 108 Mt for methane (15% of total Canadian GHG emissions) uses a global warming potential of 25 consistent with the IPCC fourth assessment report.

Figure 12: Canada's Emissions Breakdown by Greenhouse Gas (2014)



Source: National Inventory Report 1990-2014: Greenhouse Gas Sources and Sinks in Canada – Executive Summary, Environment and Climate Change Canada, 2016.

Nitrous oxide emissions account for 5% of total Canadian GHG emissions. The burning of fossil fuels results in the oxidization of the nitrogen contained in the fuel and the air creates nitrous oxide emissions. These emissions come mainly from coal-fired power plants as well as cars and trucks. Industrial processes, particularly those involved in the production of nitric and adipic acid, also cause nitrous oxide emissions through the oxidization of nitrogen compounds. Over 70% of total nitrous oxide emissions emitted in Canada are from the agricultural sector, mainly from crop and animal production. In crop production, nitrous oxide emissions arise mostly from the use of synthetic fertilizers where the addition of nitrogen to soils helps the nutrient absorption of plants and allows bacteria contained in the soil to produce extra energy to grow. Microbial processes involved in these activities then produce releases of nitrous oxide emissions.

HFCs are synthesized chemicals used as replacements for ozone-depleting substances. Internationally, atmospheric observations show that the volume of HFCs in the atmosphere is increasing rapidly, about 10 to 15% per year. To address concerns regarding an estimated increase in HFC emissions to 10% or more of total CO_2 equivalent emissions by 2050, the 197 Parties to the Montreal Protocol agreed to an amendment to phase-down the use and production of HFCs on October 15th, 2016. The "Kigali Amendment" could help to avoid almost 0.5°C of global warming by the end of the century. Canada was a strong supporter of the HFC Amendment and will continue to play a leadership role in implementing the Montreal Protocol, including the HFC amendment, notably by hosting the 29th Meeting of the Parties in 2017, which marks the Montreal Protocol's 30th anniversary.

The potency of HFCs varies by species and ranges from <1 to 10,800 times that of CO_2 over a 20-year period, and <1 to 12,400 that of CO_2 over a 100-year period.[87] HFCs are used in the same applications which ozone-depleting substances have been used. In Canada, HFC use is mainly confined to the following sectors: insulating foam products (50%), refrigeration and air-conditioning equipment in buildings and industrial operations (30%), air-conditioning in vehicles (13%), and aerosols (7%). Since HFCs are being used as replacements for ozone depleting substances, including hydrochlorofluorocarbons (HCFCs) that are still in the process of being eliminated, their use and emissions are increasing as HCFCs are being phased out. In addition, in the absence of the recent phase-down amendment to the Montreal Protocol, HFC emissions would be expected to increase because of greater demand for refrigeration and air conditioning throughout the economy.

According to Canada's black carbon emissions inventory, 43 kt of black carbon were emitted = in 2014. Black carbon emissions are estimated to be the third largest contributor to current global warming, after CO_2 and methane. Black carbon

Note: Bars on the right show estimated ranges for 2070.

influences the climate in multiple ways: by directly heating surrounding air when suspended in the atmosphere; by reducing the reflectivity of the earth's surface when deposited, an effect particularly strong over snow and ice; and through additional indirect effects related to interaction with clouds. Black carbon is estimated to be 3,200 (270 to 6,200) times more potent a warming agent than CO_2 over a 20-year period.[88] Reducing uncertainties related to quantifying the overall warming effects of black carbon represents an active area of scientific research internationally. Black carbon also has significant effects on human health, including respiratory and cardiovascular effects, as well as premature death. The transportation sector accounts for 62% of Canada's black carbon emissions, followed by residential wood-burning, accounting for about 27% of national emissions.

Ozone is not directly emitted, but forms in the atmosphere as a product of precursor gases including nitrogen oxides (NO_X), volatile organic compounds (VOCs) - including methane - and carbon monoxide (CO). Ground-level ozone is a powerful GHG, a significant contributor to current warming, and a key component of smog. It has deleterious effects on human health, damages plants, and affects agricultural crop production. In Canada, the transportation and oil and gas sectors are key sources of ozone precursors. Residential wood combustion is also a significant source of CO emissions.

88 GWP20 from Bond et al. (2013). Bounding the role of black carbon in the climate system: A scientific assessment. The use of the GWP here is to help communicate the potential contribution of black carbon mitigation to reducing near-term warming. Given the very different ways black carbon and CO_2 influence climate and their vastly different lifetimes in the atmosphere, there is not yet scientific consensus on a metric to quantify black carbon relative to CO_2. Further research to reduce uncertainties and develop more appropriate metrics is needed.

5.2 The only way to meet the 1.5 to 2°C temperature goal encompassed in the Paris Agreement is to take early global action on carbon dioxide and non-carbon dioxide emissions together.

Recent scientific studies indicate that the only way to meet temperature commitments in the Paris Agreement is to take early global action on CO_2 and SLCPs, together. The *United Nations Environmental Program's (UNEP) Integrated Assessment of Black Carbon and Tropospheric Ozone* concludes that reducing black carbon and tropospheric ozone now will slow the rate of climate change within the first half of this century.

The UNEP assessment notes that deep and immediate CO_2 reductions are required to limit long-term warming, and this cannot be achieved by addressing short-lived climate forcers alone. However, it goes on to note that implementation of measures on black carbon and methane globally by 2030 could reduce future global warming by 0.5˚C by 2050 and by as much as 0.7˚C in the Arctic by 2040, and together with early action on CO_2, this is the only way to limit the global average temperature rise to well below 2˚C (Figure 13).

The expected climate benefits of such an approach are particularly relevant for Canada as an Arctic nation. In Canada, the Arctic warmed by 2.2°C between 1948 and 2013 resulting in significant impacts to local populations and sensitive ecosystems. Black carbon is of particular significance in the Arctic due to its additional warming effect when deposited onto snow or ice, which accelerates melting.

5.3 Reducing short lived climate pollutants has considerable benefits beyond those that are climate related, improving air quality and human and ecosystem health.

Given that many SLCPs are also air pollutants, reducing emissions also provides a key opportunity to also improve air quality, generating local health benefits for Canadians and reducing impacts to ecosystems and agricultural productivity.

Ground-level ozone, a potent GHG, has several other deleterious environmental effects. As a key component of smog, ozone leads to significant human health impacts such as respiratory and cardiac problems. These health problems result in significant losses to Canada's economy through hospital visits and lost productivity.

Ground-level ozone also influences crop yield by interfering with the ability of sensitive plants to produce and store food, subsequently increasing their vulnerability to certain diseases, insects, harsh weather, and other pollutants. These negative impacts may translate into reduced crop yields and, consequently, lower sales revenue for crop producers. In addition, ground-level ozone may increase the risk of illness or premature death within sensitive wildlife or livestock populations, potentially resulting in significant treatment costs or economic losses for the agri-food industry. Thus, reducing emissions of ozone precursors, namely methane, VOCs, CO and NO_x, can reduce mortality and morbidity rates in the Canadian population, improve quality of life, as well as increase economic productivity.

Short-term and long-term exposure to $PM_{2.5}$, of which black carbon is a component, is also associated with a broad range of human health impacts, including respiratory and cardiovascular effects as well as premature death. In its 2012 assessment of the health effects of black carbon, the World Health Organization (WHO) noted that black carbon is a "carrier" of other pollutants, delivering them deep into the respiratory system, and further that a reduction in exposure to $PM_{2.5}$ containing black carbon should lead to a reduction in the health effects associated with $PM_{2.5}$.

5.4 Current technology and know-how has the potential to significantly reduce non-carbon dioxide emissions, often helping to slow the rate of near-term warming.

Many solutions exist to reduce important sources of non-CO_2 emissions. In general, measures that help promote the transition towards cleaner energy sources will reduce both CO_2 and SLCP emissions over the long term by reducing the use of fossil fuels. However, slowing the rate of near-term warming requires more targeted SLCP emissions reductions strategies, as many are emitted from a large number of small sources. Canada has made a number of recent significant commitments to advance SLCP mitigation priorities together with continental partners, under the Leaders' Statement on a North American Climate, Clean Energy and Environment Partnership (NALS Statement), including the commitment to develop and implement a national methane strategy that will consider how to address methane from key sources.

Most methane emissions from the oil and gas sector come from venting and fugitive emissions. These include venting from wells and batteries, fugitive equipment leaks, storage tanks, pneumatic devices, well completions, and compressors. Cost-effective technologies are readily available and tackling methane emissions from the oil and gas sector is one of the lowest cost reduction opportunities to achieve significant GHG reductions. Canada has committed to reducing methane emissions from the oil and gas sector by 40 to 45% below 2012 levels by 2025. To implement this commitment, Canada intends to publish proposed regulations to reduce venting and fugitive methane emissions from oil and gas sources by early 2017. Canada has also endorsed the World Bank's *Zero Routine Flaring by 2030* initiative, which will support reductions in black carbon emissions resulting from routine flaring at oil production facilities. Canada has been consulting with provinces, territories, industry, non-governmental organizations and Indigenous peoples on the development of the federal regulatory approach.

Accurately quantifying non-CO_2 emissions is challenging, particularly fugitive emissions. This can be explained by the fact that methane leaks are often only detected and repaired sometime after they start. Another source of uncertainty relates to fugitives arising from the hydraulic fracturing process required to extract shale gas, a growing source of natural gas supply in Canada. As a result, current inventory techniques are likely underestimating fugitive emissions. In response to this issue, many scientific initiatives have been initiated to better estimate these sources including research and development to estimate emissions such as undertaking atmospheric measurement campaigns, and new measurement technology such as infrared imagery.[89] The use of both top-down and bottom-up estimates will support improved understanding of methane from oil and gas sources. Canada has committed to working with continental partners to enhance the effectiveness of emission inventories for methane emissions from the oil and gas sector.

The March 10, 2016, Canada-U.S. Joint Statement recognizes the importance of improving the quantification of emissions. Canada is committed to working with continental partners to improve emission inventories of methane emissions from the oil and gas sector.

In the waste sector, technology for landfill gas recovery and utilization is well established and readily available for both new and existing landfills. Depending on landfill age and access to infrastructure, landfill gas recovery and utilization can also be highly cost-effective. Under the NALS Statement, Canada has committed to take action to reduce emissions from landfills, and to implement voluntary measures to reduce and recover food waste.

Technologies to reduce black carbon emissions from the transportation sector are also proven. Canada's low sulphur content in fuel regulations enable the use and effective operation of vehicle and engine exhaust after-treatment systems, such as diesel particulate filters, which can nearly eliminate black carbon emissions. Transportation sector air pollutant regulations for on- and off-road vehicles and engines are helping to drive down black carbon emissions from this sector.

Further reducing emissions from Canada's largest sources of black carbon emissions, existing diesel vehicles and engines, and wood-burning appliances, will require targeted actions to address barriers related to long vehicle, engine and appliance lifetimes, and influencing the consumers that own many of these small, distributed sources to retrofit or replace them with cleaner technologies.

Measures to address ozone precursors are often part of air quality policies, driven primarily by human health concerns. Measures to reduce ozone precursors in the transportation sector also often reduce black carbon as a co-benefit. Ozone precursors from industrial sources should also be addressed.

Adjusting fertilizer rates with plant needs, placing fertilizer near plant roots, applying fertilizer more frequently instead of only once, and using slow-release forms can limit nitrogen in soils and reduce nitrous oxide emission. In the same fashion, using manure more efficiently can also reduce nitrous oxide emissions. Other practices such as increased use of legumes as a nitrogen source, use of cover crops to remove excess available nitrogen, less use of summer fallow, and adjusting tillage intensity can also contribute to reducing emissions in the agriculture sector.[90] These options can yield co-benefits such as reducing the cost of production (as less fertilizer is used), saving on the use of fossil fuels needed to produce fertilizers, and reducing the pollution resulting from nitrates, ammonia, and other nitrogen substances released in the environment.

In the industrial sector, adipic acid plants can use proven and commercially available technology using catalytic and thermal destruction techniques with reduction efficiencies ranging between 90% and 99%. In nitric acid plants, the use of non-selective catalytic reduction and selective catalytic reduction is possible to reduce nitrous oxide emissions by as much as 90%.[91]

91 International Energy Agency. Abatement of other Greenhouse Gases – Nitrous Oxide.

Several Canadian companies and end users have developed and implemented innovative technologies to transition from current HFC technologies, and have an opportunity to take a lead role in the transition to non-HFC technologies. For instance, some Canadian supermarkets are converting their refrigeration systems to enable the use of refrigerants with very low global warming potentials, that are more energy efficient, and yield significant cost savings. For example, Sobeys has converted over 70 of its stores to climate-friendly, home-grown innovative technologies and plans to extend such conversions to its 1,300 stores across the country.

Meanwhile, major automobile manufacturers operating in Canada have started to manufacture new models with air conditioners using climate-friendly alternatives instead of HFCs. Those actions are also helping to increase energy efficiency. For example, for some applications, replacing HFCs with climate-friendly refrigerants and technologies can improve energy efficiency by up to 50%. The Government of Canada plans to publish proposed regulatory measures to phase down HFCs in Canada, including prohibitions on the manufacture and import of products and equipment containing or designing to contain HFCs by the end of 2016.

6 Forests

KEY MESSAGES:

- The Paris Agreement highlights the critical role that forests play in achieving the global net-zero emissions objective in the second half of the century. With its vast managed forest land, Canada has significant potential for long-term forest-based GHG mitigation.
- Choices about mitigation strategies will be influenced by the slow-growing nature and high rate of natural disturbances in Canada's forests.
- Forest-related mitigation can involve either reducing or avoiding emissions, or enhancing carbon sequestration. The potential becomes even clearer when impacts are assessed on a life-cycle basis.
- A substantial reduction in emissions and increase in removals by 2050 is possible through measures such as changes in how forests are managed, greater domestic use of long-lived wood products, greater use of bioenergy from waste wood, and afforestation.
- There are a number of emerging opportunities in which the forestry sector could contribute to mitigation outcomes that require further consideration.

6.1 The Paris Agreement highlights the critical role that forests play in achieving the global net-zero emissions objective in the second half of the century. With its vast forest land, Canada has significant potential for long-term forest-based GHG mitigation.

Forests play an important role in the carbon cycle by sequestering a significant amount of carbon, thereby reducing net CO_2 emissions to the atmosphere. It is estimated that globally, forests offset the equivalent of about 24% of anthropogenic emissions from the atmosphere.[92] As noted in the Paris Agreement, a balance between emissions and removals of greenhouse gases in the second half of the century is needed to ensure that global warming is limited to well below two degrees Celsius.[93] It is therefore important to recognise that without actions to protect, conserve, and sustainably manage forests globally, it will not be possible to achieve the net-zero emissions required to reach this objective.

Considering the vast size and economic impact of its forest, Canada has a responsibility to carefully consider the mitigation potential of its forest sector. Canada's forest is the third largest in the world, at 347.6 million hectares,[94] and Canada's forest industry contributes significantly to the economy as a major employer nationwide, with nominal GDP of $22.1 billion in 2015.[95] By value, Canada is the world's leading exporter of softwood lumber, newsprint and chemical wood pulp.[96] Canada's forward-looking forest-related mitigation actions can thus have a significant impact.

Given their traditional relationship with forests, Indigenous peoples have an important role to play in planning and managing forest resources. In 2011, 70% of Indigenous

92 Smyth et al., Quantifying the biophysical climate change mitigation potential of Canada's forest sector.

95 Natural Resources Canada's calculations based on Statistics Canada's CANSIM table 379-0031.
96 Natural resources Canada, The State of Canada's Forests 2015.

communities were located in forested areas.[97] Indigenous peoples account for 4.8% of the total forest sector workforce in Canada, compared to 3% of the total workforce.[98] The participation of Indigenous people in land-use decisions and sustainable forest management will be a key component of the long-term contribution of Canada's forests to climate change mitigation.

6.2 Choices about mitigation strategies will be influenced by the slow-growing nature and high rate of natural disturbances in Canada's forests.

A large proportion of Canada's forests are old and slow-growing. When harvested, much of the biomass is converted to wood products that can store the carbon for a long period of time, depending on the product. Harvest residues left in the forest decompose over time or may be burned to reduce the risk of wildfire. All forests harvested on public land must be regenerated according to policies and legislation on sustainable forest management,[99] but it takes time for trees to grow in Canada's cold, northern conditions. Mitigation strategies that rely on forest growth to sequester carbon must therefore be implemented soon in order for significant mitigation benefits to be realised by 2050.

The factors described above, as well as considerations related to natural disturbances such as forest fires and the impact of climate change on the forest, will influence the development of forest-related mitigation. Sustainable forest management already balances multiple objectives but now must also increasingly tackle the twin challenges of mitigation and adaptation. This underscores the importance of developing a long-term strategy that will build on actions planned in the short- to medium-term and ensure that forest-related mitigation can make a substantial contribution to the mid-century target.

6.3 Forest-related mitigation can involve either reducing or avoiding emissions, or enhancing carbon sequestration. The potential for forest-based mitigation becomes even clearer when impacts are assessed on a life-cycle basis.

As noted in the IPCC Fourth Assessment Report, it is important to examine total mitigation effects across the forest and forest products system on a life-cycle basis, taking into account emissions and removals in the forest, storage of carbon in harvested wood

97 Government of Canada, Indigenous Peoples and Forestry in Canada.
98 Natural Resources Canada, Aboriginal Participation in the Forest Sector.
99 Ibid, p.26. All areas of provincial Crown land that are harvested for timber are required to be regenerated using natural or artificial means (i.e., planting and seeding), or a mix of the two. Standards and regulations for achieving successful regeneration vary by province.

products (HWP), land-use changes, and avoided emissions in other sectors from the substitution of HWP or bioenergy for other more emissions-intensive products and fossil fuels.[100]

Assessment of mitigation strategies must take into consideration biophysical, technical and economic factors. The biophysical mitigation potential sets the boundaries around what is physically possible to achieve in the forest, while the technical and economic costs determine what is feasible to accomplish.[101]

6.4 Analyses show that a substantial reduction in emissions and increase in removals by 2050 is possible through measures such as changes in how we manage forests, greater domestic use of long-lived wood products, greater use of bioenergy from waste wood, and afforestation.

Realising forest-related GHG mitigation potential will require a focus on actions that help reduce emissions and increase the carbon stored in trees, soils, and forest products. In general, in the short- to medium-term, options that avoid emissions and maintain forest and HWP stocks may offer the largest mitigation results. In the longer-term, significant mitigation can result from options that increase harvesting over time and substitute forest biomass for more emissions-intensive products and energy sources. In order to achieve longer-term mitigation, however, action is required in the near-term, even if mitigation benefits are not immediately visible. Moreover, in some cases, options that provide the greatest short-term results may not always provide the greatest mitigation in the long term. Therefore, when assessing forest-related mitigation options, it is important to consider the potential for a longer-term contribution to a low-carbon economy and not just the potential in the short and medium term.

Analyses show that the mitigation actions with the greatest potential for medium and long-term emissions reductions by mid-century in Canada include an integrated approach to changes in forest management practices, increased afforestation, increased use of harvested wood for long-lived products, and increased use of waste wood for bioenergy in place of fossil fuels. These findings are in line with the findings of the Fourth Assessment Report of the IPCC that indicate that sustainable forest management that produces harvested wood products annually while maintaining or increasing forest carbon stocks will generate the largest sustained mitigation benefit in the long run.[102]

6.4.1 Change in Forest Management Practices

Given that close to 90% of forests in Canada are owned by provinces and territories,[103] these jurisdictions will need to identify and implement changes in forest management practices most relevant to their region. Mitigation actions must be balanced with other sustainable forest management priorities, but could include higher utilisation of residual and harvested wood, reduced burning of harvest residues in the forests, increased planting to rehabilitate forests after natural disturbances, and increased planting intensity to improve forest growth after harvest.

In addition to their substantial long-term mitigation potential, changes in forest management practices could create co-benefits, including increased employment in the forest sector, reductions in black carbon emissions (where there is a reduction in slash burning), and increased adaptation efforts to improve the resilience of forests.

6.4.2 Afforestation

A future vision for Canada could include an expanded forest area, however this would need to be achieved without negatively affecting food production. There has historically been relatively little afforestation in Canada,[104] but this could provide substantial carbon sequestration in the long-term. Various levels of afforestation using mixes of fast-growing species and slower-growing species could be used. Because of the time it takes for trees to grow in Canada it would take time for afforestation activities to begin to show substantial carbon reductions.

Investments in afforestation could lead to co-benefits such as the diversification of rural economies, reduced forest fragmentation and enhanced forest habitat for wildlife, improved soil quality and watershed protection. Plantations generate revenue over the long term through harvesting and re-growth which act as an incentive to long-term management by landowners. Challenges in achieving large-scale afforestation include the need to ensure a sufficient

100 Nabuurs et al., Forestry: Contribution of Working Group III to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change.

103 Natural Resources Canada, The State of Canada's Forests 2015, p. 50.
104 Natural Resources Canada, The State of Canada's Forests 2015, p. 23.

supply of seedlings and to engage the interest of a sufficient number of landowners, as well as concerns about the resilience of some tree species to changes in climate and natural disturbances.

6.4.3 *Increased use of residual and harvested wood products for long-lived products*

Life cycle research demonstrates that increased use of sustainably produced wood products could lead to avoided GHG emissions in other sectors. In particular, the substitution of wood-based materials for more emissions-intensive materials (such as concrete and steel) for construction and for fossil fuel in heating and energy applications provides some of the highest mitigation opportunities. Canada can further invest in projects and activities that increase the use of harvested wood products in domestic construction such as tall and mid-rise residential buildings, commercial and industrial buildings, and bridges.

The expansion of wood end-uses could also contribute to increasing the competitiveness of the Canadian forest sector by diversifying market opportunities and helping to maintain or create jobs. While the technologies to implement this option are already demonstrated, commercialised, and widely used in other countries, Canada will need to analyse its National Building Code to ensure that it promotes the use of wood products in building design.

6.4.4 *Increased use of harvested wood products for bioenergy, advanced bio-material, and bio-chemicals*

There are potential mitigation benefits from adopting waste wood biomass as a fuel source for electricity or commercial, residential, and industrial heating in place of fossil fuels or as a feedstock in the manufacturing of advanced bio-material and bio-chemicals. Mitigation benefits come from using local sustainably-sourced wood for bioenergy, with priority given to harvest residues and waste wood, which have lower emissions on a life-cycle basis compared to the use of fossil fuels.[105] Positive mitigation benefits from bioenergy-related harvesting could occur in remote communities where local electricity is produced from fossil fuels (e.g., diesel) that have been transported over long distances.

The co-benefits of using biofuels include diversification of market opportunities, leading to increased growth and competitiveness of the Canadian forest sector. In addition, there are direct and indirect benefits for rural forest-based communities including energy autonomy, regional investment, and employment opportunities. Technology to support this option includes modern wood heating systems such as biomass-fueled boilers and stoves and furnaces that use sustainable wood-based feedstock. While this technology is commercially available, a bioenergy heating initiative would depend on securing additional energy infrastructure investments as up-front costs would be high, particularly where the infrastructure in not in place.

Bio-based materials and chemicals are likely to gain importance over the long term. There is a general consensus that the mid-century will bring a larger, more urban population and along with this comes the need for primary resources to sustain urban growth. This, in turn, highlights the potential of forest-based cellulosic material to replace not only a vast array of other materials used in building and energy, as noted above, but also to replace materials and chemicals used in the manufacturing sector at large. The mitigation potential of cellulose-based products, their renewable nature, and their potential to further be recycled or to biodegrade is likely to spur increasing demand for these high value products. For example, natural fibers have already become crucial in technical composite applications due to the demand for recyclable and biodegradable raw materials. The mitigation potential of cellulose-based products is highly dependent on their life cycle and end uses as well as the uptake of bio-based material as substitutes for traditional alternative feedstock and cannot be clearly ascertained yet.

As a country advantaged with significant biomass resources and forest and agriculture sectors poised for transformation, the bioeconomy represents a substantial opportunity to generate wealth and jobs for Canadians.

6.5 There are a number of emerging opportunities in which the forestry sector could contribute to mitigation outcomes that require further consideration.

6.5.1 *Reducing deforestation*

Unlike tropical countries where deforestation is a major driver of emissions, deforestation (permanent forest loss) in Canada is relatively low. Of the approximately 0.01% of Canada's forest land that is lost annually, most is driven by agriculture and the

105 Nabuurs et al., Forestry: Contribution of Working Group III to the Fourth Assessment Report of the Intergovernmental Panel on Climate Change.

expansion of the oil and gas industry.[106] Given that the main drivers of deforestation vary across the country – and that the drivers of deforestation are usually outside of the forest sector – there has been limited ability within the forest sector to influence these emissions to date.

Nonetheless, reducing deforestation and its associated emissions is an area that Canada can explore, especially considering the role Canada plays in supporting reducing emissions from deforestation and forest degradation in developing countries, and that Canada is a signatory to the New York Declaration on Forests, which aims to end global net deforestation by 2030. Collaboration with provinces and territories is required given the need to consider how to address deforestation across jurisdictions and diverse sectors.

6.5.2 Research and Development in Advanced Bio-materials, Bio-chemicals, Bioenergy and Biofuels

The mitigation potential of using harvested wood products for bioenergy and biofuels can be further explored. Bioenergy with carbon capture and storage (BECCS) has received considerable global attention because it can generate negative emissions. A longer-term option for bioenergy could focus on reducing costs along the supply chain and increasing investments in research and development of second-generation biofuel production, advanced materials, and new platform chemicals, for example, converting cellulosic biomass into bio-crude and refining it into other biofuel products (e.g., biodiesel, bio-kerosene and bio-chemicals), as well as gasifying or liquefying biomass for power production. Further investment in research, development and deployment of such technologies could identify new areas with mitigation potential.

6.5.3 Urban Forestry

Urban forests provide a number of co-benefits in addition to sequestering GHG emissions, such as energy conservation through cooling and shade, provision of wildlife habitat, noise buffering and improved aesthetics and increased property values. Future research and analysis in improved monitoring and research to capture mitigation potential and enhance resiliency of urban forests is an option for Canada to explore.

106 Natural Resources Canada, The State of Canada's Forests 2015, p. 23.

7 Agriculture

KEY MESSAGES:

- The potential for greenhouse gas mitigation exists across the entire food system. There are opportunities and for consumers, farmers, food processors and municipalities to reduce and recycle energy and nutrients.
- Agricultural emissions result mostly from biological processes rather than from energy use.
- Technological innovations and sustainable land management practices will ensure that agricultural soils remain a net carbon sink in Canada over the long-term.
- Promoting the adoption of existing and emerging technologies and management practices could increase efficiency and reduce emissions from crop and livestock systems.
- The Agriculture sector has the potential to provide renewable energy solutions and bio-products to help reduce emissions in other sectors. In evaluating these options, consideration should be given to the full life-cycle environmental costs and benefits.

7.1 The potential for greenhouse gas mitigation exists across the entire food system. There are opportunities for consumers, farmers, food processors and municipalities to reduce and recycle energy and nutrients.

Addressing GHG emissions from agriculture requires the examination of the entire food system's life cycle from fertilizer manufacturing through to on-farm activities, food processing, distribution, and consumption. Moreover, the ultimate fate of food products, either as food waste, compost, or wastewater, needs to be taken into account.

This *holistic* approach seeks to improve the efficiency of the overall food system from "cradle to grave to cradle", and can often draw out synergies between the environmental and health impacts of food choices. In this respect, more can be done to foster positive societal engagement and cooperation to help lower GHG emissions. There are increasingly higher expectations for transparency and product environmental attributes, including the relative amount of GHGs embodied in different food choices.

In the context of a global and growing demand for food products, alternative approaches like local food movements, organic and/or urban agriculture or family farmers networks can play an important role in shaping the future of agriculture.[107] Any approach that helps to minimise waste (see Chapter 8) and helps to conserve energy and water will decrease emissions in other sectors indirectly related to agriculture, for example, during fertilizer manufacturing, or by removing nitrogen and phosphorus from wastewater.

107 Equiterre, Family Farmers Network.

7.2 Agricultural emissions result mostly from biological processes rather than from energy use.

Primary agriculture is at the heart of a complex and integrated agri-food system which provides one in eight jobs and accounted for more than 6% of GDP in 2014.[108] The agriculture sector contributes to making Canada one of very few countries currently in a position to produce more food than it consumes, and Canada is the fifth largest exporter of agriculture and agri-food products internationally.[109] Efficiency gains, sustainable land management, and innovation will enable Canadian agriculture to reduce emissions, store carbon, and meet a growing global food demand.

Most agricultural greenhouse gas emissions are not driven by energy use but rather take the form of methane and nitrous oxide resulting predominantly from biological processes inherent to animal and crop production. Nitrous oxide emissions can originate from field-applied fertilizers, crop residue decomposition, cultivation of organic soils, and from the storage of manure. Methane emissions are mainly a result of enteric fermentation in ruminant animals and decomposition of stored manure.

108 Agriculture and Agri-food Canada, *An Overview of the Canadian Agriculture and Agri-Food System 2016.*

109 Ibid.

Total emissions from agriculture have been relatively stable since the year 2000 and are not projected to significantly increase toward 2030.[110] In 2014, non-energy emissions accounted for 59 megatonnes of carbon dioxide equivalent (Mt CO_2 eq) – approximately 8% of Canada's total GHG emissions – while GHG emissions from on-farm fuel use generated 14 Mt CO_2 eq.[111] The two main sources of non-combustion agricultural emissions are enteric fermentation and fertilizer application.

7.3 Technological innovations and sustainable land management practices will ensure that agricultural soils remain a net carbon sink in Canada over the long-term.

For over twenty years, Canadian farmers in the Prairie provinces have been able to increasingly substitute conventional tillage with no-till or conservation tillage seeding techniques due to innovations such as improved seeds, fertilizers and pesticides, and changes in machinery and farm equipment, including the evolution of technologies such as global positioning systems. Increased crop rotation

110 Environment and Climate Change Canada, *Canada's Second Biennial Report on Climate Change.*

111 Environment and Climate Change Canada, *National Inventory Report 1990-2014: Greenhouse Gas Sources and Sinks in Canada.*

REDUCING METHANE EMISSIONS FROM ENTERIC FERMENTATION

Enteric fermentation is a natural process that occurs in the digestion of feed by livestock. The digestion process is not 100% efficient and releases methane as a by-product. In Canada, GHG emissions from enteric fermentation were 25 Mt CO_2e in 2014 down from 31 Mt in 2005. Dairy and beef cattle produce around 95% of these emissions while others ruminants such as buffalo, goats, horses, sheep and swine, make up the rest of the emissions.

There are a number of options to reduce methane emissions from enteric fermentation but many of these are still in the research phase. Since the demand for meat and milk is expected to increase in the future, decreasing methane output per unit or animal is important. For example, it is possible to select lower-methane producing animals through consideration of genetic characteristics. In addition, research into methane vaccines and inhibitors is ongoing in some jurisdictions.

High quality feed could lead to more efficient digestion and reduce emissions. For example, research has shown that mixing seaweed in cattle feed could reduce methane emissions. In this respect, a company from Prince Edward Island, North Atlantic Organics Ltd., is proposing organic seaweed products that can be used by dairy cattle.[112] The use of seaweed for animal feed is in fact a traditional method that has been used by coastal farmers in the past.

112 NAO organics. http://www.naorganics.com/index.asp

options have also allowed reduced reliance on summer fallow (the practice of allowing land to lie idle during the growing season).

As a result, agricultural soils in Canada have been a net sink of carbon since 2000 and will remain so over the long-term, although the rate at which carbon will be sequestered is projected to slowly diminish. Greater use of cover crops, biochar application and the use of precision agriculture to avoid disturbance of more fragile soils, among other sustainable land management practices, will help maintain the agricultural carbon sink in the future.

7.4 Promoting the adoption of existing and emerging technologies and management practices could increase efficiency and reduce emissions from crop and livestock systems.

On-farm GHG emissions are closely tied to management practices and technologies such as fertilizer types and application methods, manure storage and spreading methods, land management and tillage regimes, feeding and nutrition, as well as crop and animal genetics.

Mitigation options aimed at enhancing fertilizer use efficiency and reducing methane emissions from livestock are promising as innovative technologies such as methane inhibitor feeding additives, livestock genetics, smart-fertilizers, and precision agriculture approaches are being developed.

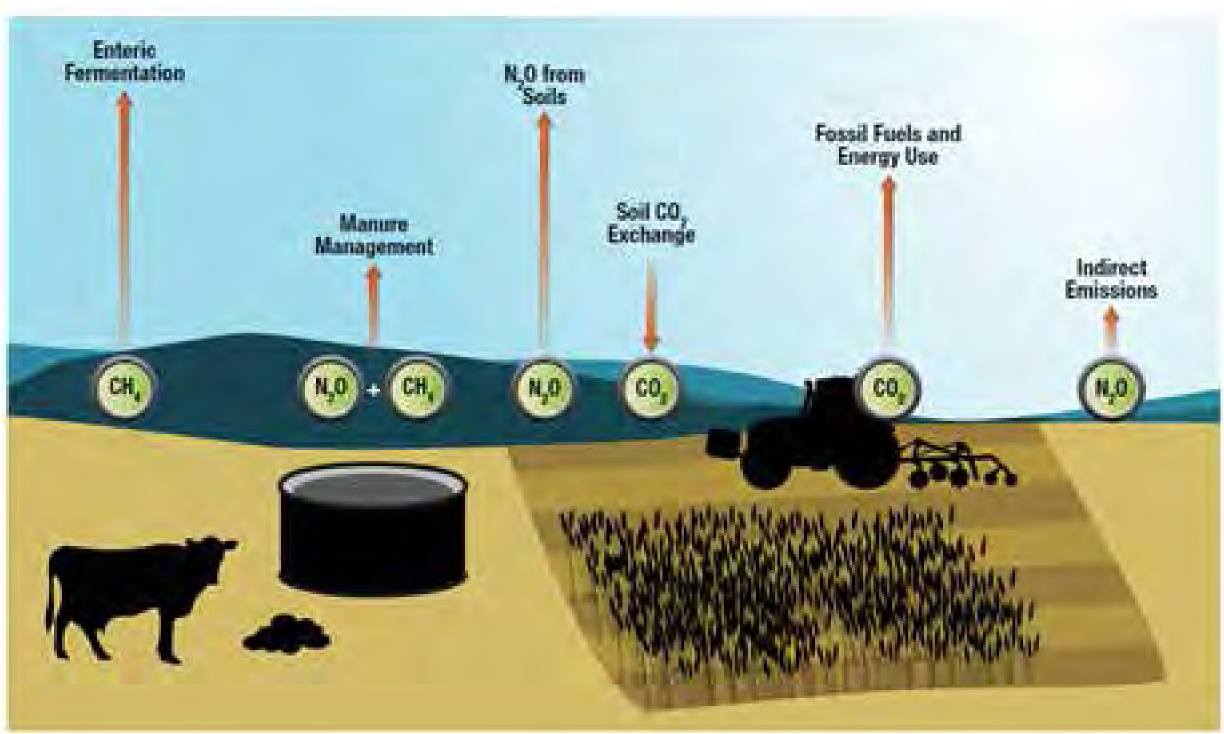
Encouraging the continued adoption of nutrient management practices, such as soil nutrient testing, optimisation of the timing of fertilizer application, incorporation of solid and liquid manure and fertilizer, and increased manure storage capacity, will continue to increase performance while minimising emissions in the sector.[113] For example, in the beef cattle sector, Canadian farmers have made significant improvements in feeding and breeding practices, and as a result, cattle reach slaughter weight sooner, and spend fewer days eating, ruminating, producing methane, and generating manure.[114]

In the livestock sector, upcoming methods to reduce methane emissions are showing significant potential.

113 Agriculture and Agri-Food Canada, *Farm Environmental Management Survey 2011.*

114 Agriculture and Agri-Food Canada, *Environmental Sustainability of Canadian Agriculture: Agri-Environmental Indicator Report Series – Report #4.*

Figure 14: Agricultural GHG emissions in Canada in 2011



The arrow length is proportional to the magnitude of the emissions; arrow direction upwards indicates a source and downwards indicates a sink. Source: *Environmental Sustainability of Canadian Agriculture: Agri-Environmental Indicator Report Series – Report #4*

These include switching to lower-methane producing ruminants, methane inhibitors and feed supplements, or even vaccines to reduce methane production in the rumen.

Technology will also continue to make a profound impact on agricultural production. Bioengineering, precision agriculture, sensors, robotics, and automated data capture and transfer, all hold promise for further agriculture GHG emission reductions. Although additional scientific validation work is still needed, preliminary, partial results point to substantial reductions in nitrous oxide emissions when an optimised nutrient management approach is adopted.

Continuing to seek improvements in efficiencies can yield further emission reductions but this will depend on the development and deployment of transformative technologies (e.g., methane inhibitors and smart-fertilizers), some expected to be ready for commercial deployment over the short-term (i.e., 5 years) while others could possibly be made available over the medium-term (i.e., 10-15 years).

On the farm inputs side, deeper penetration of precision agriculture practices, technologies and equipment should translate into lower consumption of production factors such as fertilizers and fuels, with a corresponding decrease in the GHG emissions associated with the use of these inputs. More efficient and precise production decisions should also lessen the pressure on natural resources like land and water.

As a more specific example, the province of Saskatchewan highlights the underdeveloped use of pulse crops to mitigate the use of fertilizers, as well as the potential associated with seeding marginal land for carbon sequestration, through permanent covers like legumes, or by converting them into forest stands. The province is also hopeful that advances in beef genetic selection, genomics and food additives will significantly lower the rate in which the agriculture sector emits GHG emissions. The province notes that the role of innovation and increased research in mitigation options for the agriculture sector is critical due to the challenge represented by a global population growth and the subsequent pressure on global food demand and production.

7.5 The Agriculture sector has the potential to provide renewable energy solutions and bio-products to help reduce emissions in other sectors. In evaluating these options, consideration should be given to the full life-cycle environmental costs and benefits.

From a life cycle perspective, the agriculture sector could also contribute to long-term mitigation by helping to reduce emissions in other sectors through displacement of more emission-intensive materials and fossil fuels with biomass-based energy and products.

There is an opportunity to convert growing agricultural waste, as well as agricultural by- and co-products into eco-efficient, bio-based products with direct benefits for the environment, the economy, and consumers, for example, sustainable bio-energy, bio-fertilizers and bio-chemicals. Both feedstock and technology exists to convert more wastes, agriculture and forest biomass into high quality, low GHG-emitting biofuels, for use in road transportation to air travel.

In evaluating these options, consideration should be given to net GHG savings along the full life cycle, as well as to other environmental impacts, that could result from the intensification of agricultural production.

8 Waste

KEY MESSAGES:

- The waste sector directly accounts for 3% of Canada's GHG emissions; however from a life cycle perspective, waste related activities are responsible for significant indirect GHG emissions from various sectors of the economy not typically associate with waste.
- Currently, the relatively low cost of waste disposal at landfills in many parts of Canada provides a disincentive for waste prevention and diversion activities.
- Effective management strategies, focusing on waste prevention and diversion, can bring deep cuts in direct and indirect waste-related GHG emissions.
- New policies could instigate behavioral change away from wasteful consumption patterns, as well as shift the responsibility for end-of-life management of products from consumers to producers.
- Co-benefits of waste prevention, diversion, and landfill gas capture include: greater food security, increased supply of renewable natural gas and electricity, creation of a soil amendment (i.e., compost); and a reduction in volatile organic compounds emissions, smog formation and unpleasant odours.
- In the future, progress in landfill gas capture and flaring technologies could further reduce any remaining direct landfill emissions.

Canada has performed poorly in terms of quantity of waste generated per capita compared to its OECD peers. At 777 kg of municipal waste generated per capita in 2008, the average Canadian city generated more waste than any other OECD country, twice as much as an average Japanese city, and slightly more waste than an average American city (722 kg).[115] While substantial efforts have been taken by municipalities and provinces/territories across the country, for example Nova Scotia has reduced waste generation to 386 kg per capita as of 2012, much more needs to be done.[116]

8.1 The waste sector directly accounts for 3% of Canada's GHG emissions, however from a life cycle perspective; waste related activities are responsible for significant indirect GHG emissions from various sectors of the economy not typically associate with waste.

The waste sector officially accounts for 3% of total GHG emissions and 22% of Canada's total methane emissions. This includes emissions from municipal solid waste landfills, wood waste landfills, wastewater treatment, as well as waste discharge, incineration, and open burning.

115 Conference Board of Canada, *Municipal Waste Generation. Note: For comparison purposes, construction, renovation and demolition waste were not included in the OECD definition.*

116 Conference Board of Canada, *Waste Generation: Provincial and Territorial Ranking. Readers should note that municipal waste generation per capita and waste generation per capita differs slightly, the latter being slightly more important.*

As the IPCC's fourth assessment report indicates, a life cycle approach is required to evaluate the emissions reductions potential for waste prevention and diversion. As such, waste management activities will affect GHG emissions accounted for under sectors such as transportation, forestry, energy and industrial processes. For example, the U.S. Environmental Protection Agency (EPA) estimated that approximately 42% of total U.S. greenhouse gas emissions are associated with the energy used to produce, process, transport, and dispose of commodities and food.[117] Waste prevention and diversion strategies would therefore reduce emissions in other sectors.

8.2 Currently, the relatively low cost of waste disposal at landfills in many parts of Canada provides a disincentive for waste prevention and diversion activities.

Waste disposal is relatively inexpensive in Canada compared to many peer countries. Available land for waste disposal is not in short supply in Canada, relative to many European countries. Canadian jurisdictions are using a variety of policy approaches to counter the low cost of landfill disposal. For example, Nova Scotia, Quebec, and Prince Edward Island have implemented material disposal bans from landfills (e.g., organic waste and in some instances recyclables). Quebec and Manitoba have also instituted landfill levies to provide an incentive for greater waste diversion and to support municipal recycling programs.[118] In 2014, the City of Edmonton opened its new *Waste-to-Biofuels and Chemicals Facility*, the first industrial scale waste to biofuels facility of its kind, that will help the city divert up to 90% of residential waste from landfills, as well as produce up to 38 million litres of ethanol each year.[119]

117 United States Environmental Protection Agency, *Opportunities to Reduce Greenhouse Gas Emissions through Materials and Land Management Practices.*

118 Giroux Environmental Consulting, *State of Waste Management in Canada.*

8.3 Effective management strategies, focusing on waste prevention and diversion, can bring deep cuts in direct and indirect waste-related GHG emissions.

The greatest untapped potential for GHG emissions reductions rests with waste prevention and diversion activities (e.g., composting or anaerobic digestion). Reducing avoidable food waste and increasing diversion of other organic material and recyclable materials from landfills could procure most significant emissions reductions for the sector.

In Canada, avoidable food waste is valued at $31 billion per year. Moreover, the national organics diversion rate stands as a low 7% of the total waste stream, with the recyclable materials diversion rates standing at 16%. In total, Canada's overall diversion rate stand at 25%, lower than other peers countries such as Germany or the US.[120] Nevertheless, it is important to remember that some Canadian municipalities are leading the way for diversion strategies, with Halifax, Hamilton, and Sherbrooke achieving total diversion rates between 40 and 60%.[121] An enforced target, such as the EU's 50% diversion rate by 2020, could prove useful to engage the different Canadian authorities in a concerted waste management effort. [122]

WASTE DIVERSION IN NOVA SCOTIA

The province of Nova Scotia is a North American leader in waste diversion, creating significant environmental benefit and economic advantage. Its disposal rate is 50% lower than the Canadian average and continues to decrease.

Starting in 1996 the Province implemented a strategy that included disposal bans on food and yard waste, some paper, plastic, metal and electronic items.

Some other highlights of Nova Scotia's successful and ongoing 'circular economy approach' to solid waste include:

- Financial incentives to municipalities based upon diversion performance
- A strong partnership with municipalities through a regional (solid waste) chairs committee
- Effective and sustained education, enforcement, and innovation programs
- Stewardship programs for beverage containers, tires, mercury containing products, and dairy containers
- Extended producer responsibility programs for electronics, paint, and cell phones
- Municipal commitments to implementing clear bag programs for garbage that decrease waste disposal by 15 to 30%

As a result, tonnes of materials that used to be wasted now contribute to Nova Scotia's economy, creating jobs and reducing GHG emissions.

8.4 New policies could instigate behavioral change away from wasteful consumption patterns, as well as shift the responsibility for end-of-life management of products from consumers to producers.

Effective policies can help increase waste diversion through source reduction, reuse, recycling, composting, and anaerobic digestion. For example, information and incentive programs can help shift public behavior to less wasteful practices by helping to close information gaps (e.g., public education programs), or providing financial incentives such as advance disposal fees policies. Another example can be found in the Swedish initiative to introduce a tax break for repairing activities, such as repairs of bicycles or appliances. Such policies are instrumental in shifting consumption behaviors towards waste prevention.

The true cost of landfill disposal also needs to be adequately reflected in tipping fees to account for loss of arable land and the creation of environmental liabilities. Regulatory or market-based policies could include disposal bans, higher landfill tipping fees, and differential tipping fees for unsorted waste. Practices such as keeping products for longer, reusing products, or repairing items and spare parts that can be re-used, are amongst the many ways that need to be promoted and rewarded by municipalities and provinces/territories. There are innovative solutions to reducing food waste by connecting consumers and producers in the food industry, such as industry and non-governmental organisation-led initiatives to encourage the sale and purchase of imperfect produce.

A significant step towards increasing diversion, and in turn reducing emissions associated with waste, is to shift the responsibility for end-of-life management of products from consumers and municipalities to producers. Over the past 20 years, significant progress on extended producer responsibility programs has been made in Canada on a wide variety of products and materials. The next phase will be to implement diversion programs for complex product categories such as construction, renovation, demolition materials, furniture, textiles and carpets.[123]

123 Canadian Council of Ministers of the Environment, *Progress Report on the Canada-wide Action Plan for Extended Producer Responsibility.*

Regulations and support for producers to minimise material inputs, optimise reuse and recovery of products, and develop markets for recycled materials will be essential.[124] Extended producer responsibility programs and performance-based regulations are two policies put forward to pursue that shift.[125] Improved systems for generators to manage certain materials on-site instead of relying on costly centralised infrastructure could also be further explored (e.g., plastic to oil conversion, renewable natural gas recovery from organics).

8.5 Co-benefits of waste prevention, diversion, and landfill gas capture include: Greater food security, increased supply of renewable natural gas and electricity, creation of a soil amendment (i.e., compost); and a reduction in volatile organic compounds emissions, smog formation and unpleasant odours.

There are many co-benefits to improve waste management strategies apart from reducing greenhouse gas emissions, in particular methane. Waste prevention increases food security and organic waste diversion can produce renewable biogas and/or a soil amendment. Recycling can save resources and energy, while limiting the amount of plastic discharged in the oceans. Landfill gas capture can also provide energy and electricity to municipalities and industries. In addition, cement manufacturers across the country have shown interest in using a variety of waste products (solid waste, carpets, wood waste, asphalt, non-recyclable plastics) as an alternative energy source.[126] Finally, the reduction of volatile emissions, smog formation, and unpleasant odours, will provide health and lifestyle benefits to landfill-adjacent neighborhoods and communities.

8.6 In the future, progress in landfill gas capture and flaring technologies could further reduce any remaining direct landfill emissions.

Even with waste prevention and diversion efforts, it is likely that landfill disposal will still be a practice in some parts of Canada in 2050 and that not all sources of GHGs will be diverted. In addition, there is a lag in the decomposition of organic waste in a landfill such that the organic waste disposed today, will be the source of emissions for decades to come if not mitigated. Currently, only 36% of total methane gases generated by landfills are captured, partly due to current stringency and performance standards on gas capture regulations across the country. Nevertheless, landfill gas capture technologies are widely available and expected development in flaring, gas capture and gas utilisation technologies could easily increase the ongoing reduction in landfill GHG emissions and produce more heat and electricity. In the future, thermal treatment facilities with energy recovery, small-landfill gas capture technologies or even waste mining, could become proven and commercially viable options in Canada.

126 Ibid.

9 Clean Technology Sector

As our society moves to address its environmental challenges, the clean technology sector has seen an increase in demand for its products and processes. Clean technologies are products or processes that significantly reduce environmental impacts of a given economic activity. This subset of the economy makes a compelling case for itself as it provides economic development while improving the environmental performance of the economy. As the world moves to deep decarbonisation, the clean technology sector is faced with a tremendous opportunity to produce further economic and social co-benefits for all Canadians.

KEY MESSAGES:

- The clean technology sector is growing very quickly both domestically and globally.
- Utilities, equipment suppliers, and policymakers should work together to identify strategies for reducing deployment costs of critical clean technologies and barriers to adoption.
- Further investments in RD&D and innovation in clean technology, combined with market pull mechanisms such as carbon pricing, will support Canada's competitiveness, creating high paying jobs and increased exports.
- Innovation will result in economic and environmental spill-over effects, thereby increasing resource efficiency and productivity in other sectors and reducing other types of pollution.
- Providing a clear and predictable signal for long-term investments and disclosing climate-related information will allow the market to better anticipate the transition to a low-carbon future.
- Canada has confirmed its commitment to clean energy innovation by joining the Mission Innovation international commitment, which aims to accelerate innovation by doubling investments in clean energy RD&D across the world.

9.1 The clean technology sector is growing very quickly, both domestically and globally.

Recent historical performance of the clean technology sector in Canada has been very strong, despite a leveling off between 2013 and 2014. The sector grew at a pace of 8% annually between 2011 and 2013, which represents more than three times the overall economic growth in Canada.[127] Over the same time period, global clean technology revenues increased by 10% annually. Employment in the clean technology sector in Canada has increased from 41,000 in 2012 to 55,600 in 2014, an increase of more than 16% per year.

Solutions from clean technology producers can help address challenges in high-emitting sectors, providing positive economic and environmental outcomes. Investment opportunities in clean technology are increasing at a rapid pace. For example, the

127 Analytica Advisors, *Canadian Clean Technology Industry Report.*

IEA estimates that around $1 trillion per year of incremental investment are required in renewable energy and energy efficiency investments to keep the global average temperature to well below 2°C in 2050.[128] This represents a significant opportunity for Canadian clean technology companies to tap into this growing market. Exports accounted for 50% of the clean technology sector's revenues in 2014, meaning Canadian firms are positioned to benefit from comprehensive efforts to export unique technologies and expertise to new and growing markets.

9.2 Utilities, equipment suppliers and policymakers should work together to identify strategies for reducing deployment costs of critical clean technologies and barriers to adoption.

To advance the deployment of clean technologies in Canada, it will be critical to coordinate between actors, in order to reduce the cost of achieving emission reductions and mitigate barriers to adoption. Important actors in the economy, such as Governments and utilities can play a key role in accelerating the development and adoption of clean technologies. Given their financial capacity, these actors can use their purchasing power to demonstrate clean technologies and provide a visibility that will encourage broader adoption.

Canada has a strong financial sector, which it can use as a powerful lever to encourage further low-carbon development both domestically and abroad. Although there are many significant low-cost GHG reduction opportunities in developing countries, barriers to investment such as higher perceived risk and imperfect information prevent these opportunities from being realised by Canadian companies. Through its $2.65 billion climate finance commitment, Canada will contribute to making these investments more accessible to Canadian companies, allowing for Canadian low-carbon technologies to help reduce emissions at a lower cost, while leading to significant export opportunities.

Private sector participation is of utmost importance at all stages of technology development. Technology developers and users are best positioned to bring forward new technologies that will ultimately succeed. Governments also need to play a role in providing the appropriate incentive framework for this to happen, as the private sector typically underinvests in R&D. For this to happen, there must be a good alignment of policies to allow for technology developers to most effectively advance their goals. Finally, sufficient investment is paramount to allowing good technology solutions to reach the market.

9.3 Further investments in RD&D and innovation in clean technology, combined with market pull mechanisms such as carbon pricing, will support Canada's competitiveness, creating high paying jobs and increased exports.

Clean technology is a sector that defines itself in the improvement of environmental outcomes related to economic activities in a broad sense. As such, it is a sector where innovation is of utmost importance, and therefore is very RD&D-intensive. RD&D can help solve environmental problems with current technologies, but it can also contribute to developing new clean technologies that will make it easier to reduce emissions in the future. However, for technologies to actually make a difference, successful commercialisation has to take place. For this to happen, market demand has to be there.

The right policies and frameworks can work to promote a low-carbon economy by helping to address the double market failure traditionally faced by the clean technology sector. As with innovation spending more broadly, there is a tendency for the private sector to underinvest in RD&D given that the benefits may not be fully captured by the investing firms. As well, there is the issue of businesses not accounting for environmental externalities in their decision-making. Existing and potential government policies can help address these market failures. For example, carbon pricing allows for the consideration of GHG emissions in the final price of a product, which provides a market value to the environmental benefits of clean technologies.

Other types of approaches, such as government procurement of clean technologies and regulations, could also increase demand for Canadian clean technologies. Governments will have to display leadership in providing broad support for clean technologies, coordinating innovation efforts and catalyzing private-sector involvement, particularly for early-stage R&D.

These initiatives would address an important barrier for Canada, which has historically struggled with demonstration and commercialisation of its clean technologies, increasing the challenge for companies to export untested products. Given the important growth of clean technology globally, this would position Canada favorably in terms

128 Hamilton T., *The $36-Trillion Question.*

of competitiveness in this market. Canada's competitiveness in the clean technology market would bring significant benefits to Canada, such as high paying jobs and significant increases in exports.

9.4 Innovation will result in economic and environmental spill-over effects, thereby increasing resource efficiency and productivity in other sectors and reducing other types of pollution.

Innovation in clean technologies, whether it is a breakthrough technology or one that drastically improves the efficiency of an existing process, can bring significant benefits to the economy as well as spill-over effects. Economic benefits of clean technologies can take different forms, depending on the nature of the technology. If a technology provides an efficiency improvement, benefits will be seen as reduced input costs, while they can take different forms in the case of a breakthrough technology. The internalisation of environmental externalities with the help of tools such as carbon pricing will ensure that technologies that reduce emissions have tangible economic benefits.

Another dimension where spill-over effects are tangible is the potential to reduce production costs and pollution through industrial ecology. Industrial ecology is a concept that could potentially transform the industrial sector into a highly efficient integrated ecosystem. Industrial ecology "seeks to emulate mature ecological systems in order to reduce environmental impacts through maximised efficiency of energy resource inputs and the minimisation of unutilized waste".[129] This concept promotes more interconnections between industrial sectors to optimise the flows of inputs and outputs from each industry such that all industrial processes together minimise energy use and disposal of waste products to improve resource efficiency and economic competitiveness. In other words, industrial ecology allows for output perceived as non-valuable (waste heat, wood residues, etc.) to be used as inputs by other companies within an industrial park, allowing for improved competitiveness and environmental outcomes.

9.5 Providing a clear and predictable signal for long-term investments and disclosing climate-related information will allow the market to better anticipate the transition to a low-carbon future.

> "Green investment represents a major opportunity for both long-term investors and macroeconomic policymakers seeking to jump-start growth."
>
> - Mark Carney, Governor of the Bank of England and Chairman of the G20's Financial Stability Board

The financing of climate-related initiatives is a crucial dimension of the climate change challenge with both a domestic and international component. Significant investments, most notably in adaptation measures, need to be made in order to deal with the costs of climate change, some of which may materialise over a long-term horizon. There are risks and opportunities associated with these investments that many businesses and political actors are taking steps to address. For example, the insurance sector has already been significantly exposed to climate change risks.[130] Those risks could be physical risks, where investments can be affected by major events like floods or disruption of global supply chains and could have important impacts for insurers and re-insurers. Liability risks could also arise as investors may be subject to lawsuits for carbon damages. Finally, transition risks may occur as structural change in the economy drive re-pricing of assets and values of companies.

Another key aspect of tackling climate change risks and opportunities is to provide investors with reliable and detailed information of climate change activities. Many companies, including 822 investors with US $95 trillion in assets, have chosen to disclose information on their action on climate change through the Carbon Disclosure Project or the Montréal Carbon Pledge. The Financial Stability Board's Task Force on Climate-related Financial Disclosures is working to develop voluntary, consistent climate-related financial risk disclosures for use by companies in providing information to investors, lenders, insurers, and other stakeholders. Such initiatives will allow a better understanding of the link between decarbonisation and the financial performance of firms. Further development of similar initiatives could create a virtuous circle where action is encouraged and best practices are shared. This would, in turn, provide a clear and predictable

129 McKinley A., *Industrial Ecology: A Review with Examples from the Canadian Mining Industry*, *Canadian Journal of Regional Science.*

130 Bank of England, *Breaking the Tragedy of The Horizon - Climate Change and Financial Stability - Speech by Mark Carney.*

signal for investments, allowing the market to better anticipate the transition. [131]

Finally, pricing carbon will give Canadian businesses, investors, and consumers a clear, predictable basis for decision making. Confidence that carbon pricing in Canada will continue to increase over time will encourage businesses and consumers to invest in cleaner appliances, vehicles, and technology. It will also encourage firms to invest in research into low-carbon technology, which will better position Canadian firms to compete in the rapidly-growing, low-carbon economy.

9.6 Canada has confirmed its commitment to clean energy innovation by joining the Mission Innovation international commitment, which aims to accelerate innovation by doubling investments in clean energy across the world.

On November 30, 2015, Canada announced its participation in the Mission Innovation international commitment, along with 20 other countries. This commitment is to double clean energy innovation investments from governments over the next five years, while encouraging greater levels of private-sector investment. This commitment also entails working with the Breakthrough Energy Coalition, an independent initiative that features 28 influential investors from 10 countries that commit to providing patient, early-stage capital (as opposed to venture capital, which seeks returns on investment on a much shorter time horizon) to advance clean energy technology innovation.

As part of this initiative, it is recognised that clean technology innovation often faces a so-called “valley of death”, which typically appears at the pre-commercialisation stage, where the conversion of a proven concept into a compelling product will determine whether a company will survive or not. This commitment aims to bridge that gap with increased government funding to enable more basic research, as well as more patient private capital, which will allow good concepts the time required to make it to market commercialisation. Given Canada’s particular challenges in commercialisation, this initiative could fill an important need for Canadian companies to succeed in clean energy innovation that can significantly reduce GHG emissions.

131 “[R]isks to financial stability will be minimised if the transition begins early and follows a predictable path, thereby helping the market anticipate the transition to a 2 degree world”. (Bank of England, Breaking the Tragedy of the Horizon - Climate Change and Financial Stability - Speech by Mark Carney.)

10 Achieving a Low-Carbon Future through Infrastructure Investments

Infrastructure investments are key to supporting Canada's deep decarbonisation efforts over the longer term and will help reshape the economy consistent with low-carbon pathways. Investing in infrastructure today will provide Canadians with increased employment opportunities, and cleaner, more modern communities, while also addressing climate change and air pollution.

Investing in public transit, green infrastructure, social infrastructure, Canada's trade and transportation corridors, as well as rural and northern communities, will provide a strong foundation for more inclusive and sustainable cities, and can also help to both address greenhouse gas emissions and enhance resilience to the impacts of climate change. For instance, Canadian communities building new urban transit networks and service extensions will transform the way that Canadians live, move and work.

In addition to committing significant resources (over $186 billion through to 2027-28), Canada is also establishing a new Infrastructure Bank, an arm's-length organization dedicated to increasing investment in growth-oriented infrastructure, transforming the way infrastructure is planned, funded and delivered across the country.

Considering the magnitude of investments required to develop key infrastructure projects, key linkages between infrastructure decision-making and long-term decarbonisation include:

- Investments are influential in setting long-term greenhouse gas pathways as the lifespan of infrastructure assets are long-lived, often ranging from 25 to 60 years.
- Once infrastructure investments are made, the behaviours and carbon emissions associated with infrastructure investments are more or less 'locked-in' and the shift to a new pathway can become very costly.
- Deploying infrastructure investments strategically can attract low-carbon infrastructure investments, creating a critical mass of funding for low-carbon solutions or the ability to 'anchor' future low-carbon investments. For example, making strategic investments in alternative fuel or electric vehicle infrastructure would underpin further investments in low-carbon vehicles.
- The transformative nature of infrastructure projects plays a complementary and enabling role to support the transition to a low-carbon economy. For instance, infrastructure that is designed to withstand the projected impacts of climate change can lead to cost savings over the longer term by avoiding maintenance and rehabilitation costs.

Canada is committed to working closely with all stakeholders, including provinces, territories and Indigenous peoples, to develop and implement an infrastructure plan that delivers investments across the country. As part of this plan, investments in green infrastructure and other streams, such as social and transportation, will reduce GHG emissions and support the resilience of infrastructure assets. Examples may include supporting further electrification of sectors currently reliant on fossil fuels, improving electricity transmission systems through inter-provincial transmission lines and the expansion of smart grids.

Investments in sustainable infrastructure will enable greater climate change adaptation and resilience; ensure that more communities can provide clean air and safe drinking water for their citizens; and support the transition toward more sustainable economic growth. Canada will ensure that our mid-century climate change objectives inform our infrastructure development going forward.

Conclusion

Dealing with climate change will ultimately require net-zero anthropogenic greenhouse gas emissions over the course of this century. Canada will need to fundamentally transform all economic sectors, especially patterns of energy production and consumption. Over time, this requires major structural changes to the economy and the way people live, work, and consume.

A low-greenhouse gas future also represents a massive opportunity to increase prosperity and the well-being of Canadians, to improve the livability of the built environment, modernise transportation, and enhance the natural environment. The benefits include: reducing air pollution and congestion, modernising infrastructure to provide more inclusive and sustainable cities, creating cleaner and more modern communities, growing Canada's clean technology sector, increasing economic productivity and efficiency, saving energy and reducing energy costs, and enhancing resilience to the impacts of climate change.

Much of the transformation can be achieved with existing technology, but innovation, such as through the Mission Innovation initiative, and significant investments in research, development, demonstration & deployment, and related infrastructure, will be fundamental to the transition.

Additional collaboration across industry leaders to identify common innovation priorities will be needed to seize opportunities to integrate innovation into business strategies. Funding environments, intellectual property regimes, research agendas, and communication strategies will need to be shaped to stimulate innovation investments.

Decarbonisation will require a sustained societal effort that will take many years to accomplish. This will require a technological ramp up of low greenhouse gas alternatives, and also societal engagement and action by all Canadians. Working collaboratively with Indigenous peoples by supporting their on-going implementation of climate change initiatives will be key. Likewise, all levels of government will need to implement a vast array of the various policy options that are available to them. In this respect, Canada will continue to work collaboratively with provinces and territories including through the pan-Canadian framework on clean growth and climate change. Although the pace of this transition may vary from Canadian jurisdiction to jurisdiction, the direction and orientation are clear.

Annex 1: Detailed Modelling Results from 2050 Scenarios

This annex provides modelling results for the aggregate energy economy or total economy of Canada under the described low greenhouse gas modelling analyses (see model and scenario descriptions in Chapter 3). The tables are provided for illustrative purposes only and should not be interpreted as optimal pathways. Moreover, the sectoral aggregation may differ from one model to another.

The table below illustrates results from ECCC's modelling, where a 2050 target of 80% below 2005 levels is achieved by reductions in emissions from the energy sector, industrial processes, agriculture and waste. The reductions are influenced by a common price on greenhouse gas emissions.

As illustrated by the table, the greatest emissions reductions are projected to come from energy-related emissions (89% below the 2005 level), followed by emissions from waste (55% below the 2005 level), industrial process emission (50% below the 2005 level) and agriculture (36% below the 2005 level). As there are currently relatively few moderate cost reduction opportunities for industrial process sector, a project reduction in output drives the decline in emissions.

Table A1: Environment and Climate Change Canada - Gross Emissions (2050)

Canada's 1990–2050 GHG Emissions by Sector (Mt CO_2e)				
Greenhouse Gas Categories	1990	2005	2050	% Change Relative to 2005
TOTAL: EXCLUDING LULUCF	**613**	**748**	**149**	**-80%**
ENERGY	482	597	67	-89%
Stationary Combustion Sources	285	342	46	
Transport	148	195	38	
Fugitive Sources	49	61	6	
CO_2 Capture, Transport and Storage	-	0	-23	
INDUSTRIAL PROCESSES AND PRODUCT USE	56	58	29	-50%
Mineral Products	8	10	2	
Chemical Industry	17	10	19	
Metal Production	24	20	5	
Production and Consumption of Halocarbons, SF_6 and NF_3	1	6	1	
Non-Energy Products from Fuels and Solvent Use	5	12	2	
Other Product Manufacture and Use	0	1	0	
AGRICULTURE	49	61	39	-36%
Enteric Fermentation	23	31	20	
Manure Management	8	10	6	
Agriculture Soils	17	19	12	
Field Burning of Agricultural Residues	0	0	0	
Liming, Urea Application and Other Carbon-containing Fertilizers	1	1	0	
WASTE	26	31	14	-55%
Solid Waste Disposal	24	28	13	
Biological Treatment of Solid Waste	1	1	1	
Wastewater Treatment and Discharge	1	1	0	
Incineration and Open Burning of Waste	1	1	0	

The table below illustrates results from ECCC's modelling of a scenario in which a 2050 target of 80% below 2005 levels is achieved by a 65% reduction in the combined emissions of the energy sector, industrial processes, agriculture, and waste, plus an assumed contribution from credits due to improved land sector sequestration and internationally transferred mitigation outcomes.

As depicted in the table, the greatest reductions are projected to come from energy-related emissions (74% below the 2005 level), followed by emissions from waste (55% below the 2005 level), industrial process emission (28% below the 2005 level) and agriculture (15% below the 2005 level).

Table A2: Environment and Climate Change Canada-Net Emissions (2050)

Canada's 1990–2050 GHG Emissions by Sector (Mt CO_2e)				
Greenhouse Gas Categories	1990	2005	2050	% Change Relative to 2005

The table below illustrates modelling results from Trottier Energy Futures Project, where a 2050 target of 60% below the 1990 levels is achieved by reductions in emissions from the energy sector, industrial processes, agriculture and wastes. The table below illustrated the reductions when current technologies are available, with the addition of interprovincial interconnections to the electricity grid.

As illustrated by the table, the greatest reductions are projected to come from electricity emissions (99% below the 2015 level), followed by emissions from the residential sector (87% below the 2015 level), commercial emissions (76% below the 2015 level), transportation (71% below the 2015 level) and agriculture (64% below the 2005 level).

Table A3: Trottier Energy Futures Project (Current Technology Scenario)

Canada's 1990–2050 GHG Emissions by Sector (Trottier) Mt CO_2e			
Greenhouse Gas Categories	2015	2050	% Change Relative to 2015
CURRENT TECHNOLOGY SCENARIO:			
TOTAL (EXCLUDING PROCESS EMISSIONS)	488	171	-65%
TOTAL (INCLUDING PROCESS EMISSIONS)	560	282	-50%
AGRICULTURE	16	6	-64%
COMMERCIAL	36	9	-76%
INDUSTRIAL PROCESSES AND PRODUCT USE	53	35	-34%
RESIDENTIAL	43	6	-87%

ELECTRICITY	60	0	-99%
SUPPLY - COMBUSTION	112	66	-41%
SUPPLY – PROCESS	71	112	56%

The table below is also from the Trottier Energy Futures Project. It illustrates the reductions when other new technologies are available to reduce GHG emission reduction costs. The contribution of new technologies increases the reduction from agriculture, commercial, residential and supply-combustion.

As illustrated by the table, the greatest reductions are projected to come from electricity emissions (99% below the 2015 level), followed by emissions from the residential sector (89% below the 2015 level), commercial emissions (88% below the 2015 level), agriculture (66% below the 2015 level) and supply process emissions (56% below the 2005 level).

Table A4: Trottier Energy Futures Project (New Technology Scenario)

Canada's 1990–2050 GHG Emissions by Sector (Trottier) Mt CO_2e			
Greenhouse Gas Categories	2015	2050	% Change Relative to 2015
NEW TECHNOLOGY SCENARIO:			
TOTAL (EXCLUDING PROCESS EMISSIONS)	488	171	-65%
TOTAL (INCLUDING PROCESS EMISSIONS)	560	282	-50%

Government of Canada Invests in Renewable Natural Gas

News Release

From Natural Resources Canada

March 15, 2017 Ottawa Natural Resources Canada

Investing in the production of renewable natural gas (RNG) from forest industry residue can diversify Canada's energy mix, reduce greenhouse gas emissions, improve industrial efficiency and create new economic opportunities for Canadian companies and good middle-class jobs that benefit rural communities.

Canada's Minister of Natural Resources, the Honourable Jim Carr, today announced an $800,000 investment in G4 Insights Inc. for the development of technology to convert forestry waste into RNG that can be distributed through existing natural gas pipelines in Canada.

G4 Insights is partnering with the Canadian Gas Association members Enbridge Gas Distribution, FortisBC, Gaz Metro, Union Gas, utility host ATCO, the Natural Gas Innovation Fund, Alberta Innovates, and FPInnovations, who are contributing a combined $1.35 million towards this project.

Renewable natural gas produced from sustainably managed forest residue can emit up to 85 per cent less greenhouse gas emissions than traditional fossil fuels. Forest residue, which includes all parts of the tree, can be converted into solid, liquid or gaseous biofuels such as RNG that can then be burned for energy or used as fuel substitutes for transportation or industrial processes.

G4 Insights will build a RNG demonstration plant and test it under operational conditions with a range of biomass types to generate relevant technical operating and economic data. The optimal site location has been chosen in Edmonton, Alberta to support all-season operation in outdoor conditions.

Today's announcement reaffirms the Government of Canada's commitment to preserving our natural environment and resources for future generations — to put in place real actions that will work toward Canada's climate goals.

Quotes

> "Our Government values innovation and we are proud to support this renewable natural gas project. By investing in clean technology industries we can help them be more innovative, more competitive and more successful."
>
> *Jim Carr*
> *Canada's Minister of Natural Resources*

> *"The support from Natural Resources Canada for renewable natural gas is essential to creating a pathway to greenhouse gas reductions that are affordable, reliable and sustainable. This project will advance G4 technology toward commercialization through field trials of enhanced subsystems for robust continuous operation and grid injection."*
>
> *Edson Ng*
> *Principal, G4 Insights Inc.*

"CGA and the natural gas delivery industry have made driving innovation a key focus for the last six years with initiatives and investments around the use of natural gas and natural gas delivery infrastructure. Improving the technology to convert biomass to RNG will support the industry's aspirational target of blending 10 percent RNG in the Canadian natural gas distribution system by 2030."

Timothy M. Egan
President and CEO, Canadian Gas Association

"The Natural Gas Innovation Fund is pleased to support the deployment of the G4 Insights technology in Alberta. Our funding for this project marks the first investment of our fund, and we are looking forward to partnering with NRCan and other energy stakeholders in Canada on projects like the one announced today to support innovation, ensure the availability of affordable energy for customers and reduce emissions."

John Adams
Managing Director, Natural Gas Innovation Fund

"Alberta Innovates and its subsidiary InnoTech Alberta are very pleased to support G4's technology demonstration to make renewable natural gas using Alberta biomass, and we recognize this as another important step in providing options to 'green' Alberta's energy grid."

Steve Price
Executive Director, Bioindustrial Innovation, Alberta Innovates

"ATCO is excited to host and sponsor G4 in Edmonton. RNG is a largely untapped renewable resource that Canadians can use to heat and power their homes and businesses using a carbon-neutral fuel. ATCO is supportive of RNG as a technology and is hopeful that their support will help accelerate the adoption of RNG in Alberta and commercialization of the G4 technology."

Dean Reeve
Sr. Vice President and General Manager, Gas Distribution
ATCO Pipelines & Liquids Global Business Unit

"This project demonstrates the importance of bringing together scientific expertise, industrial sector know-how and government support to solve the challenges of creating a clean tech economy. FPInnovations is proud to have provided facilities and technical support toward the development of G4 Insight's technology and looks forward to RNG becoming a viable renewable energy source in the future."

Pierre Lapointe
President and CEO of FPInnovations

Technical paper: federal carbon pricing backstop

Download the PDF version (0.45 MB)

The Pan-Canadian Framework on Clean Growth and Climate Change is Canada's plan to grow the economy while reducing greenhouse gas (GHG) emissions and building resilience to adapt to a changing climate. [1] A central component of the Pan-Canadian Framework is the commitment to pricing carbon pollution across the country by 2018.

Pricing carbon pollution is widely recognized as an efficient way to reduce GHG emissions and help achieve our objectives to protect the environment, stimulate investments in low-carbon innovation and create a sustainable clean-growth economy. Carbon pricing sends an important signal to markets and provides incentives to reduce energy use through conservation and efficiency measures, while also serving to drive fuel switching and technology advances. Applying carbon pricing to a broad set of emission sources across Canada, with increases in stringency over time, will help to reduce GHG emissions at the lowest cost to businesses and consumers, while supporting clean growth.

In October 2016, the federal government published a benchmark for ensuring that carbon pricing applies to a broad set of emission sources throughout Canada by 2018 with increasing stringency over time. [2] This benchmark provides provinces and territories with flexibility to implement their own carbon pollution pricing systems. In the benchmark, the federal government also committed to implement a federal carbon pricing backstop system that will apply in any province or territory that does not have a carbon pricing system in place by 2018 that aligns with the benchmark.

This technical discussion paper seeks to inform Canadians and stakeholders about the federal carbon pricing backstop and to obtain feedback on its design.

Interested parties are invited to provide written comments to Environment and Climate Change Canada (carbonpricing-tarificationcarbone@canada.ca) on or before June 30, 2017. There will be further opportunities to provide input as the details of the system are developed.

Federal carbon pricing benchmark

On October 3, 2016, the Government of Canada released “The pan-Canadian approach to pricing carbon pollution” – the benchmark [3] – outlining the criteria that carbon pricing systems implemented by provinces and territories need to meet. The goal of the benchmark is to ensure that carbon pollution pricing applies to a broad set of emission sources with increasing stringency over time in order to reduce GHG emissions at lowest cost to business and consumers and support innovation and clean growth.

The pan-Canadian approach to pricing carbon pollution provides jurisdictions the flexibility to implement either an explicit price-based system (a carbon tax such as the one in British Columbia, or a hybrid approach composed of a carbon levy and an output-based pricing system, such as in Alberta) or a cap-and-trade system (such as those in Quebec and Ontario).

The Pan-Canadian Framework includes a commitment for a review of the overall approach to pricing carbon by early 2022 to confirm the path forward. An interim report will also be completed in 2020, which will be reviewed and assessed by First Ministers. As an early deliverable, the review will assess approaches and best practices to address the competitiveness of emissions-intensive, trade-exposed sectors.

Federal carbon pricing backstop

The federal government plans to introduce new legislation and regulations to implement a carbon pollution pricing system – the backstop – to be applied in jurisdictions that do not have carbon pricing systems that align with the benchmark.

All elements of the backstop will apply in a jurisdiction that does not have a carbon pricing system in place. The backstop will also supplement (or “top-up”) systems that do not fully meet the benchmark. For example, the backstop could expand the sources covered by provincial carbon pollution pricing or it could increase the stringency of the provincial carbon price.

As committed in the October 3, 2016 document Pan-Canadian Approach to Pricing Carbon Pollution, the federal system will return direct revenues from the carbon price to the jurisdiction of origin. The federal government is open to feedback on the best mechanism to achieve this.

Backstop instrument

The federal carbon pollution pricing backstop will be composed of two key elements:

- A carbon levy applied to fossil fuels; and
- An output-based pricing system for industrial facilities that emit above a certain threshold, with an opt-in capability for smaller facilities with emissions below the threshold.

How GHG emissions are measured

Both the carbon levy and the output-based pricing system will price carbon on a CO2e basis. The United Nations Framework Convention on Climate Change (UNFCCC) reporting requirements apply to seven greenhouse gases (GHGs). [4] Each of these gases has a different impact on the climate. The use of CO2e is the internationally-recognized approach to establishing a standard carbon price (e.g., $10/tonne of CO2e) and translating that price to the appropriate price for each greenhouse gas. More detail on the calculation of CO2e is provided in Annex 1.

For both components of the backstop, emissions will be converted to a CO2e basis. For the levy, rates will be set out under the relevant legislation and will be based on the Canadian average CO2e emission factor for a fossil fuel (where factors differ by region for that fuel) and the technology that is most commonly used to combust that fuel. For the output-based pricing system, regulated entities will use the same factors to calculate their emissions following a methodology that will be specified in regulations.

The carbon levy component of the backstop

Scope of the carbon pricing levy

Coverage and rates of the carbon levy

Fossil fuels that will be subject to the levy include liquid fuels (e.g., gasoline, diesel fuel, and aviation fuel), gaseous fuels (e.g., natural gas) and solid fuels (e.g., coal and coke).

Carbon levy rates will initially be set for the period from 2018 to 2022. Rates for each fuel subject to the levy will be set such that they are equivalent to $10 per tonne of CO2e in 2018 and increase by $10 per tonne annually to $50 per tonne in 2022. The rates will be based on global warming potential factors and emission factors [5] used by Environment and Climate Change Canada to report Canada's emissions to the UNFCCC, and will be expressed in standard commercial units to facilitate the compliance with, and the administration of, the levy. Tables 1 to 3 below show the rates for liquid fuels, gaseous fuels, and solid fuels, respectively, over the initial 5-year period.

Table 1: Rates of levy on liquid fossil fuels from 2018 to 2022

Liquid fuel	Unit	2018 ($10/tonne)	2019 ($20/tonne)	2020 ($30/tonne)	2021 ($40/tonne)	2022 ($50/tonne)
Gasoline	¢/L	2.33	4.65	6.98	9.30	11.63
Diesel / Light Fuel Oil	¢/L	2.74	5.48	8.21	10.95	13.69
Heavy Fuel Oil	¢/L	3.19	6.37	9.56	12.75	15.93
Aviation Gasoline	¢/L	2.49	4.98	7.47	9.95	12.44
Aviation Turbo Fuel / Jet Fuel / Kerosene	¢/L	2.58	5.16	7.75	10.33	12.91
Methanol	¢/L	1.10	2.20	3.29	4.39	5.49
Naphtha	¢/L	2.25	4.51	6.76	9.02	11.27
Petroleum Coke	¢/L	3.84	7.67	11.51	15.35	19.19

Table 2: Rates of levy on gaseous fossil fuels from 2018 to 2022

Gaseous fuel	Unit	2018 ($10/tonne)	2019 ($20/tonne)	2020 ($30/tonne)	2021 ($40/tonne)	2022 ($50/tonne)
Marketable Natural Gas	¢/m3	1.96	3.91	5.87	7.83	9.79

Non-marketable Natural Gas	¢/m3	2.59	5.17	7.76	10.34	12.93
Propane	¢/L	1.55	3.10	4.64	6.19	7.74
Butane	¢/L	1.78	3.56	5.34	7.12	8.90
Ethane	¢/L	1.02	2.04	3.06	4.08	5.09
Gas Liquids	¢/L	1.67	3.33	4.99	6.66	8.32
Still Gas	¢/m3	2.70	5.40	8.10	10.80	13.50
Pentanes Plus	¢/L	1.78	3.56	5.34	7.12	8.90
Coke Oven Gas	¢/m3	0.70	1.40	2.10	2.80	3.50

Table 3: Rates of levy on solid fossil fuels from 2018 to 2022

Solid fuel	Unit	2018 ($10/tonne)	2019 ($20/tonne)	2020 ($30/tonne)	2021 ($40/tonne)	2022 ($50/tonne)
Low Heat Value Coal (i.e., Sub-bituminous Coal; Lignite)	$/tonne	17.72	35.45	53.17	70.90	88.62
High Heat Value Coal (i.e., Bituminous Coal; Anthracite)	$/tonne	22.52	45.03	67.55	90.07	112.58
Coke (coal)	$/tonne	31.80	63.59	95.39	127.19	158.99
Waste fuel / Tires	$/tonne	19.97	39.95	59.92	79.89	99.87

Application of the carbon levy

In general, the levy will apply to fuels that are used in a backstop jurisdiction, irrespective of whether the fuels were produced in, or brought into, the backstop jurisdiction.

In most cases, the levy will be applied early in the supply chain of each fuel used in a backstop jurisdiction, and will be payable by the producer or distributor. The final user of a fuel will not generally have any special rights or obligations in respect of the levy, as the user will purchase levy-paid fuel in most cases.

Fuel producers and certain distributors will be able to acquire and hold fuel without the levy being payable until the fuel is subsequently used by the producer or distributor, or, as discussed later, delivered to a final retailer or end-user.

For purposes of the levy, use will generally include fuel that is combusted, vented or flared. [6] Fuel used as a raw material, diluent or solvent in a manufacturing or petrochemical process in a manner that does not produce heat or energy will not be subject to the carbon levy. [7]

This general approach will be achieved by a series of application rules and registration requirements that are presented below.

Application framework of the carbon levy

Generally, the levy will apply to fuel that is produced, imported or brought into a backstop jurisdiction.

For the purposes of the levy, there will be four categories of persons within the fuel supply chain: Registered Fuel Distributors, Registered Fuel Importers,Registered Fuel Users, and other non-registered persons.

- Registered Fuel Distributors will generally be producers of fuel, large wholesale distributors of fuel, and natural gas retailers.
- Registered Fuel Importers will be entities that cannot become Registered Fuel Distributors and that import fuel from outside Canada at a location in a backstop jurisdiction, or that bring fuel into a backstop jurisdiction from another jurisdiction in Canada.
- Registered Fuel Users will be persons that cannot become Registered Fuel Distributors and that are required to report on fuel used in a backstop jurisdiction and, in certain circumstances, may be required to pay the levy [8] or be entitled to claim relief from the levy, where it has been previously paid. Registered Fuel Users will include inter-jurisdictional commercial transportation operators, and entities operating a facility covered by the output-based pricing system.
- Non-registered persons will generally be retailers (other than natural gas retailers) and end-users, including individuals and business consumers.

The levy will generally be payable when a Registered Fuel Distributor uses fuel in a backstop jurisdiction or delivers fuel to a person in the backstop jurisdiction that is not a Registered Fuel Distributor. Consequently, a Registered Fuel Distributor will be able to deal in fuel with other Registered Fuel Distributors without the levy being payable.

The levy will generally apply to fuel when it is imported or brought into the backstop jurisdiction by a Registered Fuel Importer. However, the levy will not be payable by a Registered Fuel Importer if the Registered Fuel Importer delivers the fuel to a person in the backstop jurisdiction that is a Registered Fuel Distributor, or delivers the fuel outside the backstop jurisdiction in a timely manner.

Registered Fuel Users that are operators of a facility covered by the output-based pricing system may be able to acquire fuel without the levy being payable, if the fuel is for use at that facility. Registered Fuel Users that are inter-jurisdictional commercial transportation operators will generally acquire fuel in a backstop jurisdiction on which the levy has been paid, except in limited circumstances as described below.

Generally, non-registered persons will acquire fuel on which the levy has been paid.

Fuels produced in a backstop jurisdiction

In the case of fuel that is produced by a Registered Fuel Distributor and used by that Registered Fuel Distributor in a backstop jurisdiction, the levy will become payable by the Registered Fuel Distributor at the time that it is used. In this case, the levy will be reported to the Canada Revenue Agency (CRA) by the Registered Fuel Distributor through a return and remitted to the Receiver General of Canada.

In the case of fuel that is produced by a Registered Fuel Distributor in a backstop jurisdiction and delivered to a purchaser in a backstop jurisdiction that is not a Registered Fuel Distributor, the levy will become payable by the Registered Fuel Distributor upon delivery to the purchaser. In this case, the levy will be reported to the CRA by the Registered Fuel Distributor through a return and remitted to the Receiver General of Canada. However, if the fuel is delivered to a purchaser that is another Registered Fuel Distributor, the levy will not become payable on that transaction. Instead, the levy will become payable by that other Registered Fuel Distributor at the time the fuel is used by that other Registered Fuel Distributor in a backstop jurisdiction, or at the time the fuel is subsequently delivered in a backstop jurisdiction to a person that is not a Registered Fuel Distributor.

- For example, if a Registered Fuel Distributor, such as an entity operating an oil refinery, delivers gasoline to another Registered Fuel Distributor, such as a wholesale distributor, then the levy will not be payable upon that delivery of the fuel. Rather, the levy will become payable when that other Registered Fuel Distributor (i.e., the wholesaler) delivers the fuel in a backstop jurisdiction to a purchaser that is not a Registered Fuel Distributor, such as a retail gas station.

The levy will not be payable on fuel that is produced by a Registered Fuel Distributor in a backstop jurisdiction and that is delivered outside a backstop jurisdiction.

- For example, gasoline that is produced in a refinery that is operated by a Registered Fuel Distributor in a backstop jurisdiction would ultimately not be subject to the levy if that gasoline is delivered outside a backstop jurisdiction.

Fuels brought into a backstop jurisdiction from another jurisdiction in Canada

Generally, anyone that brings fuel into a backstop jurisdiction from another jurisdiction in Canada will be required to register as either a Registered Fuel Distributor or, if they do not meet the minimal volume threshold or other requirements to become a Registered Fuel Distributor, as a Registered Fuel Importer.

A Registered Fuel Distributor will be able to bring fuel into a backstop jurisdiction on a levy-deferred basis. The levy will become payable by the Registered Fuel Distributor only at the time it uses the fuel in the backstop jurisdiction or delivers it in the backstop jurisdiction to a person that is not a Registered Fuel Distributor. In either case, the Registered Fuel Distributor will report to the CRA through a return and remit the levy to the Receiver General of Canada. If the fuel is instead delivered to another Registered Fuel Distributor, no levy will be applied to that transaction. The levy will become payable when the Registered Fuel Distributor that acquired the fuel uses it or delivers it to another person, unless that other person is another Registered Fuel Distributor.

Registered Fuel Importers will generally not be able to bring fuel into a backstop jurisdiction and hold it on a levy-deferred basis. The levy will apply to fuel that is brought into a backstop jurisdiction by a Registered Fuel Importer at the time the fuel is brought in. In this case, the Registered Fuel Importer will report to the CRA through a return and remit the levy to the Receiver General of Canada. However, if the Registered Fuel Importer brings in the fuel for delivery to a Registered Fuel Distributor, the levy will not become payable by the Registered Fuel Importer. The levy will become payable when the Registered Fuel Distributor that acquired the fuel uses it or delivers it to another person in the backstop jurisdiction, unless that person is also a Registered Fuel Distributor. If fuel is brought into a backstop jurisdiction by a Registered Fuel Importer for delivery to a Registered Fuel Distributor but is subsequently diverted for use in the backstop jurisdiction or delivery in the backstop jurisdiction to a person that is not a Registered Fuel Distributor, then the levy will become payable upon that use or delivery.

There will be special bringing-in rules for Registered Fuel Users that are inter-jurisdictional carriers, which are described below.

The levy will generally not be applicable on fuel that is brought into a backstop jurisdiction if the fuel is subsequently delivered outside the backstop jurisdiction in a timely manner. For example, the levy will not become payable if the fuel is merely in transit through a backstop jurisdiction, such as gasoline transiting in a tanker truck from one province to another through a backstop jurisdiction. If fuel is brought into a backstop jurisdiction by a Registered Fuel Importer for delivery outside the backstop jurisdiction but is subsequently diverted for use in the backstop jurisdiction or for delivery in the backstop jurisdiction to a person that is not a Registered Fuel Distributor, then the levy will become payable upon that use or delivery.

Fuels imported into Canada at a location in a backstop jurisdiction

Generally, anyone that imports fuel into Canada at a location in a backstop jurisdiction will be required to register as either a Registered Fuel Distributor or, if they do not meet the requirements of a Registered Fuel Distributor, as a Registered Fuel Importer.

Registered Fuel Distributors will be able to import fuel into a backstop jurisdiction on a levy-deferred basis. The levy will apply upon importation into Canada, but will become payable by the Registered Fuel Distributor that imported the fuel only at the time it uses the fuel in the backstop jurisdiction or at the time it delivers the fuel in the backstop jurisdiction to a person that is not a Registered Fuel Distributor. In this case, the Registered Fuel Distributor will report to the CRA through a return and remit the levy to the Receiver General of Canada. If the fuel is delivered outside a backstop jurisdiction, the levy will not become payable. If the fuel is instead delivered to another Registered Fuel Distributor, the levy will become payable when the other Registered Fuel Distributor uses it or delivers it to another person, unless that other person is also a Registered Fuel Distributor.

If a Registered Fuel Importer imports fuels for its own use in a backstop jurisdiction or for delivery in a backstop jurisdiction to a person that is not a Registered Fuel Distributor, then the levy will become payable at the time of importation. In this case, the Registered Fuel Importer will report to the CRA through a return and remit the levy to the Receiver General of Canada (i.e., the levy is not collected at the border upon importation).

If a Registered Fuel Importer imports the fuel for subsequent delivery outside the backstop jurisdiction in a timely manner, the levy will not be payable. If fuel is imported by a Registered Fuel Importer for delivery outside the backstop jurisdiction but is subsequently diverted for use in the backstop jurisdiction or for delivery in the backstop jurisdiction to a person that is not a Registered Fuel Distributor, then the levy will become payable upon that use or delivery.

If a Registered Fuel Importer imports fuel for delivery to a Registered Fuel Distributor, the levy will not become payable by the Registered Fuel Importer. The levy will become payable by the Registered Fuel Distributor when it uses the fuel or delivers it to another person in the backstop jurisdiction, unless that other person is also a Registered Fuel Distributor. If fuel is imported by a Registered Fuel Importer for delivery to a Registered Fuel Distributor but is subsequently diverted for use in the backstop jurisdiction or delivery in the backstop jurisdiction to a person that is not a Registered Fuel Distributor, then the levy will become payable upon that use or delivery.

If a non-registered person imports fuel at a location in a backstop jurisdiction, the person will report directly to the Canada Border Services Agency upon importation and remit the levy to the Receiver General of Canada at that time (i.e., the levy will be collected at the border upon importation).

Fuels imported into Canada at a location other than in a backstop jurisdiction for delivery in a backstop jurisdiction

Similar rules will apply to fuel that is imported into Canada at a location outside of a backstop jurisdiction if the fuel is for delivery in a backstop jurisdiction. For example, if a Registered Fuel Distributor imports gasoline into Canada at a location in a non-backstop jurisdiction, but the fuel is for delivery to a backstop jurisdiction, the levy will not be payable until the fuel is used in the backstop jurisdiction by the Registered Fuel Distributor, or is delivered to a person in the backstop jurisdiction that is not a Registered Fuel Distributor. In this case, the levy will be reported to the CRA by the Registered Fuel Distributor through a return and remitted to the Receiver General of Canada.

If a non-registered person imports gasoline into Canada at a location in a non-backstop jurisdiction, but the gasoline is for delivery to a backstop jurisdiction, the person will report directly to the Canada Border Services Agency upon importation and remit the levy to the Receiver General of Canada at that time.

Application of the carbon levy to natural gas

In addition to upstream entities that produce natural gas (e.g., gas batteries, gas production plants) in a backstop jurisdiction, natural gas retailers that deliver natural gas in a backstop jurisdiction will be required to become Registered Fuel Distributors.

The carbon levy will generally not be payable on natural gas until it is delivered to a final user (e.g., delivered to residential homes), at which time the levy will generally become payable by the natural gas retailer that delivers the fuel.

Where transactions occur in a backstop jurisdiction between natural gas distributors or producers, the levy will generally not be payable, as these would typically be transactions between Registered Fuel Distributors.

The levy will apply to natural gas that is used by a Registered Fuel Distributor in the natural gas supply chain and become payable by the Registered Fuel Distributor at the time the fuel is used. If a Registered Fuel Distributor delivers fuel to a person that is not a Registered Fuel Distributor, the levy will become payable by the Registered Fuel Distributor at the time the fuel is delivered.

Generally, the levy will not become payable on natural gas that is delivered outside a backstop jurisdiction.

Relief from the carbon levy

There will be certain situations in which relief from the levy will be provided, including in respect of:

- Fuel used at a facility whose emissions are accounted for under the output-based pricing system (once it comes into effect);
- Gasoline and diesel fuel used by registered farmers in certain farming activities;
- Fuel exported or removed from a backstop jurisdiction;
- Fuel used as international ships' stores (e.g., international aviation and marine fuels);
- In specified circumstances, fuel used as a raw material, diluent or solvent in a manufacturing or petrochemical process in a manner that does not produce heat or energy;
- Fuel purchased by visiting military forces and diplomatic representatives;
- Fuel in sealed, pre-packaged containers of one litre or less; and
- Biofuel portion of blended fuels (e.g., for gasoline or diesel blended with biofuels, the levy will apply to only the fossil fuel content).

The Government will develop a mechanism for providing relief (e.g., exemption certificate, rebate) for each of these circumstances.

Registration requirements

As noted above, certain persons will be required to register with the CRA as a Registered Fuel Distributor, a Registered Fuel Importer or a RegisteredFuel User.

The registrations will be administered on a fuel-by-fuel basis. Therefore, the registration status of a person may differ per type of fossil fuel subject to the levy.

Registered fuel distributors

Generally, all producers of fuels covered by the carbon levy operating within a backstop jurisdiction will be required to be registered as a fuel distributor with the CRA. This will include oil refiners and coal mine operators.

Large wholesale distributors (e.g., entities whose business essentially consists of purchasing fuels for purpose of resale other than at retail and above a specified annual volume threshold) of fossil fuels operating within a backstop jurisdiction will be able to become Registered Fuel Distributors. Generally, wholesale distributors of fuels are entities that purchase fuels for purpose of re-sale in a backstop jurisdiction to entities other than end-users. An entity will be considered a wholesale distributor and required to become a Registered Fuel Distributor, whether it acquires fuel from within the backstop jurisdiction or whether it imports or brings-in the fuel from another jurisdiction.

In addition to upstream entities that produce natural gas, natural gas retailers that deliver natural gas in a backstop jurisdiction will be required to become Registered Fuel Distributors.

In addition to the requirements noted above, there will be some restrictions on who will be able to become a Registered Fuel Distributor. For example, entities that will be considered as Registered Fuel Distributor of some fuels, including gasoline and diesel, may be restricted to those entities that deal in fuel above a specified quantity. In other words, for some fuel types, if an entity does not satisfy the specified minimum quantity requirement, it may not be eligible to become or to continue to be a Registered Fuel Distributor. Also, retailers and end-users will generally not be able to become Registered Fuel Distributors.

Registered fuel importers

Generally, any person that is not able to become a Registered Fuel Distributor and that imports fuel into Canada for delivery or use in a backstop jurisdiction or that brings fuel into a backstop jurisdiction from another jurisdiction in Canada will be required to become a Registered Fuel Importer.

However, a person that brings in or imports 200 litres or less will generally not be subject to this requirement.

Registered fuel users

Some persons will be required to become Registered Fuel Users, including the following:

- Commercial carriers (e.g., operators of transport trucks, operators of rail transportation, operators of marine transportation, air carriers) that operate in a backstop jurisdiction and at least one other jurisdiction;
- An operator of a facility whose emissions are covered under the output-based pricing system;
- Certain businesses that burn waste that is subject to the carbon levy (e.g., tires, asphalt shingles) in a backstop jurisdiction; and
- Certain businesses that use fuel as a raw material, diluent or solvent in a manufacturing or petrochemical process in a manner that does not produce heat or energy.

Inter-jurisdictional commercial transportation requirements

Commercial carriers (i.e., persons transporting passengers, freight, or both) that operate in a backstop jurisdiction, and in at least one other jurisdiction, will be required to be registered with the CRA as Registered Fuel Users.

Road and rail

For fuels consumed in commercial road and rail transportation, the levy will apply to only the fuel that is used within a backstop jurisdiction. In other words, the levy will apply both to fuel that is used during a journey that starts and ends in the same jurisdiction (intra-jurisdictional travel) and to fuel that is used during the portion of an inter-jurisdictional or international journey that occurs in a backstop jurisdiction.

- Inter-jurisdictional road and rail carriers will purchase fuel in a backstop jurisdiction with the levy embedded.
- These carriers will also be required to pay the carbon levy on fuel that was purchased outside the backstop jurisdiction, brought into the backstop jurisdiction and used in the backstop jurisdiction. Conversely, they will be entitled to relief for fuel that is purchased in the backstop jurisdiction but used outside the jurisdiction.
- To this end, inter-jurisdictional road and rail carriers will be required to file a return with the CRA and report fuel purchases made inside and outside each backstop jurisdiction, as well as the distance travelled inside and outside each backstop jurisdiction in order to self-assess the amount of carbon levy owing, or amount of relief to the carrier, as the case may be.
- All truck operators and commercial buses – domestic and international – that transit through a backstop jurisdiction will be required to register with CRA, report on levy paid and payable and file regular returns.

Marine

For fuels consumed in commercial marine transportation, the levy will only apply to fuel used in intra-jurisdictional travel. In other words, the levy will only apply to fuel used for commercial marine transportation that occurs between two points in the backstop jurisdiction.

- Marine carriers in a backstop jurisdiction will generally purchase fuel with the levy embedded. They will file regular returns and will be entitled to relief for levy paid on fuel that is used in inter-jurisdictional journeys (e.g., trips between a point in the backstop jurisdiction and a point outside the backstop jurisdiction).
- Further, these carriers will be required to self-assess on fuels purchased without the levy previously applied and used in intra-jurisdictional journeys. For example, if a ship ends a journey in a backstop jurisdiction with unused fuel and subsequently makes an intra-jurisdictional journey using that fuel, the marine carrier is required to self-assess on the fuel used in that journey.
- For fuel that is destined for international ships' stores, fuel could be delivered without the levy being payable if delivered by a Registered Fuel Distributor. If the fuel used for international ships' stores had levy embedded, relief will be provided for that fuel.

Aviation

To date, provinces that have introduced carbon pricing systems have either not covered GHG emissions from aviation fuels at all or not applied the carbon price to aviation fuels used in inter-jurisdictional flights within Canada. The Government recognizes that this exemption may have been made to address competitiveness concerns for local airports. The introduction of carbon pricing in all Canadian provinces and territories eliminates these inter-jurisdictional competitiveness concerns and presents an opportunity for this important source of GHG emissions to be covered across Canada. The federal government will engage with provincial and territorial governments and stakeholders to ensure that this emission source is properly covered, through a consistent national approach, and to determine which role the backstop should play in this regard, including in jurisdictions that have a carbon pricing system in place.

In the meantime, for fuels consumed in commercial aviation transportation, the backstop levy will only apply to fuel used in intra-jurisdictional travel. In other words, the levy will only apply to fuel used for commercial aviation transportation that occurs between two points in the backstop jurisdiction.

- Air carriers in a backstop jurisdiction will generally purchase fuel with the levy embedded. They will file regular returns and will be entitled to relief for levy paid on fuel that is used in inter-jurisdictional journeys (e.g., trips between a point in the backstop jurisdiction and a point outside the backstop jurisdiction).
- Further, these carriers will be required to self-assess on fuels purchased without the levy previously applied and used in intra-jurisdictional journeys. For example, if an aircraft lands in a backstop jurisdiction with unused fuel and subsequently makes an intra-jurisdictional journey using that fuel, the air carrier is required to self-assess on the fuel used in that journey.
- For fuel that is destined for international ships' stores, fuel could be delivered without the levy being payable if delivered by a Registered Fuel Distributor. If the fuel used for international ships' stores had levy embedded, relief will be provided for that fuel.

Transitional rules and rules related to rate changes

Persons that are required to register with the CRA will be able to do so on a provisional basis prior to the implementation date of the carbon levy.

Any person that possesses a quantity of fuel in a backstop jurisdiction that exceeds a minimum threshold on the implementation date of the levy will be required to self-assess and remit the levy on fuel in their possession. However, this requirement would not apply to a Registered Fuel Distributor that is registered as of the implementation date.

Registered Fuel Distributors will be required to pay the levy on fuel that is delivered in a backstop jurisdiction on or after the implementation date to a person, unless that person is a Registered Fuel Distributor.

Similarly, in respect of rate increases that occur after 2018, any person that possesses a minimum quantity of fuel in a backstop jurisdiction on the implementation date of a rate increase will be required to assess and remit the levy on fuels in their possession. This requirement would not apply to a Registered Fuel Distributor that is registered as of the implementation date of a rate increase.

Also, in respect of future rate increases, Registered Fuel Distributors will be required to pay the levy at the new rate on fuel that is delivered to a person in a backstop jurisdiction, unless that person is a Registered Fuel Distributor, on or after the implementation date of a rate increase.

Administrative aspects

Every Registered Fuel Distributor, Registered Fuel Importer and Registered Fuel User will be required to file monthly returns with the CRA. Registered persons will need to calculate in the return the total amount of levy payable for each backstop jurisdiction and remit that amount to the Receiver General of Canada.

The return for each registered person will have to be filed, and any amount payable will have to be paid, by the end of the first month following the fiscal month of the person. For example, assuming a registered person's fiscal month is also a calendar month, if a Registered Fuel Distributor delivers fuel to a purchaser that is not a Registered Fuel Distributor on June 15, the Registered Fuel Distributor will be required to file a return and remit the levy to the Receiver General of Canada by July 31. Similarly, if a Registered Fuel Distributor uses fuel it holds on June 15, the Registered Fuel Distributor will be required to file a return and remit the levy to the Receiver General of Canada by July 31.

Registered Fuel Distributors will generally need to provide information on quantities of fuels produced, brought into, and imported into each backstop jurisdiction, as well as quantities of fuels used and delivered within each backstop jurisdiction and delivered outside a backstop jurisdiction.

Registered Fuel Importers will generally need to provide information on quantities of fuels brought into and imported into, or for delivery or use into, each backstop jurisdiction, as well as quantities of fuels used and delivered within each backstop jurisdiction and delivered outside the backstop jurisdiction.

The information that Registered Fuel Users will need to provide will vary depending on the class of user (e.g., air carriers versus persons burning waste). Generally, they will be required to provide information to the CRA and determine the amount of levy payable or refundable for each backstop jurisdiction, as explained above.

Registered Fuel Distributors, Registered Fuel Importers and Registered Fuel Users will be required to keep books and records sufficient to enable a determination to be made of whether they have complied with payment requirements and other carbon levy rules in general. The basic period for retaining records will be 6 years after the end of the year in which they relate.

Registered Fuel Distributors, Registered Fuel Importers and Registered Fuel Users may be required to provide and maintain security in an amount and in a form satisfactory to the Minister of National Revenue.

To promote compliance with the carbon levy, its framework will include modern elements of an enforcement regime (e.g., interest, penalties, offences) aligned with those found in other statutes administered by the Canada Revenue Agency.

The output-based pricing system element of the backstop

The aim of an output-based pricing system is to minimize competitiveness and carbon leakage risks for activities for which those risks are high, while retaining the incentives to reduce emissions created by the carbon pricing signal.

The output-based pricing system will apply the carbon pollution price to the portion of a covered source's emissions that exceed those allowed by the emissions-intensity standard for the type of activity. Facilities in the system that emit less than the limit that corresponds to the relevant emissions-intensity standard will receive “surplus credits” from the Government of Canada that they can bank for future use or trade to another participant in the output-based pricing system. Facilities whose emissions exceed their limit will need to submit compliance units (surplus credits banked from a previous year or acquired from another facility or offset credits: see “compliance units” below) or pay the carbon price to make up the difference.

Under this system, only a portion of a covered source's emissions will be subject to a direct price obligation. However, the price incentive will apply to all of the emissions, as facilities can earn surplus credits that they can sell if they emit less than their regulatory limit.

Scope of the output-based pricing system

Facilities and sectors included in the output-based pricing system

The output-based pricing system will apply to all industrial facilities that emit 50 kilotonnes (kt) or more of CO2e per year. It will not apply to facilities in specifically listed sectors such as buildings (including municipal, hospitals, universities, schools, commercial), waste and wastewater, regardless of the quantity of their emissions.

Facilities in industrial sectors that emit less than 50 kt of CO2e per year will have the ability to “opt in” to the output-based pricing system, allowing similar treatment of competitors with varying emissions output. This will allow smaller facilities to choose between paying the carbon levy and fulfilling the administrative requirements to participate in the output-based pricing system. This will also avoid creating the perverse incentive to emit more in order to be eligible for treatment under the output-based pricing system.

Emissions covered in the output-based pricing system

The output-based pricing system will apply to emissions from fuel combustion as well as emissions of synthetically-produced greenhouse gases from industrial processes and product use.

Like the carbon levy, pricing will be applied on a CO2e basis. Because industrial emissions can include more greenhouse gases than those emitted from fuel combustion, the output-based pricing system will apply to emissions of all seven of the UNFCCC greenhouse gases – CO2, CH4, N2O, hydrofluorocarbons (HFCs), perfluorocarbons (PFCs), sulfur hexafluoride (SF6) and nitrogen trifluoride (NF3) – that can be quantified using robust and replicable quantification methodologies. This will cover emissions from all fossil fuels used by facilities subject to the output-based pricing system, including some venting, flaring and fugitive emissions. [9]

The output-based pricing system will also apply to other GHG emissions such as process emissions and emissions from solvent use.

At the outset, CO2 emissions resulting from the combustion of biomass will not be covered because these emissions are not counted in Canada's National Inventory total. [10]

Output-based standards

An output-based standard is an emissions-intensity standard for a type of activity or product (e.g., tonnes of CO2e per megawatt hour of electricity). The output-based standard will be set at a level that represents best-in-class performance (top quartile or better) in order to drive reduced emissions intensity.

Application of the output-based pricing system

Compliance reporting for the output-based pricing system will apply annually, based on a calendar year.

Determining a facility's emissions limit

The annual GHG emissions limit for a facility will be the sum of the emission limits for all activities that the facility undertakes.

For a single product facility, the annual emissions limit will be based on the applicable output-based standard and the facility's total output:

Annual Facility Emissions Limit (tonnes CO2e) = Output-based standard (tonnes CO2e/unit) x Units Produced (units)

For a multi-product facility, the same approach will apply. For example, for a facility that produces two products, the annual GHG emissions limit for the facility will be:

Annual Facility Emissions Limit (tonnes CO2e) = [Product 1 Output-based standard (tonnes CO2e/unit 1) x Product 1 Units Produced (units 1)] + [Product 2 Output-based standard (tonnes CO2e/unit 2) x Product 2 Units Produced (units 2)]

If a facility emits less than its emissions limit

A facility that emits less than its annual limit will receive surplus credits from the Government of Canada for the difference between its limit and its reported emissions, where each surplus credit represents one tonne of CO2e.

If a facility exceeds its emissions allocation

A facility that exceeds its annual emissions limit will have several options to meet its compliance obligation, including:

- Payment to the Government at the carbon price that will be set in the backstop legislation and based on the federal benchmark (i.e., $10/tonne CO2e in 2018, rising to $50/tonne CO2e in 2022);
- Use of eligible carbon offset credits (see below); and
- Use of surplus credits issued by the Government to facilities that emitted less than their regulated limits.

Facilities will have the flexibility to meet their full compliance obligation with any of these options or any combination thereof in a given year.

This flexibility will allow each regulated facility to achieve compliance at the lowest cost for its operation. Enabling the use of carbon offsets will spread the carbon price signal to all sectors of the economy that are not subject to direct carbon pricing, and allowing the use of surplus credits will encourage regulated facilities to reduce their emissions intensity as much as possible, regardless of the emissions-intensity standards that apply to them.

Compliance units

Output-based pricing system surplus credits: Credits will be issued by the Government of Canada to a regulated facility after confirming that the facility's reported emissions for the previous year were less than its limit. Subject to certain rules, surplus credits may be banked for future use or traded to another participant in the output-based pricing system.

Carbon offset credits: Credits can be generated from voluntary activities, namely those that are not subject to GHG emission reduction regulations, that are not required by law, that have not been supported by government financing, and that go beyond “business as usual” practices. The federal government will develop rules to determine which offset credits can be accepted for compliance under the output-based pricing system, which could include foreign compliance units (referred to as “internationally transferred mitigation outcomes”). This will be informed by the pan-Canadian offsets framework being developed by the Canadian Council of Ministers of the Environment.

A limit will be set on the start date for projects from which offset credits will be authorized for compliance purpose. The Government may restrict the number of years that offset credits can be banked, and may require regulated facilities to replace offset credits that are revoked or invalidated after they have been submitted for compliance. [11]

Reporting and verification requirements

After the end of each compliance year, each facility in the output-based pricing system will be required to quantify its emissions using prescribed methodologies for each of its activities. This will allow the facility to compare its reported emissions to its annual GHG emissions limit.

Each facility will also be required to submit an annual compliance report on its annual emissions limit and its emissions. These reports will need to be third-party verified to a reasonable level of assurance by verification bodies that are accredited to ISO 14065 by a member of the International Accreditation Forum.

Compliance reports will be submitted by March 31 following the calendar year of compliance (e.g., reports will be due March 31, 2020 for emissions associated with the facility from January 1 to December 31, 2019).

Administration of the output-based pricing system

Environment and Climate Change Canada will administer the output-based pricing system. Industrial facilities that are subject to the output-based pricing system will have to register with and submit compliance reports to Environment and Climate Change Canada. Verification bodies engaged by output-based pricing system participants will submit their reports directly to Environment and Climate Change Canada.

Compliance, penalties and enforcement

The output-based pricing system part of the backstop legislation will provide authorities for a modern enforcement regime aligned with the enforcement schemes found in other legislation administered by Environment and Climate Change Canada. This will include access to a variety of enforcement measures to encourage compliance or deter future non-compliance including written warnings, administrative penalties, compliance orders and prosecution.

Backstop implementation timing

The backstop will apply in a province or territory that does not have a pricing system that aligns with the benchmark.

The carbon levy will come into effect in 2018.

The output-based pricing system will not come into effect before January 1, 2019.

For the interim period between when the levy and the output-based pricing system come into force, the carbon levy will apply fully to fuels used by all industrial facilities.

How to provide input

Canadian stakeholders, businesses and the public are invited to submit feedback as part of the Government of Canada's consultation on the federal benchmark and backstop for carbon pricing.

Closing date: June 30**, 2017**

Written comments should be sent to: Carbonpricing-tarificationcarbone@canada.ca

In order to add to the transparency of the consultation process, the Government of Canada may make public some or all of the responses received or may provide summaries in its public documents. Therefore, parties making submissions are asked to clearly indicate the name of the individual or the organization that should be identified as having made the submission.

In order to respect privacy and confidentiality, when providing your submission please advise whether you:

- consent to the disclosure of your submission in whole or in part;
- request that your identity and any personal identifiers be removed prior to publication; and/or
- wish any portions of your submission to be kept confidential (if so, clearly identify the confidential portions).

Information received throughout this submission process is subject to the Access to Information Act and the Privacy Act. Should you express an intention that your submission, or any portions thereof, be considered confidential, the Government of Canada will make all reasonable efforts to protect this information.

Annex 1: CO2e

The concept of “global warming potential” allows for a comparison of the ability of each GHG to trap heat in the atmosphere relative to CO2. CO2e is a measure of the quantity of CO2 that would be required to produce a similar warming effect as another GHG over the same time horizon. It is calculated by multiplying the quantity of a GHG by its global warming potential. The United Nations Intergovernmental Panel on Climate Change regularly updates the measurement of global warming potential.

The combustion of fossil fuels results in three different GHG emissions being produced – carbon dioxide (CO2), methane (CH4), and nitrous oxide (N2O) – each of which has a unique atmospheric lifetime and heat-trapping potential. The total GHG emissions from combusting a fuel is the CO2e of all three GHG emissions added together.

The quantity of CO2 emitted is related to the carbon content in a given type of a fossil fuel and the amount of fuel combusted. The carbon content of some fuels can vary. For example, natural gas from different regions has different carbon content. As a result, natural gas from Western Canada will have a different level of GHG emissions per litre of fuel than natural gas from Eastern Canada.

The quantity of methane and nitrous oxide emitted is related to the amount of fuel combusted and the type of technology used to combust that fuel. For example, fuel that is used to heat a home will have different levels of methane and nitrous oxide emissions per litre than a fuel used in a heavy-duty vehicle.

For both components of the backstop, emissions will be converted to a CO2e basis using current global warming factors. For the levy, rates will be set out under the relevant legislation and will be based on the Canadian average emission factor for a fossil fuel (where factors differ by region for that fuel) and the technology that is most commonly used to combust a fossil fuel. For the output-based pricing system, regulated entities will use the same factors to calculate their emissions following a methodology that will be specified in regulations.

The output-based pricing system will apply to emissions from fuel combustion as well as emissions of synthetically-produced greenhouse gases from industrial processes and product use, and will cover all seven of the greenhouse gases included in the United Nations Framework Convention on Climate Change reporting requirements: CO2, methane (CH4), nitrous oxide (N2O), perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), sulphur hexafluoride (SF6) and nitrogen trifluoride (NF3).

The global warming factors for both components may be updated from time to time when changes are made to requirements for inventory reporting under the United Nations Framework Convention on Climate Change.

1 Pan-Canadian Framework on Clean Growth and Climate Change

2 Pan-Canadian Approach to Pricing Carbon Pollution

3 Backgrounder: Pan-Canadian Approach to Pricing Carbon Pollution

4 The seven UNFCCC GHGs are CO_2, methane (CH_4), nitrous oxide (N_2O), perfluorocarbons (PFCs), hydrofluorocarbons (HFCs), sulphur hexafluoride (SF_6) and nitrogen trifluoride (NF_3).

5 For the purposes of determining the levy rates, the CO_2e of a fossil fuel includes the following GHG emissions: CO_2, CH_4 and N_2O.

6 Venting is the direct release of gas, which is predominately methane, into the atmosphere without combustion. Flaring is the controlled combustion of a gas from industrial activities, in maintenance or emergency circumstances that require a release of pressure by removing the gas.

7 Petrochemicals are organic chemicals made from crude oil and natural gas, such as methanol, ethylene, benzene, or butadiene, for use in industrial processes (i.e., feedstock to make other chemicals).

8 For example, inter-jurisdictional carriers may, depending on where they purchase fuel and where they actually travel, be required to remit the levy on fuel purchased outside a backstop jurisdiction or be entitled to a rebate of the levy on fuel purchased inside a backstop jurisdiction.

9 Forthcoming methane reduction regulations for the oil and gas sector will complement carbon pollution pricing.

10 For more information, please see Technical Guidance on Reporting Greenhouse Gas Emissions

11 To maintain program integrity, authorities will be able to revoke credits issued for projects that do not meet program requirements. In such cases, the Government would require the facility to replace compliance obligation made with the revoked credits.

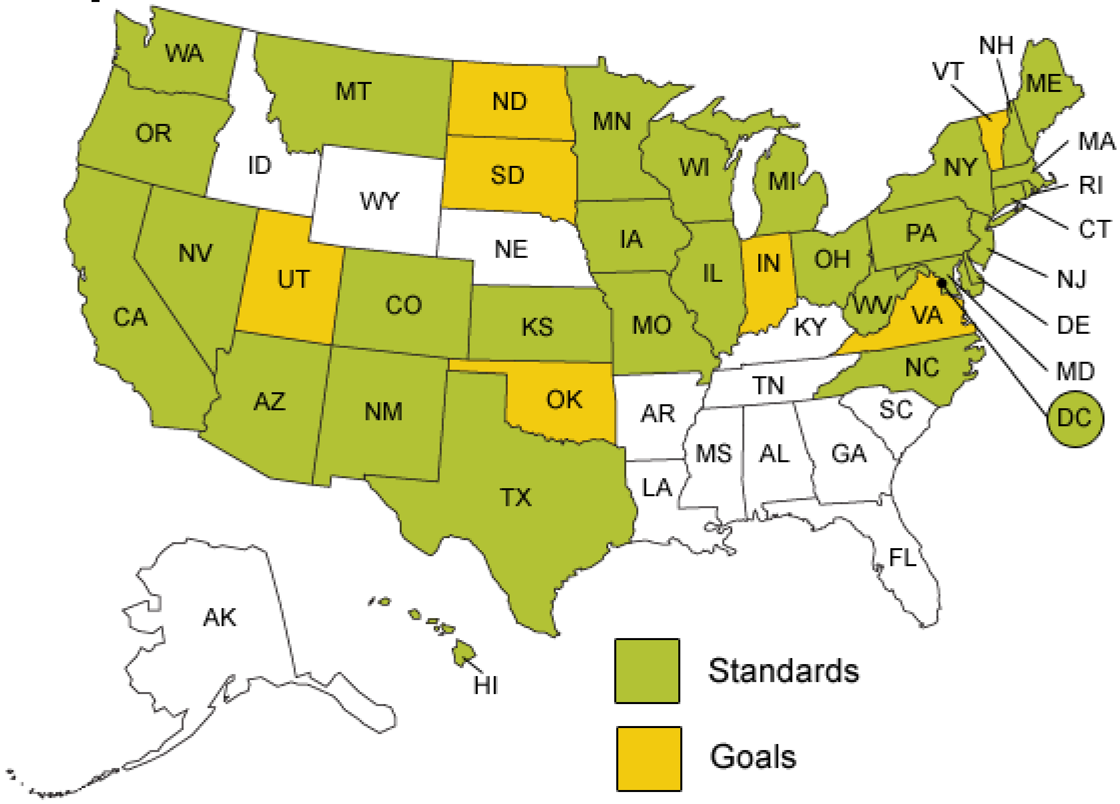
Today in Energy

February 3, 2012

Most states have Renewable Portfolio Standards

States with Renewable Portfolio Standards (mandatory) or Goals (voluntary), January 2012



Source: N.C. Solar Center at N.C. State University, Database of State Incentives for Renewables and Efficiency (accessed July 2012). (Correction: Amended source corrects the source listed in original publication of February 3, 2012.)
Note: The map includes West Virginia as a State with a Renewable Portfolio Standard, although the Interstate Renewable Energy Council categorizes it as a goal State rather than an RPS State.

Renewable portfolio standards (RPS), also referred to as renewable electricity standards (RES), are policies designed to increase generation of electricity from renewable resources. These policies require or encourage electricity producers within a given jurisdiction to supply a certain minimum share of their electricity from designated renewable resources. Generally, these resources include wind, solar, geothermal, biomass, and some types of hydroelectricity, but may include other resources such as landfill gas, municipal solid waste, and tidal energy.

Although several RPS proposals have advanced part way through the U.S. Congress in recent years, there is currently no RPS program in place at the National level. However, 30 States and the District of Columbia had enforceable RPS or other mandated renewable capacity policies, as of January 2012. In addition, seven States had voluntary goals for renewable generation. These programs vary widely in terms of program structure, enforcement mechanisms, size, and application.

In California, for example, an RPS of 20% of retail sales was originally enacted in 2002. As of April 2011, the RPS requires California's electric utilities to derive 33% of their retail sales from eligible renewable energy resources in 2020. The law also established interim targets of 20% by the end of 2013, and 25% by the end of 2016.

A large range of policies are considered to be under the RPS umbrella. In general, an RPS sets a minimum requirement for the share of electricity to be supplied from designated renewable energy resources by a certain date/year. Often, the selected eligible resources are tailored to best fit the State's particular resource base or local preferences. Some States also set targets for specific types of renewable energy sources or technologies to encourage their development and use. Many State RPS programs have "escape clauses" if the extra cost of renewable generation exceeds a specified threshold. (Detailed descriptions of State RPS programs are available from the Database of State Incentives for Renewables & Efficiency.)

Another common feature of many State policies is a renewable electricity credit (REC) trading system structured to minimize the costs of compliance. Under these policies, a producer who generates more renewable electricity than required to meet its own RPS obligation may either trade or sell RECs to other electricity suppliers who may not have enough RPS-eligible renewable electricity to meet their own RPS requirement. In some cases, a State will make a certain number of credits available for sale. Such a system accommodates timing differences associated with planning and construction of new generation. Only one entity—the generator or the REC holder—may take credit for the renewable attribute of generation from RPS-eligible sources.

An RPS is one policy mechanism to encourage development of renewable energy. States with RPS policies have seen an increase in the amount of electricity generated from eligible renewable resources. At the same time, other States without RPS policies have also seen significant increases in renewable generation over the past few years resulting from a combination of Federal incentives, State programs, and market conditions. Increases in renewable generation have been driven by the availability of Federal tax incentives, as well as by State RPS policies.

State Renewable Portfolio Standards and Goals

8/1/2017 Jocelyn Durkay

States have been active in adopting or increasing renewable portfolio standards, and 29 states now have them. These standards require utilities to sell a specified percentage or amount of renewable electricity. The requirement can apply only to investor-owned utilities (IOUs) but many states also include municipalities and electric cooperatives (Munis and Co-ops), though their requirements are equivalent or lower.

Renewable energy policies help drive the nation's $44 billion market for wind, solar and other renewable energy sources. These policies can be integral to many state efforts to diversify their energy mix, promote economic development and reduce emissions. Twenty-nine states, Washington, D.C., and three territories have adopted an RPS, while eight states and one territory have set renewable energy goals.

Iowa was the first state to establish an RPS and Hawaii has the most aggressive RPS requirement. In many states, standards are measured by percentages of kilowatt hours of retail electric sales. Iowa and Texas, however, require specific amounts of renewable energy capacity rather than percentages and Kansas requires a percentage of peak demand. According to Lawrence Berkeley National Laboratory, 20 states and Washington, D.C., have percentage-based cost caps in their RPS bills to limit increases in ratepayers' bills. One state caps RPS gross procurement costs.

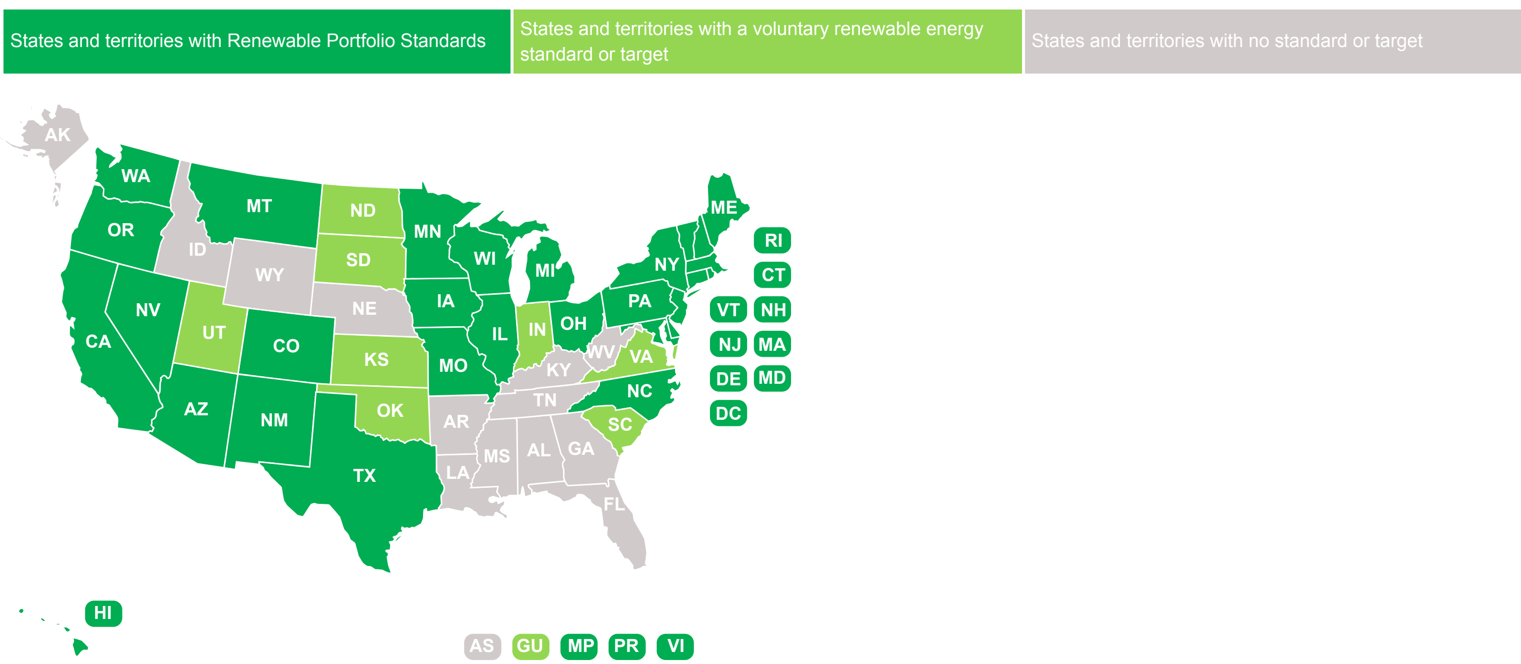


Table: Renewable Portfolio Standards or Voluntary Targets

Note: States and territories listed in italics have voluntary renewable energy goals.

Alaska

- **Enabling Statute, Code or Order:** *In the 2009-2010 legislative session, the Alaska legislature enacted* House Bill 306 *with the goal that "the state receive 50 percent of its electrical generation from renewable energy sources by 2025." This language does not appear in codified statutes.*

Arizona

- **Title:** Renewable Energy Standard.
- **Established:** 2006.
- **Requirement:** 15 percent by 2025.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** None.
- **Details:** Distributed Generation: 30 percent of annual requirement in 2012 and thereafter. The state has several credit multipliers for different technologies.
- **Enabling Statute, Code or Order:** Ariz. Admin. Code §14-2-1801 et seq.

California

- **Title:** Renewables Portfolio Standard.
- **Established:** 2002.
- **Requirement:** 33 percent by 2020; 40 percent by 2024; 45 percent by 2027; 50 percent by 2030.
- **Applicable Sectors:** Investor-owned utility, municipal utilities.
- **Cost Cap:** Determined by the California Public Utilities Commission.
- **Details:** A 2013 amendment allows the California Public Utilities Commission to adopt additional requirements.
- **Enabling Statute, Code or Order:** Cal. Public Utilities Code §399.11 et seq.; Cal. Public Resources Code §25740 et seq.; CA A 327 (2013); CA S 350 (2015).

Colorado

- **Title:** Renewable Energy Standard.
- **Established:** 2004.
- **Requirement:** 30 percent by 2020 (IOUs); 10 percent or 20 percent for municipalities and electric cooperatives depending on size.
- **Applicable Sectors:** Investor owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** 2.0 percent.
- **Details:** Distributed Generation: 3 percent of IOU retail sales by 2020, 1 percent of cooperative retail sales by 2020 (for those providing service to 10,000 or more meters) or 0.75 percent of cooperative retail sales by 2020 (for those providing service to less than 10,000 meters). The state has several credit multipliers for different technologies.
- **Enabling Statute, Code or Order:** Colo. Rev. Stat. §40-2-124; CO S 252 (2013).

Connecticut

- **Title:** Renewables Portfolio Standard.
- **Established:** 1998.
- **Requirement:** 27 percent by 2020.
- **Applicable Sectors:** Investor-owned utility, local government, retail supplier.
- **Cost Cap:** 7.1 percent.
- **Details:** Class I renewable energy sources (including distributed generation): 20 percent by 2020. Class I or II (biomass, waste-to-energy and certain hydropower projects: 3 percent by 2010. Class III (combined heat and power, waste heat recovery and conservation): 4 percent by 2010.
- **Enabling Statute, Code or Order:** Conn. Gen. Stat. §16-245a et seq.; Conn. Gen. Stat. §16-1.

Delaware

- **Title:** Renewables Energy Portfolio Standard.
- **Established:** 2005.
- **Requirement:** 25 percent by 2025-2026.
- **Applicable Sectors:** Investor-owned utility, local government, retail supplier.
- **Cost Cap:** 3 percent; 1 percent (PV).
- **Details:** Photovoltaics: 3.5 percent requirement by 2025-2026. The state has multiple credit multipliers that apply to different technologies.

- **Enabling Statute, Code or Order:** Del. Code Ann. 26 §351 et seq..

Hawaii

- **Title:** Renewable Portfolio Standard.
- **Established:** 2001.
- **Requirement:** 30 percent by 2020; 40 percent by 2030; 70 percent by 2040; 100 percent by 2045.
- **Applicable Sectors:** Investor-owned utility.
- **Cost Cap:** None.
- **Enabling Statute, Code or Order:** Hawaii Rev. Stat. §269-91 et seq.; House Bill 623 (2015).

Illinois

- **Title:** Renewable Portfolio Standard.
- **Established:** 2001 (voluntary target); 2007 (standard).
- **Requirement:** 25 percent by 2025-2026.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 1.3 percent.
- **Details:** Distributed Generation: 1 percent of annual requirement beginning in 2015 for IOUs. Wind: 75 percent of annual requirement for IOUs, 60 percent of annual requirement for alternative retail electric suppliers. Photovoltaics: 6 percent of annual requirement beginning in 2015-2016.
- **Enabling Statute, Code or Order:** Ill. Rev. Stat. ch. 20 §688 (2001); Ill. Rev. Stat. ch. 20 §3855/1-75 (2007); Senate Bill 2814 (2016).

Indiana

- **Title:** Clean Energy Portfolio Goal.
- **Established:** 2011.
- **Requirement:** 10 percent by 2025.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities, retail supplier.
- **Details:** 30 percent of the goal may be met with clean coal technology, nuclear energy, combined heat and power systems, natural gas that displaces electricity from coal and other alternative fuels.
- **Enabling Statute, Code or Order:** Ind. Code §8-1-37.

Iowa

- **Title:** Alternative Energy Law.
- **Established:** 1983.
- **Requirement:** 105 MW of generating capacity for IOUs.
- **Applicable Sectors:** Investor-owned utility.
- **Cost Cap:** None.
- **Enabling Statute, Code or Order:** Iowa Code §476.41 et seq.

Kansas

- ***Title:*** *Renewable Energy Goal.*
- ***Established:*** *2009 (standard); 2015 (goal).*
- ***Requirement:*** *15 percent by 2015-2019; 20 percent by 2020.*
- ***Applicable Sectors:*** *Investor-owned utility.*
- ***Cost Cap:*** *Caps gross RPS procurement costs.*
- ***Details:*** *20 percent requirement for peak demand capacity.*
- ***Enabling Statute, Code or Order:*** Kan Stat. Ann. §66-1256 et seq.*;* Goal: Senate Bill 91.

Maine

- **Title:** Renewables Portfolio Standard.
- **Established:** 1999.

- **Requirement:** 40 percent by 2017.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 6.1 percent.
- **Details:** Includes a 10 percent requirement by 2017 for Class I (new) sources. The state also has separate goals for wind energy: 2,000 MW of installed capacity by 2015; 3,000 MW of installed capacity by 2020, including offshore and coastal; and 8,000 MW of installed capacity by 2030, including 5,000 MW from offshore and coastal. The state has a credit multiplier for community-based renewable energy.
- **Enabling Statute, Code or Order:** Me. Rev. Stat. Ann. 35-A §3210 et seq.; Me. Rev. Stat. Ann. 35-A §3401 et seq. (wind energy).

Maryland

- **Title:** Renewable Energy Portfolio Standard.
- **Established:** 2004.
- **Requirement:** 25 percent by 2020.
- **Applicable Sectors:** Investor-owned utility, local government, retail supplier.
- **Cost Cap:** 6.5 percent.
- **Details:** Solar: 2.5 percent by 2020. Offshore wind: 2.5 percent maximum by 2017.
- **Enabling Statute, Code or Order:** Md. Public Utilities Code Ann. §7-701 et seq.; Senate Bill 921; House Bill 1106 (2016 enrolled, 2017 veto override).

Massachusetts

- **Title:** Renewable Portfolio Standard.
- **Established:** 1997.
- **Requirement:** Class I: 15 percent by 2020 and an additional 1 percent each year after. Class II: 5.5 percent by 2015.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 8 percent.
- **Details:** Photovoltaic: 400 MW required. Class I resources are new sources. Class II (resources in operation by 1997) requirement includes 3.6 percent renewable energy and 3.5 percent waste-to-energy.
- **Enabling Statute, Code or Order:** Mass. Gen. Laws Ann. ch. 25A §11F.

Michigan

- **Title:** Renewable Energy Standard.
- **Established:** 2008; 2016.
- **Requirement:** 15 percent by 2021 (standard), 35 percent by 2025 (goal, including energy efficiency and demand reduction).
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities, retail supplier.
- **Cost Cap:** 3.1 percent.
- **Details:** The state has several credit multipliers for different technologies.
- **Enabling Statute, Code or Order:** Mich. Comp. Laws §460.1001 et seq.; Senate Bill 438 (2016).

Minnesota

- **Title:** Renewables Energy Standard.
- **Established:** 2007.
- **Requirement:** 26.5 percent by 2025 (IOUs), 25 percent by 2025 (other utilities).
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** None.
- **Details:** Xcel Energy has a separate requirement of 31.5 percent by 2020; 25 percent must be from wind or solar. Solar: 1.5 percent by 2020 (other IOUs); Statewide goal of 10 percent by 2030.
- **Enabling Statute, Code or Order:** Minn. Stat. §216B.1691.

Missouri

- **Title:** Renewable Electricity Standard.
- **Established:** 2007.
- **Requirement:** 15 percent by 2021 (IOUs).
- **Applicable Sectors:** Investor-owned utility.
- **Cost Cap:** 1 percent.
- **Details:** Solar-Electric: 2 percent carve-out.
- **Enabling Statute, Code or Order:** Mo. Rev. Stat. §393.1020 et seq.

Montana

- **Title:** Renewable Resource Standard.
- **Established:** 2005.
- **Requirement:** 15 percent by 2015.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 0.1 percent.
- **Enabling Statute, Code or Order:** Mont. Code Ann. §69-3-2001 et seq.

Nevada

- **Title:** Energy Portfolio Standard.
- **Established:** 1997.
- **Requirement:** 25 percent by 2025.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** None.
- **Details:** Solar: 5 percent of annual requirement through 2015, 6 percent for 2016-2025. The state has a credit multiplier for photovoltaics and on peak energy savings.
- **Enabling Statute, Code or Order:** Nev. Rev. Stat. §704.7801 et seq.

New Hampshire

- **Title:** Electric Renewable Portfolio Standard.
- **Established:** 2007.
- **Requirement:** 24.8 percent by 2025.
- **Applicable Sectors:** Investor-owned utility, cooperative utilities, retail supplier.
- **Cost Cap:** 7.3 percent.
- **Details:** Solar: 0.3 percent by 2014. Requires at least 15 percent of requirement to be met with new renewables.
- **Enabling Statute, Code or Order:** N.H. Rev. Stat. Ann. §362-F.

New Jersey

- **Title:** Renewables Portfolio Standard.
- **Established:** 1991.
- **Requirement:** 24.5 percent by 2020.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 12.6 percent.
- **Details:** 20.38 percent Class I or Class II (resource recovery or hydropower) renewables by 2020-2021. 4.1 percent solar-electric by 2027-2028. Offshore wind: 1,100 MW.
- **Enabling Statute, Code or Order:** N.J. Rev. Stat. §48:3-49 et seq.

New Mexico

- **Title:** Renewables Portfolio Standard.
- **Established:** 2002.
- **Requirement:** 20 percent by 2020 (IOUs); 10 percent by 2020 (co-ops)
- **Applicable Sectors:** Investor-owned utility, cooperative utilities.
- **Cost Cap:** 3.5 percent.

- **Details:** Solar: 20 percent by 2020 (IOUs). Wind: 30 percent by 2020 (IOUs). Other renewables including geothermal, biomass and certain hydro facilities: 5 percent by 2020 (IOUs). Distributed Generation: 3 percent by 2020 (IOUs). The state has a credit multiplier for solar energy that was operational before 2012.
- **Enabling Statute, Code or Order:** N.M. Stat. Ann. §62-15; N.M. Stat. Ann. §62-16.

New York

- **Title:** Renewable Portfolio Standard; Reforming the Energy Vision (REV).
- **Established:** 2004.
- **Requirement:** 29 percent by 2015; 50 percent by 2030 (REV- *currently in process*)
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities, retail supplier.
- **Cost Cap:** 1.7 percent.
- **Details:** Distributed Generation: 8.4 percent of annual incremental requirement.
- **Enabling Statute, Code or Order:** NY PSC Order Case 03-E-0188; 2015 New York State Energy Plan.

North Carolina

- **Title:** Renewable Energy and Energy Efficiency Portfolio Standard.
- **Established:** 2007.
- **Requirement:** 12.5 percent by 2021 (IOUs); 10 percent by 2018 (munis and coops).
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** 1.4 percent.
- **Details:** Solar: 0.2 percent by 2018. Swine Waste: 0.2 percent by 2018. Poultry Waste: 900,000 MWh by 2015. The state offers credit multipliers for biomass facilities located in cleanfields renewable energy demonstration parks.
- **Enabling Statute, Code or Order:** N.C. Gen. Stat. §62-133.8.

North Dakota

- ***Title:*** *Renewable and Recycled Energy Objective.*
- ***Established:*** *2007.*
- ***Requirement:*** *10 percent by 2015.*
- ***Applicable Sectors:*** *Investor-owned utility, municipal utilities, cooperative utilities.*
- ***Enabling Statute, Code or Order:*** N.D. Cent. Code §49-02-24 et seq.

Ohio

- **Title:** Alternative Energy Resource Standard.
- **Established:** 2008.
- **Requirement:** 25 percent by 2026. Senate Bill 310 (2014) created a two-year freeze on the state's standard while a panel studied the costs and benefits of the requirement. The freeze was not extended in 2016.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 1.8 percent.
- **Details:** 12.5 percent Renewable Energy Resources. 12.5 percent Advanced Energy Resources (advanced energy resources includes co-generation, advanced nuclear power and clean coal). Solar: 0.5 percent.
- **Enabling Statute, Code or Order:** Ohio Rev. Code Ann. §4928.64 et seq.

Oklahoma

- ***Title:*** *Renewable Energy Goal.*
- ***Established:*** *2010.*
- ***Requirement:*** *15 percent by 2015.*
- ***Applicable Sectors:*** *Investor-owned utility, municipal utilities, cooperative utilities.*
- ***Enabling Statute, Code or Order:*** Okla. Stat. tit. 17 §801.1 et seq.

Oregon

- **Title:** Renewable Portfolio Standard.
- **Established:** 2007.
- **Requirement:** 25 percent by 2025 (utilities with 3 percent or more of the state's load); 50 percent by 2040 (utilities with 3 percent or more of the state's load); 10 percent by 2025 (utilities with 1.5–3 percent of the state's load); 5 percent by 2025 (utilities with less than 1.5 percent of the state's load).
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities, retail supplier.
- **Cost Cap:** 4 percent.
- **Details:** Photovoltaics: 20 MW by 2020 (IOUs). The state has a credit multiplier for photovoltaics installed before 2016. The state's two investor-owned utilities must phase out coal generation by 2035.
- **Enabling Statute, Code or Order:** Or. Rev. Stat. §469a; Senate Bill 1547 (2016).

Pennsylvania

- **Title:** Alternative Energy Portfolio Standard.
- **Established:** 2004.
- **Requirement:** 18 percent by 2020-2021.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** None.
- **Details:** Tier I: 8 percent by 2020-2021 (includes photovoltaic). Tier II (includes waste coal, distributed generation, large-scale hydropower and municipal solid waste, among other technologies): 10 percent by 2020-2021. Photovoltaic: 0.5 percent by 2020-2021.
- **Enabling Statute, Code or Order:** Pa. Cons. Stat. tit. 66 §2814.

Rhode Island

- **Title:** Renewable Energy Standard.
- **Established:** 2004.
- **Requirement:** 14.5 percent by 2019, with increases of 1.5 percent each year until 38.5 percent by 2035.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 9.5 percent.
- **Details:** The state has a separate long-term contracting standard for renewable energy, which requires electric distribution companies to establish long-term contracts with new renewable energy facilities.
- **Enabling Statute, Code or Order:** R.I. Gen. Laws §39-26-1 et seq.; R.I. Gen. Laws §39-26.1 et seq. (contracting standard); House Bill 7413a (2016).

South Carolina

- **Title:** Renewables Portfolio Standard.
- **Established:** 2014.
- **Requirement:** 2 percent by 2021.
- **Applicable Sectors:** Investor-owned utility.
- **Details:** Systems less than 1 MW: 1 percent of aggregate generation capacity, including at least 0.25 percent of total generation from systems less than 20kW. 1 – 10 MW facilities: 1 percent of aggregate generation capacity.
- **Enabling Statute, Code or Order:** House Bill 1189.

South Dakota

- ***Title:*** *Renewable, Recycled and Conserved Energy Objective.*
- ***Established:*** *2008.*
- ***Requirement:*** *10 percent by 2015.*
- ***Applicable Sectors:*** *Investor-owned utility, municipal utilities, cooperative utilities.*
- ***Enabling Statute, Code or Order:*** S.D. Codified Laws Ann. §49-34A-94; S.D. Codified Laws Ann. §49-34A-101 et seq.

Texas

- **Title:** Renewable Generation Requirement.
- **Established:** 1999.
- **Requirement:** 5,880 MW by 2015. 10,000 MW by 2025 (goal; achieved).
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 3.1 percent.
- **Details:** Non-wind: 500 MW (goal).
- **Enabling Statute, Code or Order:** Tex. Utilities Code Ann. §39.904.

Utah

- ***Title:*** *Renewables Portfolio Goal.*
- ***Established:*** *2008.*
- ***Requirement:*** *20 percent by 2025.*
- ***Applicable Sectors:*** *Investor-owned utility, municipal utilities, cooperative utilities.*
- ***Enabling Statute, Code or Order:*** Utah Code Ann. §54-17-101 et seq.*;* Utah Code Ann. §10-19-101 et seq.

Vermont

- **Title:** Renewable Energy Standard.
- **Established:** 2005 (voluntary garget); 2015 (standard).
- **Requirement:** 55 percent by 2017; 75 percent by 2032.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities, retail supplier.
- **Cost Cap:** None.
- **Details:** Distributed Generation: 10 percent by 2032. Energy Transformation: 12 percent by 2032 (includes weatherization, thermal energy efficiency and heat pumps).
- **Enabling Statute, Code or Order:** Vt. Stat. Ann. tit. 30 §8001 et seq.; Standard: House Bill 40.

Virginia

- ***Title:*** *Voluntary Renewable Energy Portfolio Goal.*
- ***Established:*** *2007.*
- ***Requirement:*** *15 percent by 2025.*
- ***Applicable Sectors:*** *Investor-owned utility.*
- ***Details:*** *The state has several credit multipliers for different technologies.*
- ***Enabling Statute, Code or Order:*** Va. Code §56-585.2*.*

Washington

- **Title:** Renewable Energy Standard.
- **Established:** 2006.
- **Requirement:** 9 percent by 2016, 15 percent by 2020.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** 4 percent.
- **Details:** Standard is applicable to all utilities that serve more than 25,000 customers. Requirement also includes all cost-effective conservation. The state has a credit multiplier for distributed generation.
- **Enabling Statute, Code or Order:** Wash. Rev. Code §19.285; Wash. Admin. Code §480-109; Wash Admin. Code §194-37.

West Virginia

- ***Title:*** *Alternative and Renewable Energy Portfolio Standard-* ***REPEALED.***
- ***Established:*** *2009;* ***Repealed 2015.***
- ***Requirement:*** *10 percent from 2015-2019, 15 percent from 2020-2024, 25 percent by 2025.*
- ***Details:*** *Goal is applicable to IOUs that serve more than 30,000 residential customers. Goal includes alternative energy sources, including coal technology, coal bed methane, natural gas, combined cycle technologies, waste coal and pumped storage hydroelectric projects.*

- ***Enabling Statute, Code or Order:*** *W. Va. Code §24-2F; Repeal: H.B. 2001.*

Wisconsin

- **Title:** Renewable Portfolio Standard.
- **Established:** 1998.
- **Requirement:** 10 percent by 2015.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** None.
- **Details:** Standard varies by utility. 2011-2014: utilities may not decrease its renewable energy percentage below 2010 percentages. 2015: utilities must increase renewable energy percentages by at least 6 percent above their 2001-2003 average. Utilities may not decrease their renewable energy percentage after 2015.
- **Enabling Statute, Code or Order:** Wisc. Stat. §196.378.

Washington, D.C.

- **Title:** Renewable Portfolio Standard.
- **Established:** 2005.
- **Requirement:** 20 percent by 2020, 50 percent by 2032.
- **Applicable Sectors:** Investor-owned utility, retail supplier.
- **Cost Cap:** 7.6 percent.
- **Details:** Solar: 2.5 percent by 2023.
- **Enabling Statute, Code or Order:** D.C. Code §34-1431 et seq., Bill 650 (2016).

Guam

- ***Title:*** *Renewable Energy Portfolio Goal.*
- ***Established:*** *2008.*
- ***Requirement:*** *25 percent by 2035.*
- ***Applicable Sectors:*** *Investor-owned utility, municipal utilities, cooperative utilities.*
- ***Details:*** *Goal applies to net electricity sales.*
- ***Enabling Statute, Code or Order:*** Guam Public Law §29-62*.*

Northern Mariana Islands

- **Title:** Renewables Portfolio Standard.
- **Established:** 2007; goal reduced in 2014.
- **Requirement:** 20 percent by 2016.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** Data unavailable.
- **Details:** Requirement applies to net electricity sales. Requirement allows for non-compliance if it is not cost-effective.
- **Enabling Statute, Code or Order:** N. M. I. Public Law §15-23; House Bill 165 (2014).

Puerto Rico

- **Title:** Renewable Energy Portfolio Standard.
- **Established:** 2010.
- **Requirement:** 20 percent by 2035.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Cost Cap:** Data unavailable.
- **Details:** Requirement does not take effect until 2015.
- **Enabling Statute, Code or Order:** PR S 1519 (2010); PR H 2610 (2010).

U.S. Virgin Islands

- **Title:** Renewables Portfolio Targets.

- **Established:** 2009.
- **Requirement:** 20 percent by 2015; 25 percent by 2020; 30 percent by 2025; up to 51 percent after 2025.
- **Applicable Sectors:** Investor-owned utility, municipal utilities, cooperative utilities.
- **Details:** Standard applies to peak demand generating capacity. Standard will increase until a majority of capacity is from renewable or alternative energy.
- **Enabling Statute, Code or Order:** VI B 9 (2009).

SEVENTH NORTHWEST CONSERVATION AND ELECTRIC POWER PLAN

TABLE OF CONTENTS:

Final Plan – Released February 25, 2016

CHAPTER 1: EXECUTIVE SUMMARY

The Pacific Northwest power system faces a host of uncertainties, from compliance with federal carbon dioxide emissions regulations to future fuel prices, resource retirements, salmon recovery actions, economic growth, a growing need to meet peak demand, and how increasing renewable resources would affect the power system. The Council's Seventh Power Plan addresses these uncertainties and provides guidance on which resources can help ensure a reliable and economical regional power system over the next 20 years.

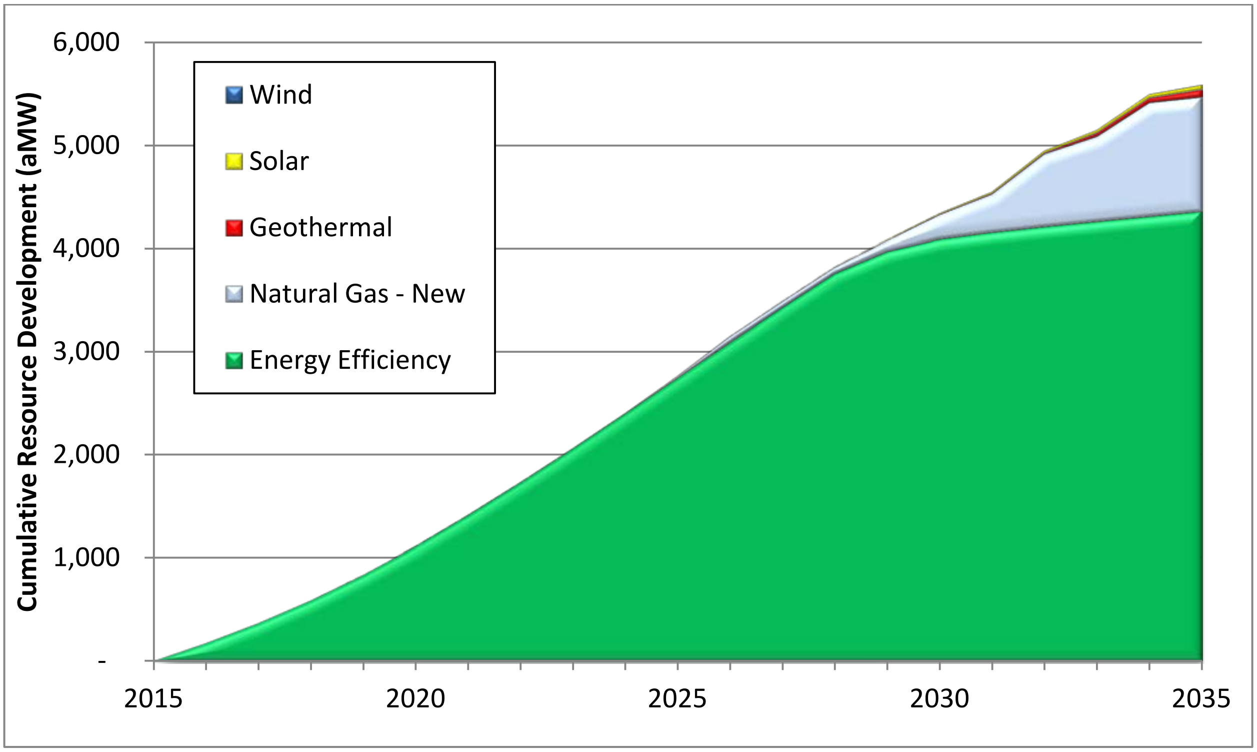
In developing its plan, the Council relies on feedback from technical and policy advisory groups and input from a broad range of interests, including utilities, state energy offices, and public interest groups.

The plan also recognizes that individual utilities, which have varying access to electricity markets and varying resource needs, may require near-term investments in resources to meet their adequacy and reliability needs. For example, some utilities face significant near-term resource challenges, particularly if there is limited access to surplus resources from others. These factors limit the ability of the regional resource strategy to be specific about optioning and construction dates for natural gas-fired resources, or for the types of natural gas-fired generation. As a result, new gas-fired generation may be required, even if utilities deploy demand response resources and develop the energy efficiency called for in the plan.

Using modeling to test how well different resources would perform under a wide range of future conditions, energy efficiency consistently proved the least expensive and least economically risky resource. In more than 90 percent of future conditions, cost-effective efficiency met *all* electricity load growth through 2030 and in more than half of the futures *all* load growth for the next 20 years. It's not only the single largest contributor to meeting the region's future electricity needs; it's also the single largest source of new peaking capacity. If developed aggressively, in combination with past efficiency acquisition, the energy efficiency resource could approach the size of the region's hydroelectric system's firm energy output, adding to the Northwest's heritage of clean and affordable power. Figure 1 - 1 shows the composition of the plan's resource portfolio.

Acquiring this energy efficiency is the primary action for the next six years. The plan's second priority is to develop the capability to deploy demand response resources or rely on increased market imports to meet system capacity needs under critical water and weather conditions. While the region's hydroelectric system has long provided ample peaking capacity, it's likely that under low water and extreme weather conditions we'll need additional peaking capacity to maintain system adequacy. Because the probability of such events is low (but real), demand response resources, which have low development and "holding" costs are best-suited to meet this need. However, whether and to what extent the region should rely on demand response or increase its reliance on power imports to meet regional resource adequacy requirements for winter capacity depends on their comparative availability, reliability, and cost.

Figure 1 - 1: Seventh Plan Resource Portfolio[1]



After energy efficiency and demand response, new natural gas-fired generation is the most cost-effective resource option for the region in the near-term. Similarly, after energy efficiency, the increased use of existing natural gas generation offers the lowest cost option for reducing regional carbon emissions. Combined with investments in renewable generation, as required by state renewable portfolio standards, improved efficiency, demand response resources, and natural gas generation are the principal components of the plan's resource portfolio.

A key question for the plan was how the region could lower power system carbon dioxide emissions and at what costs. The Council's modeling found that without additional carbon control policies, carbon dioxide emissions from the Northwest power system are forecast to decrease from about 54 million metric tons in 2015 to around 34 million metric tons in 2035,[2] the result of retiring the Centralia, Boardman, and North Valmy coal plants between 2020 and 2026; using existing natural gas-fired generation to replace them; and developing about 4,300 average megawatts of energy efficiency by 2035, which is expected to meet nearly all forecast load growth over that time frame.

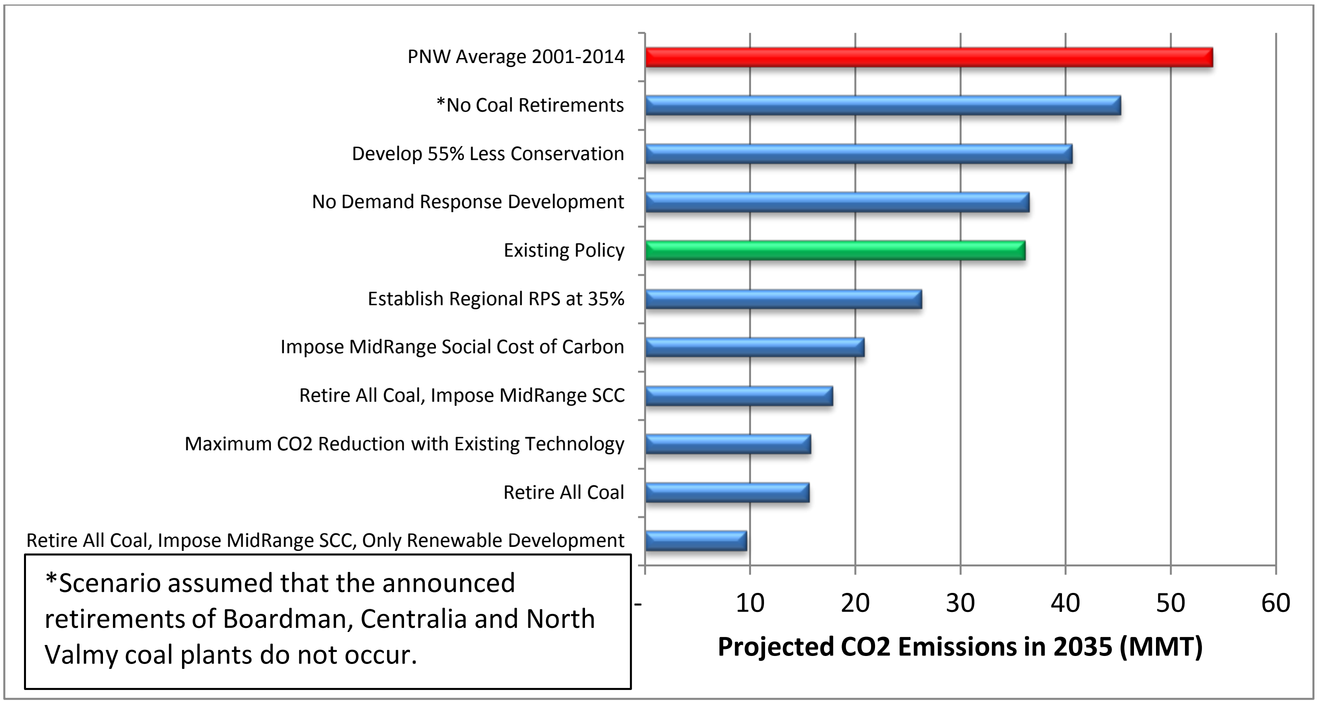
[1] Figure 1 - 1 shows the average resource development across all 800 futures tested in the Regional Portfolio Model. Actual development, particularly of non-energy efficiency resources, will depend on actual future conditions.

[2] This is the level of carbon dioxide emissions estimated to be generated to serve regional load under average water and weather conditions. Actual 2015 carbon dioxide emissions could differ significantly from this level based on actual water and weather conditions. Average regional carbon dioxide emissions from 2001–2014 were 54 million metric tons (MMT), but ranged from 43 MMT to 60 MMT.

In these circumstances, the region, as a whole, will be able to comply with the Environmental Protection Agency's (EPA's) carbon emissions limits, even under critical water conditions. However, since the Council did not evaluate compliance with the EPA's carbon emissions limits at the state level, individual Northwest states, especially Montana, may need to take additional actions to comply with these new emissions limits.

Figure 1 - 2 shows the forecast average carbon dioxide emissions in 2035 under the various scenarios tested in developing the plan.

Figure 1 - 2: Forecast Northwest Power System Carbon Dioxide Emissions in 2035 by Scenario



The Council also assessed alternative policies to further reduce emissions. With today's technology, carbon dioxide emissions could be reduced to about 16 million metric tons by 2035, 70 percent below historical average regional emissions levels. This would require retiring all the coal generation serving the region, which is responsible for more than 85 percent of system emissions, and acquiring additional energy efficiency and demand response resources. The estimated cost of doing this is nearly $16 billion or 20 percent over the cost of other resource portfolios that comply with federal carbon dioxide emissions limits at the regional level.[3] Reducing the region's power system carbon footprint below that level is technically feasible, but only if renewable resources are developed to replace retiring coal plants and a carbon cost equivalent to the federal government's

[3] The cost of resource strategies reported in the Seventh Power Plan generally exclude revenues from a carbon price in order to compare scenarios based only on power system costs. The text will identify whether carbon revenues are included or not. In practice, carbon revenue may not be considered a cost if all of it is returned to ratepayers, for example, in the form of a tax reduction.

mid-range estimate of the social cost of carbon (approximately $40 - $60 per metric ton) is imposed throughout the entire Western electricity market. While this would reduce projected carbon dioxide emissions to 10 million metric tons by 2035, or 80 percent below historical average regional emission levels, the cost of this strategy (excluding the carbon revenue) is $44 billion or 55 percent more than the cost of other resource portfolios that comply with federal carbon dioxide emissions limits at the regional level. The Council also found that reaching a zero-carbon emissions power system is not technically feasible without developing new technologies.

Investments to add transmission capability and improve operational agreements are important for the region, both to access growing site-based renewable energy and to better integrate low and zero-emissions resources into the existing power system. The Council also expects that there are small-scale resources available at the local level in the form of cogeneration or renewable energy opportunities. The plan encourages investment in these resources when cost-effective.

The plan encourages research in advanced technologies to improve the efficiency and reliability of the power system. For example, emerging smart-grid technologies could make it possible for consumers to help balance supply and demand. Providing information and tools to consumers to adjust electricity use in response to available supplies and costs would enhance the capacity and flexibility of the power system. Smart-grid development could also help integrate electric vehicles with the power system to aid in balancing the system and reduce carbon emissions in the transportation sector. Research on how distributed solar generation with on-site storage might affect system load shape is also encouraged.

Other resources with potential, given advances in technology, include geothermal, ocean waves, advanced small modular nuclear reactors, and emerging energy efficiency technologies. New methods to store electric power, such as pumped storage or advanced battery technologies may enhance the value of existing variable generation like wind.

Developing these technologies is a long-term process that will require many years to reach full potential. The region can make progress through investments in research, development, and demonstration projects.

FUTURE REGIONAL ELECTRICITY NEEDS AND PRICES

Pacific Northwest regional loads are expected to increase by between 1,800 and 4,400 average megawatts between 2015 and 2035 before accounting for the impact of the cost-effective energy efficiency called for in the Seventh Power Plan. This translates to an average increase of between 90-220 average megawatts per year, or a growth rate of between 0.4 – 0.95 percent per year. The regional peak load for power, which typically occurs in winter, is forecast to grow from about 30,000 - 31,000 megawatts in 2015 to around 31,900-35,800 megawatts by 2035. This equates to an average annual growth rate of between 0.3 – 0.8 percent.

Residential and commercial sectors account for much of the growth in demand. Contributing to this growth is increasing air conditioning load, new data centers, and growth in indoor agriculture. Also, summer peak electricity use is expected to grow more rapidly than annual energy demand. All of this growth in demand must be met by a combination of existing resources, energy efficiency, and new generation.

An important finding of the plan is that future electricity needs can no longer be adequately addressed by only evaluating average annual energy requirements. Planning for capacity to meet peak load and flexibility to provide within-hour, load-following, and regulation services will also need to be considered.

Requirements for within-hour flexibility reserves have increased because of the growing amount of variable wind generation in the region. While the plan doesn't foresee renewable resource development beyond what is required to satisfy existing state renewable portfolio standards, improved regional coordination could reduce the need for resources used to integrate existing renewables. For example, establishing energy imbalance markets could enable sharing resources reserved for integrating wind resources.

Wholesale electricity prices at the Mid-Columbia hub remain relatively low, reflecting the abundance of low-variable cost generation from hydro and wind, as well as continued low natural gas prices. The average wholesale electricity price in 2014 was $32.50 per megawatt-hour. By 2035, prices are forecast to range from $25 – $68 per megawatt-hour in 2012 dollars. The upper and lower bounds for the forecast wholesale electricity price were set by the associated high and low natural gas price forecast. Although the dominant generating resource in the region is hydropower, natural gas-fired plants are often the marginal generating unit for any given hour. Therefore, natural gas prices exert a strong influence on the wholesale electricity price, making the natural gas price forecast a key input. The region depends on externally sourced gas supplies from Western Canada and the U.S. Rockies.

Prices for natural gas have dropped significantly since reaching a high in 2008, and they're expected to remain relatively low going forward. Historically, natural gas prices have been volatile, so the plan uses a range of forecasts to capture most potential futures. The low price forecast range starts at $2.64 per MMBtu in 2015 and increases in real dollars to $3.56 per MMBtu by 2035. This low-range case represents a future with slow economic growth, low gas demand, and robust supplies. The high price forecast range climbs to $10 per MMBtu by 2035. This forecast represents a future with high economic growth, high demand for natural gas, and a limited gas supply.

Recent promulgation of federal regulations that limit carbon emissions from both new and existing power generation are expected to increase the demand for natural gas. These higher natural gas prices result in higher wholesale electricity prices. Therefore, some of the futures used to develop this plan include a wide range of possible natural gas and electricity prices. Additional carbon regulations or costs could further increase electricity costs for consumers. While higher prices reduce demand, they also stimulate new sources of supply and efficiency and make more efficiency measures cost-effective.

RESOURCE STRATEGY

The plan's resource strategy provides guidance to the Bonneville Power Administration and regional utilities on resource development to minimize the costs and risks of the future power system. Timing of specific resource acquisitions will vary for each utility.

Energy Efficiency: The region should aggressively develop energy efficiency with a goal of acquiring 1,400 average megawatts by 2021; 3,000 average megawatts by 2026; and 4,300 average megawatts by 2035. Efficiency is by far the least expensive resource available to the region, avoiding the risks of volatile fuel prices and large-scale resource development, while mitigating the risk of potential carbon pricing policies. Along with its annual energy savings, it helps meet future capacity needs by reducing both winter and summer peak demand.

Demand Response: In order to satisfy regional resource adequacy standards, the region should be prepared to develop significant demand response resources by 2021 to meet additional winter peaking capacity. The least-cost solution for providing new peaking capacity is to develop cost-effective demand-response resources, the voluntary and temporary reduction in consumers' use of electricity when the power system is stressed. The Northwest's power system has historically relied on the hydrosystem to provide peaking capacity, but under critical water and weather conditions we'll need additional capacity to meet the region's adequacy standard.

The Seventh Power Plan action plan recommends that the annual regional resource adequacy assessment compare the cost and economic risk of increased reliance on external market purchases to developing demand response resources to meet capacity. The Council will determine if the region has made sufficient progress toward acquiring cost-effective demand response or confirm the ability to import a minimum of at least 600 megawatts of additional peaking capacity in its mid-term assessment of the Seventh Power Plan.

Natural Gas: Increased use of existing natural gas generation is expected to replace retiring coal plants and meet carbon-reduction goals in the near term. Only low to modest amounts of new natural gas-fired generation is likely to be needed to supplement energy efficiency, demand response, and renewable resources, unless the region experiences prolonged periods of high load growth or additional coal plants beyond those already announced are retired. Even if the region has adequate resources, individual utilities or areas may need additional supply for energy, capacity or wind integration. In these instances, the strategy relies on natural gas-fired generation to provide energy, capacity, and ancillary services.

Renewable Resources: Modest development of renewable generation will meet existing renewable portfolio standards. On average, renewable resources developed to fulfill state RPS mandates will contribute about 100 - 150 average megawatts of energy, or around 300 megawatts of installed capacity. While wind generation has been the dominant renewable resource developed in the region, lower costs for solar photovoltaic technology are expected to make it more competitive. As a result, compliance is expected to be met through both wind and solar PV systems and conventional geothermal resources. However, except for geothermal resources, these renewable resources lack dependable winter peak capacity and also require within-hour balancing reserves. Therefore, the plan's resource strategy encourages research and demonstration of other potential renewable resources, such as geothermal and wave energy, which have more consistent output. The resource strategy also encourages developing other renewable alternatives that may be available at the local, small-scale level and are cost-effective now.

Regional Resource Use: Continue to improve system scheduling and operating procedures across the region's balancing authorities. These cost-effective steps will help minimize reserves needed to integrate renewable resources. The region also needs to invest in its transmission grid to improve market access for utilities, reduce line losses, and help develop diverse cost-effective renewable generation. Finally, the least-cost resource strategies rely first on regional resources to satisfy the region's resource adequacy standards. Under many futures conditions, these strategies reduce regional exports.

Carbon Policies: To support policies that cost effectively achieve state and federal carbon dioxide emissions reduction goals, while maintaining regional power system adequacy, the region should develop the energy efficiency and demand response resources called for in this plan and replace retiring coal plants with only those resources required to meet regional capacity and energy adequacy requirements. As stated earlier, after energy efficiency, increasing use of existing natural gas generation offers the lowest cost option for reducing regional carbon emissions. Developing new gas-fired generation to meet local needs for ancillary services, such as wind integration or capacity requirements beyond the modest levels anticipated in the plan, will increase carbon dioxide emissions. If Northwest electricity generation is dispatched first to meet regional adequacy standards for energy and capacity rather than to serve external markets, carbon dioxide emissions can be minimized.

Future Resources: In the long term, the Council encourages the region to expand its resource alternatives. The region should explore other sources of renewable energy, especially technologies that provide both energy and winter capacity; new efficiency technologies; new energy-storage techniques; smart-grid technologies and demand-response resources; and new or advanced low-carbon generating technologies, including advanced nuclear energy. Research, development, and demonstration funding should be prioritized in areas where the Northwest has a comparative advantage or where unique opportunities emerge.

Adaptive Management: The Council will annually assess the adequacy of the regional power system to guard against power shortages. Through this process, the Council will be able to identify when conditions differ significantly from planning assumptions so the region can respond appropriately. The Council will also conduct a mid-term assessment to review the plan's implementation and ensure the successful implementation of the Council's Columbia River Basin Fish and Wildlife Program.

Energy Efficiency

The dominant new resource in the Seventh Power Plan's resource strategy is improved energy efficiency. Figure 1 - 3 shows that under scenarios that consider carbon risk and those that do not, and even when natural gas and wholesale electricity prices are lower than expected, the region's net load after developing all cost-effective efficiency is basically the same over the next 20 years. In more than 90 percent of the 800 futures evaluated by the Council, across more than 20 different scenarios, the least-cost resource strategy developed sufficient energy efficiency resource to meet all regional load growth through 2030. Indeed, even in the scenario (Lower Energy Efficiency) that assumed only energy efficiency costing less than short-term wholesale market prices would be acquired, nearly all regional load growth in the medium forecast through 2025 was met with energy efficiency. However, it should be noted that developing this lower level of efficiency increased regional power system cost by $15 billion, an 18 percent higher cost compared to resource strategies that developed sufficient energy efficiency to meet all load growth through 2030.

This is because improved efficiency is relatively cheap, it provides both energy and capacity savings, and it has no major risks. It costs half of what other resources cost, without the risk of volatile fuel prices or costs of carbon reduction policies. It also has a short lead time and is available in small increments, both of which reduce risk. Therefore, improved efficiency reduces the cost of, and risks to, the power system.

Figure 1 - 3: Average Net Regional Load After Accounting for Cost-Effective Energy Efficiency Resource Development

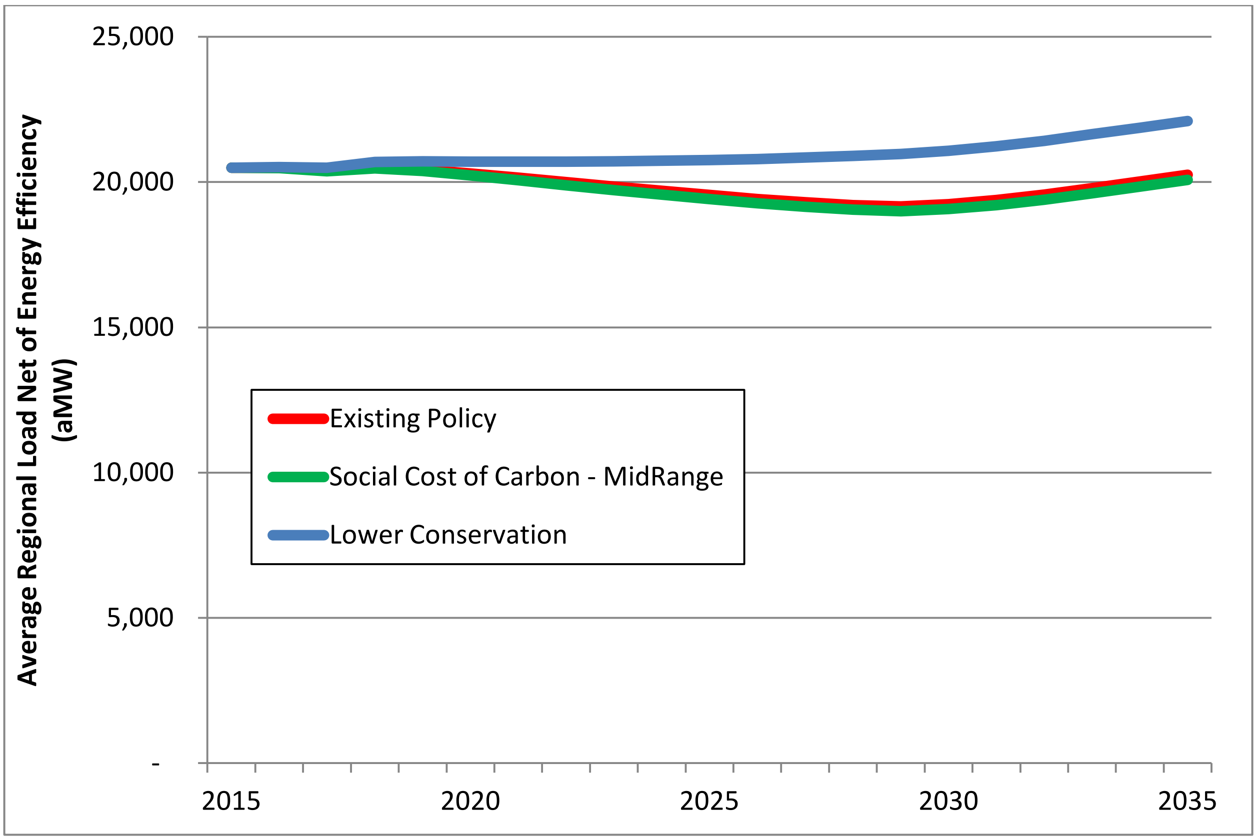


Figure 1 - 4 compares the average cost of energy efficiency resources and the cost of generating resources considered in the plan's development. Two estimates of the cost of energy efficiency are shown. The lower average cost ($18 per megawatt-hour) reflects energy efficiency's impact on the need to expand distribution and transmission systems. The higher cost ($30 per megawatt-hour) does not include these power system benefits.

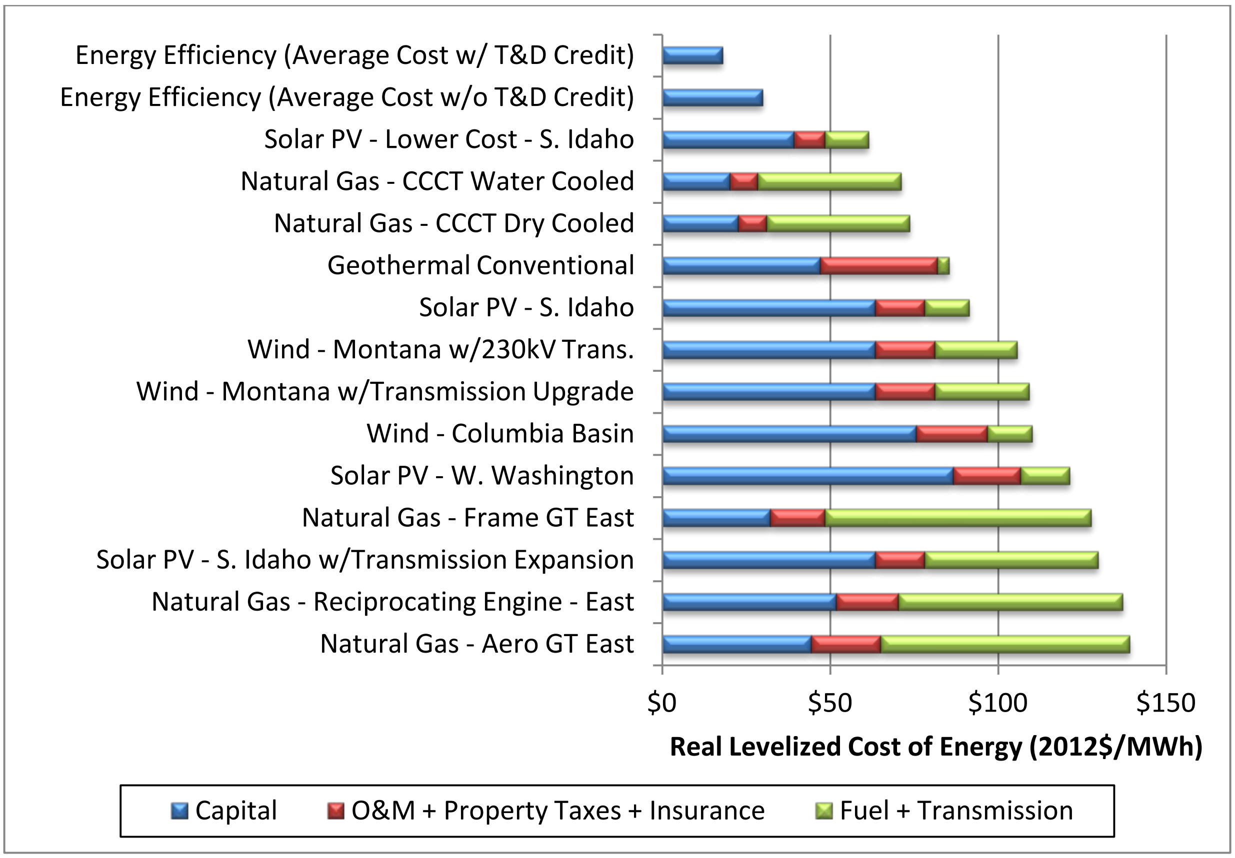
The comparable estimated cost of a natural gas-fired combined-cycle combustion turbine is around $71 per megawatt-hour. The current cost of utility-scale solar photovoltaic systems is approximately $91 per megawatt-hour and Columbia Basin wind costs $110 per megawatt-hour. Significant amounts of improved efficiency also cost less than the forecast market price of electricity, since nearly 2,400 average megawatts of energy savings are available below the average cost of $30 per megawatt-hour.

In the Council's analysis, additional resources provide insurance against an uncertain future. Efficiency improvements are particularly attractive as insurance because of their low cost and modular size. When the resources aren't needed, the energy savings from low-cost energy efficiency resources can be sold in the market, paying for itself and then some.

In all of the scenarios and sensitivity studies examined by the Council, similar amounts of improved efficiency are found to be cost-effective even without carbon costs. If carbon reduction policies are enacted, efficiency improvements can help the region meet those goals. In all scenarios tested by the Council, the amount of cost-effective efficiency developed averaged between 1,200 and 1,450 average megawatts by 2021 and between 3,900 and 4,500 average megawatts by 2035.

Figure 1 - 4: Energy Efficiency and Generating Resource Cost Comparison[4]



[4] In Figure 1-4 the levelized cost of solar PV resources have been reduced by the impact of a 30% Federal Investment Tax Credit (ITC) until 2022 and a 10% ITC for the remainder of the planning period. Geothermal costs have also been reduced by a 10% ITC throughout the entire planning period. In addition, solar, wind and geothermal resource costs are also reduced by accelerated depreciation. No state or local tax or other financial incentives are reflected in resource costs. The cost of these resources also reflect integration costs equivalent to current integration rates for wind resources charged by Bonneville and Idaho Power Company's integration rates for solar PV systems. The integration cost of additional renewable resource development in the region may be higher.

Demand Response

Demand response resources are voluntary reductions in customer electricity use during periods of high demand and limited resource availability. The plan's resource strategy uses demand response to meet winter and summer peak demands, primarily under critical water and extreme weather conditions. The strategy doesn't consider other possible applications of demand response--to integrate variable resources like wind for example.

The Council's assessment identified more than 4,300 megawatts of regional demand response potential. A significant amount of this potential, nearly 1,500 megawatts, is available at relatively low cost; less than $25 per kilowatt of peak capacity per year. When compared to the alternative of constructing a simple cycle gas-fired turbine, demand response can be deployed sooner, in quantities better matched to the peak capacity need, deferring the need for transmission upgrades or expansions.

In particular, demand response is the least expensive means to maintain peak reserves for system adequacy. Its low cost is especially valuable because the need for peaking capacity in the region largely depends on water and weather conditions. The Council's analysis indicates that a minimum of 600 megawatts of demand response resources would be cost-effective to develop under all future conditions tested across all scenarios that don't rely on increased firm capacity imports. Moreover, even if additional firm peak power imports during winter months are assumed to be available, developing a minimum of 600 megawatts of demand response resources is still cost-effective in over 70 percent of the futures tested.

Alternatively, the region could rely on external power markets to meet its winter peak capacity needs. In one scenario tested by the Council, the region relied more on external markets (Canada, California, and the Southwest) which greatly reduced the need to develop demand response. That scenario relaxed the Council's current assumptions about the availability of firm power imports from out-of-region sources and from in-region market resources. Since that scenario's system cost and economic risk were lower than scenarios in which cost-effective demand response was acquired, the plan's resource strategy recommends that the Council's Resource Adequacy Advisory Committee reexamine all potential sources of imported energy and capacity to minimize cost and avoid the risk of overbuilding.[5]

Generation Resources

The Council analyzed a large number of alternative generating technologies. Each was evaluated in terms of risk characteristics, cost, and potential for improvements in its efficiency over time. In addition, resources were considered in terms of their energy, capacity, and flexibility characteristics, such as their ability to ramp up and down to accommodate variations in the output of wind and solar PV resources. In the near term, generating technology options that are technologically mature, meet the emissions requirements for new plants, and are cost-effective are limited in number.

[5] See Council Action Item 10.

Improvements in the efficiency and operation of natural gas-fired generation make it the most cost-effective option and the third major element in the plan's resource strategy. After energy efficiency, increased use of *existing* natural gas generation is the lowest cost option to reduce regional carbon dioxide emissions. It plays a major role in the least-cost resource strategies to reduce carbon dioxide emissions. Existing natural gas generation increases immediately in scenarios where carbon costs are imposed.

Across the scenarios evaluated, the optioning and completion of new gas-fired generating resources varied widely. New gas-fired plants are optioned (sited and licensed) so that they are available to develop if needed in each future. The plan's resource strategy includes optioning new gas-fired generation as local needs dictate. However, from an aggregate regional perspective, which is the plan's focus, the need for additional new natural gas-fired generation is very limited in the near term (through 2021) and only slightly higher in the mid-term (through 2026) under nearly all scenarios. That is, options for new gas-fired generation are brought to construction in only a relatively small number of futures.

Across most scenarios that did not assume additional coal plant retirements beyond those already announced, the probability of gas development is less than 10 percent by 2021. By 2026, the probability of constructing a new gas-fired thermal plant increases to almost 50 percent in scenarios where utilities are unable to develop demand response, and to over 80 percent in scenarios where existing coal plants and less efficient gas-fired generation are retired to lower carbon emissions.

While energy efficiency and the minimum amount of demand response and renewable resource development were fairly consistent across most scenarios, the future role of natural gas-fired generation varied depending on the specific scenario studied. The average build-out of new natural-gas fired generation over the 800 futures in most scenarios was less than 50 average megawatts of generation by 2026. Since the average nameplate capacity of a new combined-cycle combustion turbine assumed in the analysis is 370 megawatts, this implies that "on average" only a single plant, operating less than 15 percent of the time is needed. By 2035, the average build-out across all 800 futures was 300 to 400 average megawatts of annual output from new gas-fired generation--one or two additional plants. In the carbon-risk scenario, the amount of energy actually generated from new combined-cycle combustion turbines, when averaged across all 800 futures, is just 10 average megawatts, but close to 100 average megawatts in scenarios that assume no demand response resources are developed.

On the other hand, some utilities may need to develop new natural gas-fired generation, even if they deploy demand response and develop the plan's recommended efficiency. The regional transmission system hasn't evolved as rapidly as the electricity market, resulting in limited access to market power. Individual utilities may need within-hour balancing reserves or have near-term resource challenges.

The varying needs of individual utilities limit the ability of the regional resource strategy to be specific about optioning and construction dates for natural gas-fired resources or for the types of natural gas-fired generation. But it also underscores the value of a regional approach to resource development where resources are part of an interconnected system.

Renewable resource generation development in the plan is driven by state renewable portfolio standards. In the absence of higher standards, few additional renewable resources are developed.

The Council recognizes that additional small-scale renewable resources are available and cost-effective, and the plan encourages their development as an important element of the resource strategy. For example, Snohomish PUD recently completed the Youngs Creek hydroelectric project and Surprise Valley Electric Cooperative is developing the Paisley Geothermal Project, a low-temp geothermal power project in rural Oregon. There are many other potential renewable resources that may, with additional research and demonstration, prove to be cost-effective and valuable for the region to develop.

The amount of additional renewable energy acquired *on average* in the least-cost resource strategies across scenarios didn't vary significantly, even in scenarios that assumed a carbon cost of $40 to $60 per metric ton. This is because the two most economically competitive renewable resources available in the region, wind and solar PV, provide limited reliable peaking capacity, especially in winter. Partly because of the significant wind development in the region over the past decade, the Northwest has a significant energy surplus, yet under critical water conditions the region faces the probability of a peak capacity shortfall–again, because wind provides little winter capacity.

While wind continues to be the primary large-scale, cost-effective renewable resource, decreasing costs for utility-scale and distributed-scale photovoltaic systems have made them cost-competitive sources of energy supply. Consequently, the plan's resource strategy recommends that utilities, especially those with increasing summer peak demands, consider utility-scale solar resources to satisfy their renewable portfolio standard obligations.

Other generating resource alternatives may become available over time, and the plan recommends actions to encourage their development, especially those that don't produce greenhouse gas emissions.

In addition to utility scale renewable resource development, the Seventh Power Plan also recognizes the increasing adoption by homeowners and businesses of distributed solar PV systems. The use of these systems is forecast to dampen regional load growth. By the end of 2014, over 100 megawatts of distributed solar PV capacity had been installed in the region, lowering system energy requirements by an estimated 18 average megawatts. By 2035, the Council forecasts that 500 to 1,400 megawatts of solar PV systems will be installed in the region. On an annual basis, the energy generated from these distributed PV systems is forecast to reduce regional loads by 80 to 220 average megawatts. In addition, these distributed solar PV systems also reduce winter and summer peak loads. Summer peak impacts from distributed solar PV are forecast to be lower by as much as 600 megawatts by 2035.

Regional Resource Use

The existing Northwest power system is a significant asset for the region. The Federal Columbia River Power System provides low-cost and carbon dioxide-free energy, capacity, and flexibility. The network of transmission constructed by the Bonneville Power Administration and the region's utilities has supported a highly integrated regional power system. The Council's resource strategy assumes that ongoing efforts to improve system scheduling and operating procedures across the region's balancing authorities will, in some form, succeed. While the Council doesn't directly model the sub-hourly operation of the region's power system, its models presume resources located anywhere in the region can provide balancing reserve services to any other location in the region, within the limits of existing transmission. This assumption minimizes the need for new resources to integrate renewable resources.

Along with reducing physical and technical barriers, there are more efficient ways to dispatch and use existing regional resources that could minimize the need for new resource development. The analyses conducted for the Seventh Power Plan reveal in particular that the region could benefit from a different approach to using existing generation so as to keep more of that generation in the region serving load under longer-term arrangements.

The Council's analysis shows that the total cost to the region would be lower if more effective use of surplus power available from Bonneville and some of the region's utilities could be used in-region to offset the need that other utilities have to develop new generation to meet resource adequacy standards. The Council recognizes that significant equity, risk, institutional, and legal issues must be overcome to effect such a change. For example, Bonneville and other utilities in the region that control hydropower generation often, but not always, generate substantial surplus power above critical water conditions. Most of that surplus is sold into short-term markets, much of it leaving the region. The Council's analysis indicates that the region would benefit if, instead, some significant portion of this surplus hydropower generation could be sold to other utilities in the region under longer-term contracts to meet regional firm power needs. In order for this to happen, however, either the sellers or the buyers, or both, would have to take on some additional risk since the surplus generation would not always be available due to poor water conditions. As a result, the power price for such contracts would need to somehow reflect additional risk.

The region needs to be creative in crafting new power sales arrangements that address in an appropriate and equitable way the issues of risk inherent in any scheme to rely on this surplus generation to help meet regional adequacy standards. However, the Council encourages the region to find ways to overcome these barriers since the benefit to the region could be substantial.[6]

CLIMATE CHANGE POLICY

Evolving climate change policies to lower carbon emissions from power plants was identified by stakeholders as one of the most important issues for the plan to address. Most recently, with the promulgation by the Environmental Protection Agency's final rules limiting carbon dioxide emissions from both new and existing power generating facilities, the goal of those policies became clearer. [7]

---

[6] Absent such an outcome, the trend over the past decade that shows the average revenue per kilowatt-hour for residential customers of investor-owned utilities increasing while the average revenue per kilowatt-hour for residential customers of public utilities has remained nearly flat will likely continue. Between 2005 and 2014, the average revenue per kilowatt-hour sold by IOUs increased from 7.7 cents to 9.9 cents, while the average revenue per kilowatt-hour sold for public utilities remained barely changed, increasing from 7.7 cents to 8.0 cents per kilowatt-hour. Similar trends have occurred for commercial and industrial customers.

[7] U.S. Environmental Protection Agency, "Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64,662 (October 23, 2015). A coalition of states, utilities, utility organizations and others challenged the rule applying to existing sources in the federal D.C. Circuit Court of Appeals. The U.S. Supreme

However, since states are charged with developing and implementing plans to comply with EPA's regulations, uncertainty still exists about specific approaches Northwest states will follow to satisfy the regulation.

Reduced carbon dioxide emissions can be encouraged through various policy approaches, including regulatory mandates (renewable portfolio standards, energy efficiency resource standards, emission standards), carbon pricing policies, such as emissions cap-and-trade systems and emissions taxes or negotiated agreements to retire carbon dioxide emitting generation. To date, state policy responses within the region have focused on renewable portfolio standards and new generation emissions limits. Oregon and Washington also have carbon reduction targets adopted by statute. While regulatory and carbon pricing policies have been discussed at the national level, the EPA's new emissions limits are the most concrete policy option adopted.

The plan doesn't address whether carbon dioxide emissions should be reduced, by when or to what level. For now, these questions have been settled by EPA's regulations.[8] The questions for the plan are: What are the least-cost resource strategies to reduce carbon dioxide emissions and satisfy the federal emissions limits? And, what state (or regional) policies are likely to result in those least-cost resource strategies? The Council analyzed multiple carbon reduction scenarios, including three alternative carbon pricing policies and three regulatory policies.

The key findings from the Council's analysis of climate change policies include the following:

- Without any additional carbon control policies, carbon dioxide emissions from the Northwest power system are forecast to decrease from about 54 million metric tons in 2015 to around 36 million metric tons in 2035.[9] This reduction is driven by: 1) The retirement of three coal-fired power plants (Centralia, Boardman, and North Valmy) by 2026. These plants currently serve the region, but their retirement has already been announced; 2) Increased use of existing natural gas-fired generation to replace these retiring resources; and 3) Developing roughly 4,300 average megawatts of energy efficiency by 2035, which is sufficient to meet all forecast load growth over that time frame under most future conditions. If these actions do not occur, the level of forecast emissions is likely to increase. If these actions do occur, then

Court stayed the effectiveness of the rule in an order issued February 9, 2016, pending not just review on the merits by the court of appeals but also the resolution of any petition for further review in the Supreme Court following whatever decision is issued by the court of appeals. The litigation is ongoing as the Council completed the Seventh Power Plan.

[8] By "settled" the Council does not mean to imply that pending litigation over the EPA's regulations may not still alter those regulations. In this context, the Council simply means that in developing the plan it used EPA's draft and final regulations as the basis for its analysis of the cost and effectiveness of alternative carbon reduction policies.

[9] This is the level of carbon dioxide emissions estimated to be generated to serve regional load under average water and weather conditions. Actual 2015 carbon dioxide emission could differ significantly from this level based on actual water and weather conditions. Average regional carbon dioxide emissions from 2001 – 2012 were 54 MMTE, but ranged from 43 MMT to 60 MMT.

the region will have a very high probability (98 percent) of complying with the EPA's carbon emissions limits, even under critical water conditions.

- Retiring all of the coal plants serving the region could reduce regional power system carbon dioxide emissions from approximately 54 million metric tons today to about 16 million metric tons, a nearly 70 percent reduction. Implementing this resource strategy would increase the present value average power system cost by nearly $16 billion, 20 percent over the cost of resource strategies that are projected to satisfy the EPA's recently established limits on carbon dioxide emissions *at the regional level*.

- If all of the region's existing coal plants are retired and replaced exclusively with renewable resources and all generation is dispatched to reflect a mid-range estimate of the social cost of carbon, regional power system carbon emissions could be reduced to 10 million metric tons per year by 2035, 80 percent below historical levels. This is the equivalent to imposing the federal government's mid-range estimate of the social cost of carbon throughout the entire Western electricity market and developing only renewable resources to replace retiring generation. The cost of this strategy, excluding carbon taxes, is estimated to be $44 billion, or 55 percent over the cost of resource strategies that are projected to satisfy the EPA's recently established limits on carbon dioxide emissions *at the regional level*.

- At present, it's not possible to entirely eliminate carbon dioxide emissions from the power system without the use of nuclear power or emerging technology breakthroughs in both energy efficiency and non-carbon dioxide emitting renewable resource generation.

- Deploying renewable resources to achieve maximum carbon reduction presents significant power system operational challenges, in particular by dramatically increasing the need for balancing and flexibility reserves.

- The most cost-effective carbon dioxide emissions reduction policies are those that retire or significantly reduce the use of existing coal plants. The single policy option for reducing carbon dioxide emissions with the lowest cost per unit of emissions reduction imposes the equivalent of the federal government's mid-range estimate of the social cost of carbon throughout the entire Western electricity market. The single policy option for reducing carbon dioxide emissions with the highest cost per unit of emissions reduction establishes a regional renewable portfolio standard at 35 percent. The high per unit cost of carbon dioxide emissions reduction from this policy occurs because it does not retire or significantly reduce the use of existing coal plants.

FISH AND WILDLIFE PROGRAM AND THE POWER PLAN

The Columbia River Basin Fish and Wildlife Program is by statute incorporated into the Council's power plan. The fish and wildlife program guides the Bonneville Power Administration's efforts to mitigate the adverse effects of the Columbia River hydroelectric system on fish and wildlife. One of the roles of the power plan is to ensure the implementation of hydrosystem operations to benefit fish and wildlife while maintaining an adequate, efficient, economic, and reliable energy supply.

The hydroelectric operations for fish and wildlife have a sizeable impact on power generation. On average, hydroelectric generation is reduced by about 1,100 average megawatts compared to operation without constraints for fish and wildlife. Since 1980, the power plan and Bonneville have addressed this impact through changes in secondary power sales and purchases; by acquiring energy efficiency and some generating resources; by developing resource adequacy standards; and by implementing other strategies to minimize power system emergencies and events that might compromise fish operations.

In addition to operational changes, most of the direct and capital costs of the fish and wildlife program have been recovered through Bonneville revenues, and Bonneville has absorbed the financial effects of lost generation, resulting in higher electricity prices. The power system is less economical as a result of fish and wildlife program costs, but still affordable when compared to the costs of other reliable and available power supplies.

The future presents a host of uncertain changes that are sure to pose challenges to integrating power system and fish and wildlife needs: potential new fish and wildlife requirements; increasing wind generation and other renewables that require more flexibility in power system operations; conflicts between climate change policies and fish and wildlife operations; possible changes to the water supply from climate change that intensify conflict between fish and power needs; and possible revisions to Columbia River Treaty operations to match 21st century power, flood control, and fish needs.

Operations to benefit fish and wildlife have a significant biological value, and also a significant effect on the amount and patterns of generation from the hydrosystem. The Council encourages the federal action agencies to continue to monitor, evaluate, and report on the benefits and impacts to fish from flow augmentation and passage measures, including spill, and to work to revise and improve these evaluation methods as much as possible.

To address current operations and prepare for the challenges ahead, the Council will track changes and recommend actions by: annually assessing the region's power supply using its regional adequacy standard to ensure that events like the 2000-01 energy crisis, in which fish operations and power costs were affected, do not happen again; working with partners on its wind integration forum to help integrate wind generation into the power system; and completing a mid-term assessment of its power plan to measure our progress.

CHAPTER 2: STATE OF THE NORTHWEST POWER SYSTEM

Contents

INTRODUCTION

All planning processes start with information and assumptions about current conditions. This chapter summarizes the key assumptions regarding the state of the region that affected the Council's power system planning process or could potentially influence its implementation.

For example, the Northwest Power Act requires the Council's power plan to include a forecast of electricity demand for the next 20 years. Demand, to a large extent, is driven by economic growth, but it is also influenced by the price of electricity and other fuels. Therefore, recent economic trends and energy prices represent a starting point for plan development.

The Northwest Power Act also requires the Council's power plan set forth a forecast of the region's power resources need, including that portion that can be met by resources in each of the priority resource categories identified in the Act. Since the power plan treats cost-effective energy efficiency as a priority resource for meeting future electricity demand, an assessment of its potential must reflect recent accomplishments and factors, such as the impact of codes and standards on future demand. Similarly, assessments of the need for resource development must account for the status of existing generating resources, including planned additions and retirements.

In addition to the state of the region's economy and status of conservation and generating resources, other factors such as environmental regulations, public policy and technology trends also influence plan development. For example, recently finalized federal carbon dioxide emission regulations and changes in California's regulations, such as the state's renewable portfolio standards, may alter energy prices and wholesale market supplies.

The following discussion describes the key assumptions used as the starting point for the Council's analysis. For many of these assumptions, while the current status is known, there is significant uncertainty about the future. That uncertainty creates risks that are addressed in the Seventh Power Plan's resource strategy, set forth in Chapter 3.

KEY FINDINGS

- Since 2011, regional employment has grown by over 500,000 jobs per year. During the last five years, gross state product for Idaho, Montana, Oregon, and Washington increased by $110 billion (2012$). The regional economy grew at a nominal annual rate of 2.26 percent per year during 2010 to 2014.
- While overall regional loads have gradually returned to pre-recession levels, the increase has been slow. Regional electric loads finally returned to pre-recession levels in about 2014. On a weather-adjusted basis, total regional loads (excluding direct service industries or DSIs) reached a high of 20,454 average megawatts in 2008. This is identical to the regional weather-adjusted loads reported for 2014. However, since these loads are net of the energy-efficiency accomplishments over this period, they mask a far more robust underlying growth rate. Between 2010 and 2014, regional electricity efficiency savings totaled over 1500 average megawatts, exceeding the Sixth Power Plan's five-year goal of 1,200 average megawatts by 25 percent. Without those savings,

regional loads, exclusive of the DSIs, would have grown from 20,111 average megawatts in 2010 to 21,611 average megawatts in 2014, or by nearly 8 percent over five years.

- While the region's highest peak loads still occur during the winter months, summer peak demands are growing faster than winter peak demands. In fact, winter peak demands have not grown significantly since 1995, while summer peaks have been increasing at about 0.4 percent annually. Nevertheless, for the region as a whole, winter peak capacity is forecast to remain the more significant need for at least the next 10 to 15 years.
- The Council's forecast for future natural gas prices over the next twenty years spans a range from a low of $3.56 per MMBtu to a high of $10.00 per MMBtu by 2035. This is a lower range of future gas prices than was used in the Sixth Power Plan.
- In June of 2014, the Environmental Protection Agency (EPA) released its draft regulations limiting carbon dioxide emissions from existing power generation facilities under section 111(d) of the Clean Air Act. These regulations were finalized in August of 2015 and call for a 32 percent reduction in carbon dioxide emissions by 2030 compared to 2005. Along with releasing its final regulations for existing generation facilities, the EPA issued its final regulations limiting carbon dioxide emissions from *new* power generating facilities under Section 111(b) of the Clean Air Act. States have until 2018 to develop plans for complying with these new carbon dioxide regulations.
- Both the Sixth Power Plan and this plan include summer bypass spill requirements identified in the FCRPS Biological Opinion and also in the Council's 2014 Fish and Wildlife Program. Since the Sixth Power Plan, the bypass spill requirements have been adjusted to better reflect the intent of the biological opinion. While bypass spill continues to reduce the generation of the hydro system, these modifications have little impact on summer hydroelectric generation relative to the Sixth Power Plan. However, increasing reliance on the hydroelectric system to provide within-hour balancing needs[1] for wind generation has diminished the system's use to meet peak needs.
- In the Northwest, the retirements of three existing coal-fired plants serving the region have been announced. The 550 megawatt Boardman plant is now scheduled to shut down by 2020, avoiding the nearly $500 million in upgrades that would have otherwise been required. At the 1,340 megawatt Centralia plant, one unit is now scheduled to close in 2020 and the other is scheduled to close in 2025. In April of 2015, NV Energy announced the retirement of the 522 megawatt North Valmy plant, which serves a portion of Idaho Power Company's load. In addition, the J.E. Corette coal-fired power plant which does not serve the region, but is located in Montana, shut down in August of 2015.
- Also since 2010, one of region's non-utility owned existing natural gas plants, the 248 megawatt Big Hanaford combined cycle turbine in Washington State, has been retired as have the Elwha and Condit small hydroelectric power plants.

[1] For more information on balancing needs see Chapter 9 and Chapter 16.

- Since the Sixth Power Plan was adopted in early 2010, three new natural gas-fired generating resources have been added in the region. The largest is Idaho Power's Langley Gulch Power Plant located near Boise. Langley Gulch is a 300 megawatt combined-cycle project that entered service in July 2012. Portland General Electric built the 220 megawatt Port Westward II, a generating set of twelve reciprocating engines, in 2014 and is currently building the Carty Generating Station, a new 440 megawatt combined-cycle project at Boardman which is expected to be in service in 2016.
- From 2010 through 2014, 4,230 megawatts of wind nameplate capacity was added to the region – with nearly 2,000 megawatts coming online in 2012 alone. By the end of 2014, wind nameplate capacity in the region totaled about 8,700 megawatts. However, only about two-thirds of that nameplate capacity currently serves Northwest loads. The remaining one-third (~3,000 megawatts) of wind nameplate capacity is presently contracted to utilities outside the region, primarily California.
- Spot market prices for wholesale power continue to be quite low, due to increasing penetration of renewable resources with low variable operating costs and low natural gas prices, and do not provide an accurate representation of the avoided cost of new resources. The low spot market prices for power affect the region's utilities differently. Utilities with limited exposure to market prices may be largely unaffected. For example, utilities whose resources closely match their customers' demands have little need to buy or sell power in the wholesale spot market. On the other hand, utilities whose resources and loads are not as closely balanced can be greatly – and very differently – affected depending on whether their resources are surplus or deficit.
- The region exceeded the Sixth Power Plan's five-year goal of 1,200 average megawatts of energy efficiency for 2010-2014 by 25 percent, achieving over 1,500 average megawatts of energy and approximately 2500 megawatts of peak savings. Actual average utility costs for energy efficiency acquisitions have remained well below the cost of other types of new resources and wholesale market prices.
- The character of the region's power system is changing. Historically, needs for new resources were driven mostly by energy deficits. Today, however, needs for peaking capacity and system flexibility are also emerging, expanding the focus of the region's planning and development of new resources to address these system needs in addition to energy. Since 2000, about 5,900 megawatts of natural gas-fired generation has been added in the region. During that same period, about 8,700 megawatts of wind power has also been built in the region. The large increase in wind generation has meant that utilities must hold more resources in reserve to help balance demand minute-to-minute; hence the need for system flexibility has become a concern. The Council estimates that the region will have sufficient generation and demand side capability on its existing system to meet balancing and flexibility reserve requirements over the next six years if the Seventh Power Plan's energy efficiency and demand response development goals are achieved. The mechanism for accessing this capability, however, may not be available to all Balancing Authorities depending on market structure/availability.
- Conditions vary across the region and from utility to utility. Some have growing loads; others are flat or have lost large customers. Some have surplus resources and others face deficits. These differences affect utilities' incentives to acquire resources, including energy efficiency.

- Regional power supply planning matters are becoming increasingly linked with electric transmission and natural gas matters, requiring greater coordination.

STATE OF THE SYSTEM

Regional Economic Conditions

Employment and job creation in the Pacific Northwest remained sluggish during 2010 and 2011, growing from 6.11 million jobs in 2009 to 6.14 million jobs in 2011, adding just 150,000 jobs each year. Since 2011, however, employment has grown by over 500,000 jobs per year to 6.3 million jobs in the region in 2014. During the last five years, gross state product (expressed in constant 2012 dollars) for Idaho, Montana, Oregon, and Washington increased from about $560 billion dollars in 2010 to about $670 billion in 2014, a net increase of $110 billion. Based on these figures, the regional economy grew at a nominal annual rate of 2.26 percent per year during 2010 to 2014.

Sectors with economic growth during the last several years included durable goods manufacturing, information technology, health care, and technical services. Declining sectors included construction, mining, transportation, wholesale trade, and government services. Overall, these changes are consistent with an ongoing general structural shift in the regional economy towards less energy-intensive industries.

Forecasts used for the Seventh Power Plan showed the region's economy growing at a fairly healthy pace, consistent with long-term historical trends. The region's population is projected to grow to over 16 million by 2035 at an annual rate of 0.9 percent. Regional personal income, both in total and on a per-capita basis, has been on the upswing and is projected to continue, although at a slower rate. From 1989 through 2009 regional personal incomes grew by about 3.9 percent per year. The Seventh Power Plan forecasts personal income growth to average 2.9 percent per year over the coming two decades. Between 2015 and 2035, commercial employment is expected to grow at an annual rate of 0.9 percent, with total employment growing from 6.4 million in 2015 to about 7.7 million by 2035.

Economic conditions also vary within the region. For example, metropolitan areas with diverse economic bases have tended to fare better than rural areas, which have traditionally been more dependent on specific industries.

Electricity Demand

Between 2010 and 2014, regional electricity weather normalized loads, inclusive of the Direct Service Industries or DSIs (the large industrial customers historically served directly by Bonneville) increased slightly, growing from 20,617 average megawatts to 21,164 average megawatts. This five year increase of just under 550 average megawatts represents a total growth of just over 3 percent. If these large customer's loads are excluded, regional electricity loads grew from 20,111 average megawatts in 2010 to 20,454 average megawatts in 2014. This is an increase of 343 average megawatts or just under 2 percent growth over five years.

While overall regional loads appear to be gradually returning to pre-recession levels, the increase has been slow. On a weather-adjusted basis, total regional loads (excluding DSIs) reached a high of 20,454 average megawatts in 2008. This is identical to the regional weather-adjusted loads reported for 2014. Thus, regional electric loads finally returned to pre-recession levels in about 2014.

However, since these loads are net of the energy-efficiency accomplishments over this period, they mask a far more robust underlying growth rate. Between 2010 and 2014, the Council estimates, based on Bonneville, utility, Energy Trust of Oregon, and NEEA reporting, that regional electricity efficiency savings totaled over 1,500 average megawatts. Without those savings, regional loads, inclusive of the DSIs, would have grown from 20,617 average megawatts in 2010 to 22,660 average megawatts in 2014, or by nearly 10 percent over five years.

While the region's highest peak loads still occur during the winter months, summer peak demands are growing faster than winter peak demands. In fact, winter peak demands have not grown significantly since 1995, while summer peak demands have been increasing at about 0.4 percent annually. At least two of the region's investor owned utilities, Idaho Power Company and Portland General Electric, have summer peak demands that are higher or nearly equivalent to their winter peak demands. Nevertheless, for the region as a whole, winter peak capacity is forecast to remain the more significant need for at least the next 10 to 15 years.

One of the newer segments contributing to demand has been data centers. Custom and mid-tier data centers have been attracted to the Pacific Northwest by financial and tax incentives, low electricity prices, and a skilled professional base. The Seventh Power Plan forecasts that electricity use by data centers could increase from their current level of 350 to 400 average megawatts to as much as 900 average megawatts by 2035. More recently, as a result of the legalization of cannabis production in Washington and Oregon, indoor agriculture is anticipated to contribute to between 100 and 200 average megawatts of increased electricity demand over the next twenty years. The Council's Seventh Power Plan also anticipates significant growth in electricity use in the transportation sector, forecasting that plug-in electric vehicles could add 160 to 625 average megawatts to regional electricity use by 2035, a significant increase from 8 average megawatts of load in 2015 created by the region's over 22,000 existing electric vehicles.

Acting in the opposite direction are the anticipated impacts of new federal appliance, lighting, equipment standards and distributed solar photovoltaic (PV) systems. More than 30 new and revised federal standards have been enacted since 2010. These standards are forecast to reduce future load growth by nearly 1500 average megawatts over the 20 year period covered by the Seventh Power Plan.

The increasing adoption by homeowners and businesses of distributed solar PV systems are also forecast to dampen regional load growth. As of the end of 2014, over 100 megawatts of distributed solar PV capacity had been installed in the region, lowering system energy requirements by an estimated 18 average megawatts. By 2035, the Council forecasts that 500 to 1,400 megawatts of solar PV systems will be installed in the region. On an annual basis, the energy generated from these distributed PV systems is forecast to reduce regional loads by 80 to 220 average megawatts. In addition, these distributed solar PV systems also reduce winter and summer peak loads. Summer peak impacts from distributed solar PV are forecast to be lower by as much as 600 megawatts by 2035.

Natural Gas Markets and Prices

When the Council adopted its Sixth Power Plan in early 2010, market prices for natural gas had just dropped dramatically. U.S. average wellhead prices for natural gas, which averaged $8.24 per million British thermal units (MMBtu) in 2008, fell by more than half to $3.76 per MMBtu in 2009.

The rapid decline in natural gas prices was the result of the unanticipated, yet massive, transformation of the natural gas industry in the late 2000s. This change was driven by the sudden emergence of the huge potential to produce natural gas from shale formations using hydraulic fracturing techniques.

To a large degree, the natural gas price forecasts used in the Sixth Power Plan reflected the shale gas phenomenon. The forecasts were reasonably accurate during the first two years of the planning period. The plan's medium case forecast showed U.S. wellhead prices of $4.78 per MMBtu in 2010 and $5.07 per MMBtu in 2011. These forecasts turned out to be higher than actual market prices, which averaged $4.53 per MMBtu in 2010 and $3.91 per MMBtu in 2011.

Beginning in mid-2011, monthly wellhead gas prices fell fairly rapidly, reaching a low of $1.98 per MMBtu for the month of April 2012 before rebounding after that. Annual average prices averaged about $2.59 per MMBtu for 2012, significantly below the Sixth Power Plan's forecast of $5.10 per MMBtu.

The decline in market prices reversed and began to increase in April 2012, but since late 2014 prices began to decline due to a crash of world oil prices and glut of natural gas production from U.S. shale plays. Wellhead prices in 2014 averaged about $3.84 per MMBtu (in 2012 dollars). As of January 2015 the outlook for 2015 composite wellhead prices was $3.60 per MMBtu. Since January 2015, oil and natural gas prices have declined further. By September 2015, wellhead prices declined to $2.70 per MMBtu (in 2012 dollars).

The U.S. Department of Energy's (DOE) Annual Energy Outlook 2015 forecasts Henry Hub gas prices will average about $3.63 per MMBtu during 2015. DOE forecasts that by 2025, Henry Hub gas prices will increase to $5.35 per MMBtu. By 2035, DOE forecasts natural gas prices will range from a low of $4.00 per MMBtu to a high of $8.64 per MMBtu. The final Seventh Power Plan uses a bench mark price of natural gas at Henry Hub of $2.64 per MMBtu for 2015 and a range forecast of $2.60-$3.70 per MMBtu in 2016. However, the Council's forecast for future natural gas price over the next twenty years spans a wider range; from a low of $3.60 per MMBtu to a high of $10.00 per MMBtu by 2035.

Increasingly, because of its low prices and apparent adequate supplies, natural gas-fired generation is displacing coal-fired generation. Coal to gas fuel switching is partly the result of environmental concerns, but it also reflects changed economics. In particular, it appears that lower market prices for natural gas are combining with higher market prices for coal to make natural gas-fired generating facilities more cost-effective.

This has raised concerns about methane emissions from the natural gas production, storage and transportation sectors. During the development of the natural gas price forecast, the issue of increased reliance on natural gas was discussed by the Council's Natural Gas Advisory Committee. In the judgment of the advisory committee, the Council's high range of the gas price forecast was sufficient to reflect the potential regulatory cost of reducing methane emissions.

Emissions Regulations and Impacts

Since the Council issued the Sixth Power Plan there has been extensive environmental regulatory activity that affects the electricity industry, much of it (but not all) relating to the production of electricity from fossil-fueled and especially coal-fired power plants. The list includes:

- Clean Air Act/national ambient air quality standards: The EPA has adopted more stringent standards for NO2, SO2, and particulate emissions, and proposed more stringent standards for ground-level ozone, all of which affect coal-fired power plants.
- Clean Air Act/regional haze rule: Continuing assessments and modifications of coal plants are required.
- Clean Air Act/ mercury and air toxics rule: The U.S. Supreme Court recently struck down and remanded the rule to the lower appellate court for further review. Regardless of the appellate court's decision, the EPA is not likely to substantially alter the rule. Many coal-plant owners have already invested in compliance measures.
- Resource Conservation and Recovery Act/fly ash regulation: In 2015, the EPA issued a new final regulation for handling coal combustion residuals, including boiler bottom ash, fly ash (ash carried in the flue gas), boiler slag, and products of flue gas desulfurization
- Clean Water Act/proposed revisions to effluent standards: In 2013, EPA proposed revisions to the standards for effluent from steam-electric power generation. The purpose is to strengthen existing controls and reduce wastewater discharges of toxic materials and other pollutants, including mercury, arsenic, lead and selenium, from especially coal-fired generation. The final rule was issued on September 30, 2015.
- Clean Water Act/cooling water intake regulations finalized: The EPA recently issued final regulations establishing new requirements for cooling water intake structures in order to protect aquatic organisms.
- Clean Air Act / carbon dioxide emissions regulations: Most notably, EPA finalized regulations under Sections 111(b) and 111(d) of the Clean Air Act limiting carbon emissions from new and existing fossil-fueled power plants. The Section 111(d) regulations call for a 32 percent reduction in carbon dioxide emissions by 2030 compared to 2005. The regulations are the subject of litigation. [2]
- Nuclear Regulatory Commission regulations: In the wake of the Fukushima Reactor accident in Japan, the Commission is requiring upgrades to existing nuclear power generating facilities to better prepare for external events beyond ordinary design criteria.

[2] U.S. Environmental Protection Agency, "Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64,662 (October 23, 2015). A coalition of states, utilities, utility organizations and others challenged the rule applying to existing sources in the federal D.C. Circuit Court of Appeals. The U.S. Supreme Court stayed the effectiveness of the rule in an order issued February 9, 2016, pending not just review on the merits by the court of appeals but also the resolution of any petition for further review in the Supreme Court following whatever decision is issued by the court of appeals. The litigation is ongoing as the Council completed the Seventh Power Plan.

- Clean Air Act/development of regulations to reduce fugitive methane emissions from the production and transportation of natural gas.
- Developing regulatory environment to protect eagles and other migratory birds from threats posed by the development and operation of wind and solar generating facilities.

Details about these regulatory efforts and their impacts are discussed elsewhere in the power plan, including Appendix I. Noteworthy here, is the collective effect of these environmental regulatory efforts, especially on the region's coal-fired power plants. In addition to the federal regulations, Northwest states' policies on carbon emissions and other environmental impacts have all but eliminated construction of *new* coal-fired generating facilities as an option for meeting future resource needs. The issue for the regional power system is the effect of the announced retirements of *existing* plants, and the effect on the power system of state and federal policies that may lead to the retirement of other existing plants.

The U.S. Energy Information Administration's (EIA's) Annual Energy Outlook 2014 (AEO2014) Reference Case projects that a total of 60 gigawatts of capacity will retire by 2020, which includes the retirements that have already been reported to the EIA. Retirements are being driven in some cases by the costs of complying with new environmental regulations or the need to reduce greenhouse gas emissions. Retirements are also being driven by the age of many existing plants and the need to refurbish them. In addition, as coal prices have risen over the last several years and natural gas prices have dropped, the operating cost advantage that coal has traditionally enjoyed has shrunk.

In the Northwest, the retirements of three existing coal-fired plants serving the region have been announced. The 550 megawatt Boardman plant is now scheduled to shut down by 2020, avoiding the nearly $500 million in upgrades that would have otherwise been required. At the 1,340 megawatt Centralia plant, one unit is now scheduled to close in 2020 and the other is scheduled to close in 2025. In April of 2015, NV Energy announced the retirement of the 522 megawatt North Valmy plant, which serves a portion of Idaho Power Company's load. In addition, the J.E. Corette coal-fired power plant which does not serve the region, but is located in Montana, shut down in August of 2015.

The trend toward retiring existing coal-fired power plants across the U.S. is having other spillover effects on the Northwest region. As domestic coal-fired generation falls, coal producers are turning their attention to offshore markets as a way to continue production. This includes major companies in the Powder River Basin of Wyoming that have ramped up efforts to market their coal to Asian markets and are seeking to ship coal through the Northwest to export terminals near the coast.

Meanwhile, Northwest cities and counties that have climate policies or initiatives include: Seattle, Anacortes, Bellingham, King County, Olympia, and Whatcom County in Washington; Portland, Bend, Corvallis, and Multnomah County in Oregon; Boise, Idaho; and Bozeman and Missoula in Montana.

Developments Affecting Power Imports from California

The Northwest and California are interconnected through AC and DC transmission interties with approximately 7,900 megawatts of maximum transfer capability, including 4,800 megawatts on the AC intertie and 3,100 megawatts on the DC intertie. Due to transmission loading on either end, the actual amount of transfer capability is closer to 6,000 megawatts and could be much lower if one of the lines is undergoing maintenance.

The two regions use these interties to share their power resources to help keep costs down. Because California's peak loads occur in the summer, that system normally has surplus capacity during the winter when Northwest loads are highest.

However, a number of changes have occurred in California since the Sixth Power Plan was adopted that have the potential to reduce the availability of winter imports to the Northwest and increase the need for new resources.

In May 2010, the California Water Resources Board adopted a statewide water quality control policy to meet the federal Clean Water Act's requirement to use the best technology available in power plant cooling processes. This is expected to force about 6,659 megawatts of older California generating plants into retirement by 2017. Other expected California resource retirements through 2017 are expected to reduce generation by an additional 1,030 megawatts.

Much of the retiring capacity in California is being replaced with modern gas-fired generation, including combined-cycle combustion turbines that are more fuel-efficient than the once-through-cooling plants and also have lower air emissions. Retiring capacity is also being replaced in California with fast responding simple-cycle combustion turbines that will provide capacity and help integrate renewables.

Also affecting the California market, both units at the San Onofre Nuclear Generating Station (SONGS), with about 2,200 megawatts of nameplate capacity, were taken out of service in January 2012 due to excessive wear in steam generator tubes. In June of 2013, the decision was made to retire the SONGS units.

Based on this information regarding California resources and considering California's load projections, the Council's Resource Adequacy Advisory Committee recommended limiting available on-peak spot market imports to 2,500 megawatts during winter and none during summer. A review of historical south-to-north intertie transfer capability for winter months led the advisory committee to also recommend limiting the maximum south-to-north transfer capability to 3,400 megawatts.

Prior to the development of the Seventh Power Plan, the Council commissioned a study of market supplies available from California. The Energy GPS[3] study concluded that power surpluses from California during winter months are highly likely to exceed the south-to-north intertie transfer capability.

Another major factor is California's increasing reliance on renewable resources to meet its energy needs. In 2011, the California legislature passed a law requiring the state's utilities to serve 25 percent of their retail customers' loads with qualified renewable resources by 2016; this requirement increases to 33 percent by 2020. The law also established new policies limiting the use of renewable

[3] Belden, Tim and Turkheimer, Joel, "Southwest Import Capacity", June 12, 2014, see www.nwcouncil.org/energy/resource/home/.

generation from outside California to meet the requirements. In September of 2015, the California legislature increased the minimum requirement to 50 percent by 2030. Many California utilities are already serving 20 percent or more of their customers' needs with renewable energy.

In order to meet these increasing renewable portfolio standards (RPS), California utilities have been increasingly turning to solar power development, as costs for photovoltaic systems have been falling rapidly. In 2014, solar power plants in California produced 10,555 gigawatt-hours (GWh) or 5.35 percent of the state's total electricity production. In August of 2015, California recorded its highest solar output to date, with 6,341 megawatts of solar capacity contributing to meeting that states electricity needs. The large scale of solar development in California, however, presents significant challenges for power system operations and affects Northwest power markets.

Since the RPS are based on an energy metric (i.e. RPS resources must meet a minimum share of annual retail electricity sales) and both solar and wind generation only operate a fraction of the hours in a year, the peak output of such systems is significantly (3 to 6 times) higher than the average output. As a result, integrating these resources into the existing power system requires that generation (usually gas-fired) must be ready to ramp-up or ramp-down to offset increases or decreases in wind and solar output. This gas-fired generation cannot be used to provide other types of reserves when it is designated for integration.

Separate from the physical integration challenges associated with increasingly larger amounts of wind and solar generation on the system, is the impact that these low-variable cost resources have on wholesale market prices. The spring and early summer months are when Northwest hydroelectric generation peaks due to spring runoff. This is also the period of the year when both wind and solar generation tend to be at their highest. The coincidence of the peak output of all three renewable resources, hydro, solar, and wind, can produce extremely low market prices due to supply far outstripping demand.

Unfortunately, wind resources contribute little to meeting peak demands and solar generation is typically much higher during summer months, which means less capacity would be available during the Northwest's peak season in winter. However, combustion turbines are used to provide within-hour balancing needs for renewable resources, some of their capacity might be available in winter for Northwest use. California is using summer-only demand response programs to help reduce its summer resource needs. This may reduce the amount of thermal generation peaking capacity available to serve Northwest loads in winter.

The final development affecting the California market's influence on the Northwest is that in June of 2014 the California Independent System Operator (CAISO) won approval from the Federal Energy Regulatory Commission (FERC) to expand its real-time energy imbalance market (EIM) beyond state borders, with PacifiCorp and NV Energy the first to join. In addition to PacifiCorp and NV Energy, at least three other non-California utilities, Portland General Electric in Oregon, Washington's Puget Sound Energy, and Arizona's Arizona Public Service have signed agreements to participate in the CAISO's EIM. All of the Northwest utilities had been participating in negotiations to create a regional EIM through the Northwest Power Pool.

Among the most significant issues raised by the CAISO's expanded footprint is whether it will grow into something more than a simple energy imbalance market that could lead to improved operational efficiencies for the 38 independently operated balancing authorities in the western interconnection.

Such developments were too speculative to consider in the analysis supporting the Seventh Power Plan, but could be a significant issue for the Eighth Power Plan.

Wholesale Power Markets and Prices

For the Seventh Power Plan, three factors were identified as being likely to significantly influence future conditions in wholesale power markets: market prices for natural gas; potential new regulatory requirements for generating resources that emit greenhouse gases; and development of renewable resources to satisfy requirements of state renewable portfolio standards. A range of forecasts of wholesale power prices was then prepared using alternative assumptions about these factors.

Since the Sixth Power plan was adopted in early 2010, developments across all three of these areas have occurred that will directly impact future wholesale power market prices. First, the supply-side impacts of shale gas continue to unfold, causing market prices for natural gas to remain at low levels. Second, there are now federal regulatory mechanisms to reduce greenhouse gas emissions. Third, renewable resource development has added significant amounts of new generating resources whose output has very low variable operating cost. The combination of large amounts of new renewable resources in the Western wholesale power market and large supplies of hydroelectric generation, both of which have low variable operating costs, is producing very low spot market prices for wholesale power more often.

These and other factors (modest growth in demand for electricity) have caused actual spot market prices for wholesale power supplies during the last several years to be at or even below the low end of the range of forecasts used for the Sixth Power Plan. For example, actual spot market prices for wholesale power supplies bought and sold at the Mid-Columbia trading hub averaged about $26 per megawatt-hour during the period July 2014 through June 2015. In contrast, average prices for calendar year 2008 were 240 percent higher. The Council's Seventh Power Plan forecast for spot market prices ranges from an average of $25 per megawatt hour to an average of $68 per megawatt hour over the next twenty years.

The low spot market prices for power affect the region's utilities differently. Utilities with limited exposure to market prices may be largely unaffected. For example, utilities whose resources closely match their customers' demands have little need to buy or sell power in the wholesale spot market. On the other hand, utilities whose resources and loads are not as closely balanced can be greatly – and very differently – affected depending on whether their resources are surplus or deficit.

Some of the region's hydro-based utilities have surplus power supplies at certain times of the year and depend on revenues from sales of their excess power into the wholesale market to keep power rates low. These utilities can experience significant revenue shortfalls and budgetary pressures when wholesale market prices are low. For hydro-based utilities, the impacts are magnified if the surplus energy they have to sell during the spring runoff coincides with surplus generation from other hydro systems, driving spot market prices to very low levels. This occurred during the period from April 2011 through July 2011, when spot market prices averaged well under $15 per megawatt-hour.

Conversely, utilities that do not have enough long-term resources to meet all of their customers' loads are net buyers in the short-term wholesale markets. When spot market prices are low, their power purchase costs are also low, reducing upward pressure on their retail electric rates. Relying on market purchases can be risky, as illustrated during the 2001 Western energy crisis. However, for now, these utilities are reaping the benefits of low market prices.

For all utilities, the depressed spot market prices for wholesale power are currently below the full cost of virtually any new form of generating resource.

Implementation of Bonneville Tiered Rates

In October 2011, the Bonneville Power Administration implemented tiered rates for its sales of wholesale power to the region's public utilities. Bonneville's tiered rates are designed to allocate the benefits of the existing federal power system and provide more direct price signals about the costs of new resources to meet load growth.

Under tiered rates, Bonneville's power sales are divided into two distinct blocks, or tiers. The rate for tier 1 power sales is based on the embedded cost of the existing federal power system. The tier 2 rate is set at Bonneville's cost to acquire power supplies from other sources. When a utility customer exceeds its allocation of tier 1 power, it can elect to buy tier 2 power from Bonneville, or it can acquire new resources itself. The alternatives include utility development of new energy-efficiency and/or generating resources, as well as wholesale power purchases from third party suppliers.

Currently, the average cost of Bonneville's tier 1 power is roughly $32 per megawatt-hour. With the exception of energy efficiency, this is below the typical cost to develop new resources. Ninety of Bonneville's public utility customers are projected to exceed their tier 1 allocations in 2017 and thus will have to acquire additional resources.[4] The prospect of exceeding their tier 1 allocation in the future may already be influencing their behavior. There is anecdotal evidence that some utilities are taking action to avoid spot market purchases. So to a certain extent, tiered rates are achieving the intended purpose of providing more efficient pricing signals to Bonneville's utility customers.

However, prices for wholesale power purchased in the wholesale market remain relatively low, often below the cost of new resources or even below Bonneville's tier 1 rate. While spot market prices can be quite volatile, the addition of large amounts of new renewable resources with low variable operating costs has contributed to low spot market prices. To the extent that Bonneville or utilities purchase power in the short-term market to meet their incremental resource needs, this mutes the tier 2 price signal.

Finally, there is also the matter of whether and how the price signal provided by Bonneville's tiered rates is passed through to each utility's retail electric customers. Retail customers are the end-users of electricity; their behavior affects load growth and load shapes. By incorporating Bonneville's price signals, utilities could influence their retail customers to reduce their total use of electricity and their peak demand by modifying their retail rate structures, by designing and executing energy efficiency and demand response programs, or a combination of these policies.

The Region's Utilities Face Varying Circumstances

Utilities across the region have experienced a variety of challenges and successes in the last few years. Some were expected and some are new, reflecting an ever-changing operating environment. As a result, the needs and incentives to acquire new resources also vary among the region's utilities.

Continued economic stagnation, particularly in the region's rural areas, has meant low overall load. Poor economic conditions have also triggered the loss of existing industrial loads as certain manufacturing facilities were shut down. For example, Snohomish County Public Utility District lost a big portion of its industrial load when customer Kimberly-Clark was forced to close its mill in early 2012.

Some utilities now find themselves with power supply resources that exceed their retail customers' demands. For these utilities, low spot market prices for wholesale power reduce the revenues they generate from sales of surplus power, putting pressure on utility budgets. In turn, this can create upward pressure on the utility's retail electric rates.

Meanwhile, those utilities that have not yet exceeded their entitlements to purchase power from Bonneville at tier 1 rates face lower near-term price signals than the cost of new resources. Consequently, their short-term economic incentives to acquire new energy-efficiency resources at costs above the tier 1 rate are reduced.

On the other hand, the region has been a hotbed for new data center loads as companies like Google, Microsoft, and Facebook take advantage of the mild climate and low electricity prices to develop facilities in the Northwest. For example, Amazon has recently built data centers in the Umatilla Electric service territory, increasing their load substantially. Several of the Mid-Columbia public utility districts have also seen significant growth as new data centers locate in their territory.

Certain utilities adding large new retail customers face the prospect of growing enough to become subject to higher state renewable requirements. These utilities may also exceed their entitlement to purchase power from Bonneville at tier 1 rates.

The first Centralia and Boardman coal-fired power plants will be retired in 2020 and the second Centralia and North Valmy coal-fired power plants will be retired in 2025. These planned retirements will eventually increase regional and individual utilities' needs for new resources, particularly among the region's investor-owned utilities.

As noted above, low spot market prices for wholesale power can be detrimental for utilities with surplus resources. However, low market prices can be beneficial for utilities whose long-term resources (including tier 1 purchases from Bonneville) are not sufficient to meet their retail customers' demands. Purchases from the short-term wholesale market can be a low-cost source of power to help fill these utilities' deficits. This can create an economic incentive to rely on short-term market purchases as an alternative to making long-term investments in higher-cost new resources, including energy efficiency.

Small and rural utilities face special challenges in acquiring efficiency resources. These include the absence of economies of scale enjoyed by larger utilities in urban areas and less availability of qualified contractors. Approaches to acquire energy efficiency must be tailored to meet their unique needs. Pursuant to actions recommended in the Sixth Power Plan, Bonneville, NEEA, and the Council's Regional Technical Forum established work groups and policies to address those needs. In addition, Bonneville also established a low-income working group to address the needs of those consumers in the region who lack the means to participate in utility programs but may have significant opportunities for energy efficiency in their residences.

Energy Efficiency Achievements

The Sixth Power Plan identified a range of likely energy efficiency resource acquisition during 2010 to 2014 of between 1,100 and 1,400 average megawatts. Within this range, the Sixth Plan recommended setting budgets and taking actions to acquire 1,200 average megawatts of savings from utility program implementation, market transformation efforts, and codes and standards.

The plan estimated that the region would ramp up its pace of acquisition during the initial five-year period. Despite a sluggish economy, which limited new building construction and equipment replacement, the region's overall acquisition exceeded the Council's ramp-up expectations surpassing the high end of the expected savings range.

Over the first five years of the Sixth Power Plan, the region's utilities, the Bonneville Power Administration, Energy Trust of Oregon, and Northwest Energy Efficiency Alliance (NEEA) acquired nearly 1,300 average megawatts of efficiency. In addition to the savings acquired by the utilities, Bonneville, Energy Trust, and NEEA, all four states recently adopted new building energy codes. NEEA estimates that improvements in state energy codes have produced 18 average megawatts of savings over the last five years.

Another significant contributor to savings in recent years is due to the adoption of minimum efficiency standards for energy-using products. Since 2009, the federal Department of Energy has issued final product standards for more than 36 products ranging from refrigerators to utility transformers. Some of these standards took effect in between 2010 and 2014, producing about 50 average megawatts of additional savings during that period. States have also begun to adopt minimum standards for products not covered by federal standards, such as battery chargers.

In addition, consumer uptake of efficient products, outside of direct utility-funded programs, has been particularly strong for lighting equipment since 2010. In part, this consumer uptake is due to prior utility programs pushing efficient products into markets and in part it may be due to consumer preference. Together, minimum product standards and consumer uptake added about 220 average megawatts of documentable savings outside of direct utility-funded programs in the 2010 to 2014 period.

All told, between utility-funded programs, state codes and standards, federal standards, and consumer uptake, the region captured just over 1500 average megawatts of energy and approximately 2500 megawatts of peak savings during 2010-2014, achieving 125 percent of the Sixth Power Plan goal and surpassing the high end of the expected energy savings range.

Demand Response Activities

The two regional utilities with the most experience in acquiring and using demand response (DR), PacifiCorp and Idaho Power, have continued to expand and refine their programs. Both are now exercising control over 700 megawatts of their in-region peak loads. While other regional utilities have not acquired DR to this extent, some are gaining experience with it. PGE has contracted for 28 megawatts of DR in the industrial and commercial sectors, and continues to conduct pilot programs, currently focusing on the residential sector. BPA continues to explore pilot programs and demonstration projects in cooperation with its utility customer, Energy Northwest, and EnerNOC, testing the capability of DR resources to provide winter peak reductions, within-hour balancing of variable energy resources, and strategic transmission relief. BPA has also arranged for 35 to 100 megawatts of contingent reserves to be provided by industrial customers.

Puget Sound Energy and Avista have both conducted demand response pilot programs in the recent past. However, while both companies have identified the technical potential of demand response and evaluated DR as part of their resource planning process, neither of these utilities is currently acquiring DR resources.

Renewable Resources Development

Since the adoption of the Sixth Power Plan, renewable generating resources development has increased significantly. This development was prompted by renewable portfolio standards (RPS) adopted in three of the four Northwest states and in California. Wind energy has been the principal focus of renewable resource development in the Pacific Northwest. From 2010 through 2014 about 4,100 megawatts of wind nameplate capacity was added to the region, with nearly 2,000 megawatts of capacity coming online in 2012 alone. By the end of 2014, wind nameplate capacity in the region totaled just over 8,700 megawatts. However, only about two-thirds of that nameplate capacity currently serves Northwest loads. The remaining one-third (~3,000 megawatts) of wind nameplate capacity is presently contracted to utilities outside the region, primarily California.

Snohomish PUD began producing power from its 7.5 megawatt Youngs Creek run-of-river hydroelectric project in October 2011. It is the first new hydroelectric power plant to be built in Snohomish County since the early 1980s.

As noted above, until recently, a considerable amount of wind power was developed in the Northwest for sale to California utilities subject to that state’s renewable portfolio standards. However, it is expected that few additional Northwest wind resources will be built for this purpose, despite California having raised its RPS requirement to 33 percent by 2020, and recently increased to 50 percent by 2030. The reason is that restrictions imposed by the California legislature in 2011 effectively block further imports from outside the state to meet RPS needs. Another contributing factor is that costs for solar photovoltaic generation have come down to the point where in-state solar is increasingly competitive with imported wind generation.

In terms of developing renewable resources to meet Northwest RPS needs, actual results have been generally consistent with the Sixth Power Plan. The Sixth Power Plan’s resource strategy incorporated projections that the region would add over 1,400 average megawatts of renewable resources over 20 years to meet renewable portfolio standards that the states have enacted. The new renewable resources were anticipated to be almost wholly wind power.

Notable differences between the Sixth Power Plan and this Seventh Power Plan in terms of renewables development include the following:

1. While the Sixth Plan assumed renewable resources would be developed to meet 95 percent of RPS targets, recent experience suggests most utilities are actually achieving 100 percent (and sometimes more) of their target levels several years in advance of the requirement.
2. Construction of renewable resources to serve the California market is expected to slow, if not end completely.

The quantity of reserves on the Bonneville system to provide balancing services has remained relatively constant, even as wind on the system has increased. Nevertheless, the ability of the hydro system to provide balancing services varies, and at times it has dropped to near zero. At such times, wind generation or delivery schedules are limited to maintain the power system supply and demand balance. This has occurred primarily during very high flow spring months when the hydro system must pass prescribed flow levels for flood control and environmental requirements constrain the ability to pass water over spillways. This occurs when the generation level is high and relatively fixed.

In addition to the limited ability to provide balancing services during these oversupply events, Bonneville has at times had trouble finding markets for its power at acceptable (non-negative) prices. It implemented a controversial policy of displacing wind resources with hydro generation under negative market price conditions when hydro turbine generating capability is available but it could not spill additional water without exceeding Clean Water Act limits on dissolved gas levels.

The Council convened an Oversupply Technical Oversight Committee to recommend actions to reduce oversupply events. The committee developed a number of recommendations to more cost-effectively deal with oversupply events. The region continues to develop methods to integrate wind generation into the grid and the last Bonneville oversupply event was in 2011.

Meanwhile, as noted, costs for solar photovoltaic generation have dropped dramatically during the last several years. In the Sixth Power Plan, the Council estimated that solar photovoltaic generation would cost about $254 per megawatt hour. The Seventh Power Plan's estimated cost of solar photovoltaic generation located in Southern Idaho now ranges from as low as $61 to $91 per megawatt hour – a 64 to 76 percent cost reduction. Although solar potential is lower in much of the Northwest compared to other areas such as the Southwest, the economic and commercial viability of solar power has improved such that in the best Northwest sites (e.g., Southern Idaho), the levelized cost of solar production is lower than the levelized cost of wind generation.

Additions and Changes to Fossil-Fueled Generating Resources

The Sixth Power Plan's resource strategy called for phased optioning (siting and licensing) of new natural gas-fired generation facilities, including up to 650 megawatts of single-cycle combustion turbines and 3,400 megawatts of combined-cycle combustion turbines. The Sixth Power Plan's resource strategy also recognized it may be necessary to develop additional natural gas-fired generation when individual utilities need to address local capacity, flexibility, or energy needs not captured in the plan's region-wide analysis.

Since the Sixth Power Plan was adopted in early 2010, the largest new natural gas-fired generating resource added in the region is Idaho Power's Langley Gulch Power Plant located near Boise. Langley Gulch is a 300 megawatt combined-cycle project that entered service in July 2012. Portland General Electric built the 220 megawatt Port Westward II, a generation set of twelve reciprocating engines, in 2014 and is currently building the Carty Generating Station, a new 440 megawatt combined-cycle project at Boardman which is expected to be in service in 2016.

Since the adoption of the Sixth Plan some utilities have issued requests for proposals (RFPs) to acquire generating resources. An informal survey conducted for the Mid-Term Assessment Report (2012-13) identified RFPs calling for over 3,100 megawatts of conventional generating resources, including base load, intermediate, and peaking resources. It is likely that some of their needs will be met by uncommitted power plants in the region.

For example, in late July 2012, Puget Sound Energy (PSE) and TransAlta announced a power sales contract that will supply base load generation from the Centralia coal-fired plant to PSE from December 2014 to December 2025, including 380 megawatts of coal-fired generation during the period December 2016 to December 2024.

After the Sixth Power Plan was issued, planned retirements of several generating resources were announced, including closure of the 550 megawatt Boardman coal plant in 2020 and closure of one 670 megawatt unit at the Centralia coal plant in 2020 and the other 670 megawatt unit in 2025. More recently the retirement of the 522 megawatt North Valmy coal plant in Nevada scheduled for 2025 was announced as well as the closure of the 172 megawatt J.E. Corette coal plant in Montana in 2015. In addition to coal plant retirements, the 248 megawatt Big Hanaford combined cycle natural gas generator, a non-utility owned plant, was taken out of service in 2014. The replacement of the energy and capacity lost as a result of these retirements is addressed in the Seventh Power Plan's resource strategy.

Hydroelectric System Operational Changes

The operational flexibility and generating capability of the Columbia River Basin hydroelectric system has been reduced since 1980 primarily due to efforts to better protect fish and wildlife. Over the past thirty years, the pattern of reservoir storage and release has shifted some winter river flow back into the spring and summer periods during the juvenile salmon migration period. In addition, minimum reservoir elevations have been modified to provide better habitat and food supplies for resident fish. The results of these changes have reduced the hydroelectric system's firm energy generating capability by about ten percent or by roughly 1,100 average megawatts. Most of these changes have occurred between 1980 and the early 2000s. More recent summer bypass spill requirements, identified in the FCRPS Biological Opinion and included in the Council's 2014 Fish and Wildlife

Program, for example, do not significantly affect hydroelectric generation. Since about 1995, the hydroelectric system's peaking capability devoted to meeting firm load has dropped by about 5,000 megawatts. This is due, in part, to the high development of wind resources and the correspondingly greater allocation of hydroelectric system capability toward providing within-hour balancing needs.[5]

Shifting Regional Power System Constraints

In most of the other regions of the country, power system planning and development tend to focus on making sure that resources will be adequate to meet customer demands during relatively short extreme peak periods such as cold winter or hot summer weather events. In those regions, if resources are adequate to meet peak demands, they are usually sufficient to meet energy needs throughout the year. This is largely because other regions mainly rely on fossil-fueled and nuclear power, whose fuel supplies are relatively abundant and controllable. These systems are described as capacity constrained.

In contrast, the Pacific Northwest power system has traditionally been characterized more as energy-constrained. The main reason for this has been our region's abundance of hydroelectric generation. Unlike other forms of generation that consume fossil or nuclear fuels, the amount of energy the hydro system can produce fluctuates with supplies of water, which in turn depend on uncertain streamflows and limited reservoir capacities. As a result, in the past, the Northwest power system had more than adequate resources to meet peak demands. When constraints occurred, they were usually related to the availability of energy across longer periods of time.

However, during the last decade or so, the Northwest power system has gradually become less energy constrained and more capacity constrained. New resources, partly to meet load growth and partly to meet state-mandated renewable portfolio standards, are driving this shift, and as these new resources have been added, hydro generation's share of the region's total portfolio of resources has gradually declined.

For example, since 2000, about 5,900 megawatts of natural gas-fired generation has been added in the region. During that same period, over 8,700 megawatts of wind power has also been built in the region. The large increase in wind generation has meant that utilities must hold more resources in reserve to help balance demand and resources minute to minute; therefore, the need for system flexibility has become a growing concern. The Council estimates that the region will have sufficient generation and demand side capability on its existing system to meet balancing and flexibility reserve requirements if the Seventh Power Plan's energy efficiency and demand response development goals are achieved. The mechanism for accessing this capability, however, may not be available to all Balancing Authorities depending on market structure/availability.

Persistent low spot market prices for wholesale power are another sign that the Northwest power system has become less energy-constrained. To a degree, low power prices are the result of low prices for natural gas. However, they also reflect direct and ongoing competition between hydro generation and newly-added wind power. Both have very low incremental operating costs and during

[5] For more information on balancing needs see Chapter 9 and Chapter 16.

periods of strong runoff and robust winds, competition between the two can drive spot market prices to very low levels.

The region is making progress developing a variety of additional mechanisms to integrate wind power, including recent activity in the region and California regarding the establishment of a sub-hourly energy imbalance market. Improving market liquidity across balancing authorities is likely to have a positive effect on the region's needs for peaking capacity and flexibility.

Looking forward, it is apparent that regional power planning needs to take into account shifting constraints on the system. These include reduced constraints for energy and increasing constraints for peaking capacity and for system flexibility.

Power and Transmission Planning

Momentum to coordinate power resource and transmission system planning activities has grown in the last few years. Several forces are driving this, including:

- Renewable resources development which, because of their variability, affect power markets and system operations;
- Changes to generation and/or transmission facilities in one area can often cause impacts in other areas;
- Recent major outages that have cascaded across multiple systems, including a widespread event that occurred in the Southwest in September 2011;
- More stringent and comprehensive reliability standards;
- A growing need for new transmission facilities; and
- Increasing costs to transmit and integrate renewable and other new generating resources.

In response, various activities and initiatives have been undertaken:

- Federal Energy Regulatory Commission (FERC) Order 1000 requiring transmission planning and cost allocation;
- Western Electricity Coordinating Council (WECC) Transmission Expansion Planning Policy Committee (TEPPC);
- Changing roles for WECC (pending division into two organizations);
- Planning activities of Columbia Grid, Northern Tier Transmission Group (NTTG), California Independent System Operator; and
- Activities to restructure the market and develop new practices (diversifying area control management, investigating energy imbalance markets).

Historically, a major focus for transmission planning was analyzing power flows under peak loading conditions and during contingency events. More recently, attention has broadened to include simulating power flows during various market and operating scenarios. As a result, production simulation models similar to those used for integrated resource planning are also being used for transmission system planning studies. Transmission studies also require assumptions about what new resources will be added by type, quantity, and location.

Past Council power plans have addressed various transmission issues, but intra-regional transmission system constraints and alternative approaches to address such constraints have not been extensively analyzed.

Given the changing situation, regional power and transmission system planning should coordinate by:

- Including the intra-regional transmission constraints and major planned transmission projects in the Council's power system analyses;
- Including the Council's power plan assumptions, forecasts, and results in transmission planning studies; and
- Cross-checking for consistency of major inputs to power and transmission planning studies.

The Council continues to work with ColumbiaGrid to identify areas for coordination and to improve coordination with other organizations, including WECC, TEPPC, and NTTG.

Power and Natural Gas System Convergence

During the last decade, natural gas-fired generation has become the leading fossil-fueled resource, both in the Pacific Northwest and nationally. Over 5,900 megawatts of gas-fired generation has been added in the region since 2000. Gas-fired generation is relatively flexible and can be used to supply energy and capacity, as well as help balance variable output from other resources, including wind power.

As gas-fired generation has become a bigger part of the power system, it has also become a significant source of demand on the existing natural gas pipeline and storage system. This has raised questions about the adequacy of the natural gas system to serve direct end users and to fuel electric generation. Challenges resulting from increased use of gas-fired generation which are being addressed in regional and national forums include:

- Different scheduling and operating practices used by the electric and natural gas industries;
- Gas-electric communication and coordination during extreme weather conditions or outage events;
- Planning and development of pipeline and underground storage infrastructure;
- Access to pipeline and storage facilities for local distribution companies and electric generation; and
- The impact of rapid swings in use of natural gas for generation to balance variable energy resources like wind power.

In response to these issues, several activities have been launched, including the following:

- The Pacific Northwest Utilities Conference Committee and the Northwest Gas Association formed a joint power and natural gas planning task force; this has established strong dialog and closer coordination.
- During the summer of 2012 and in February 2013, the Federal Energy Regulatory Commission held a series of technical conferences on gas-electric coordination.
- The Northwest Mutual Assistance Agreement was revamped and expanded to improve utility industry responses to emergency conditions.

- A committee of the Western Interstate Energy Board was convened to assess gas-electric issues in the Western U.S., including planning to ensure gas infrastructure remains adequate.

To date, the results of these activities have identified various opportunities to improve communication by the electric and natural gas industries. As natural gas continues to be used to generate electricity, further attention to power and gas convergence will likely be needed.

Fortunately, it is becoming apparent that our region's natural gas infrastructure is relatively robust when compared with other regions. For example, the Northwest has more underground gas storage capacity than some other regions. In addition, deliverability from interstate pipelines has not been significantly impacted by regional shifts in gas production due to rapid growth in shale gas production, as may be occurring elsewhere. Further, the great majority of natural gas-fired generating facilities in the Northwest have firm pipeline capacity rights, fuel-switching capability, or both.

Columbia River Treaty Review

One of the uncertainties with the Pacific Northwest power supply over the next decade is the fate of the Columbia River Treaty, the agreement with Canada executed in the early 1960s. Under the treaty, Canada agreed to build three projects in the portion of the Columbia River in British Columbia that stores more than 15 million acre feet of Columbia River runoff. BC Hydro manages the treaty storage projects primarily for flood control and power generation optimization. The U.S. delivers to Canada a share of the downstream power benefits known as the Canadian Entitlement, calculated by a method set forth in the treaty and an accompanying protocol. This delivery ranges from 1,176 to 1,369 megawatts (MW) of capacity and 465 to 567 annual average megawatts (aMW) of energy.

Under the treaty, the annual assured flood control operations ends in 2024, to be replaced with a "called upon" flood control operation which has yet to be specified in any detail. Unless the two nations agree to a new arrangement for flood control, there is a good chance flood control operations at both the U.S. and Canadian storage projects will change significantly after 2024, affecting generation patterns as well.

The treaty's provisions governing coordinated power operations do not change automatically in 2024. Either nation may terminate the treaty beginning in 2024, with at least 10 years' notice.

The Bonneville Power Administrator and the Corps of Engineers' Northwestern Division Engineer (together the designated U.S. Entity under the treaty) joined with other federal agency, state, and tribal personnel from 2011-13 to review the current treaty and recommend changes. Out of this effort came the "U.S. Entity Regional Recommendation for the Future of the Columbia River Treaty after 2024," delivered to the State Department in December 2013. The U.S. Entity regional recommendation recommended neither termination nor the status quo, calling instead for the two nations to negotiate a "modernized" treaty with modifications that respond to the current issues with flood control, coordinated power operations, ecosystem needs, and the calculation and sharing of benefits. The Province of British Columbia led a similar review, and produced what it called its "Columbia River Treaty Review: B.C. Decision" at the same time. Neither the U.S. State Department nor Foreign Affairs Canada has responded officially to the regional recommendations. The NW region is waiting for confirmation from the U.S. State Department that they are ready to begin negotiations which could commence within the year.

The main point for this assessment is that the region is heading into a period of uncertainty after many decades of relative certainty and international cooperation. For the purposes of the Seventh Power Plan, it is impossible to know at this time whether and how storage operations in Canada and thus flows across the border may change after 2024, nor what changes may need to be made to storage operations at U.S. projects, both affecting the generation output and patterns of the system. Nor is it possible to know whether and to what extent there will be a change in the power benefits the U.S. will deliver to Canada in the future. This is a level of uncertainty the Council needs to consider in its resource planning.

CHAPTER 3: RESOURCE STRATEGY

Contents

List of Tables and Figures

KEY FINDINGS

The resource strategy for the Seventh Power Plan relies on energy efficiency, demand response, and natural gas-fired generation to meet the region's needs for energy and peaking capacity. In addition, the region needs to better utilize, expand, and preserve its existing electric infrastructure and research and develop technologies for the long-term improvement of the region's electricity supply. This resource strategy, with its heavy emphasis on low-cost energy efficiency and demand response, provides a least-cost mix of resources that assures the region an adequate and reliable power supply that is highly adaptable and reduces risks to the power system.

The resource strategy for the Seventh Power Plan consists of eight primary actions: 1) achieve the energy efficiency goals in the Council's plan, 2) meet short-term needs for peaking capacity through the use of demand response except where expanded reliance on extra-regional markets can be assured, 3) increase the near term use of existing natural gas fired generation, 4) satisfy existing renewable-energy portfolio standards, 5) increase the utilization of regional resources to serve regional energy and capacity needs, 6) support policies that cost effectively achieve state and federal carbon dioxide emission reduction goals while maintaining regional power system adequacy, 7) support the research and development of emerging energy efficiency and clean energy resources and 8) adaptively manage future resource development to match actual future conditions.

A RESOURCE STRATEGY FOR THE REGION

The Council's resource strategy for the Seventh Power Plan provides guidance for Bonneville and the region's utilities on choices of resources that will supply the region's growing electricity needs while reducing the economic risk associated with uncertain future conditions, especially those related to state and federal carbon emission reduction policies and regulations. The resource strategy minimizes the costs and economic risks of the future power system for the region as a whole. The timing of specific resource acquisitions is not the essence of the strategy. The timing of resource needs will vary for every utility. Some utilities now find themselves with power supply resources that exceed their retail customers' demands. For these utilities, low spot market prices for wholesale power reduce the revenues they generate from sales of surplus power, putting pressure on utility budgets. In contrast, the region has been a hotbed for new data center loads as companies like Google, Microsoft, and Facebook take advantage of the mild climate and low electricity prices to develop facilities in the Northwest. The addition of loads from these new data centers to service territory can dramatically change the utilities resource needs. The important message of the resource strategy is the nature and priority order of resource development.

Summary

The resource strategy is summarized below in eight elements. The first two are high-priority actions that should be pursued immediately and aggressively. The next five are longer-term actions that must be more responsive to changing conditions in order to provide an array of solutions to meet the long-term needs of the regional power system. The final element recognizes the adaptive nature of the power plan and commits the Council to regular monitoring of the regional power system to identify and adjust to changing conditions.

Energy Efficiency: The Council's analysis found that development of between 1300 and 1450 average megawatts of energy efficiency by 2021 was cost-effective across a wide range of scenarios and future conditions. The Seventh Power Plan's resource strategy calls upon the region to aggressively develop conservation with a goal of acquiring 1,400 average megawatts by 2021, 3000 average megawatts by 2026 and 4,300 average megawatts by 2035. Conservation is by far the least-expensive resource available to the region and it avoids risks of volatile fuel prices, financial risks associated with large-scale resources, and it mitigates the risk of potential carbon emission reduction policies to address climate-change concerns. In addition, conservation resources not only provide annual energy savings, but contribute significantly to meeting the region's future needs for capacity by reducing both winter and summer peak demands.

Demand Response: The Northwest's power system has historically relied on its large hydroelectric generators to provide peaking capacity. While the hydrosystem can typically meet the region's peak demands, that likelihood decreases under critical water and weather conditions, which increases the probability of not meeting the Council's resource adequacy standard without development of additional peaking resources.

The least-cost solution for providing new regional peaking capacity is to develop cost-effective demand-response resources – voluntary and temporary reductions in consumers' use of electricity when the power system is stressed. However, the Council's analysis also found that the need for demand response resources is sensitive to assumptions regarding the availability and prices of importing power from outside the region to meet peak demands under lower water and extreme temperature conditions. The Council's analysis indicates that a minimum of 600 MW of demand response resources would be cost-effective to develop under all future conditions tested across all scenarios which do not rely on increased firm capacity imports. Moreover, even if additional firm peak power imports during winter months are assumed to be available, developing a minimum of 600 MW of demand response resources is still cost-effective in over 70 percent of the futures tested.

In order to satisfy regional resource adequacy standards the region should develop significant demand response resources by 2021 to meet the need for additional peaking capacity. The Seventh Power Plan Action Plan recommends that the annual assessment of regional resource adequacy consider the comparative cost and economic risk of increased reliance on external market purchases versus development of demand response resources to meet winter capacity needs within the region. The Council will determine if the region has made sufficient progress towards acquiring cost-effective demand response or confirming import capability to provide the region with a minimum additional peaking capacity of at least 600 MW in its mid-term assessment of progress on the Seventh Power Plan.

Natural Gas: It is clear that after efficiency and demand response, new natural gas-fired generation is the most cost-effective resource option for the region in the near-term. Moreover, after energy efficiency, the increased use of existing natural gas generation offers the lowest cost option for reducing regional carbon emissions.[1] At the regional level, the probability that new natural gas-fired

[1] The Council recognizes that in addition to the carbon dioxide emissions produced by the combustion of natural gas, the fugitive methane emissions from natural gas production and transportation could have significant climate change impacts.

generation will be needed to supply peaking capacity prior to 2021 is quite low. If the region does not deploy the demand response resources and develop the level of energy efficiency resources called for in this plan, the need for more costly new gas-fired generation increases. In the mid-term (by 2026) there appears to be a modest probability that new gas fired generation could be needed to replace retiring coal generation or potentially to displace additional coal use to meet federal carbon-reduction goals. Nevertheless, even if the region has adequate resources, individual utilities or areas may need additional supply for capacity or wind integration when transmission and power market access is limited. In these instances, the Seventh Power Plan's resource strategy relies on new natural gas-fired generation to provide energy, capacity, and ancillary services.

Renewable Resources: The Seventh Power Plan's resource strategy assumes that only modest development of renewable generation, approximately 100 - 150 average megawatts of energy, or around 250 to 400 megawatts of installed capacity by 2035, is necessary to fulfill existing renewable portfolio standards. While the majority of historical renewable development in the region has been wind resources, recent and forecast further cost reductions in solar photovoltaic (solar PV) technology are expected to make electricity generated from such systems increasingly cost-competitive. In addition, solar PV systems, particularly when coupled with storage, can provide summer peaking services for which regional demand is increasing faster than winter peaking needs. As a result, solar PV systems should be seriously considered when determining which resources to acquire to comply with existing renewable portfolio standards. In addition, while to date regional development of geothermal resources has been limited, these resources offer significant potential and can provide both winter and summer capacity.

The Seventh Power Plan's resource strategy encourages the development of other renewable alternatives that may be available at the local, small-scale level and are cost-effective now. Because power production from wind and solar PV projects creates little dependable peak capacity and increases the need for within-hour balancing reserves the strategy also encourages research on and demonstration of different sources of renewable energy for the future, especially those with a more consistent output like geothermal or wave energy.

The Council did not evaluate whether the increased use of renewable resources would be a cost-effective alternative for state level compliance with federal carbon dioxide emissions regulations or state level carbon emissions goals. The Council did find that increasing the requirements of state renewable portfolio standards alone would not result in the development of the least cost resource strategy for the region nor the least cost resource strategy for reducing carbon at the regional level.

See Appendix I for more detailed discussion methane emissions from natural gas production and distribution. A discussion of how fugitive emissions of methane were considered in the development of the Council's resource strategy appears in the following section.

Regional Resource Utilization: The region should continue to improve system scheduling and operating procedures across the region's balancing authorities to maximize cost-effectiveness and minimize the need for new resources needed for integration of variable energy resource production. In addition, the region needs to invest in its transmission grid to improve market access for utilities and to facilitate development of more diverse cost-effective renewable generation. Finally, the Council identified least cost resource strategies for the region that rely first on regional resources to satisfy the region's resource adequacy standards. Under many future conditions, these strategies reduce regional exports.

Carbon Policies and Methane Emissions: To support policies that cost effectively achieve state and federal carbon dioxide emission reduction goals while maintaining regional power system adequacy the region should develop the energy efficiency and demand response resources called for in this plan and replace retiring coal plants with only those resources required to meet regional capacity and energy adequacy requirements. As stated above, after energy efficiency, the increased use of existing natural gas generation offers the lowest cost option for reducing regional carbon emissions in the near term. Utility development of new gas-fired generation to meet local needs for ancillary services, such as wind integration, or capacity requirements beyond the modest levels anticipated in this plan will increase carbon dioxide emissions. If Northwest electricity generation is dispatched first to meet regional adequacy standards for energy and capacity rather than to serve external markets, the increase in regional carbon dioxide emissions can be minimized.

The Northwest will likely have a competitive advantage if pricing policies are used throughout the western electricity market to reduce carbon dioxide emissions. The region's large existing non-carbon emitting resource base increases in value under most carbon pricing policies. If west-wide or national carbon prices are imposed, the value of low or no carbon content power exports will increase. Revenues from these exports will partially offset the regional cost of achieving carbon dioxide emission reductions.

As noted above, a central element in transitioning the Northwest power system to an even lower carbon footprint involves the increased use of natural gas, which consists primarily of methane. While burning natural gas produces significantly less carbon dioxide emissions per unit of electricity generation, its production and distribution releases methane into the atmosphere. Methane is a highly active greenhouse gas, with a global warming potential 28 to 36 times that of carbon dioxide.[2] The Seventh Power Plan's overall resource strategy seeks to minimize the need to develop new gas generation by meeting most future energy and capacity needs with energy efficiency and demand response. Successful implementation of this strategy provides time to take actions to reduce current fugitive methane emissions and minimize new methane emissions, so that the use of natural gas does produce a reduction in climate change impacts.

Future Resources: In the long term, the Council encourages the region to expand its resource alternatives. The region should explore additional sources of renewable energy, especially technologies that can provide both energy and winter capacity, improved regional transmission

[2] See Appendix I for a more complete description of methane's potential environmental impacts and the uncertainties surrounding fugitive emission sources and levels.

capability, new conservation technologies, new energy-storage techniques, smart-grid technologies and demand-response resources, and new or advanced low-carbon generating technologies, including advanced nuclear energy. Research, development, and demonstration funding should be prioritized in areas where the Northwest has a comparative advantage or unique opportunities. For example, the potential for developing geothermal and wave energy in the Northwest is significantly greater than in many other areas of the country.

Adaptive Management: The Council will annually assess the adequacy of the regional power system. Through this process, the Council will be able to identify whether actual conditions depart so significantly from planning assumptions that it would require adjustments to the plan. This annual assessment will provide the region time to take actions necessary to reduce the probability of power shortages. The Council will also conduct a mid-term assessment to review plan implementation.

SCENARIO ANALYSIS – THE BASIS OF THE RESOURCE STRATEGY

Scenarios combined elements of the future that the region controls, such as the type, amount and timing of resource development, with factors the region does not control, such as natural gas and wholesale market electricity prices. Sensitivity studies alter one parameter in a scenario to test how the least-cost resource strategy is affected by that input assumption. For example, several scenarios were run with and without future carbon cost to assess the impact of that input assumption on the various components of the least cost resource strategy.

All of the scenarios evaluated for the Seventh Power Plan include the same range of uncertainty regarding future fuel prices, hydropower conditions, electricity market prices, capital costs, and load growth. However, several scenarios were specifically designed to provide insights into the cost and impacts of specific alternative resource strategies and carbon dioxide emissions reduction policies. For example, the Council tested scenarios that excluded the development of demand response resources or required the development of a minimum amount of renewable resources.

To investigate policy options for reducing carbon dioxide emissions some scenarios included either the federal government's estimates of the societal damage cost of carbon dioxide emissions or the economic risk associated with future carbon dioxide regulation or pricing or "non-pricing" policies. Each of these scenarios assumed differing levels of carbon dioxide damage or regulatory cost. Also, as noted above, several sensitivity studies were conducted to assess the impact of such factors as the near term pace of conservation development, lower natural gas and wholesale electricity prices, greater reliance on external markets, or the loss of major resources.

The US Environmental Protection Agency (EPA) released its draft Clean Power Plan in June, 2014, and its final set of regulations in August, 2015. [3] These regulations establish carbon dioxide

[3] U.S. Environmental Protection Agency, "Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64,662 (October 23, 2015). A coalition of states, utilities, utility organizations and others challenged the rule applying to existing sources in the federal D.C. Circuit Court of Appeals. The U.S. Supreme

emissions limits for both new and existing power plants. Eight of the scenarios summarized below: the two **Social Cost of Carbon** (**Mid-Range and High**), **Carbon Cost Risk**, **Regional Renewable Portfolio Standards at 35 Percent**, **Maximum Carbon Reduction – Existing Technology, Coal Retirement, Coal Retirement with the Social Cost of Carbon** and **Coal Retirement with the Social Cost of Carbon and No New Gas** were designed to test alternative policies that may be considered at the regional or state level to identify resource strategies that would comply with those regulations. Two other scenarios, the **Planned Loss of a Major Non-Greenhouse Gas (GHG) Emitting Resource** and the **Unplanned Loss of a Major Non-GHG Emitting Resource** were analyzed to provide insights into the effect of the loss of a major non-greenhouse gas-emitting would have on the region's ability to reduce power system carbon dioxide emissions.

Each scenario and sensitivity analysis tested thousands of potential resource strategies against 800 alternative future conditions to identify the least cost and lowest economic risk resource portfolios. Since the discussion of the elements of the resource strategy draws on those scenarios and sensitivity studies, an introduction to the scenarios and studies and their findings is needed. Each scenario or sensitivity study was designed to explore specific components of resource strategies (e.g. strategies with and without demand response).

The Seventh Power Plan's resource strategy is based on analysis of over 25 scenarios and sensitivity studies.[4] Eighteen of principal scenarios or sensitivity studies that informed the development of the Seventh Power Plan's final resource strategy are summarized below. Not all scenarios or sensitivity studies "stress test" the same element of a resource strategy or policy option, so not all provide useful insight regarding that element or policy. Therefore, the following discussion of findings compares different subsets or combinations of scenarios and sensitivity studies when discussing a specific element of the Seventh Power Plan's resource strategy.

- **Existing Policy –** The existing-policy scenario includes current federal and state policies such as renewable portfolio standards, new plant emissions standards, and renewable energy credits, but it does not assume any additional carbon dioxide regulatory cost or economic risk in the future. Specifically, it does not reflect any actions Northwest states may

---

Court stayed the effectiveness of the rule in an order issued February 9, 2016, pending not just review on the merits by the court of appeals but also the resolution of any petition for further review in the Supreme Court following whatever decision is issued by the court of appeals. The litigation is ongoing as the Council completed the Seventh Power Plan.

[4] Ten scenarios were analyzed between the draft and final adoption of the Seventh Power Plan. These include updates to seven scenarios analyzed during the development of the draft plan and three new scenarios suggested by public comment. The draft plan's findings for any of the scenarios and sensitivity studies not updated for the final plan are described in Appendix O.

take in order to comply with recently finalized limits on carbon dioxide emissions from existing power generation. However, this scenario does serve as a point of departure for assessing the regional effect of carbon dioxide cost and economic risk when added to existing policies. Other major uncertainties regarding the future, such as load growth and natural gas and market electricity prices are considered.

Updated results for this scenario are reported in the final plan.

- **Social Cost of Carbon (SCC) –** Two scenarios, the **Social Cost of Carbon – Mid-Range (SCC-MidRange)** and **Social Cost of Carbon – High (SCC-High)**, use the US Interagency Working Group on Social Cost of Carbon's estimates of the damage cost of forecast global climate change. According to the Working Group:

    - *The SCC is an estimate of the economic damages associated with a small increase in carbon dioxide (CO2) emissions, conventionally one metric ton, in a given year. This dollar figure also represents the value of damages avoided for a small emission reduction (i.e. the benefit of a CO2 reduction).*

      Therefore, in theory, the cost and economic risk of the resource strategy that achieves carbon dioxide emissions reductions equivalent to the social cost of carbon would offset the cost of damage. The **SCC-MidRange** scenario uses the Interagency Working Group's mid-range estimate of the damage cost from carbon dioxide emissions based on a three percent discount rate. The **SCC-High** scenario uses the Interagency Working Group's estimate of damage cost that encompasses 95 percent of the estimated range of damage costs.[5]

      Updated results for the **SCC-MidRange** scenario are reported in the final plan. The final plan's findings for the **SCC-High** scenario would not be materially different than those reported in the draft plan, although due to the use of a lower range of natural gas prices the average system cost of this scenario would be slightly lower. The draft plan's findings for the **SCC-High** scenario are discussed in Appendix O.

- **Carbon Cost Risk –** The carbon cost risk scenario is intended to explore what resources result in the lowest expected cost and economic risk given existing policy plus the economic risk that additional carbon dioxide reduction policies will be implemented. Each of the 800 futures imposes a carbon dioxide price from $0 to $110 per metric ton at a random year during the 20 year planning period. Over time, the probability of a carbon dioxide price being imposed and the level of that price both increase. By 2035, the average price of carbon dioxide rises to $47 per metric ton across all futures. It should be noted, that the use of a carbon dioxide price does not presume that a "pricing policy" (e.g., carbon tax, cap and trade system) would be used to reduce carbon dioxide emissions. The prices imposed in this

[5] Chapter 15 provides the year-by-year social cost of carbon used in these scenarios.

scenario could also be a proxy for the cost imposed on the power system through regulation to reduce carbon dioxide emissions (e.g., caps on emissions).

This scenario was initially designed to represent the current state of uncertainty about future carbon dioxide control policies and develop a responsive resource strategy. It is identical to a scenario analyzed for the development of the Sixth Power Plan. While with the promulgation of Environmental Protection Agency's carbon dioxide emissions regulations there is less uncertainty regarding federal regulations, the specific form of state and/or regional compliance plans with EPA's regulations are unknown. Moreover, some states may choose to adopt additional policies beyond the federal regulations to limit power system emissions.

Updated results for the **Carbon Cost Risk** scenario are not reported in the final plan. The final plan's findings for the **Carbon Cost Risk** scenario would not be materially different than those reported in the draft plan, although due to the use of a lower range of natural gas prices the average system cost of this scenario would be slightly lower. The draft plan's findings for the **Carbon Cost Risk** scenario are discussed in Appendix O.

- **Regional Renewable Portfolio Standard at 35 Percent (Regional RPS at 35%) –** This scenario assumes that a region wide Renewable Portfolio Standard (RPS) is established at 35 percent of regional retail electricity sales across all four Northwest states. Presently, three states in the region have RPS. Montana and Washington require that 15 percent of the retail sales of be served by renewable resources. Montana's RPS must be satisfied in 2015 and Washington's by 2020. Oregon requires that 20 percent of retail sales be served by renewable resources by 2020. These state level RPS generally only apply to investor owned utilities and larger public utilities, while this scenario assumes that all of the region's retail sales are covered. Since this scenario was designed to test the cost and effectiveness of this policy for reducing regional power system carbon dioxide emissions, it did not include future carbon dioxide regulatory cost risk uncertainty or estimated damage cost. The cost-effectiveness of a policy that only requires use of additional renewable generation can, therefore, be compared to other scenarios that tested alternative policy options to reduce carbon dioxide emissions, including those use a combination of strategies such as limiting the type of new resources that can be developed and imposing a carbon price.

  Updated results for the **Regional Renewable Portfolio Standard at 35%** scenario are reported in the final plan.

- **Maximum Carbon Reduction – Existing Technology –** This scenario was designed to explore the maximum carbon dioxide emissions reductions that are feasible with current commercially available technologies. In this scenario all of the existing coal plants serving the region were assumed to be retired by 2026. In addition, the least efficient (i.e., those with heat rates exceeding 8,500 Btu/kWh) existing natural gas-fired generating facilities were assumed to be retired by 2031. No carbon dioxide cost risk or estimated damage cost was assumed, so this scenario can be compared to the cost-effectiveness of other policy options (e.g., **Carbon Cost Risk**, **Regional RPS at 35%**, **Social Cost of Carbon**, **Retire Coal w/SCC MidRange**, etc. scenarios) for reducing carbon dioxide emissions.

Updated results for the **Maximum Carbon Reduction – Existing Technology** scenario are reported in the final plan.

- **Maximum Carbon Reduction – Emerging Technology –** This scenario considers the role of new technologies might play in achieving carbon dioxide reduction. Due to the speculative nature of the performance and ultimate cost of technologies considered in this scenario the Council's Regional Portfolio Model (RPM) was not used to identify this scenario's least cost resource strategy. Rather, the RPM was used to define the role (e.g., capacity and energy requirements) that new and emerging technologies would need to play in order to achieve carbon dioxide reductions beyond those achievable with existing technology.

  Updated results for the **Maximum Carbon Reduction – Emerging Technology** scenario are not reported in the final plan. The results of the **Maximum Carbon Reduction – Emerging Technology** scenario would not differ materially from those reported in the draft plan. The draft plan's findings for the **Maximum Carbon Reduction – Emerging Technology** scenario are discussed in Appendix O.

- **Retire Coal –** This scenario is identical to the **Maximum Carbon Reduction – Existing Technology** scenario, except that it does not retire any existing natural gas generation. This scenario was designed to establish the lowest carbon dioxide emission level achievable by retiring all of the existing coal plants serving the region while assuming the continued operation of existing gas-fired generation. Since this resource strategy relies on existing gas generation rather than investing new resource development it could potentially have lower costs than the **Maximum Carbon Reduction – Existing Technology** scenario, but might produce similar carbon dioxide emissions. This scenario constructed based on public comment on the draft plan, and therefore was not considered during its development.

- **Retire Coal with Social Cost of Carbon Mid-Range (Retire Coal w/SCC MidRange) –** This scenario is identical to **Retire Coal** scenario, except that it assumes that the US Interagency Working Group on Social Cost of Carbon's Mid-Range estimate of the damage cost of forecast global climate change are reflected in fossil fuel costs. This scenario was designed to test the cost, economic risk and carbon emissions impacts that internalizing the damage cost of climate change would have on the resource dispatch and development. It was assumed that this scenario's resource strategy would rely more on renewable resources. Therefore, this scenario assumes greater availability and lower solar PV system cost for both utility scale projects and distributed systems. This scenario was constructed based on public comment on the draft plan, and therefore was not considered during its development.

- **Retire Coal with Social Cost of Carbon Mid-Range and No New Gas Generation (Retire Coal w/SCC MidRange & No New Gas) –** This scenario is identical to **Retire Coal w/SCC MidRange** scenario, except that it assumes that no new natural gas-fired generation resources can be constructed to replace retiring coal plants or existing gas generation if such plants are uneconomic to operate. This scenario was designed to test the cost, economic risk and carbon emissions impacts of restricting new resource development to renewable resources when compared to the **Retire Coal w/SCC MidRange** scenario. This scenario was constructed based on public comment on the draft plan, and therefore was not considered during its development.

- **Resource Uncertainty –** Four scenarios explored resource uncertainties and carbon dioxide regulatory compliance cost and economic risk. Two examined the effect that the loss of a major non-greenhouse gas-emitting resource might have on the region's ability to reduce power system carbon dioxide emissions. The **Unplanned Major Resource Loss** scenario assumed that a significant (approximately 1000 average megawatt) non-greenhouse gas emitting generator was unexpectedly taken out of service. The **Planned Major Resource Loss** scenario assumed that similar magnitudes of the region's existing non-greenhouse gas emitting resources were phased out over the next 20 years. Since both of these scenarios were designed to identify resource strategies that would maintain regional compliance with federal carbon dioxide emissions limits they assumed the cost of future carbon dioxide regulatory risk used in the **Carbon Cost Risk** scenario.

  The **Planned Major Resource Loss** scenario also provides insight into the resource implications that would occur in the event of the planned removal of any specific non-carbon resource in the region, including the removal of major hydroelectric projects such as the four federal dams on the lower Snake River The lower Snake River dams have a combined nameplate capacity of 3,033 megawatts. However, because of limited reservoir storage, their useful peaking capability (e.g. 10-hour sustained-period capacity) ranges from about 1,700 to 2,000 megawatts, which represents about 11 percent of the aggregate hydroelectric system's sustained peaking capability.[6] Annually, on average, these four projects produce about 1,000 average megawatts of energy or about 5 percent of the region's annual average load.

  The effect on the Council's resource strategy of removing these dams was assessed in the Sixth Power Plan.[7] In that assessment, however, generation from all four projects was removed in one year (2020). A more practical approach would be to remove the projects in sequence over a number of years to minimize disruption to both energy and fish needs as was assumed in **Planned Major Resource Loss** scenario in the Seventh Power Plan.

  While the Seventh Power Plan does not include an explicit analysis of the effects of removing the four lower Snake River dams, it does provide a scenario for the planned loss of a large (1,000 average megawatt) non-carbon resource in four stages over a period of 10 years. And, although this scenario is more generic, it better represents the timing of the loss of generation. What it does not include are details of potential shifts in generation at other

---

[6] This range is based on information from the Bonneville Power Administration's 2015 White Book, Technical Appendix – Volume 2, Capacity Analysis (DOE/BP-4741), pages 246 and 247. From that data, the peaking capability of the four lower Snake River dams relative to the total regional hydroelectric peaking capability is 11 percent. The 1,700 to 2,000 megawatt range for the four lower Snake River dams was calculated by multiplying the Council's estimated regional firm (low water) 10-hour sustained peaking capability by 11 percent for each season (quarter) of the year.

[7] Sixth Northwest Conservation and Electric Power Plan, Chapter 10: Resource Strategy, pages 10-27 and 10-28. http://www.nwcouncil.org/media/6344/SixthPowerPlan_Ch10.pdf

hydroelectric projects that would result from the loss of the four lower Snake River dams. On a comprehensive scale, however, these shifts are relatively small and will even out in the long run because the hydroelectric system cannot simply make up for the loss of generation from the lower Snake River dams. Thus, the resulting effects on the resource strategy should be similar for both cases in the sense of the types and magnitude of replacement resources. If the Council had analyzed the timed removal of the four lower Snake River dams, resource strategies would have had to also account for the 1,700 to 2,000 megawatts of sustained peaking loss and not just the loss of 1,000 average megawatts of energy generating capability. This would have likely increased the magnitude of the requirement for replacement resources.

Two additional scenarios tested the economic benefits or cost resulting from a faster or slower near term pace of conservation deployment. The **Faster Conservation Deployment** scenario allowed the Regional Portfolio Model to increase the pace of acquiring conservation savings by 30 percent above the baseline assumption. The **Slower Conservation Deployment** scenario restricted the RPM's option to acquire conservation savings to a pace that was 30 percent below the baseline assumption. Since both of these scenarios were designed to test resource strategies that might reduce the cost or increase the economic risk of compliance with federal carbon dioxide emissions limits, they assumed the carbon dioxide regulatory cost risk used in the **Carbon Cost Risk** scenario.

Updated results for the **Resource Uncertainty** scenarios are not reported in the final plan. The results of these scenarios would not differ materially from those reported in the draft plan. That is, the replacement resource strategy and relative impact on regional carbon emissions would remain unchanged. However, since the final plan assumed lower natural gas and wholesale electricity prices the average system cost and economic risk of these scenarios would be slightly less due to the reduced the cost of fuel supplying replacement resources. The lower range of natural gas prices assumed in the final plan would also decrease the cost of the **Faster Conservation Deployment** and **Slower Conservation Deployment** scenarios, but not their cost relative to one another. The draft plan's findings for all four of the resource uncertainty scenarios are discussed in Appendix O.

- **No Demand Response –** This sensitivity study assumed that no demand response resources were available to meet future regional peak capacity needs. It estimated the cost and risk of not using demand response to provide regional capacity reserves under both the Existing Policy scenario and with the future carbon dioxide regulatory cost assumed in the Carbon Cost Risk scenario. Updated results for the **No Demand Response** scenario are reported in the final plan.

- **Low Natural Gas and Wholesale Electricity Prices –** This sensitivity study assumed that the range of future natural gas and wholesale electricity prices the region would experience was systematically lower than the baseline assumptions. It was designed to test the impact of lower gas and electricity prices on the amount of cost-effective conservation and on the best future mix of generating resource development. This sensitivity study was tested under both the **Existing Policy** scenario and with the future carbon dioxide regulatory cost assumed in the **Carbon Cost Risk** scenario. The final plan assumed lower natural gas and wholesale electricity market prices than the draft plan so results for the **Low Natural Gas and Wholesale Electricity Prices** sensitivity study are not reported in the final plan. The draft plan's findings for these two scenarios are discussed in Appendix O.

- **Increased Market Reliance –** This scenario explored the potential benefits and risk of increased reliance on out-of-region markets to meet regional resource adequacy standards. It evaluated the cost of meeting near-term peak capacity needs with demand response and other regional resources compared to reliance on external Southwest and Canadian markets. This sensitivity study was conducted using the **Existing Policy** scenario. Updated results for the **Increased Market Reliance** scenario are reported in the final plan.

- **Lower Conservation –** This sensitivity study explored the potential costs and benefits associated with less reliance on energy efficiency. Under this scenario, the acquisition of conservation was limited to what would be cost-effective to acquire based on short-run market prices, rather than full consideration of long-term resource costs and economic risks. This sensitivity study was conducted using the **Existing Policy** scenario, so no carbon dioxide regulatory cost risk or damage costs were assumed. Updated results for **Lower Conservation** scenario are reported in the final plan.

Results of these studies are compared in the discussion of the eight elements of the resource strategy in the following section. A discussion of the specific input assumptions for each of these scenarios as well as a more comprehensive discussion of carbon dioxide emissions, rate and bill impacts, and the Regional Portfolio Model appears in Chapter 15 and Appendix L.

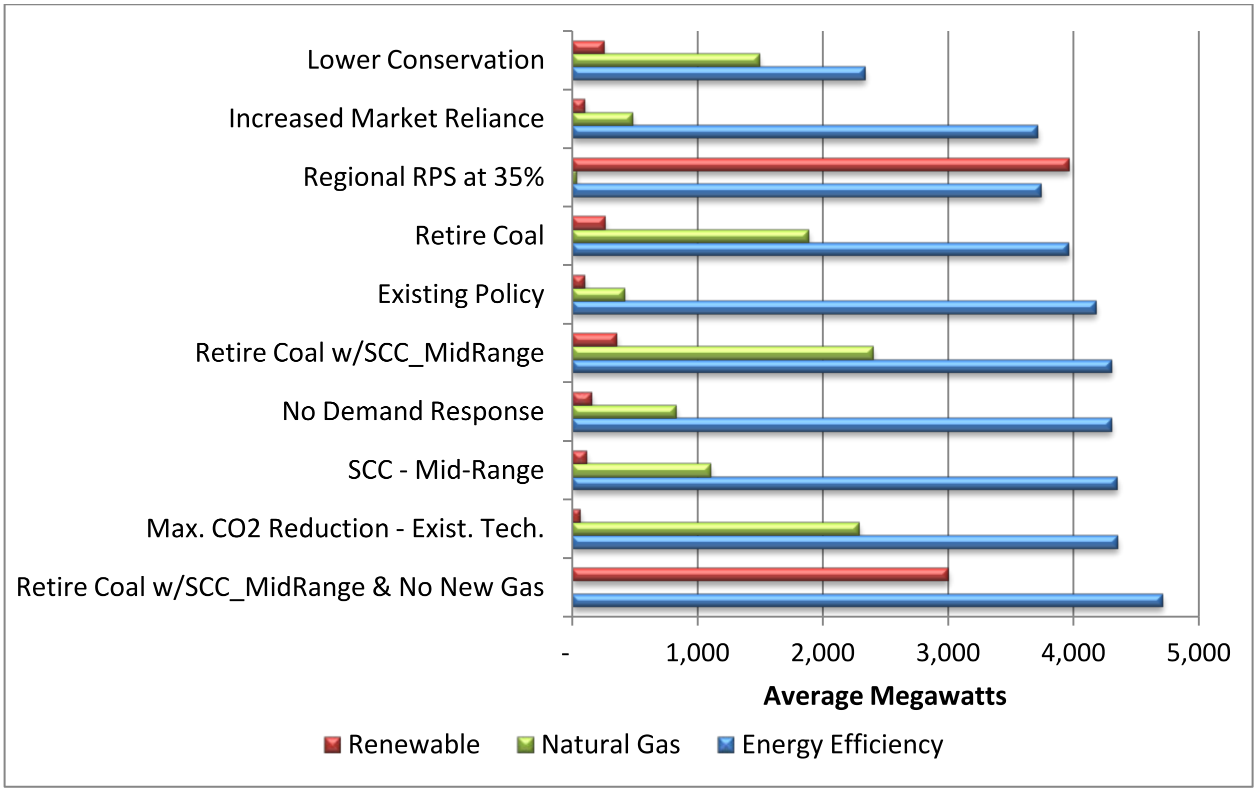
THE RESOURCE STRATEGY

The resource strategy of the Seventh Power Plan is designed to provide the region a low-cost electricity supply to meet future load growth. It is also designed to provide a low economic risk electricity future by ensuring that the region develops and controls sufficient resources to maintain resource adequacy, limiting exposure to potential market price extremes. Therefore the amount and type of resources included in the strategy are designed to meet loads, minimize costs, and help reduce the economic risks posed by uncertain future events.

Figure 3 - 1 shows the average resource development by resource type for the least cost resource strategy under the major scenarios and sensitivity studies carried out to support the development of the final Seventh Power Plan. The resource development shown in Figure 3 - 1 is the *average* over all 800 futures modeled in the Regional Portfolio Model (RPM). In the RPM the specific timing and level of resource development is unique to each of the 800 potential futures modeled. The Seventh Power Plan's principal of adaptive management is based on the reality that, as in the RPM, the timing and level of resource development in the region will be determined by actual conditions as they unfold over the next 20 years. However, what should not change are the Seventh Power Plan's priorities for resource development. In that regard, Figure 3 - 1 shows the significant and consistent role of energy efficiency across all scenarios. This is because of its low cost, its contribution to regional winter capacity needs and its role in mitigating economic risk from fuel price uncertainty and volatility.

After energy efficiency, the *average* development of new natural gas generation and renewable resources by 2035 varies significantly across scenarios. New natural gas-fired resources are developed to meet regional capacity needs and to replace existing coal generation in scenarios where all of those resources are assumed to be retired (e.g., **Retire Coal, Retire Coal w/SCC MidRange, Maximum Carbon Reduction – Emerging Technology).** Renewable resource development is driven by state renewable resource portfolio standards. Not shown in Figure 3 - 1 is the deployment of demand response resources because these resources primarily provide capacity (megawatts) not energy (average megawatts) and the increased dispatch of existing gas generation to replace already announced coal generation retirements. Both of these resources also play significant roles in the Seventh Power Plan's resource strategy. Each element of the resource strategy is discussed below.

Figure 3 - 1: Average Resource Development in Least Cost Resource Strategy by 2035 in Alternative Scenarios



Energy Efficiency Resources

Energy efficiency has been important in all previous Council power plans. The region has a long history of experience improving the efficiency of electricity use. Since the Northwest Power Act was enacted, the region has developed nearly 5,800 average megawatts of conservation. This achievement makes efficiency the second-largest source of electricity in the region following hydroelectricity.

As in all prior plans, the highest priority new resource in the Seventh Power Plan resource strategy is improved efficiency of electricity use, or conservation. Figure 3 - 2 shows that the region's net load after development of all-cost effective energy efficiency remains essentially the same over the next 20 years. This finding holds under scenarios that both consider damage cost and those that do not. The only scenario that developed significantly less energy efficiency was the scenario specifically designed to do so. The **Lower Conservation** scenario developed roughly 1800 average megawatts less energy efficiency by 2035 than the **Existing Policy** scenario. The **Lower Conservation** scenario had significantly higher ($15 billion) average system cost and exposed the region to much larger ($22 billion) economic risk than the **Existing Policy** scenario.[8] However, as Figure 3 - 2 shows, even under that scenario, the development of energy efficiency offsets nearly all regional load growth through 2025.

The attractiveness of improved efficiency is due to its relatively low cost coupled with the fact that it provides both energy and capacity savings and is not subject to major sources of economic risk. The average cost of conservation developed in the least cost resource strategies across all scenarios tested was half the cost of alternative generating resources. The average levelized cost of the cost-effective efficiency developed in the Seventh Power Plan's resource strategy is $30 per megawatt-hour.[9] The comparable estimated cost of a natural gas-fired combined-cycle combustion turbine is around $71 per megawatt-hour. The current cost of utility scale solar photovoltaic systems is approximately $91 per megawatt-hour and Columbia Basin wind costs $110 per megawatt-hour, including the cost of integrating these variable output resources into the power system.[10] The projected cost of conventional geothermal resources is around $85 per megawatt-hour, although this resource poses significant development risk. Significant amounts of improved efficiency also cost less than the forecast market price of electricity. Nearly 2,400 average megawatts of energy efficiency are available at cost below $30 per megawatt-hour.

Energy efficiency also lacks the economic risk associated with volatile fuel prices and carbon dioxide emission reduction policies. Its short lead time and availability in small increments also reduce its economic risk. Therefore, improved efficiency reduces both the cost and economic risk of the Seventh Power Plan's resource strategy.

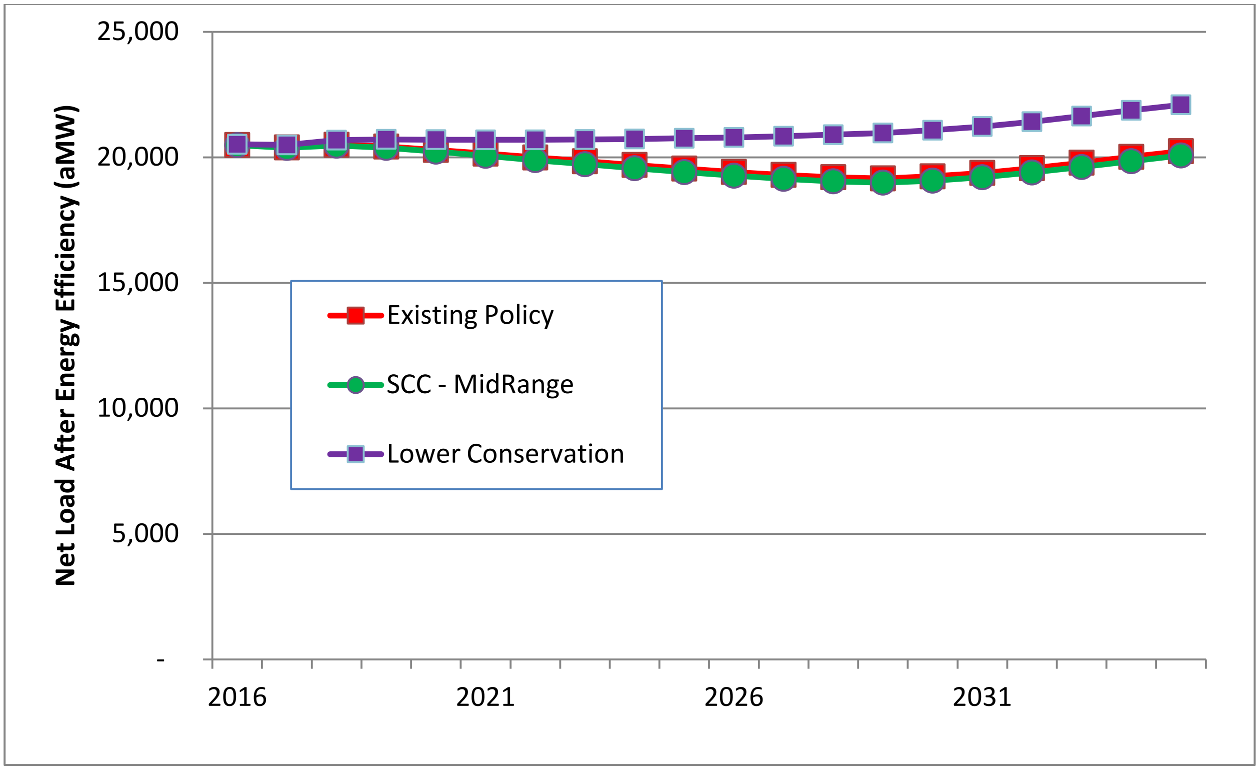
---

[8] The cost of resource strategies reported in the Seventh Power Plan generally exclude revenues from carbon prices in order to compare scenarios based only on power system costs. The text will identify whether carbon revenues are included or not. In practice, carbon revenue may not be considered a cost if all of it is returned to ratepayers, for example, in the form of tax reduction.

[9] This is the average real levelized cost of all conservation measures acquired in the resource strategy, excluding a cost-offset that is expected to occur as a result of lower load growth which defers the need to expand distribution and transmission systems. In evaluating conservation's cost-effectiveness in the RPM, this cost-offset was included, as well as other non-energy benefits, such as water savings from more efficient clothes washers. If the cost-offset benefits provided by energy efficiency's deferral of investments in distribution and transmission expansion are considered, the average levelized cost is $18 per megawatt-hour.

[10] The levelized cost of solar PV resources has been reduced by the impact of a 30% Federal Investment Tax Credit (ITC) until 2022 and a 10% ITC for the remainder of the planning period. Geothermal cost have been also been reduced by 10% ITC throughout the entire planning period. In addition, solar, wind and geothermal resource costs are also reduced by accelerated depreciation. No state or local tax or other financial incentives are reflected in resource costs. The cost of these resources also reflect integration costs equivalent to current integration rates for wind resources charged by Bonneville and Idaho Power Company's integration rates for solar PV systems. The integration cost of additional renewable resource development in the region may be higher.

Figure 3 - 2: Average Net Regional Load After Accounting for Cost-Effective Conservation Resource Development



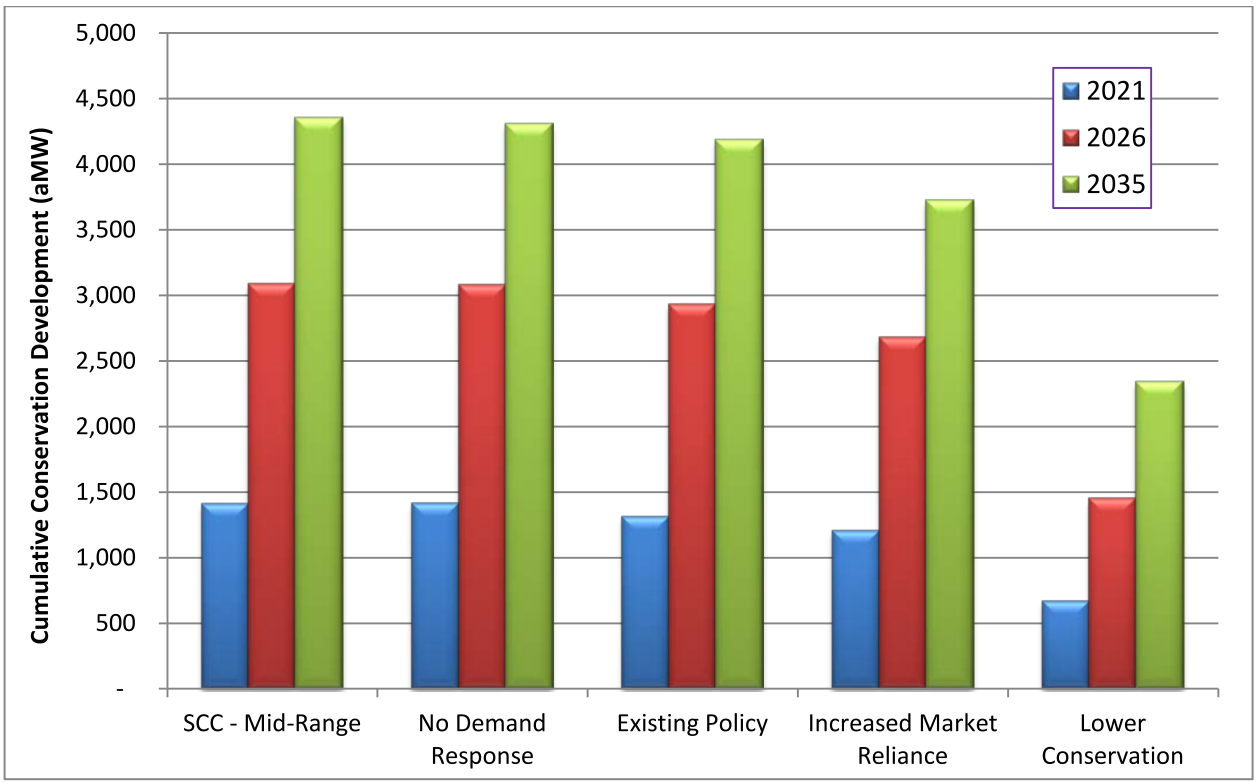
In the Council's analysis, additional resources are added to provide insurance against future uncertainties. Efficiency improvement provides attractive insurance for this purpose because of its low cost. In futures or time periods when the extra resources are not immediately needed, the energy and capacity can be sold in the market and all or at least a portion of their cost recovered. This is not true for generating resources, for in periods when market prices are at or below their variable operating cost; these resources cannot recover any of their capital cost. In addition, because of its low average cost to utilities, the development of energy efficiency offers the potential opportunity to extend the benefits of the Northwest's hydro-system through increased sales.

In all of the scenarios and sensitivity studies examined by the Council, similar amounts of improved efficiency were found to be cost-effective.[11] The selection of energy efficiency as the primary new resource does not depend significantly on whether carbon dioxide policies are enacted. However, since energy efficiency is being developed in part because it provides winter and summer peaking capacity the amount developed is related to other resource options for meeting winter and summer peak needs.

[11] The only exceptions are the **Lower Conservation** scenario which as explicitly designed to develop less energy efficiency and the **Increased Market Reliance** scenario which assumes that the region can rely more on imports to meets its peak capacity needs.

Figure 3 - 3 shows the average amount of efficiency acquired in various scenarios considered by the Council in the power plan by 2021, 2026, and 2035. In the **Existing Policy**, **Social Cost of Carbon-MidRange** and **No Demand Response** scenarios, the amount of cost-effective efficiency developed averages between 1,300 and 1,450 average megawatts by 2021 and 3,000 and 4,300 by 2035. In scenarios that assume that peaking capacity can be provided by demand response or increased reliance on external markets, the amount of cost-effective energy efficiency developed is slightly less, averaging 1200 aMW by 2021 and 2600 aMW by 2026 and 3700 aMW by 2035. The amount of conservation developed varies in each future considered in the Regional Portfolio Model. For example, in the **Social Cost of Carbon - MidRange** scenario, the average conservation development is 4,460 average megawatts, but individual futures can vary from just over 3900 average megawatts to as high as just under 4,900 average megawatts.

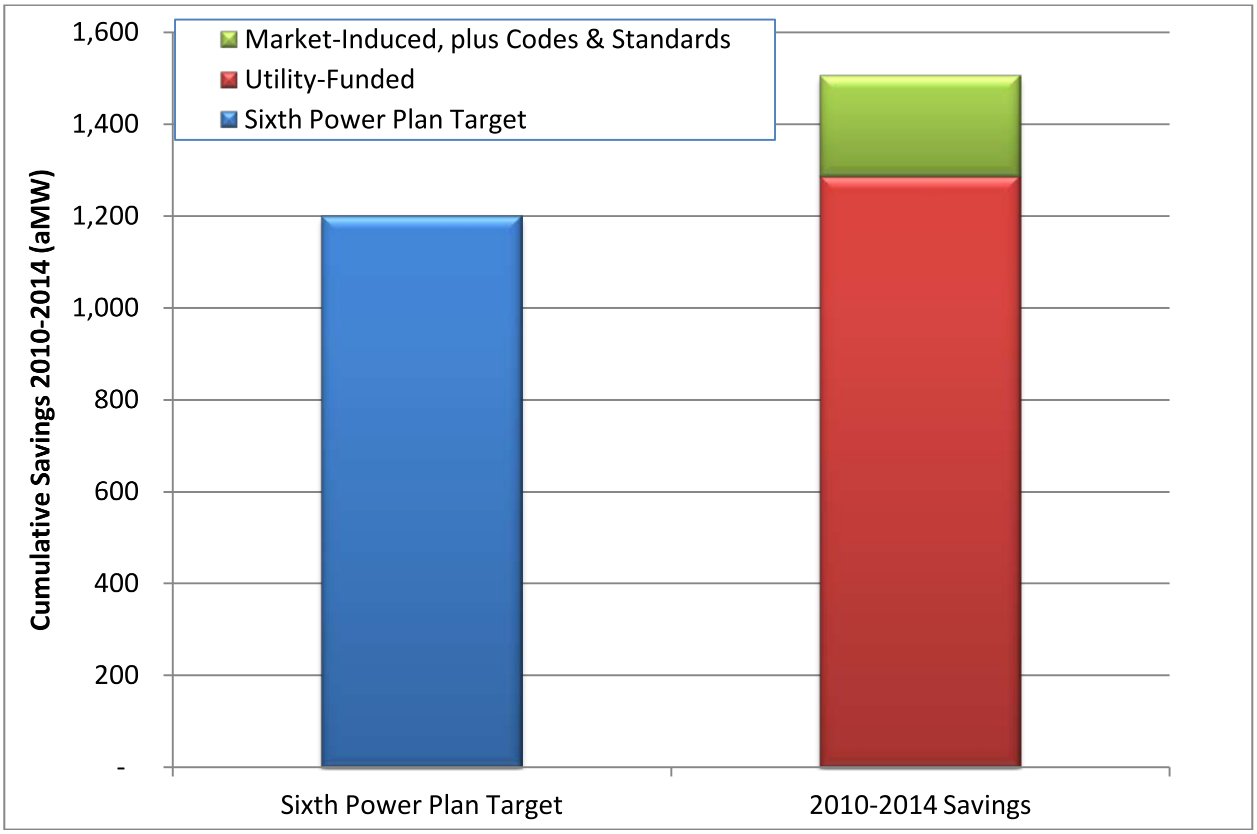
Figure 3 - 3: Quantity of Cost-Effective Conservation Resources Developed Under Different Scenarios



The nature of efficiency improvement is that the total cost is recovered over a smaller number of sales. Average cost per kilowatt-hour sold will increase, but because total consumption is reduced, average consumer electricity bills will be smaller. Consumers who choose not to improve their efficiency of use could see their bills increase. However, if the region does not capture the efficiency, the higher cost of other new generating resources will increase the average bill. The impact on both bills and average revenue requirement per megawatt-hour is discussed later in this chapter.

The amount of efficiency included in the Seventh Power Plan is comparable to that identified in the Council's Sixth Power Plan; even though the 20-year goal is lower (4,300 aMW vs. 5,800 aMW). To a large extent, this decrease is the result of regional energy efficiency program achievements since the Sixth Power Plan was adopted in 2010 as well as significant savings that will be realized as a result of federal standards and state codes enacted since the Sixth Power Plan was adopted. Figure 3 - 4 shows regional utility cumulative conservation program achievements from 2010 through 2014 compared to the Sixth Power Plan's conservation goal for the same period. In addition, Figure 3 - 4 shows the savings achieved from the combined impact of federal and state appliance and equipment standards, state building codes, and market-induced savings. In aggregate, actual achievements from 2010 through 2014 were over 1500 average megawatts, exceeding the Sixth Power Plan's five year goal of 1200 average megawatts by 25 percent.

Figure 3 - 4: Regional Conservation Achievements Compared To Sixth Plan Goals

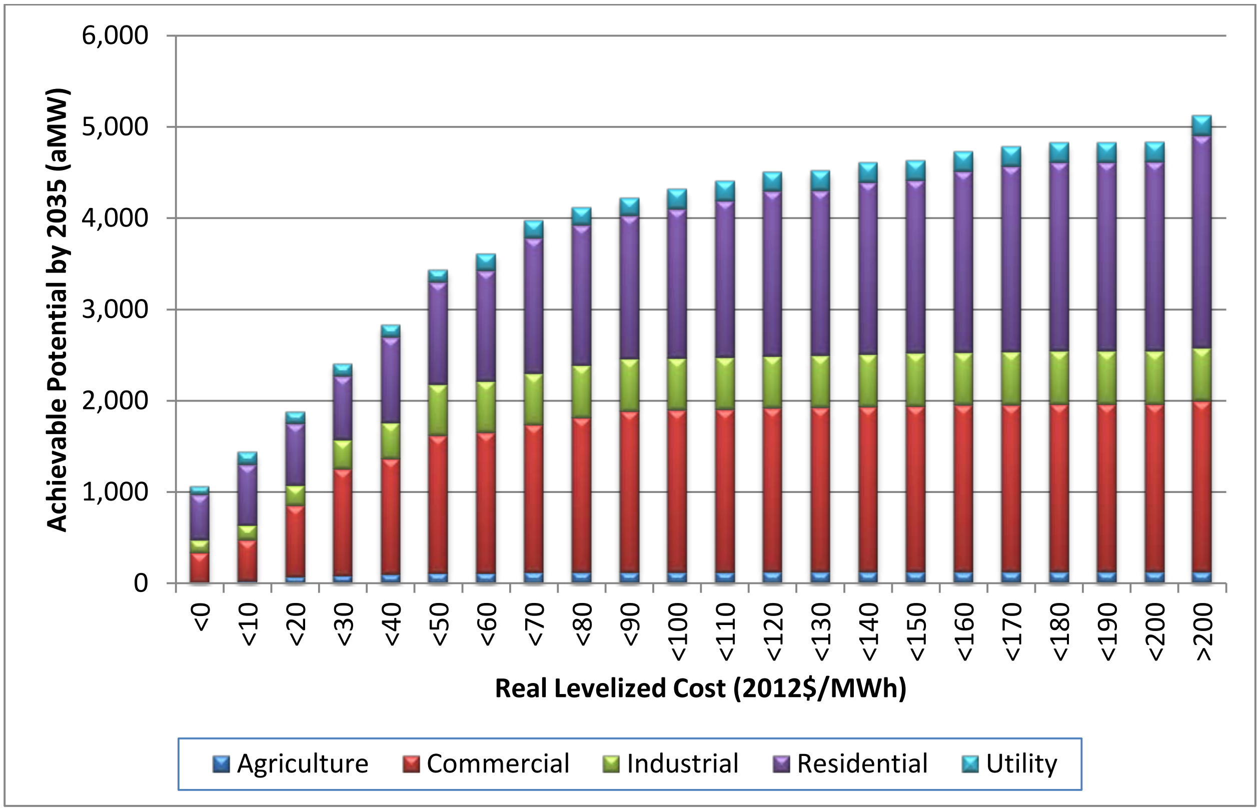


Since the adoption of the Sixth Plan, the US Department of Energy has adopted new or revised more than 30 standards for appliances and equipment that have or will take effect over the next 10 years. These standards reduce load growth by capturing all or a portion of the conservation potential identified in the Sixth Plan. The Council estimates that collectively these standards will reduce forecast load growth by nearly 1500 average megawatts by 2035.

The Council has identified significant new efficiency opportunities in all consuming sectors. Figure 3 - 5 shows by levelized cost the sectors of efficiency improvements. Additional information on the sources and costs of efficiency improvements is provided in Chapter 12 and Appendix G.

Improved efficiency contributes not only to meeting future energy requirements, but also provides capacity during peak load periods. The savings from conservation generally follow the hourly shape of energy use, saving more energy when more is being used. As a result, efficiency contributes

Figure 3 - 5: Achievable Energy Efficiency Potential by Sector and Levelized Cost by 2035



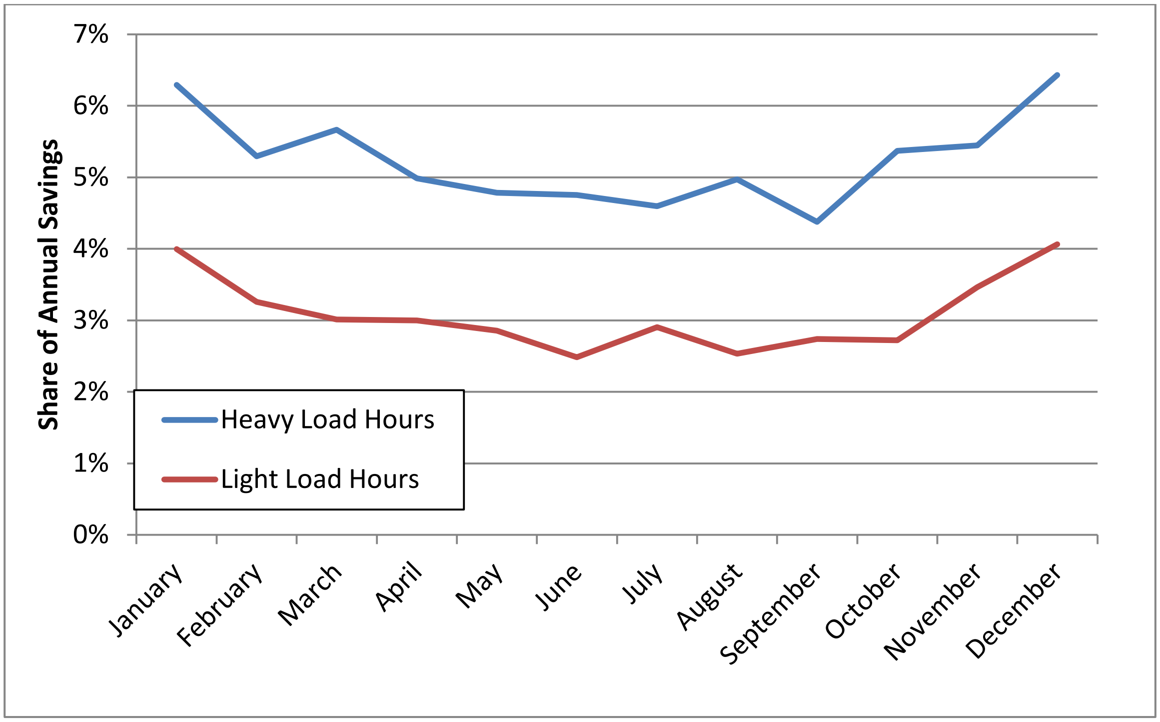
more to load reduction during times of peak usage. To model the impact of energy efficiency on the hourly demand for electricity, the Council aggregated the load shapes of efficiency savings from the hourly shape of individual end-uses of electricity and the cost-effective efficiency improvements in those uses. Figure 3 - 6 shows the shape of the savings for all measures during heavy and light load hours. As is shown, the energy savings are greater during the winter season than summer, in large part due to significant savings from conversion of electric resistance heating to more efficient heat pump technologies and increased use of efficient lighting during the winter period.

The capacity impact of energy efficiency is almost two times the energy contribution in winter. For example, efficiency improvements that yield average annual savings of 4,360 average megawatts create 9,060 megawatts of peak hour savings during the winter months.[12] This reduction in both system energy and capacity needs makes energy efficiency a valuable resource relative to generation because efficiency provides energy and capacity resources shaped to load. Because each efficiency measure has a specific shape, or capacity impact, the Seventh Power Plan explicitly

[12] See Chapter 12 for a description of how the capacity savings of energy efficiency measures are estimated and Chapter 11 for a description of how the system level capacity savings, or Associated System Capacity Contributions, of conservation and generation resources are estimated.

incorporates the value of deferred generation capacity in the cost-effectiveness methodology for measures and programs.[13]

Figure 3 - 6: Monthly Shape of 2035 Energy Efficiency Savings



Demand Response

Demand response resources (DR) are voluntary reductions (curtailments) in customer electricity use during periods of high demand and limited resource availability. As deployed in the Seventh Power Plan, demand response resources are used to meet fall, winter and summer peak demands primarily under critical water and extreme weather conditions. Other potential applications of demand response resources, such as the integration of variable resources like wind, were not explicitly modeled for the development of the Seventh Power Plan. However, this does not mean that such applications of demand response would not provide cost-effective options for providing such services. Therefore, the Seventh Power Plan resource strategy recommends that demand response resources be considered for the provision of other ancillary services, such as variable resource integration.

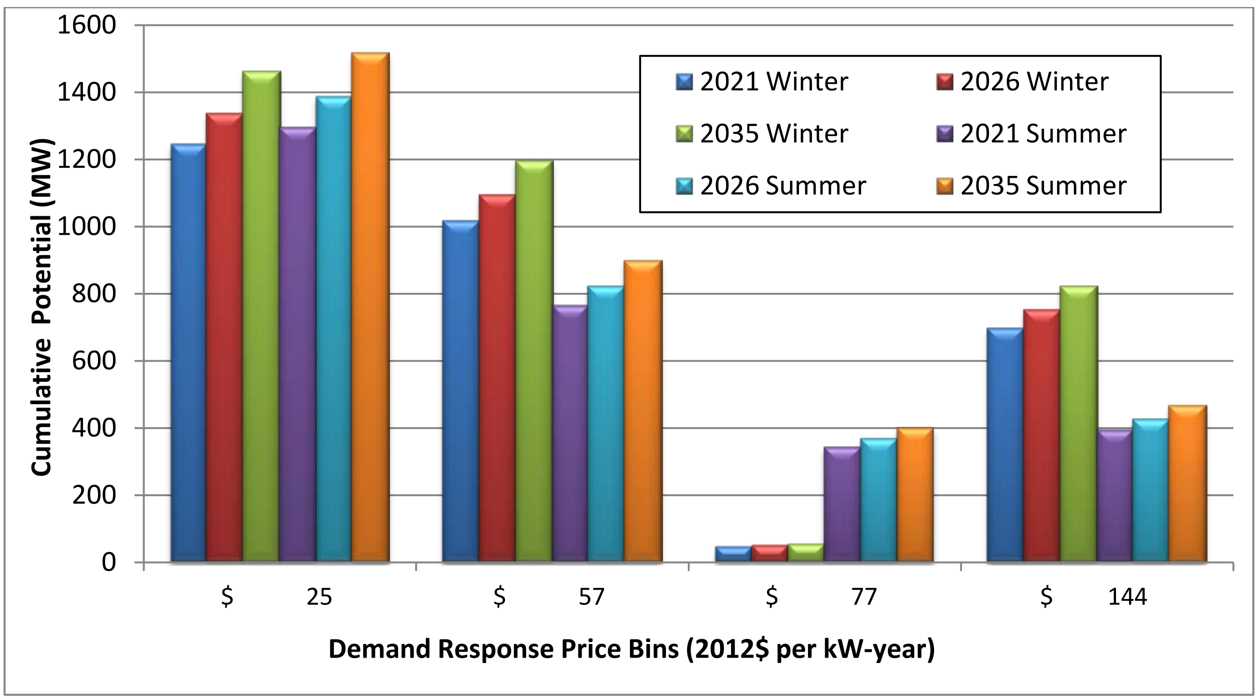
In many areas of the US, demand response resources have long been used by utilities to offset the need to build additional peaking capacity. In the Northwest, the existing hydropower system has been able to supply adequate peaking capacity, so the region has far less experience with deployment of demand response resources. To assess the economic value of developing demand response in the Northwest, the Council conducted sensitivity studies that assumed demand

[13] See action items RES-2 and RES-3 in Chapter 4 and Appendix G.

response resources were not available. The average net present value *system cost* and *economic risk* of the least cost resource strategy without demand response were $5.4 billion higher than in the least cost resource strategy that was able to deploy this resource. Therefore, from the Seventh Power Plan's analysis it appears that if barriers to development can be overcome and the Council's analysis of the cost of demand response are accurate; demand response resources could provide significant regional economic benefits.[14]

The Council's assessment identified more than 4300 megawatts of regional demand response potential. A significant amount of this potential, more than 1500 megawatts, is available at relatively low cost, under $25 per kilowatt of peak capacity per year. When compared to the alternative of constructing a simple cycle gas-fired turbine, demand response resources can be deployed sooner and in quantities better matched to the peak capacity need. Figure 3 - 7 shows the cumulative potential for each of the four blocks (i.e., price bins) of demand response modeled in the Regional Portfolio Model. Cumulative achievable potential by the years 2021, 2026, and 2035 is shown for both winter and summer capacity demand response programs. Note that the largest single block of estimated demand response potential is also the least costly.

Figure 3 - 7: Demand Response Resource Supply Curve



The low cost of demand response resources make them the most economically attractive option for maintaining regional peak reserves to satisfy the Council's Resource Adequacy Standards. The low cost of demand response resources also make them particularly valuable because the need for peaking capacity resources to meet resource adequacy in the region is a function of a combination

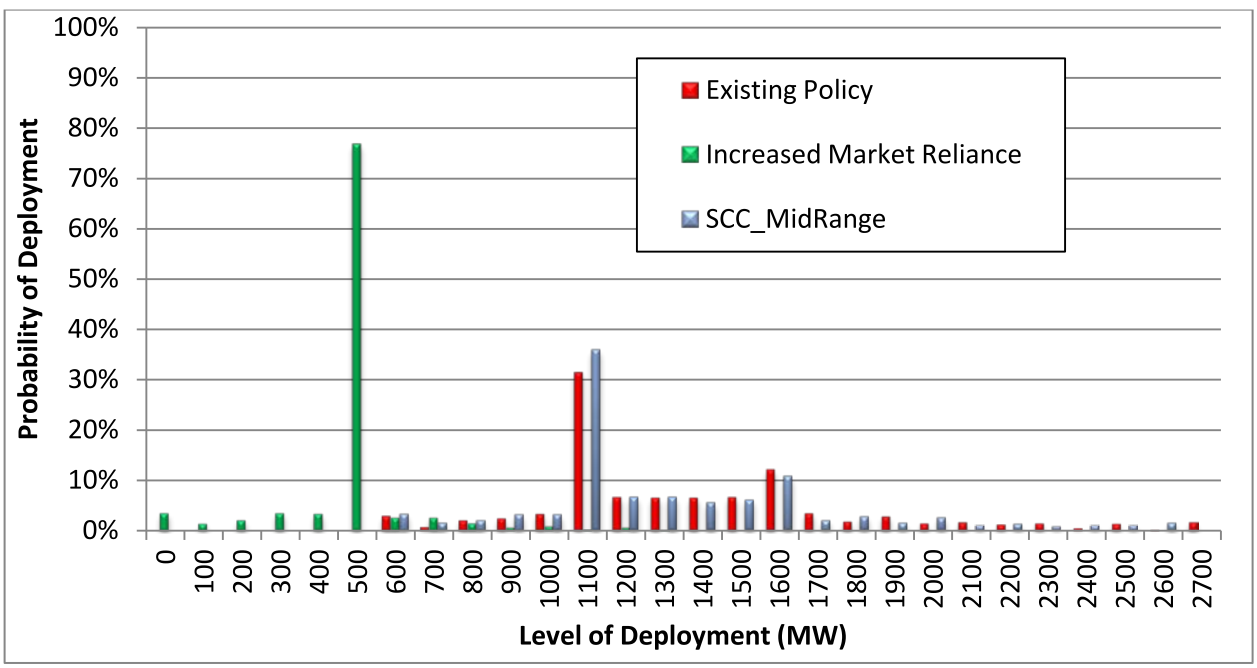
[14] See Action Items RES-4 and BPA-3 in Chapter 4 for the Seventh Power Plan recommends the region and Bonneville should engage to specifically address the barriers to development of demand response resources.

of water and weather conditions that have low probability of occurrence. This is illustrated by Figure 3 - 8 which shows the amount of demand response resource developed by 2021 across the 800 futures tested in the RPM across multiple scenarios.

Figure 3 - 8 shows that there is a wide range of both the amount and probability of development from zero up to 2700 MW, depending on what scenario is being analyzed. In the **Increased Market Reliance** scenario**,** more than 70 percent of the futures require 600 MW demand response development and only a two percent probability exists that none will be needed. Under the **Existing Policy** and **Social Cost of Carbon-MidRange** scenarios there is around a 30 to 35 percent probability that as much as 1100 MW of demand response will need to be developed by 2021 and just over a 10 percent probability that as much as 1600 MW would need to be developed.

From Figure 3-8 it is also clear that the probability of deploying demand response development in the **Increased Market Reliance** scenario**,** which assumed the region could place greater reliance on external power markets to meet its winter peak capacity needs is less than other scenarios that used the limits on external market reliance used in the Regional Resource Adequacy Assessment. The amount of demand response developed *on average* across all futures is around 700 MW in the **Existing Policy** and **Social Cost of Carbon-MidRange,** but only about 400 MW in the **Increased Market Reliance** scenario. In this scenario, net present value system cost and economic risk were also significantly ($5.4 billion) lower than the **Existing Policy** scenario. This highlights the sensitivity of the assumed limits on external market reliance used in the Council Regional Resource Adequacy Assessment and the potential value to the region if it can rely upon additional imports.

Figure 3 - 8: Demand Response Resource Development by 2021 Under Alternative Scenarios



Natural Gas-Fired Generation

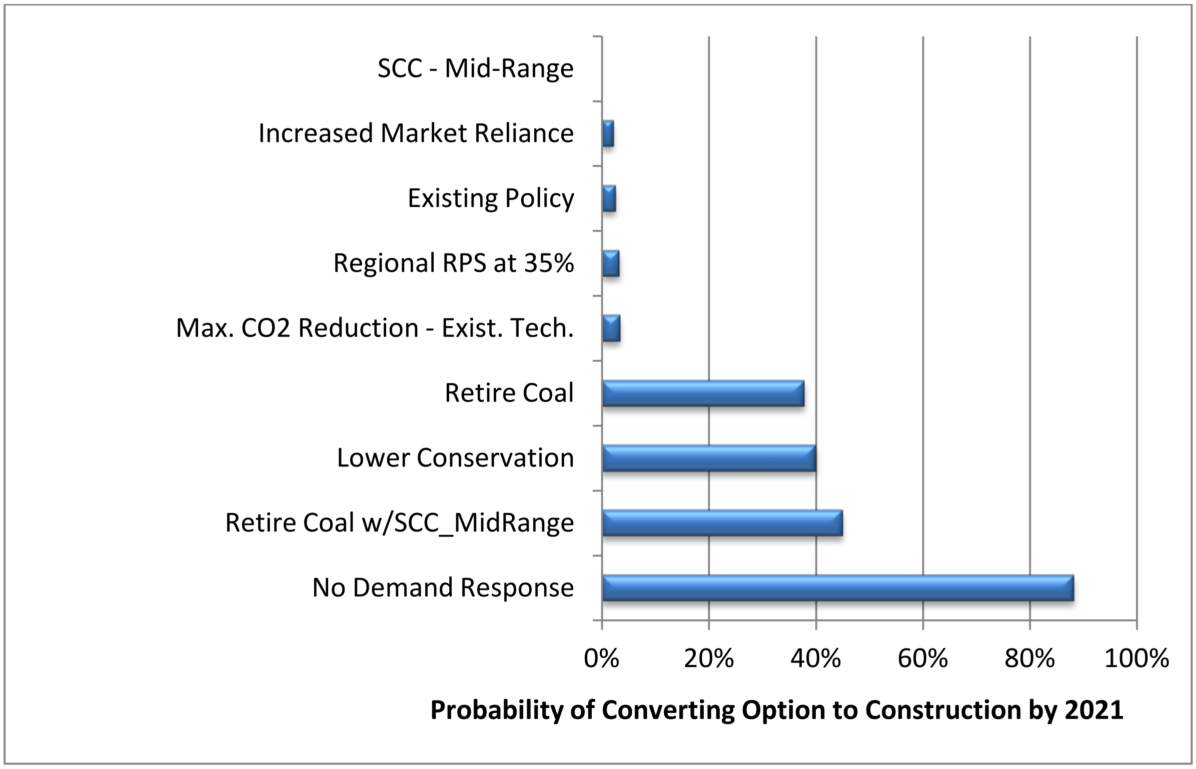
Natural gas is the third major element in the Seventh Power Plan resource strategy. It is clear that after efficiency and demand response, new natural gas-fired generation is the most cost-effective resource option for the region in the near-term. Moreover, also after energy efficiency, the Seventh Power Plan identified the increased use of existing natural gas generation as offering the lowest cost option for reducing regional carbon dioxide emissions. Other resource alternatives may become available over time, and the Seventh Power Plan recommends actions to encourage expansion of the diversity of resources available, especially those that do not produce greenhouse gas emissions.

Across the scenarios evaluated, there is significant variance in the amount of new gas-fired generating resources that are optioned and in the likelihood of completing the plants. New gas-fired plants are optioned (sited and licensed) in the RPM so that they are available to develop if needed in each future. The Seventh Power Plan's resource strategy includes optioning new gas fired generation as local needs dictate. However, from an aggregate regional perspective, which is the plan's focus, the need for additional new natural gas-fired generation is very limited in the near term (through 2021) and low in the mid-term (through 2026) under nearly all scenarios. That is, options for new gas-fired generation are taken to construction in only a relatively small number of futures. Figures 3 - 9 and 3 - 10 show the probability that a thermal resource option would move to construction by 2021 and by 2026. The scenarios are rank-ordered based on the probability of any new gas resource development by 2021 and by 2026. Scenarios with the lowest probability of development are at the top of the graphs.

As can be observed from a review of Figure 3 - 9, the probability of gas development is less than 10 percent by 2021 in five of the scenarios shown in the figure. The four scenarios where the probability of new gas development is 40 percent or higher are those that either develop significantly less energy efficiency or demand response and those that assume retirement of all of the region's existing coal generation by 2026.

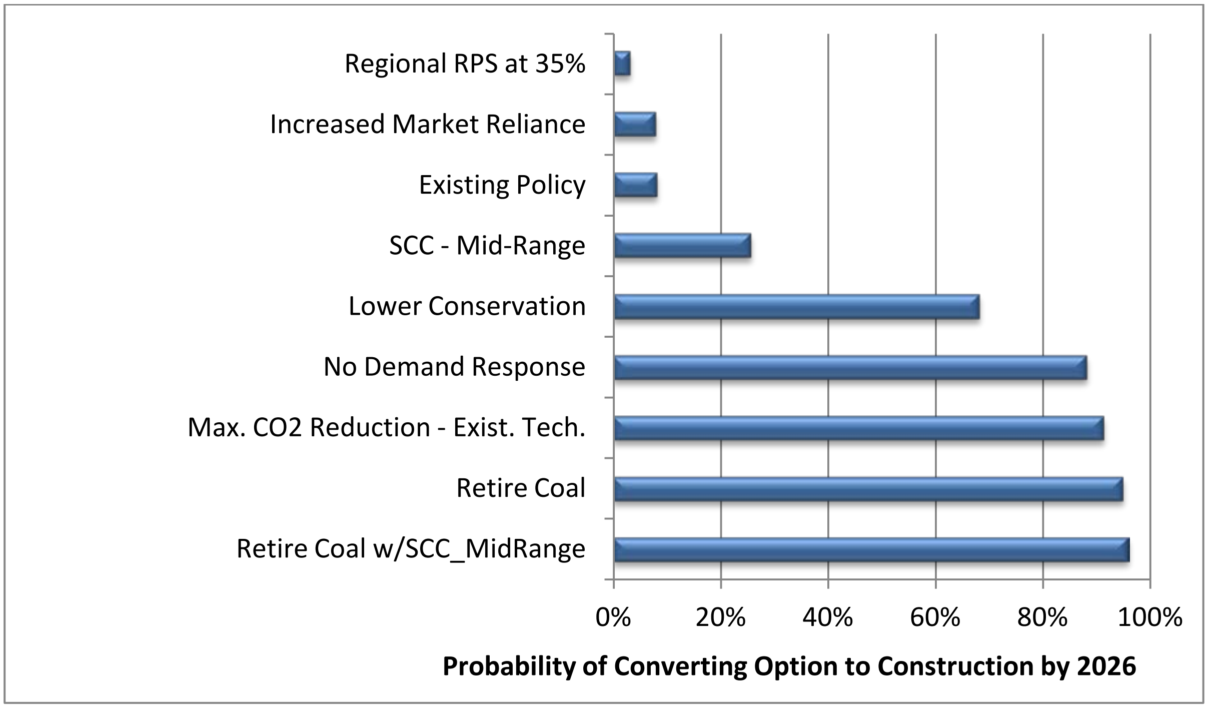
By 2026, Figure 3 - 10 shows that the probability of moving from an option to actual construction of a new gas-fired thermal plant increases to more than 65 percent in the **Lower Conservation** scenario and to above 80 percent in the **No Demand Response** scenario. All of the scenarios that assume the region's existing coal plants are retired by 2026, including **Maximum Carbon Reduction – Existing Technology** scenarios have a 90 percent probability or higher of constructing one or more new natural gas generating resources. This occurs because under these scenarios existing coal plants are retired and, in the scenarios that assume a social cost of carbon, inefficient gas-fired generation is displaced by new, highly efficient natural gas generation to reduce regional carbon dioxide emissions.

Figure 3 - 9: Probability of New Natural Gas-Fired Resource Development by 2021



The development of natural gas combined cycle combustion turbines is largest when there is a need for both new capacity and energy to meet regional adequacy standards. As can be observed from the data shown in Figures 3 - 9 and 3 - 10, this occurs in scenarios that must replace energy generation lost due to the retirement of resources, such as in the five scenarios that retire or decrease the use of existing coal and inefficient existing gas plants or those that assume no demand response resources or develop significantly less amounts of energy efficiency.

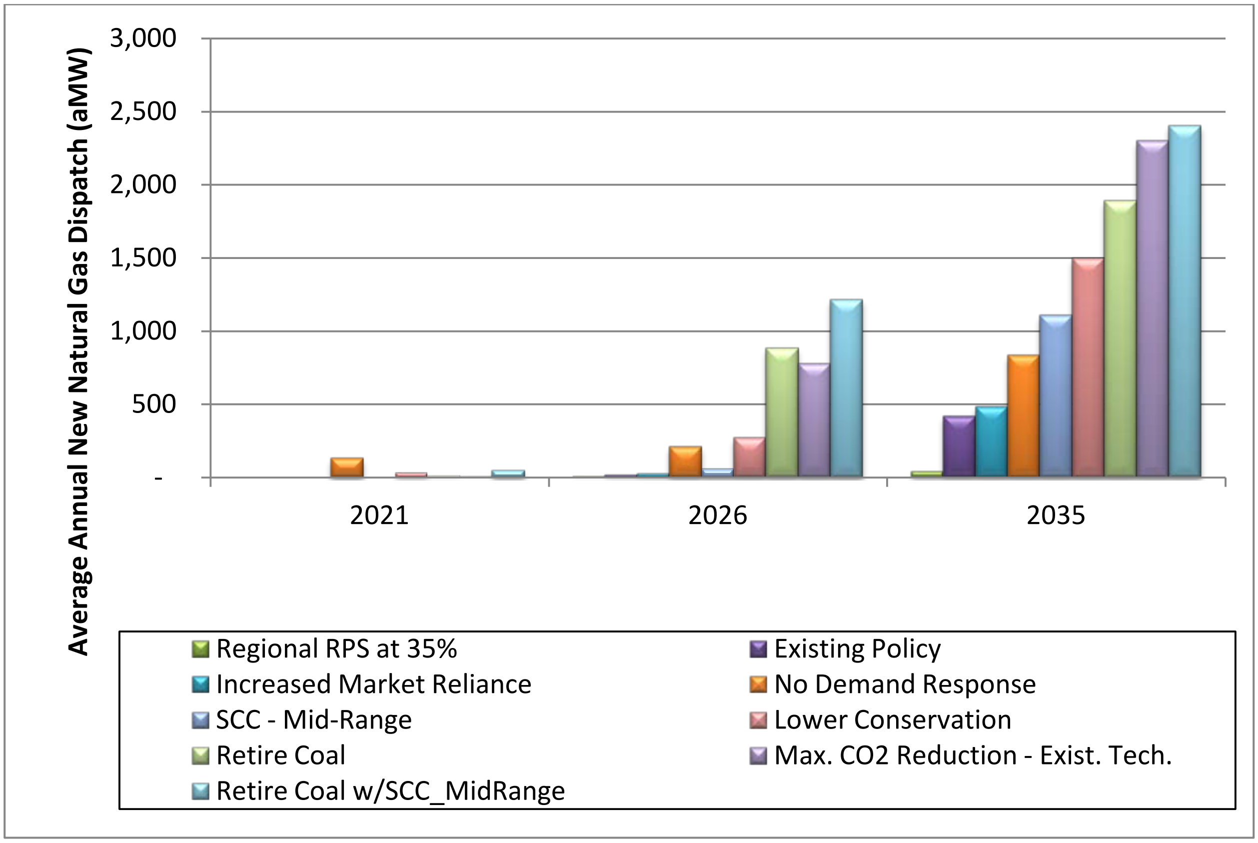
Figure 3 - 10: Probability of New Natural Gas-Fired Resource Development by 2026



As can be seen from the prior discussion, while the amounts of efficiency and the minimum amount of demand response were fairly consistent across most scenarios examined, the future role of new natural gas-fired generation is more variable and specific to the scenarios studied. Figure 3 - 11 shows the average amounts of gas-fired generation across 800 futures considered in each of the principal scenarios. The amount of new natural gas-fired generation constructed varies in each future. In most scenarios the average annual dispatch of new natural gas-fired generation is less than 50 average megawatts by 2021 and only between 300 to 400 average megawatts by 2026 except in scenarios that assume all existing coal plants are retired. In the **Existing Policy** scenario, the amount of energy generated from new combined cycle combustion turbines, when averaged across all 800 futures examined, is just 20 average megawatts in 2026. In contrast, the average amount generated across 800 futures is between 200 - 300 average megawatts in 2026 in the scenarios that assume no demand response resources are developed or that develop significantly lower amounts of conservation.

However, the role of natural gas is larger than it appears in the Council's analysis of the regional need for new natural gas fired generation for a number of reasons. First, the Council models the region as if it were a single utility, even though it is not. This understates the need for resource development because it does not capture the physical and institutional barriers present in the region. For example, the regional transmission system has not evolved as rapidly as the electricity market, resulting in limited access to market power for some utilities. Second, some utilities have significant near-term resource challenges, particularly if there is limited access to surplus resources from others. These factors limit the ability of the regional resource strategy to be specific about optioning and construction dates for natural gas-fired resources, or for the types of natural gas-fired generation. As a result, some amount of new gas-fired generation may be required in such instances even if the utilities deploy demand response resources and develop the energy efficiency as called for in Seventh Power Plan.

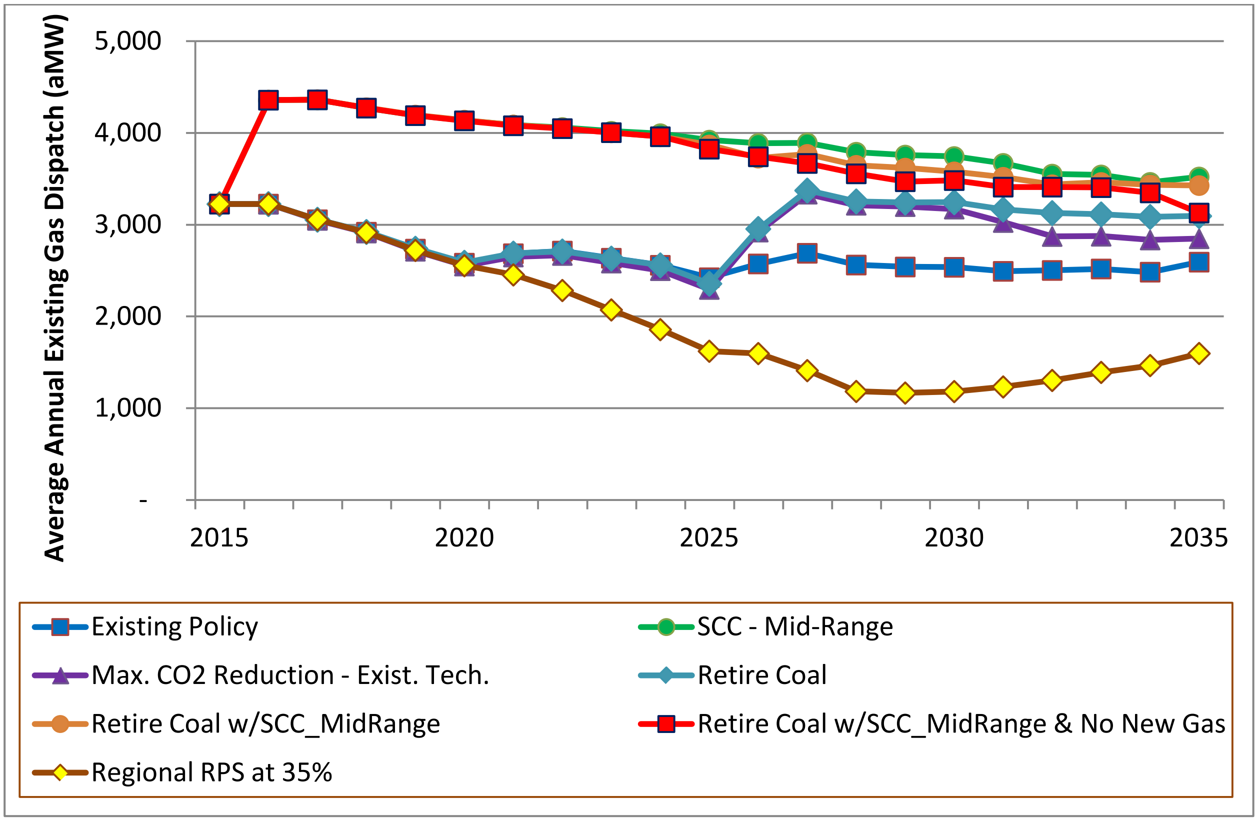
Figure 3 - 11: Average New Natural Gas-Fired Resource Development



Third, the increased use of the *existing* natural gas generation in the region plays a major role in many of scenario's least cost resource strategies, particularly those that explored alternative carbon dioxide emissions reduction policies. Figure 3 - 12 shows the average annual dispatch of the existing natural gas generation in the region through time for the six carbon dioxide reduction policy scenarios as well as the **Existing Policy** scenario. A review of Figure 3 - 12 reveals that the annual dispatch of existing natural gas generating resources increases in response to carbon dioxide emission reduction policies.

For example, under the three scenarios that assume the mid-range estimate of the social cost of carbon is imposed beginning in 2016, existing natural gas generation increases immediately following the imposition of carbon dioxide damage cost. In the three scenarios that assume all of the region's existing coal plants are retired in 2025, existing gas generation increases post-2025 when the entire region's existing coal-fired generation fleet is retired. Under the **Regional RPS at 35%** scenario, existing natural gas generation actually declines through time as low variable cost resources are added to the system, generally lowering market prices and diminishing the economics of gas dispatch.

Figure 3 - 12: Average Annual Dispatch of Existing Natural Gas-Fired Resources



Renewable Generation

Since the adoption of the Sixth Power Plan renewable generating resources development has increased significantly. This development was prompted by Renewable Portfolio Standards (RPS) adopted in three of the four Northwest states and in California. Wind energy has been the principal focus of renewable resource development in the Pacific Northwest. From 2010 through 2014 about 4,100 megawatts of wind nameplate capacity was added to the region, with 2,000 megawatts coming online in 2012 alone. By the end of 2014, wind nameplate capacity in the region totaled just over 8,700 megawatts. However, only about 5,550 megawatts of that nameplate capacity currently serves Northwest loads. The remaining 3,150 megawatts of wind nameplate capacity is presently contracted to utilities outside the region, primarily California.

Existing wind resources are estimated to provide about 2,400 average megawatts of energy generation per year in the region, or about 8 percent of the region’s electricity energy supply. However, on a firm capacity basis, existing wind resources only provide about 1 percent of the region’s total system peaking capability.[15]

[15] See Chapter 11 for the analysis of the ability of new wind resources to provide peak capacity.

Aside from hydropower, the renewable resources evaluated in the Regional Portfolio Model (RPM) are wind, utility scale and distributed solar photovoltaic (solar PV) and conventional geothermal.[16] The Council recognizes that additional small-scale renewable resources are likely available and cost-effective. These small-scale renewables were not modeled in the RPM but the plan encourages their development as an important element of the resource strategy. In addition, there are many potential renewable resources not captured in the resource strategy that are currently either too expensive or unproven technologies that may, with additional research and demonstration, prove to be valuable future resources.

New wind resources that have ready access to transmission produce energy at costs that are competitive on an energy basis with other generation alternatives. Recent and forecast reductions in solar PV system cost are making utility scale PV system's energy production cost increasingly cost-competitive. Even though conventional geothermal resources are currently estimated to have the lowest cost of all renewable resources in the region, only limited development of these resources has occurred, largely due of their exploration risk.

Despite the increasingly competitive cost per megawatt-hour of these renewable resources, renewable generation development in the scenarios tested for the Seventh Power Plan is driven by state renewable portfolio standards (RPS) and not economics. This is because in most of the futures tested in the RPM the region is short on peaking capacity and has surplus energy. Consequently, resource selection is based more on the each resource's cost per megawatt of peak capacity and less on its cost per megawatt-hour of energy output. Since, with the exception of geothermal resources, renewable resources have a very high cost per peak megawatt, the vast majority of renewable resource development in scenarios tested is in response to existing state mandates (RPS).

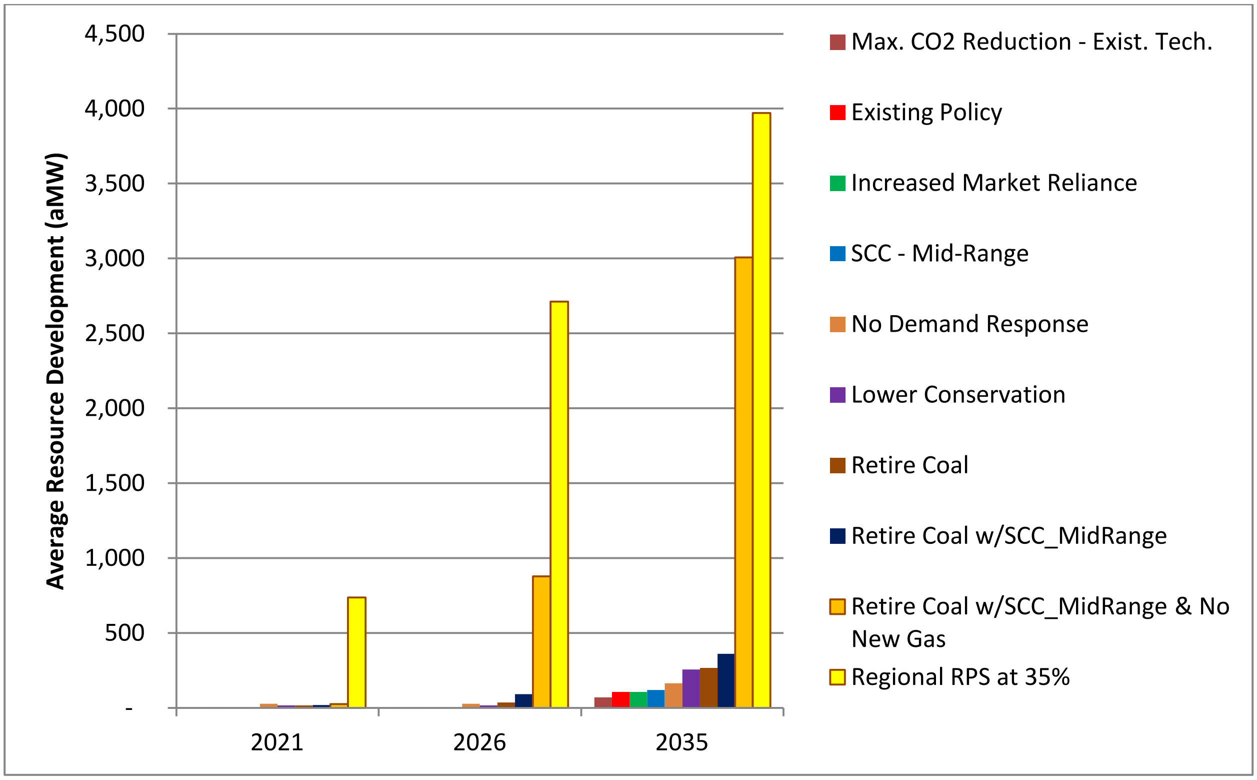
The amount of renewable energy acquired depends on the future demand for electricity because state requirements specify percentages of retail sales that have to be met with qualifying renewable sources of energy. Figure 3 - 13 shows the average development of renewable resources across scenarios analyzed for the Seventh Power Plan. As can be seen from this figure, under all least cost resource strategies for all scenarios, except in the **Regional Renewable Resource Standards at 35%** and **Retire Coal with SCC-MidRange & No New Gas** scenarios, less than 400 average megawatts of renewable resource development occurs, and then only later in the planning period (post-2026) after the Oregon and Washington renewable credit bank balances are forecast to be drawn down. Even in the **Social Cost of Carbon-MidRange** scenario where carbon damage cost of between $40 and $60 per metric ton are imposed, the amount of wind, solar PV and conventional geothermal resources developed on average is only about 120 average megawatts.

The significant development of renewable resources in the **Regional Renewable Resource Standards at 35%** scenario occurs because they would be required by law, while their development in the **Retire Coal with SCC-MidRange & No New Gas** scenario is because they are the only

[16] Distributed solar PV systems are evaluated in three scenarios, Retire Coal w/SCC MidRange, Retire Coal w/SCC MidRange and the Maximum Carbon Reduction – Emerging Technology. Distributed solar PV systems are also assumed to be installed in the baseline frozen efficiency forecast. See Chapter 7 and Appendix E for a more complete discussion.

resource option assumed to be available to replace retiring coal generation and meet future load growth.

Figure 3 - 13: Average Renewable Resource Development by Scenarios by 2021, 2026 and 2035



The explanation for the outcome described above is that while the two widely available renewable resources in the region, wind and solar PV, produce significant amounts of energy, they provide little or only modest peaking capacity. Partly as a result of the significant wind development in the region over the past decade, the Northwest has a significant energy surplus, yet under critical water and extreme weather conditions the region faces the probability of a peak capacity shortfall. In short, the generation characteristics of the currently economically competitive renewable resources do not align well with regional power system needs.

The Council's current analysis of wind, solar PV and geothermal resources ability to supply peaking capacity accounts for the ability of the region's existing power system to store energy as fuel or water when renewable resource generation is available for later use to meet peak demands. The contribution to peak of all resources, including renewable resources, modeled in the RPM were determined by comparing how much nameplate capacity must be added to the system to reduce capacity shortfalls by specific predetermined amounts. The peak capacity contribution of wind and solar resources is based on hourly modeling of their output against hourly system loads and takes into account their interaction with the region's existing power system.[17]

This analysis found that wind can only be relied upon to provide between 3 to 11 percent of its nameplate capacity (depending on the season of the year) toward meeting peak loads due to the variable nature of the resource. This means that, for example, a 100 megawatt wind farm can only be relied upon to provide 3 megawatts of peak capacity during the winter quarter.[18] Solar PV resources contribute more to meeting peaking needs, ranging from a low of 26 percent of nameplate capacity in the winter months to a high of just over 80 percent of nameplate capacity in the summer. Conventional geothermal resources are assumed to be able to provide peaking capability similar to gas generation across the year, but this resource has a much longer development lead time, high development risk and is more limited in supply.

As stated above, the development of renewable generation is driven by state renewable portfolio standards more so than regional energy need. Based on the analysis for the Seventh Power Plan, in the absence of higher renewable portfolio standards or limitations on the development of new natural gas generation little additional renewable development would take place, even under scenarios where a very high estimate of the social cost of carbon dioxide is imposed on the power system raising the cost of gas and coal generation.

Carbon Policies and Methane Emissions

The Northwest power system, due to its significant reliance on hydropower and its historical deployment of energy efficiency to offset the need for new thermal generation, has the lowest carbon emissions level of any area of the country. The Seventh Power Plan supports policies that cost-effectively achieve state and federal carbon dioxide emission reduction goals while maintaining regional power system adequacy. The plan calls upon the region to aggressively develop the energy-efficiency resources. In addition, the plan recommends replacing retiring coal plants with only those resources required to meet regional capacity and energy adequacy requirements. As stated above, after energy efficiency, the increased use of existing natural gas generation offers the lowest cost option for reducing regional carbon emissions. Utility development of new gas-fired generation to meet local needs for ancillary services, such as wind integration, or capacity requirements beyond the modest levels anticipated in this plan will increase carbon dioxide emissions. If Northwest electricity generation is dispatched first to meet regional adequacy standards for energy and capacity rather than to serve external markets, the increase in carbon dioxide emissions can be minimized.

As noted above, a central element in transitioning the Northwest power system to an even lower carbon footprint involves the increased use of natural gas, which consists primarily of methane.

---

[17] See Chapter 11 for a more complete description of the derivation of the peak contribution of renewable and other resources modeled in the RPM.

[18] Winter quarter as modeled in the RPM includes January through March.

While burning natural gas produces significantly less carbon dioxide emissions per unit of electricity generation than coal, its production and distribution release methane into the atmosphere. Methane is a highly active greenhouse gas, with a global warming potential 28 to 36 times that of carbon dioxide.[19] Recent studies have indicated that fugitive emissions of methane from some natural gas production areas and existing gas pipelines could be as high as 10 percent. In contrast, fugitive methane emissions from new production facilities and pipelines have been shown to be far lower, on the order of one percent. In developing the resource strategy for the Seventh Power Plan the Council seriously considered whether the carbon dioxide reduction benefits of the increased use of natural gas would be significantly offset by increases in methane emissions.

Although there is no debate about methane global warming potential, there is considerable uncertainty around such issues as whether its impacts compared to carbon dioxide are over or under-stated, whether its increased use results in a proportional increase in fugitive emissions, whether accounting for the methane emissions from coal production would also raise that fuel's full life-cycle climate impacts and whether the cost of reducing methane emissions would significantly alter the price of natural gas. With respect to the last issue, even with the uncertainty surrounding the anticipated impact of regulations to reduce methane emissions in production and distribution, the best information available to the Council indicates that these emissions can be reduced to what is viewed by scientists as an acceptable level at a cost that leaves the price of natural gas well within the range of the natural gas prices assumed for the Seventh Plan's development.[20]

The Council also observed that increasing the region's use of existing gas generation or relying more on new gas generation, will likely draw on gas production from new wells which have lower fugitive emissions than the old fields/wells that appear to be the primary source of methane emissions. Moreover, pipeline leaks are a not significantly driven by throughput, they are primarily a function of a pipeline's total capacity which is fixed within a range of operating pressures. Therefore, unless new pipeline capacity is needed, fugitive emissions from pipeline leaks remain relatively constant. Consequently, existing gas generation can be supplied with existing pipeline capacity, so only new gas generation that requires additional pipeline capacity produces incrementally more methane emissions.

The Seventh Power Plan's overall resource strategy seeks to minimize the need to develop new gas generation by meeting most future energy and capacity needs with energy efficiency and demand response. Successful implementation of this strategy provides time to take actions to reduce current fugitive methane emissions and minimize new methane emissions, so that the use of natural gas does produce a reduction in climate change impacts.

The basis for the Seventh Power Plan's carbon dioxide policy recommendations are more fully described in the Carbon Dioxide Emissions section of this chapter.

---

[19] See Appendix I for a more complete description of methane's potential environmental impacts and the uncertainties surrounding fugitive emission sources and levels.

[20] See Chapter 13 for a discussion of the potential impacts on natural gas prices from regulations designed to reduce methane emissions at new production facilities.

Regional Resource Utilization

The existing Northwest power system is a significant asset for the region. The FCRPS (Federal Columbia River Power System) provides low-cost and carbon dioxide-free energy, capacity, and flexibility. The network of transmission constructed by Bonneville and the region's utilities has supported a highly integrated regional power system. The Council's Seventh Power Plan resource strategy assumes that ongoing efforts to improve system scheduling and operating procedures across the region's balancing authorities will, in some form, succeed.

While the Council does not directly model the sub-hourly operation of the region's power system, both the Regional Portfolio Model and the GENESYS models presume resources located anywhere in the region can provide energy and capacity services to any other location in the region, within the limits of existing transmission. This simplifying assumption also minimizes the need for new resources needed for integration of variable energy resource production. To the extent that actual systems can be developed that replicate the model's assumptions, fewer new resources will be required. This likely means the region needs to invest in its transmission grid to improve market access for utilities, to facilitate development of more diverse cost-effective renewable generation and to provide a more liquid regional market for ancillary services.

Along with reducing physical and technical barriers, there are more efficient ways to dispatch and use existing regional resources that could minimize the need for new resource development. The analyses conducted for the Seventh Power Plan reveal in particular that the region could benefit from a different approach to using existing generation so as to keep more of that generation in the region serving load under longer-term arrangements.

The least cost resource strategies identified by the RPM often reduce regional exports in order to serve in-region demands for energy and capacity. That is, since the RPM treats the region as a single system, any resources that are available within the region to meet regional adequacy standards for energy and capacity are allocated to that purpose.[21] For example, in scenarios that retired or significantly reduced the dispatch of existing coal-fired generation serving the region, the vast majority of which serves investor-owned utilities, the RPM reduces regional exports in order to maintain resource adequacy. The RPM does not differentiate between investor-owned, publicly owned and Bonneville's generation when it balances regional loads and resources. The resource strategies that satisfied regional adequacy standards by inter-regional transfers resulted in lower total system cost and lower system economic risk because they delayed or avoided the need for new resource development within the region. Figure 3 - 14 shows the average net (i.e., exports minus imports) exports for their least cost resource strategies across these five scenarios.

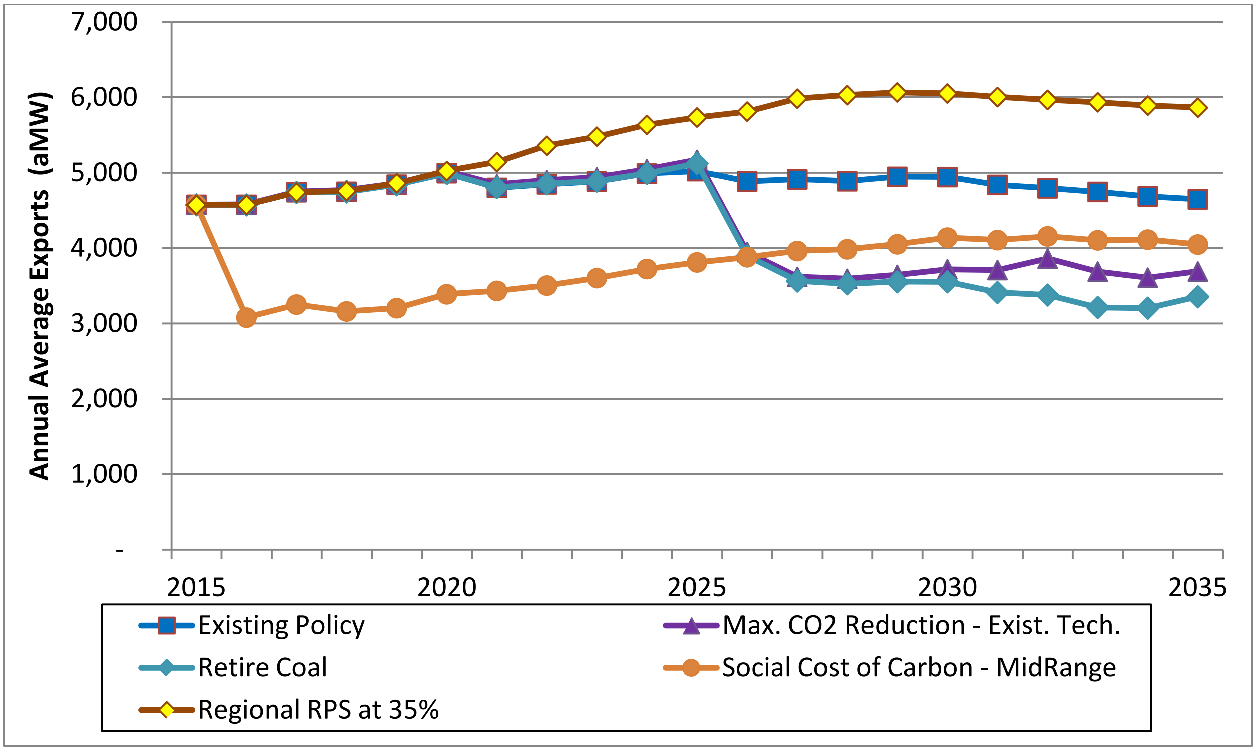
Inspection of Figure 3 - 14 reveals how net exports change across time in response to the resource strategy for each scenario. For example, under the **Existing Policy** scenario exports grow slowly until 2021 then decline slightly after 2021 and 2025 following the closure of coal plants currently

[21] See Chapter 11 for a more complete discussion of the Council's resource adequacy assessment.

serving the region. After 2030, under this same scenario, net exports continue to gradually decline as loads grow and conservation no longer offsets load growth.

In contrast, under the **Social Cost of Carbon - MidRange** scenario which assumes that carbon dioxide damage costs are imposed in 2016, net exports decline immediately. This reduction in exports offsets the reduction in regional coal plant dispatch in response to increased carbon dioxide costs. In the following years, exports gradually increase as highly efficient gas-fired generation developed in the region displaces less efficient generation outside the region. In the two scenarios shown in Figure 3-14 that assume all of the region's existing coal plants are retired by 2025, net

Figure 3 - 14: Average Annual Net Regional Exports for Least Cost Resource Strategies



exports drop immediately following their assumed closure and remain lower for the remainder of the planning period. At the other extreme, under the **Regional RPS at 35%** scenario, regional net exports expand significantly over time as the region develops large amounts of additional renewable resources. These resources have very low variable cost, which makes them competitive outside the region *and* they produce energy that is surplus to regional needs during many months of the year.

The Council's analysis shows that the total cost to the region would be lower if more effective use of surplus power available from Bonneville and some of the region's utilities could be used in-region to offset the need that other utilities have to develop new generation to meet resource adequacy standards. The Council recognizes that significant equity, risk, institutional and legal issues must be overcome to effect such a change. For example, Bonneville and other utilities in the region that control hydropower generation often, but not always, generate substantial surplus power above critical water conditions. Most of that surplus is sold into short-term markets, much of it leaving the region. The Council's analysis indicates that the region would benefit if, instead, some significant portion of this surplus hydropower generation could be sold to other utilities in the region under longer-term contracts to meet regional firm power needs. In order for this to happen, however, either the sellers or the buyers, or both, would have to take on some additional risk since the surplus generation would not always be available due to poor water conditions. As a result the power price for such contracts would need to somehow reflect additional risk.

The region needs to be creative in crafting new power sales arrangements that address in an appropriate and equitable way the issues of risk inherent in any scheme to rely on this surplus generation to help meet regional adequacy standards. However, the Council encourages the region to find ways to overcome these barriers since the benefit to the region could be substantial.[22]

Develop Long-Term Resource Alternatives

The seventh element of the Council's resource strategy recognizes that technologies will evolve significantly over the 20 years of the Seventh Power Plan. When the Council next develops a power plan, the cost-effective, available and reliable resources will most likely be different from those considered in the Seventh Power Plan. But the Seventh Power Plan identifies areas where progress is likely to be valuable and includes actions to explore and develop such resources and technologies. In many instances entities in the region can influence the development of technology and the pace of adoption.

Areas of focus in the long-term resource strategy include additional efficiency opportunities and the ability to acquire them, energy-storage technologies to provide capacity and flexibility, development of smart-grid technologies, expansion of demand response capability, and tracking and supporting the development of no-carbon dioxide or low-carbon dioxide emitting generation. The latter includes renewable technologies such as enhanced geothermal and wave energy and small modular nuclear generation.

Research, development, and demonstration of these technologies are an important part of the Council's resource strategy. Tracking these developments, as well as plan implementation and assumptions such as resource availability, cost and load growth, will identify needed changes in the power plan and near-term actions. These elements of the resource strategy are addressed primarily in the action plan.

[22] Absent such an outcome, the trend over the past decade that shows the average revenue per kilowatt-hour for residential customers of investor-owned utilities increasing while the average revenue per kilowatt-hour for residential customers of public utilities has remained nearly flat will likely continue. Between 2005 and 2014, the average revenue per kilowatt-hour sold by IOUs increased from 7.7 cents to 9.9 cents, while the average revenue per kilowatt-hour sold for public utilities remained barely changed, increasing from 7.7 cents to 8.0 cents per kilowatt-hour. Similar trends have occurred for commercial and industrial customers.

Adaptive Management

The eighth element of the Council's resource strategy is to adaptively manage its implementation. The Council's planning process is based on the principle that "there are no facts about the future." The Council tests thousands of resource strategies across 800 different futures to identify the elements of these strategies that are the most successful (i.e., have lower cost and economic risk) over the widest range of future conditions. This means that during the period covered by the Seventh Power Plan's Action Plan, actual conditions must deviate significantly from the conditions tested in the 800 futures explored in the Regional Portfolio Model before the basic assumptions and action items in the Seventh Power Plan are called into question.

However, the fact that a wide range of strategies were tested against a large number of potential future conditions in developing the Plan does not mean that *all* near term actions called for in the Seventh Power Plan will be perfectly aligned with the actual future the region experiences. Therefore, the Council will annually assess the adequacy of the regional power system to identify conditions that could lead to power shortages. Through this process, the Council will be able to identify whether actual conditions depart so significantly from planning assumptions as to require adjustments to the action plan.

The Council will also conduct a mid-term assessment to review plan implementation and compare progress against specific metrics. This includes assessing how successful plan implementation has been at reducing and meeting Bonneville's obligations, both the power sales contracts and the assistance the plan's resource scheme provides in the successful implementation of the Council's Columbia River Basin Fish and Wildlife Program.

CARBON DIOXIDE EMISSIONS

As in the Sixth Plan, one of the key issues identified for the Seventh Power Plan is climate-change policy and the potential effects of proposed carbon dioxide regulatory policies. In addition, the Council was asked to address what changes would need to be made to the power system to reach a specific carbon dioxide reduction goal and what those changes would cost. This section also summarizes how alternative resources strategies compare with respect to their cost and ability to meet carbon dioxide emissions limits established by the Environmental Protection Agency (EPA).

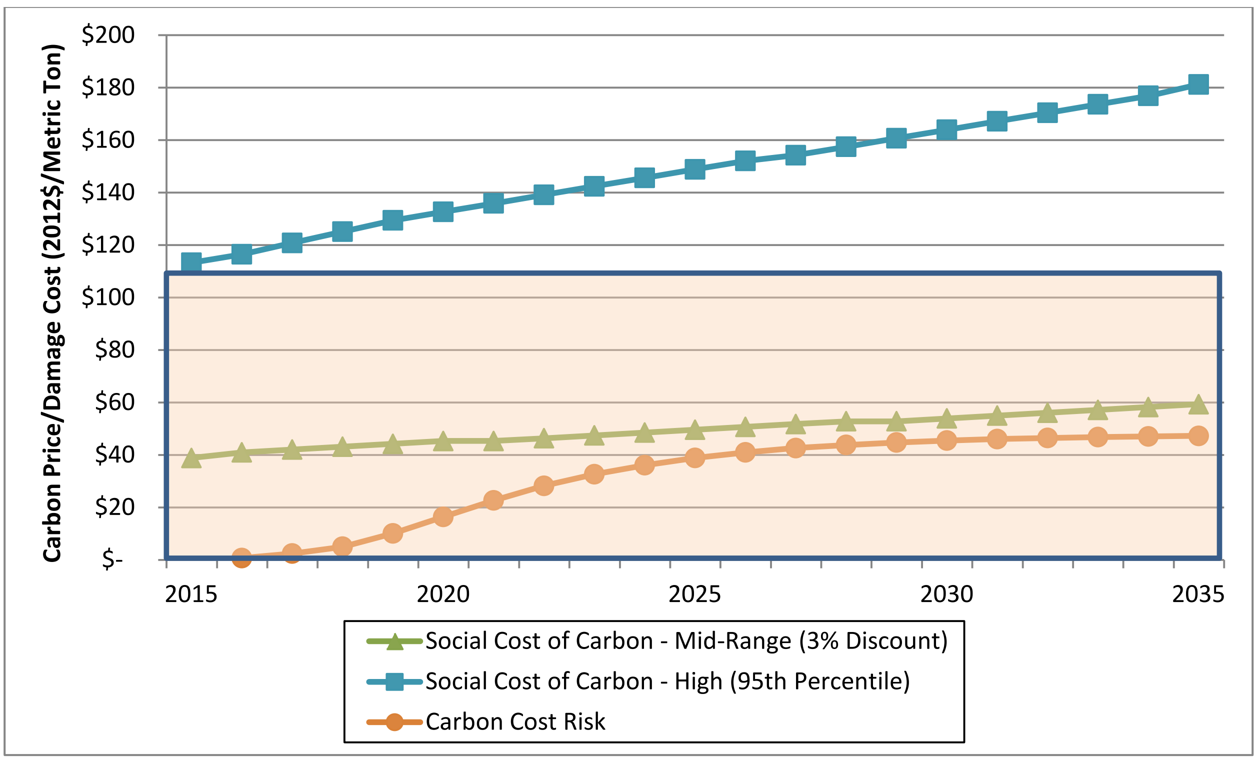
In providing analysis of carbon dioxide emissions and the specific cost of attaining carbon dioxide emissions limits, the Council is not taking a position on future climate-change policy. Nor is it taking a position on how individual Northwest states or the region should comply with EPA's carbon dioxide emissions regulations. The Council's analysis is intended to provide useful information to policy-makers. Chapter 15 discusses the results of the Council's analysis of alternative carbon dioxide emissions reduction policy scenarios in more detail.

Three "carbon dioxide pricing" policy options were tested. Two scenarios assumed that alternate values of the federal government's estimates for damage caused to society by climate change due to carbon dioxide emissions, referred to as the "social cost of carbon," are imposed beginning in 2016. The policy basis for these scenarios is that the cost of resource strategies developed under conditions which fully internalized the damage cost from carbon dioxide emissions would be the maximum society should invest to avoid such damage.

The third carbon dioxide pricing policy tested, **Carbon Cost Risk** is identical to the scenario analyzed in the Sixth Plan. This scenario exposes the power system to random changes in carbon dioxide pricing each year over the 20 year planning period. This scenario was designed to reflect the uncertainty regarding future carbon dioxide regulation. In this scenario, carbon dioxide pricing, reflecting differing levels of carbon dioxide regulatory costs, between $0 and $110 per metric ton were imposed randomly, but with increasing probability and at higher levels through time.

Figure 3 - 15 shows the two US Government Interagency Working Group's estimates used for the **SCC - MidRange** and **SCC-High** scenarios and the range (shaded area) and average carbon dioxide prices across all futures that were evaluated in the $0-to-$110-per-metric ton **Carbon Cost Risk** scenario.

Figure 3 - 15: Carbon Dioxide Regulatory Cost or Price and Societal Cost of Carbon Tested in Scenario Analysis



Four other carbon dioxide emission reduction policies were tested that did not involve using carbon dioxide pricing. The first of these, the **Maximum Carbon Reduction** - **Existing Technology** scenario was designed to reduce carbon dioxide emissions by deploying all currently available and economically viable technology. The second, the **Maximum Carbon Reduction** - **Emerging Technology** scenario was designed to reduce carbon dioxide emissions by deploying technology that may become commercially available and economically viable over the next 20 years. Under both of these scenarios all existing coal plants serving the region were assumed to be retired by 2026. In addition, all existing natural gas plants with heat-rates (a measure of efficiency) above 8,500 BTU/kilowatt-hour were retired by 2030. Also, in the **Maximum Carbon Reduction –**

Emerging Technology scenario, no new natural gas-fired generation was considered for development.

The **Maximum Carbon Reduction – Emerging Technology** scenario was designed to assess the magnitude of potential additional carbon dioxide emission reductions that might be feasible by 2035. As stated above, the Council created this resource strategy based on energy-efficiency resources and non-carbon dioxide emitting generating resource alternatives that might become commercially viable over the next 20 years. While the Regional Portfolio Model (RPM) was used to develop the amount, timing and mix of resources in this resource strategy, no economic constraints were taken into account. That is, the RPM was simply used to create a mix of resources that could meet forecast energy and capacity needs, but it made no attempt to minimize the cost to do so. The reason the RPM's economic optimization logic was not used is that the future cost and resource characteristics of many of the emerging technologies included in this scenario are highly speculative. This scenario was not updated for the draft plan. However, draft plan's results for this scenario are Appendix O, along with a more detailed discussion of the emerging technologies considered in this scenario.

The third "non-price" carbon reduction policy tested, **Retire Coal**, is a variation on the two **Maximum Carbon Reduction** scenarios. Under this scenario, only the region's existing coal generation is retired while existing gas generation remains available for deployment.

The fourth "non-price" carbon dioxide emission reduction policy option tested was the **Regional RPS at 35%** scenario. Under this scenario, the region's reliance on carbon dioxide-free generation was increased by assuming that the region would satisfy a region wide Renewable Portfolio Standard requiring 35 percent of the region's retail sales of electricity are met with such resources by 2030.

The Council also tested two other scenarios that combined both pricing and non-pricing strategies to assess their collective impact. The **Coal Retirement with the Social Cost of Carbon** scenario was designed to test whether the addition of carbon cost would alter the resources selected to replace retired coal plants. The **Coal Retirement with the Social Cost of Carbon & No New Gas** scenario was designed to assess the emissions reduction benefits and cost of restricting coal replacement resources to renewables.

In order to compare the cost of resource strategies that reflect both "carbon-pricing" and "non-carbon pricing" policy options for reducing carbon dioxide emissions it is useful to separate their cost into two components. The first is the direct cost of the resource strategy. That is, the actual the cost of building and operating a resource strategy that reduces carbon dioxide emissions. The second component is the revenue collected through the imposition of carbon taxes, through a cap and trade system or pricing carbon damage cost into resource development decisions. This second cost component, either in whole or in part, may or may not be paid directly by electricity consumers. For example, the "social cost of carbon" represents the estimated economic damage of carbon dioxide emissions worldwide. In contrast to the direct cost of a resource strategy which will directly affect the cost of electricity, these "damage costs" are borne by all of society, not just Northwest electricity consumers. In the discussion that follows, only the direct cost (i.e., costs net of carbon revenues) of resource strategies are reported.

Table 3 - 1 shows the average net present value system cost for the least cost resource strategy and average carbon dioxide emissions across all 800 futures for the year 2035 for the seven

scenarios and sensitivity studies conducted to specifically evaluate carbon dioxide emissions reductions policies (and economic risks) for the development of the Seventh Power Plan. [23] Scenarios are listed based on their average level of carbon dioxide emissions in 2035, which the highest emission scenario at the top of the table. Table 3- 1 also shows this same information for the **Existing Policy** and **Lower Conservation** scenarios which were not designed to reduce carbon emissions. As a point of comparison, the carbon dioxide emissions from the generation serving the Northwest loads averaged approximately 54 million metric tons per year from 2001 through 2014.

Table 3 - 1: Average System Costs Excluding Carbon Revenues and PNW Power System Carbon Dioxide Emissions by Scenario

Scenario	System Cost w/o Carbon Dioxide Revenues (billion 2012$)	2035 PNW Carbon Dioxide Emissions (MMT)
Lower Conservation	$ 97	41
Increased Market Reliance	$ 76	37
No Demand Response	$ 86	37
Existing Policy	$ 82	36
Regional RPS at 35%	$ 128	26
SCC - Mid-Range	$ 78	21
Retire Coal w/SCC_MidRange	$ 91	18
Max. CO2 Reduction - Exist. Tech.	$ 117	16
Retire Coal	$ 98	16
Retire Coal w/SCC_MidRange & No New Gas	$ 126	10

Table 3 - 1 shows the **Existing Policy** scenario which assumed no additional carbon dioxide emissions reductions policies beyond those in place prior to the issuance of the Environmental Protection Agency's Clean Air Act 111(b) and 111(d) regulations results in carbon dioxide emissions in 2035 of 36 million metric tons. The direct cost of this resource strategy is $82 billion (2012$). The **Regional RPS at 35%** scenario's least cost resource strategy reduces projected 2035 carbon dioxide emissions by about 10 million metric tons. However, this policy has a direct cost of $128 billion, or $46 billion above the **Existing Policy** scenario's resource strategy. Two scenarios, the **Retire Coal** and **Maximum Carbon Reduction - Existing Technology** scenarios produce equivalent carbon dioxide emissions in 2035 (16 MMTE), but the **Retire Coal** scenario has a $19 billion lower average system cost. The only difference between these two scenarios is that the **Retire Coal** scenario does not retire inefficient natural gas plants, whereas **the Maximum Carbon –**

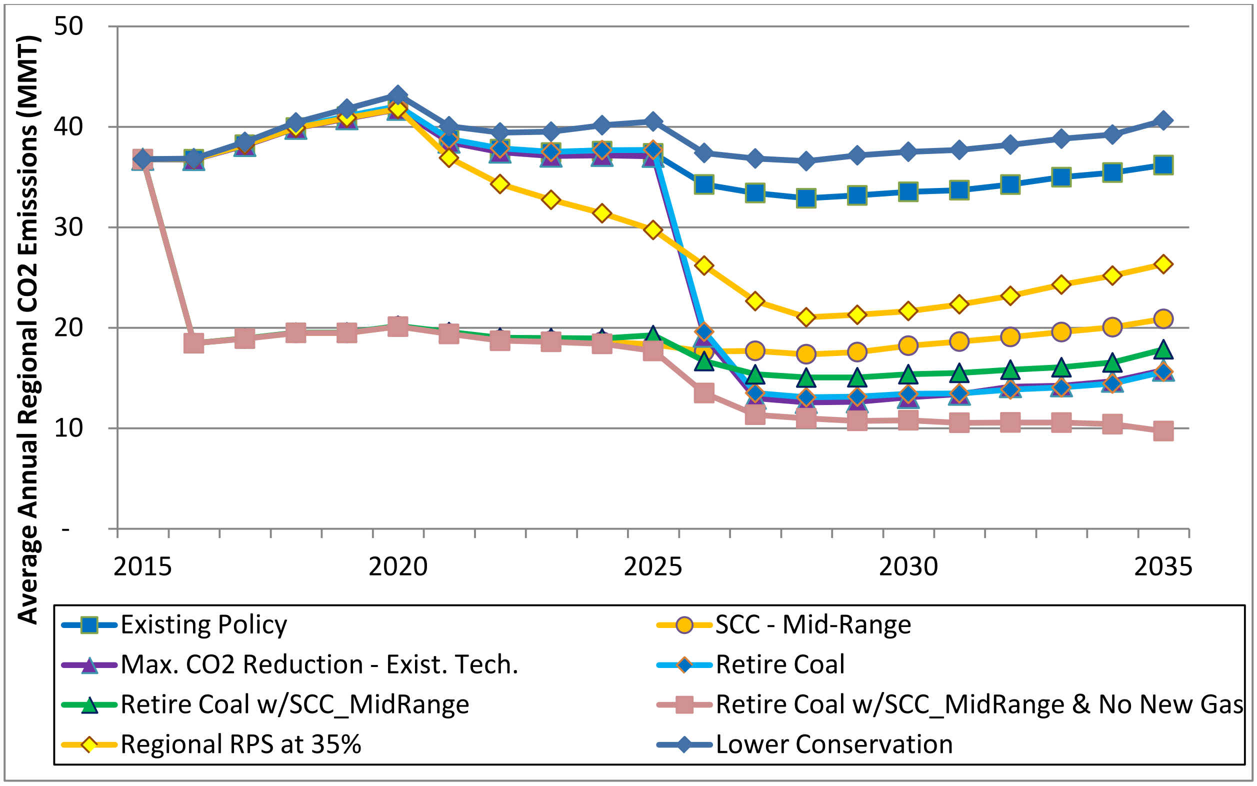
[23] The emissions forecast shown in Table 3-1 are slightly lower than anticipated actual regional emissions. This is because the Council's modeling assumes that all resources serving the region are economically dispatched as if operated by a single utility. In reality, both technical constraints and institutional barriers prohibit this optimized level of system integration from occurring. As a result, the most efficient thermal generator may not be used to serve load, even if it could have been dispatched to do so which understates the regional emissions.

Existing Technology scenario does. Thus, it appears that retaining existing natural gas plants, even relatively inefficient ones does not materially increase carbon dioxide emissions and avoids the cost of constructing new gas-fired replacement generation.

The average system cost for all of the carbon emission scenarios which impose a price on carbon emissions (**SCC-MidRange**, **Retire Coal w/SCC MidRange** and **Retire Coal w/SCC MidRange & No New Gas)** are affected by the interaction of the Northwest region with the rest of the western power market. For these scenarios it was assumed that the social cost of carbon was imposed throughout the west, not just in the region. As a result, the relative carbon dioxide content in the region compared to the rest of the western market plays an important role in determining whether the region imports or exports. For example, the **SCC MidRange** scenario, which reduces 2035 carbon dioxide emissions to 21 million metric tons or to about 15 million metric tons below that of the **Existing Policy** scenario has an average system cost that is $4 billion lower ($78 vs. $82 billion). This scenario's lower cost results from increased regional revenue from exports that reduce the cost of developing the scenario resource strategy. This scenario illustrates that the Northwest will likely have a competitive advantage if pricing policies are used throughout the western electricity market to reduce carbon dioxide emissions.

Comparing the results of these scenarios based on a single year's emissions can be misleading. Each of these policies alters the resource selection and regional power system operation over the course of the entire study period. Figure 3 - 16 shows the annual emissions level for each scenario. A review of Figure 3 - 16 reveals that the three scenarios that assume that the "mid-range" estimate of the social cost of carbon dioxide damage costs is imposed in 2016, immediately reduce carbon dioxide emissions and therefore have impacts throughout the entire twenty year period covered by the Seventh Power Plan. In contrast, the other three carbon dioxide reduction policies phase in over time, so there cumulative impacts are generally smaller.

Figure 3 - 16: Average Annual Carbon Dioxide Emissions by Carbon Reduction Policy Scenario



The **Regional RPS at 35%** scenarios gradually reduce emissions, while the **Retire Coal, Maximum Carbon Reduction – Existing Technology** and **Maximum Carbon Reduction - Emerging Technology** scenarios dramatically reduce emission as existing coal and inefficient gas plants are retired post-2025. The difference in timing results in large differences in the cumulative carbon dioxide emissions reductions for these policies. All scenarios show gradually increasing emissions beginning around 2028 as the amount of annual conservation development slows due to the completion of cost-effective and achievable retrofits. This lower level of conservation no longer offsets regional load growth, leading to the increased use of carbon dioxide emitting generation.

Table 3 - 2 shows cumulative emission reductions from 2016 through 2035 for each of the carbon dioxide reduction policy scenarios compared to the **Existing Policy** scenario. It also shows the average present value system cost per million metric ton of carbon dioxide reduction for these five carbon dioxide reduction policy options. Table 3-2 reveals that **SCC MidRange** scenario has negative cost per unit of carbon reduction. As discussed above, this lower present value system cost is a result of the increase in regional net revenues from electricity exports that occurs when carbon costs are imposed throughout the entire western electricity market. The cost per unit of carbon dioxide emission reduction for all the three scenarios that include imposing the social cost of carbon as one policy element are all lower as a consequence of this circumstance.

Table 3 - 2: Average Cumulative Emissions Reductions and Present Value Cost Excluding Carbon Revenues of Alternative Carbon Dioxide Emissions Reduction Policies Compared to Existing Policies - Scenario

CO2 Emissions - PNW System 2016 - 2035 (MMT)	Cumulative CO2 Emission Reduction Over Existing Policy - Scenario (MMT)	Incremental Present Value Average System Cost of Cumulative Emission Reduction Over Existing Policy - Scenario (2012$/MT)
SCC - Mid-Range	351	$ (11)
Existing Policy	-	-
Retire Coal w/SCC_MidRange	377	$ 23
Retire Coal	197	$ 78
Retire Coal w/SCC_MidRange & No New Gas	430	$ 100
Max. CO2 Reduction - Exist. Tech.	201	$ 170
Regional RPS at 35%	132	$ 349

The single policy option with the lowest cost per unit of carbon dioxide emission reduction shown in Table 3-2 is the **SCC-MidRange** scenario. This scenario reduces cumulative carbon dioxide emissions by 351 million metric tons between 2016 and 2035. The single policy option with the highest cost per ton of carbon dioxide reduction is the **Regional RPS at 35%** scenario. The high per unit cost of carbon dioxide emissions reduction from this scenario occurs because it does not result in the retirement or significantly reduce the use of existing coal plants. All of the other policy options tested either retire the region's existing coal plants, or dramatically reduce their dispatch as a result of the imposition of carbon pricing.

The next least expensive option combines two policies by adding a retire coal policy to the imposition of social cost of carbon policy, illustrated by the **Retire Coal w/SCC MidRange** scenario. This scenario reduces cumulative carbon dioxide emissions by another 26 million metric tons. Combining three policy options reduces emissions still further. This is illustrated by the **Retire Coal w/SCC-MidRange & No New Gas** scenario that restricts new resource development to renewable resources in addition to retiring coal plants and imposing the social cost of carbon. This scenario reduces cumulative carbon dioxide emissions by another 53 million metric tons at a cost of $100 per metric ton.

However, in order to judge the incremental costs and benefits of restricting new resource development to renewable resources it is useful to compare the difference in cumulative emissions and costs between the **Retire Coal w/SCC_MidRange** and the **Retire Coal w/SCC_MidRange & No New Gas** scenarios. From data in Tables 3-1 and 3-2 it can be determined that cumulative carbon dioxide emissions are reduced by 53 million metric tons and average system cost increase from $91 to $126 billion, or $35 billion. Thus, on an incremental basis the cost of these additional carbon dioxide emission reductions is $635 per metric ton. This illustrates the value of isolating the incremental impacts of each carbon reduction policy so that the most effective combinations can be identified.

It is important to note that in all scenarios than impose the social cost of carbon the coal plants serving the region dispatch infrequently following the imposition of carbon cost. This occurs because these plants are more expensive than existing natural gas generation once carbon cost are considered. As a result, such plants might be viewed by their owners as uneconomic to continue operation. If this is indeed the case, and these plants are retired, then the cost of replacement resources needed to meet the energy or capacity needs supplied by the retiring plants would add to the average present value system cost of this scenario. As a result, the actual cost of the **Social Cost of Carbon – MidRange** scenario would likely be higher and much closer to the **Retire Coal w/SCC-MidRange** scenario.

In the analysis discussed above, only the cost incurred during the planning period (i.e. 2016-2035) and the emissions reductions that occur during this same time frame are considered. Clearly, investments made to reduce carbon dioxide emissions will continue beyond 2035, as will their carbon dioxide emissions impacts. These “end-effects” could alter the perceived relative cost-efficiency of carbon dioxide reduction policy options shown in Table 3 - 2. For example, over a longer period of time the cumulative emissions reductions from the **Maximum Carbon Reduction – Existing Technology** scenario could exceed those from the **SCC-MidRange** scenario because by 2035 the **Maximum Carbon Reduction – Existing Technology** scenario results in 5 MMTE per year lower emissions. In this instance, if the difference in emissions rates for these two scenarios were to remain the same for an additional 30 years, then their cumulative emissions reductions over 50 years would be nearly identical. Since it is impossible to forecast these “end effects,” readers should consider the scenario modeling results shown in Table 3 - 2 as directional in nature, rather than precise forecast of either emissions reductions or the cost to achieve them.

The key findings from the Council’s assessment of the potential to reduce power system carbon dioxide emissions are:

- The retirement of all of the existing coal generation serving the region could reduce Northwest power system carbon dioxide emissions from a historical average of 54 million metric tons per year to about 16 million metric tons per year, or by nearly 70 percent. Achieving this level of carbon dioxide emission reduction is nearly $16 billion or nearly 20 percent above the cost of the least cost resource strategies that are anticipated to comply *at the regional* level with the newly established federal emissions limits.
- If all of the region’s existing coal plants are retired and replaced exclusively with renewable resources and all generation is dispatched to reflect a mid-range estimate of the social cost of carbon, regional power system carbon emissions could be reduced to 10 million metric tons per year by 2035, or 80 percent below historical levels. The cost of achieving this level of carbon emission reduction is $44 billion, or nearly 55 percent above the cost of the least cost resource strategies that are anticipated to comply *at the regional* level with the newly established federal emissions limits. The average cost of this scenario is significantly lowered by the expected increase in net power sales revenues from exports assuming a western or national power market imposition of a carbon cost.
- At present, it is not possible to entirely eliminate carbon dioxide emissions from the power system without the development and deployment of nuclear power and/or emerging technology for both energy efficiency and non-carbon dioxide emitting generation that require technological or cost breakthroughs.

- Deploying renewable resources to achieve maximum carbon reduction presents significant power system operational challenges, in particular by dramatically increasing the need for balancing and flexibility reserves.

- The most cost-effective carbon dioxide emissions reduction policies are those that result in the retirement or significantly reduce the use of existing coal plants. The single policy option for reducing carbon dioxide emissions with the lowest cost per unit of emission reduction imposes the equivalent of the federal government's mid-range estimate of the social cost of carbon throughout the entire Western electricity market. The single policy option for reducing carbon dioxide emissions with the highest cost per unit of emission reduction establishes a regional renewable portfolio standard at 35 percent. The high per unit cost of carbon dioxide emissions reduction from this policy occurs because it does not result in the retirement or significantly reduce the use of existing coal plants.

Federal Carbon Dioxide Emission Regulations

As the Seventh Power Plan was beginning, development the US Environmental Protection Agency (EPA) issued proposed rules that would limit the carbon dioxide emissions from new and existing power plants. Collectively, the proposed rules were referred to as the Clean Power Plan. In early August of 2015, after considering nearly four million public comments the EPA issued it final Clean Power Plan (CPP) rules. The "111(d) rule," referred to by the Section of the Clean Air Act under which EPA regulates carbon dioxide emissions for existing power plants, has a goal of reducing national power plant carbon dioxide emissions by 32 percent from 2005 levels by the year 2030. This is slightly more stringent than the draft rule which set an emission reduction target of 30 percent. [24] EPA also issued the final rule under the Clean Air Act section 111(b) for new power plants and the proposed federal plan and model rules that would combine the two emissions limits.

To ensure the 2030 emissions goals are met, the rule requires states begin reducing their emissions no later than 2022 which is the start of an eight year compliance period. During the compliance period, states need to achieve progressively increasing reductions in carbon dioxide emissions. The eight year interim compliance period is further broken down into three steps, 2022-2024, 2025-2027, and 2028-2029, each associated with its own interim goal.

Under the EPA's final rules, states may comply by reducing the average carbon dioxide emission rate (pounds of carbon dioxide/kilowatt-hour) emitted by all power generating facilities located in their state that are covered by the rule. In the alternative, states may also comply by limiting the total emissions (tons of carbon dioxide per year) from those plants. The former compliance option is referred as a "rate-based" path, while the latter compliance option is referred to as a "mass-based"

[24] U.S. Environmental Protection Agency, "Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64,662 (October 23, 2015). A coalition of states, utilities, utility organizations and others challenged the rule applying to existing sources in the federal D.C. Circuit Court of Appeals. The U.S. Supreme Court stayed the effectiveness of the rule in an order issued February 9, 2016, pending not just review on the merits by the court of appeals but also the resolution of any petition for further review in the Supreme Court following whatever decision is issued by the court of appeals. The litigation is ongoing as the Council completed the Seventh Power Plan.

path. Under the "mass-based" compliance option EPA has set forth two alternative limits on total carbon dioxide emissions. The first, and lower limit, includes only emissions from generating facilities either operating or under construction as of January 8, 2014. The second, and higher limit, includes emissions from both existing and new generating facilities, effectively combining the 111(b) and 111(d) regulations.

The Council determined that a comparison of the carbon dioxide emissions from alternative resource strategies should be based on the emissions from both existing and new facilities covered by the EPA's regulations. This approach not only better represents the total carbon dioxide footprint of the power system, but it more fully captures the benefits of using energy efficiency as an option for compliance because it reduces the need for new generation. Table 3 - 3 shows the final rule's emission limits for the four Northwest states for the "mass-based" compliance path, including both existing and new generation.

Table 3 - 3: Pacific Northwest States Clean Power Plan Final Rule Carbon Dioxide Emissions Limits[25]

Mass Based Goal (Existing) and New Source Complement (Million Metric Tons)					
Period	Idaho	Montana	Oregon	Washington	PNW
Interim Period 2022-29	1.49	11.99	8.25	11.08	32.8
2022 to 2024	1.51	12.68	8.45	11.48	34.1
2025 to 2027	1.48	11.80	8.18	10.95	32.4
2028 to 2029	1.48	11.23	8.06	10.67	31.4
2030 and Beyond	1.49	10.85	8.00	10.49	30.8

EPA's regulations do not cover all of the power plants used to serve Northwest consumers. Most notably, the Jim Bridger coal plants located in Wyoming serve the region, but are not physically located within the regional boundaries defined under the Northwest Power Act.[26] In addition, there are many smaller, non-utility owned plants that serve Northwest consumers located in the region, but which are not covered by EPA's 111(b) and 111(d) regulations. Therefore, in order for the Council to compare EPA's carbon dioxide emissions limits to those specifically covered by the agency's regulations, it was necessary to model a sub-set of plants in the region.

[25] Note: EPA's emissions limits are stated in the regulation in "short tons" (2000 lbs). In Table 3-2 and throughout this document, carbon dioxide emissions are measured in "metric tons" (2204.6 lbs) or million metric ton equivalent (MMT).
