7) The EPA received significant comment that 2012 was not a representative year for natural gas prices, and thus the EPA should use another year. The EPA disagrees with this comment, and does not view it as grounds for a change to the baseline period. While the EPA does recognize that Henry Hub natural gas prices were lower in 2012 relative to previous years, this does not invalidate the suitability of the data year selection. The EPA's objective in selecting a baseline is to identify potential reductions when BSER technologies are applied; year-to-year variation in market prices for natural gas does not frustrate this effort. For instance, a region may have generated only 5 MWh of NGCC generation in 2011 when gas prices were higher, and 10 MWh of NGCC generation in 2012 when gas prices dropped. However, this does not change the outcome of the quantification of the BSER, because the building block is based on the emission reduction *potential* of the fleet. That potential (e.g., a

fuller realization of the existing NGCC generation potential equivalent to 15 MWh) does not change regardless of the year used for baseline NGCC generation. Therefore, a different data year may change a baseline data point, but it would not change the total potential NGCC generation for quantifying the emission performance rates in these circumstances.

In summary, the EPA believes that continuing to rely on 2012 data while incorporating select data adjustments as detailed below is not only a reasonable choice and adequately supported, but a more reliable and preferable starting point for determining the BSER requirements.

3. Adjustments that the EPA made to the 2012 data

The EPA made corrections to unit-level 2012 data based on commenter feedback. In addition, we also made some adjustments to 2012 data, not to address a correction, but to address a concern about the representativeness of the data. Although the EPA determined that the 2012 data year better informed its BSER determination than a preceding year or a multi-year average, commenters did identify some limitations that we are addressing through targeted adjustments. These are discussed below:

1) Adjustments to state-level data to account for annual variation in the hydrologic cycle as it relates to fossil generation.

Hydropower plays a unique role in a handful of states in that 1) it is a significant portion of their generation portfolio, 2) it varies on an annual basis, and 3) 2012 was an outlier year for snow-pack (meaning hydropower was above and fossil generation was below its historical average).The EPA notes that these three conditions are not present in other weather-based RE technologies like solar or wind.[744] Therefore, no similar adjustment was needed to account for weather patterns with these technologies.

Unlike market conditions (e.g., changes in natural gas prices) that may produce different generation profiles year-to-year but that do not change the overall generating potential of the state’s power fleet, variation in the hydrologic cycle does fundamentally change the generating potential of the state’s power fleet in hydro-intensive states as they no longer have the same generating potential in an average year as they had in a “high hydro” year. The CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule provides analysis and explains the adjustment that the EPA made to the state-level 2012 data

[744] While solar and wind generation may vary on an hourly or daily basis, their annual generation profiles are subject to notably less variation compared to hydropower. The EPA’s calculation of the BSER relies on annual generation data, not on hourly or daily generation data.

for Idaho, Maine, Montana, Oregon, South Dakota, and Washington to better reflect fossil generation levels when hydro generation performed at its average level as observed over a 1990-2012 timeframe. The EPA agrees with commenters that using a 2010-2012 baseline would not address the concern as 2011 was also an outlier year relative to historical snow-pack and hydro generation.

2) Extended unit outages due to maintenance.

Generally, because of the regional-level approach to calculate performance rates, the EPA does not believe that unit-level variations in operation influence the subcategory-specific performance rates reflecting BSER. For instance, as some units ramp down, and others ramp up to replace their load at the regional level, total fossil generation changes little due to these fossil-for-fossil substitutions. Unit-level variation does not inherently entail region-wide variation.

However, the EPA did receive comment that in limited cases, this could have a substantial impact on an individual state if it chooses to use a rate-based or mass-based statewide goal. Even though the EPA is calculating subcategory-specific performance rates that it believes are not affected by this type of unit-level variation, it still evaluated the possible impacts it may have when converting to state goals in the next section. The EPA examined units nationwide with 2012 outages to determine where an individual unit-level outage might yield a significant difference in state goal computation. When applying this test to all of the units informing the computation of the BSER, emission performance rates, and statewide goals, the EPA determined that the only unit with a 2012 outage that 1) decreased its output relative to preceding and subsequent years by 75 percent or more (signifying an outage), and 2) could potentially impact the state's goal as it constituted more than 10 percent of the state's generation was the Sherburne County Unit 3 in Minnesota. The EPA therefore adjusted this state's baseline coal steam generation upwards to reflect a more representative year for the state in which this 900 MW unit operates.

3) Many commenters also noted that because the EPA uses annual data, 2012 was not representative for units coming online part way through the year. The EPA relies on annual data, so if a unit is underrepresented in a certain part of the year because it is not yet online, then another unit is likely over-represented as it is operating more than it otherwise would when the second unit commences operation. Therefore, the resulting state-level and regional-level aggregate annual generation level used in determining the

BSER may be considered to be representative and there is not necessarily a need for any adjustment.

However, the EPA recognizes that the over-represented and under-represented units do not necessarily fall within the same state, and therefore this potential difference in the state location of the affected units could have an impact when estimating appropriate statewide goals. To address this comment, the EPA adjusted the 2012 generation data for fossil units coming online during 2012 to a more representative annual operating level for that type of unit reflecting its incremental impact on generation and emissions. This effectively resulted in increased baseline emissions and generation assumed for those units beyond their reported partial-year operations in 2012.

Conceptually, the assumption of full-year operation at units that came online partway through 2012 could pair with an assumed reduction in the operation of other units somewhere in the same region. However, the EPA made no corresponding deduction to represent this likely decreased utilization at other affected units because it was impossible to project the state location of such units with certainty and the assumed utilization level was meant to reflect the incremental impact on the baseline. As a result, this data adjustment increases the total generation and emissions for units reporting in the 2012 baseline beyond the 2012 reported levels.

Additionally, as done in proposal, the EPA continued to identify under construction units that did not begin operation in 2012, but had commenced construction prior to January 8, 2014 and would commence operation sometime after 2012. As described in the next section, the EPA estimated baseline generation and emissions for these units as they had no 2012 reported data.

In summary, this final rule continues to rely on the latest reported 2012 data as the foundation for quantifying the BSER. However, the EPA has made limited adjustments, in addition to corrections identified by commenters, to the 2012 data to address some of the relevant concerns raised by commenters. Therefore, the baseline is informed by 2012 data, but not limited to 2012 data.[745]

4. Equations

In this section we describe how we develop the equations used to determine the emission performance rates for fossil steam and NGCC units that express and implement BSER. More

[745] Updated unit-level data reflecting corrections identified by commenters to the underlying 2012 file are provided in Appendix 1 of the CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule. The adjustments made to the aggregate data to address representativeness concerns are provided in Appendix 3.

detailed information regarding rate computation, including example calculations, can be found in the CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule, which is available in the docket for this action. Here we first present the general principles we follow when developing equations to express the BSER; then, we summarize the steps taken to assemble baseline data to reflect 2012 baseline emissions and generation, and apply the building blocks that constitute the BSER to derive performance rates that will be used by states to implement BSER. Section VII then explains how these nationwide performance rates are reconstituted into a statewide goal metric similar to the proposal in order to allow a state (at its discretion) to use a statewide goal as a mechanism for demonstrating compliance at the aggregate state level in a state plan, as an alternative to applying the emission performance rates to its affected EGUs directly.

When developing equations to implement BSER, we adhere to a number of basic principles. First, we ensure that the equations are consistent with the BSER itself, and in particular, reflect the redistribution of generation among fossil steam, NGCC and renewables embodied in building blocks 2 and 3. In doing this, we account for the interactions between building blocks in a way that is consistent with the assessment of incremental building block generation potential and the compliance framework for

Emission Reduction Credits (ERCs). In particular, we must ensure that each increment of building block 3 emission reduction potential is applied to either fossil steam or NGCC units but not both. The equations we develop must also take account of the dual status of existing NGCC units, which are simultaneously affected units and provide generation that is an element of the BSER itself.

In addition, we are applying the BSER, as we have done in calculating other section 111(d) standards, to a defined population of existing affected sources, represented in this case by the generation of the source category in the 2012 adjusted baseline. This provides an empirical historical baseline against which we define the performance rates and their state goal equivalents. In doing so, we must account for any offsetting increases in emissions that result from applying the BSER control measures, as we have done in setting other standards. For example, when determining BSER for particulate matter control, a number of pollution control devices (such as sorbent injection technologies) themselves create particulate matter. If the particulate matter created by these control devices were not appropriately accounted for when developing the standard intended to address the primary emissions of particulate, this could create an unreasonably stringent PM standard. In the current context, this means recognizing that increasing NGCC capacity utilization in accordance with building block 2 both offsets higher emitting steam generation and increases emissions at the NGCC units themselves, which are also affected entities that must demonstrate compliance with the BSER. Thus, it is essential that we apply the building blocks in a way that avoids creating a level of stringency in the performance standards for affected EGUs that goes beyond what we have determined to be the BSER – while at the same time ensuring that equations apply the building blocks to generate performance standards that represent the full application of the BSER to the affected EGUs.

Under section 111, the EPA adopts emission performance standards that are based on the BSER. The emission performance rates reflect our recognition of the value of giving sources the flexibility to adopt equivalent emissions reduction strategies and measures that for them may be preferable (in a specific circumstance) to the technologies and measures that we define as the BSER. An important function of the emission performance rates representing the BSER is to provide the flexibility needed to allow alternative compliance options, including the development of new technologies or the deployment of effective technologies outside of the BSER technologies. In the guidelines we issued under section 111(d) for landfill gas, for example, we adopted the primary standard based on flaring of any captured landfill gas, but we also developed equations that led to an expression of the BSER that allowed for the alternative of capturing the gas and combusting it in an electrical generating unit.

Finally, in deriving the emission performance rates, there are a number of considerations we took into account. First, it is important that the baseline from which the rates are derived be transparent and based on observable, historical data. Second, the emission performance rates must reflect the emission reductions achievable through the best system of emission reduction. Because the BSER includes shifting of emissions from higher-emitting to lower-emitting sources, state compliance frameworks will likely involve a combination of physical measures at the plant (where either rate or generation may be reduced) and some form of credit for lower-emitting generation (or demand side measures) outside of the plant. In this context, the emission performance rates must provide appropriate incentives for affected entities to achieve the emission reductions encompassed in the BSER, including through state plans that provide crediting for lower-emitting generation. Third, and as set forth below, we must account for the EPA’s determination that pro rata implementation of building block 3 is the best reflection of the potential for RE to displace both fossil steam and NGCC, and the dual role of NGCC units as both affected sources and a BSER compliance technology.

This set of considerations was central to the development of the BSER equations that the EPA describes next. They were particularly important for steps five through seven below which address building blocks 2 and 3, building blocks that have both significant overlap with each other and which impact steam and NGCC units in an integrated way.

Step-by-Step Discussion of Equations

Step one (compilation of baseline data). On a unit-level basis, the EPA obtained total annual quantities of CO_2 emissions, net generation (MWh), and capacity (MW) from reported 2012 data for likely affected EGUs that had commenced operation prior to 2012.[746] The EPA made changes to the historical unit-level data

[746] EGUs whose capacity or fossil fuel combustion were insufficient to qualify them as likely affected EGUs were not included in the subcategory-specific rate and goal computations. Most simple cycle combustion turbines (CTs) were excluded on this basis at proposal, and all simple cycle CTs were excluded at final reflecting changes to the applicability language. IGCC's were designated as "other" generation at proposal, but they are grouped with coal units for purposes the final rule category-specific rates. Useful thermal output (UTO) was also translated to a MWh equivalent and included in state goals at proposal, resulting in more stringent rates for states with more cogeneration sources, but UTO is not included in this final rule emission performance rate or state goal calculations as a result of comments regarding potentially adverse impacts on cogeneration units and uncertainty of thermal load outputs. As described in the state plan section of the preamble, units may still quantify and convert UTO (i.e., taking credit for waste

based on comments received at proposal. For each state and region, the agency aggregated the 2012 operating data for all coal-fired steam EGUs as one group, all oil- and gas-fired steam EGUs as a second group, and all NGCC units as a third group. The EPA adjusted these state values upwards in a limited number of instances to reflect the hydropower and unit outage concerns raised in comments and described above. As discussed above, the EPA first only aggregated the reported data for units that commenced operation prior to 2012. For those likely affected units that commenced operation during 2012, the EPA treated that capacity consistent with its framework for under construction affected units, which were added next. This was done in response to comments recognizing the fact that the year during which a unit commences operation may not have been representative of its potential generation and emissions.

For the under construction units (i.e., those under construction prior to January 8, 2014 but which had not commenced operation by December 31, 2011), the EPA estimated their incremental impact on the baseline generation and emissions using their capacity. The EPA assumed a 55 percent capacity factor for under construction NGCC units and a 60

---

heat capture) when demonstrating compliance. See the applicability criteria described in Section IV.D above.

percent capacity factor for under construction fossil steam units, which are consistent with the values and methodology the EPA proposed for under construction units.[747] These values are informed by the 2012 capacity factors for other units in these technology classes that recently commenced operation.[748] Using these capacity factors along with the capacity for the units, the EPA estimated an annual baseline generation value for these units. The agency then estimated annual baseline CO_2 emissions for these under construction units using the average emission rate of generating units of the same technology in the state where the under construction unit is located. Where no generators of the same technology existed in a given state, the

[747] The EPA notes that we did not identify any under construction coal units at proposal, but we are using a methodology in this final rule for newly categorized under construction coal units similar to our under construction assessment of NGCC at proposal.

[748] The EPA received comment on the assumed 55 percent capacity factor for under construction NGCC EGUs. Some comments suggested the value was too large of an estimation for incremental generation as some of that 55 percent utilization would have a replacement impact on 2012 operating generation. Others suggested it should be larger as a particular planned under construction unit was anticipated to have a higher utilization rate. The EPA reviewed operating patterns of EGUs that came online, and determined a 55 percent and 60 percent capacity factor assumption for under construction NGCC and coal EGUs respectively are a reasonable estimate for informing the incremental emissions and generation from under construction units. It recognizes that some of these units may indeed operate at a higher utilization level, but also recognizes that some of the generation may have a replacement effect instead of an incremental one.

EPA used the national baseline average for that technology. This is similar to the adjustment made at proposal for under construction units, with the main difference being units that commenced operation in 2012 are now also treated as under construction for baseline data purposes in the final rule.

The estimated emissions and generation for under construction units were added to the 2012 reported emissions and generation data for the affected units that had already commenced operation prior to 2012 to derive an adjusted historical baseline total for each state that was reflective of all likely affected 111(d) sources.[749]

Step two (aggregation to the regional level). The EPA took comment on applying building blocks at the regional level, and received significant comment supporting such an approach. Therefore, whereas the proposal aggregated the baseline data to the state level, the final rule further aggregated it to the regional level prior to building block application. The regions reflect the Eastern, Western, and Texas Interconnections. The shift to a regional framework was based on comments suggesting that the EPA would better capture the interstate impacts of the

---

[749] The EPA received some comments suggesting that under construction units should not be included in the quantification of BSER and/or rate calculations, and other comments supporting their inclusion. The EPA determined that including it was consistent with our responsibility under the 111(d) statute to define a Best System of Emission Reduction for existing units.

building blocks and reflect the interconnected nature of the electric grid under a regional structure. The basis for the regions is defined and discussed in Section V.A.3.

Step three (identification of source category baseline emission rates). As discussed in the beginning of this section, the EPA took a technology-specific approach to quantifying guidelines. Therefore, whereas the proposal first averaged the fossil steam rate and NGCC rate together before applying the building blocks and defining state goals, the final rule applied the building blocks at the regional level to give a separate fossil steam rate and NGCC rate for each region. The starting point for calculating the subcategory-specific emission performance rates was the baseline regional emission rates for both fossil steam and NGCC in the year 2012 with the modifications discussed above.

Step four (application of building block 1). The baseline CO_2 emissions amount for the coal-fired steam EGU fleet in each region was reduced by 2.1, 2.3, and 4.3 percent in the Western, Texas, and Eastern Interconnections respectively, while the coal generation level was held constant, reflecting the EPA's assessment of the average opportunities in each region to reduce CO_2 emission rates across the existing fleet of coal-fired steam EGUs through heat rate improvements that are technically achievable at a reasonable cost. The EPA then averaged together the region's baseline oil- and natural gas-fired steam rate with its building block 1 adjusted coal steam rate to get a fossil steam rate post-building block 1.[750,751]

Step five (application of building block 3). At proposal, the EPA incorporated incremental RE MWhs (where incremental means the amount above the adjusted 2012 baseline) by adding them to the denominator of the emission rate goal. In response to comments on this approach, the EPA issued a NODA discussing an alternative methodology of incorporating building block 3 in a manner more analogous to building block 2 treatment, where the incremental MWhs identified for the building block replace baseline fossil MWhs on a one-to-one basis. The EPA is adopting this replacement methodology for building block 3 in the final rule consistent with comments noting that such a computational procedure better reflects the reduction potential of that building block.

Under this methodology, all of building block 2 incremental NGCC potential and part of building block 3 incremental RE potential were ultimately applied to replace higher-emitting

[750] Building block 1 analysis acknowledges some variation in heat rate improvement potential at different units. The implementation of this building block reflects a heat rate improvement on average across a region's coal fleet, not necessarily a heat rate improvement at every unit.
[751] Baseline OG steam emissions are added to adjusted coal emissions and divided by baseline OG steam generation and baseline coal generation.

fossil steam generation and emissions, while the remaining building block 3 potential was applied to replace NGCC generation and emissions. Commenters noted that under this approach building block 3 should be applied first, or the EPA would understate the potential of building block 2 by subtracting out some NGCC generation after the 75 percent utilization level of NGCC had been applied to replace fossil steam. The EPA agrees and calculated the building block 3 impacts first in developing the emission performance rates.

To implement this, first, building block 3 replacement potential was identified for each region to arrive at a total amount of incremental zero-emitting generation hours available to replace fossil generation in the region. Because renewable generation can replace both fossil steam and NGCC on the grid, the EPA determined that it was appropriate to apply these incremental zero-emitting generation hours to replace generation and associated emissions from each of the fossil steam and NGCC fleets in the region on a pro-rata basis in the following manner.[752] The EPA determined the percent of fossil steam

[752] The EPA took comment on a pro-rata or an intensity-based replacement approach. In this final rule, the EPA agrees with commenters that a pro-rata approach is a better reflection of the BSER. Incremental RE generation has, and is likely to continue, to replace both steam and gas turbine generation and the BSER captures this through a pro-rata distribution of identified building block 3 potential.

generation and the percent of NGCC generation of total affected fossil generation in each region's baseline. We then assigned those percentages of the incremental zero-emitting MWhs to each of those technology source categories.[753] The incremental zero-emitting generation assigned to each technology replaced the same amount of fossil generation from that technology's baseline value.

Step six (application of building block 2). If the remaining generation level for the NGCC fleet in a region, taking into account the previous step's replacement of NGCC generation, was less than 75 percent of the fleet's potential summertime generating capacity (the potential capacity factor the EPA determined to represent the BSER), then the NGCC generation in the region was assumed to increase to levels equal to the lesser of 1) its potential at a 75 percent capacity factor[754] or 2) a generation level above which there is no longer fossil steam generation remaining within the same region to replace. In other words, the regional NGCC capacity factor was

---

[753] For example, if 100 MWh of incremental zero emitting generation is available in a given region and that region had 70 percent of its affected fossil generation coming from fossil steam units in the baseline and 30 percent from NGCC units – then 70 MWhs of the incremental zero-emitting generation are applied to baseline fossil steam generation and 30 MWhs are applied to baseline NGCC generation.

[754] In early years, will be less than 75 percent due to building block 2 gradual deployment.

only assumed to reach 75 percent if there was sufficient higher-emitting fossil steam generation that it could replace after step five. The increase in NGCC generation at this step compared to the post-building block 3 level was matched by an equal decrease in fossil steam generation reflecting the 1 for 1 MWh hour replacement. At this point, the generation for both steam and NGCC reflect the final distribution of generation between the subcategories after application of the building blocks. But the emission performance rates must account for CO_2 emissions and generation from incremental gas and renewable generation that comprise building blocks 2 and 3, to reflect and enable the emission reductions achievable under the best system of emission reduction, and ensure that the shared implementation of the BSER by steam and NGCC generation is reflected in the rates.

Step seven (accounting for and facilitating the emission reductions achievable through the implementation of the best system of emission reduction).

This step quantifies the aggregate emission changes associated with the emission rate improvement and generation replacement patterns described in steps four, five, and six to arrive at an adjusted fossil steam emission rate and an adjusted NGCC emission rate for each region that will, as discussed above, (1) enable the implementation of all three building blocks, (2) be based on observable, concrete baselines, and (3) reflect the BSER.

First, in developing the emission performance rates, the EPA had to answer the question of how to reflect the building blocks in the equations defining the rates in a manner that would enable the generation shifts that are essential components of the BSER. In the case of building block 3, the EPA accomplished this by incorporating the pro rata share of incremental (above baseline) zero emitting generation into the emission rates for each group of affected EGUs, thus ensuring that these EGUs would have to include a corresponding amount of zero-emitting generation in their compliance calculations, either through the acquisition of credits or through some other mechanism as determined by their state in its implementation plan.

For building block 2, a similar mechanism is needed. Accordingly, a portion of the NGCC generation and emissions used to replace fossil steam must be averaged into the steam rate, analogous to what was done with building block 3. The EPA considered two approaches to define the quantity of NGCC generation and emissions to be averaged into the steam rate: (1) incremental NGCC generation after the implementation of building block 3 and (2) incremental NGCC generation from baseline levels. For the reasons below, the EPA has determined that the second approach better reflects the considerations discussed above.

As discussed above, it is beneficial that the baseline from which emission performance rates are derived be transparent and based on observable historical data. The first approach, however, depends on the level of incremental NGCC generation relative to what is available after the implementation of building block 3. This level of NGCC generation (obtained after replacing baseline levels of generation with NGCC's pro rata share of incremental RE generation) only exists as an intermediate step in the BSER calculation. It is not based on an observable or concrete level of generation.

In Section VIII we discuss methods for creating ERCs for implementing shifting of generation from steam to NGCC, and this discussion illustrates the value of relying on an observable and concrete baseline. In that section we suggest that incentivizing and facilitating the purchase of ERCs as a compliance option for steam units could be implemented through the use of a factor that creates a fraction of an allowable credit for each hour that an NGCC operates. This factor is derived from the incremental generation of NGCC post-building block 2, relative to the baseline. While a different factor could be derived from the hypothetical intermediate level resulting from the pro rata application of zero emitting generation to NGCC in building block 3 (by transferring the full amount of NGCC emissions and generation replacing steam generation in building block 2), the EPA believes that grounding baselines in historical data (such as those used to derive the 2012 baseline) is both more transparent and easier to understand in a way that is more useful to states and utilities, in contrast to the practical challenges of relying on a calculated level that corresponds to an interim step within the emission performance rate calculation. As long as the crediting framework for creating ERCs is consistent with the amount of gas emissions and generation that is transferred to the coal rate, either the chosen option or the option of transferring the entire quantity of gas emissions and generation that occurred in step six to the coal rate would provide an incentive for the power market to implement the shift in generation from coal to gas.[755]

Also as discussed above, it is important that the compliance equations reflect the BSER pro rata allocation of RE to fossil steam and NGCC generation. The first approach to

[755] The EPA recognizes that real world market dynamics will necessarily differ from the BSER assumptions, and has designed the emission guidelines to provide flexibility beyond the emission reduction opportunities identified in the BSER. The essential criteria, however, are that the emission rates and crediting framework are consistent with the BSER and provide the incentives needed to facilitate the emission reduction measures reflected in the BSER and together produce an achievable compliance framework for sources.

define the quantity of NGCC generation and emission to be averaged into the steam rate would require the steam rate to take into account the total additional NGCC generation that results from the application of building block 3 before building block 2 has been applied. This approach would reflect in the compliance rate for steam units a greater share of the implementation of building block 3. Ensuring that emission performance rates for both steam and gas units reflect the emission reduction potential of building block 3 is integral to the building block 3 methodology and also recognizes that application of building block 3 on a pro-rata basis was intended to achieve emission reductions from both NGCC and fossil steam commensurate with their emissions reduction opportunities.

If the EPA were to use the increment of NGCC emissions and generation derived at the intermediary step after the application of building block 3, rather than the increment relative to the 2012 baseline, the effect would be to largely assign to fossil steam the building block 3 generation shift apportioned to NGCC. That, in turn, would have undermined the fact that building block 3 was determined to be a BSER measure applicable to the entire source category, comprising NGCC as well as fossil steam, and would have conflicted with the preceding steps we are taking to develop the equations. Instead, by using only the incremental NGCC generation relative to the baseline, the EPA has ensured that the logic behind the pro rata displacement of fossil generation by RE generation is reflected in the emission rates. Having established the appropriate way to measure the amount of incremental gas generation placed in the fossil steam rate, the EPA is able to calculate the subcategory-specific emission performance rates. For the numerator of the fossil steam rate, the EPA multiplied the remaining fossil steam generation (post-step six) by the fossil steam rate reflecting the heat rate improvement from building block 1 (step four). We then added in the emissions associated with the incremental NGCC generation from step six by multiplying the incremental NGCC generation as discussed above (difference between the baseline NGCC generation level and post-step six NGCC generation) by the baseline NGCC rate for that region.[756] This constitutes the numerator of the fossil steam emission rate.

For the fossil steam denominator, the EPA added the remaining fossil steam generation (post-step six), the incremental NGCC generation defined above, and the amount of zero emitting building block 3 MWhs apportioned to fossil steam generation in the region (step five). Dividing the fossil steam

[756] See CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule for an illustration of this step. The EPA defined the "incremental NGCC generation" in this step in a manner consistent with its measurement and use described in section VIII of this preamble.

numerator described above by this fossil steam denominator resulted in a regional adjusted fossil steam rate reflecting the three building blocks.

For the NGCC performance rate, the EPA calculated a numerator in a similar manner. First, we took the remaining NGCC generation (post step six) and multiplied it by the regional baseline NGCC rate to calculate the total emissions in the numerator. For the denominator, the EPA added the remaining NGCC generation (post step six) to the amount of zero-emitting building block 3 generation assigned to that technology in step five. Dividing the emissions by this total generation value (inclusive of the RE generation apportioned to NGCC) provided a regional adjusted NGCC rate.[757]

Step eight (determining the nationwide subcategory-specific emission performance rate).

[757] See CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule for an illustration of this step. We note that the entire NGCC generation level (inclusive of the amount assigned to the fossil steam rate) expected post building block application is included in the NGCC rate calculation. Including the entire NGCC generation in the NGCC rate recognizes the simultaneous compliance responsibility of affected NGCC units while the fossil steam rate recognizes its mitigation potential through incorporation of the incremental NGCC generation component. Failing to do so would result in a NGCC rate lower than that expected after full implementation of the building blocks and create a compliance inconsistency when reporting all generation.

Following step seven, we evaluated the resulting adjusted fossil steam rates and NGCC rates for each region and identified the highest (least stringent) emission rate among the three regions for each technology category. This becomes the nationwide emission performance rate for that technology class. This ensures that the same rates are applied to facilities in each region and that these rates are achievable by facilities in all three regions.

Finally, the EPA repeated steps four through eight for each year 2022-2030.[758] The resulting annual rates vary because the amount of building block 2 and 3 potential in each year varies. The rates for years 2022-2029 were averaged together to calculate an interim rate, and the 2030 value becomes the final emission performance rate for that year forward.

It bears emphasis that the procedure described above was used only to determine emission performance rates, and the particular data inputs used in the procedure are not intended to represent specific requirements that would apply to any individual EGU or to the collection of EGUs in any state. The

[758] At proposal, the EPA repeated this step over a 10 year period. The building blocks and corresponding BSER emission rates increased for ten consecutive years (2020-2029) in the EPA's rate calculation. In this final rule, the EPA has maintained the same 2030 compliance period for final rates but adjusted the start date to 2022 based on comments. Therefore, the deployment of building blocks is spread over a nine year period (2022-2030) instead of the proposed 10 year period.

specific requirements applicable to individual EGUs, to the EGUs in a given state collectively, or to other affected entities in the state, would be based on the emission standards established through that state's plan. The details of how states could demonstrate compliance with the emission performance rates or statewide goals through different state plan approaches that recognize emission reductions achieved through all the building blocks are discussed further in section VIII on state plans.

Finally, the procedures and assumptions in the equation to calculate emission performance rates are not intended to reflect a compliance scenario in a future year, but rather reflect a representative year in which the building blocks are applied. The power sector fleet will continue to turn over, and in some cases has already experienced turnover beyond the baseline period. However, while the system's fleet may change, the EPA believes this turnover will only further promote the feasibility of the emission performance rates. Fleet turnover has trended towards, and is expected to continue to trend towards, lower-emitting generation sources that will make reductions more readily available.

VII. State-Specific CO_2 Goals

A. Overview

In section VI of this preamble, the EPA provides the methodology for computing subcategory-specific CO_2 emission performance rates, based on the BSER. The subcategory-specific CO_2 emission performance rates are the quantitative expression of the BSER as determined by the EPA. In this section, we provide state rate-based goals and mass-based goals that can be used in the alternative, by states, as an equivalent quantitative expression of the BSER in establishing standards of performance for affected EGUs in state plans. In this section, the EPA also describes reasons for providing state-specific rate-based goals and mass-based goals equivalent to the emission performance rates, supported by the many requests from commenters for the provision of these alternative expressions of the BSER established by the EPA. We further ensure this equivalence, and therefore reflection of the BSER, by requiring that rate-based state goals and mass-based state goals fully implement the BSER, including by ensuring that affected EGUs operating under mass-based emission standards are not incented by dint of the mass-emissions constraint to shift generation to unaffected fossil fuel-fired sources to an extent that deviates from, or negates, the implementation of the BSER.

The EPA is reconstituting the emission performance rates discussed in section VI into statewide CO_2 emission performance goals for each state for the purpose of facilitating states' development of state plans encompassing maximum flexibilities in implementing the BSER. This state-specific goal is not a compliance requirement, but rather an alternative yet equivalent expression of the BSER that the state may choose to use to establish emission standards for its affected EGUs. The state goal is the equivalent of the technology-specific CO_2 emission performance rates and represents the equivalent of the state's applying the emission performance rates directly to its affected EGUs in the form of standards of performance. As discussed further in section VIII on state plans, the states are charged with setting emission standards for the affected EGUs in their respective jurisdictions such that the affected EGUs operating under those standards together satisfy the requirements of the final emission guidelines and statute by meeting the emission performance rates or equivalent statewide emission performance goals, and thereby meet emission standards that reflect the BSER.

In the June 2014 proposal, the EPA proposed a set of state-specific emission rate-based CO_2 goals (in lbs of CO_2 per MWh of electricity generated). In addition, the EPA proposed emission rate-based CO_2 goals for areas of Indian country and U.S. territories with affected EGUs in a supplemental proposal on November 4, 2014. To provide flexibility to states, territories, tribes and implementing authorities, the proposals authorized each implementing authority to translate the form of the goal to a mass-based form (i.e., goals expressed in terms of total tons of CO_2 per year from affected EGUs), as long as the translated goal was equivalent to the rate-based goal. Upon issuance of the proposed rule, the EPA continued the extensive outreach effort to stakeholders and members of the public that the EPA had engaged in for many months preceding the proposal. We also issued a notice of data availability (79 FR 67406, November 13, 2014) and technical support document (Docket ID: EPA-HQ-OAR-2013-0602-22187) to further clarify potential methods for the translation to a mass-based equivalent. The outreach provided additional opportunities for all jurisdictions with affected EGUs – both individually and in regional groups – as well as numerous industry groups and non-governmental organizations, to meet with the EPA and ask clarifying questions about, and give initial reactions to, the proposed components, requirements and timing of the rulemaking. As a result of the outreach and notice of data availability, the EPA received informed substantive comments for the EPA to consider for the final rule.

Numerous commenters encouraged and supported the EPA's efforts to allow states the maximum possible degree of flexibility in developing plans for their affected EGUs, either as a mass-based or rate-based CO_2 goal. States and other stakeholders supported the option to translate rate-based goals to mass-based goals for state plans and requested a simple and transparent method for determining mass-based statewide CO_2 goals that are equivalent to statewide rate-based CO_2 goals and thus reflective of the BSER. We received substantial comments on the potential methodologies for the translation of rate-based goals to mass-based goals. Several commenters requested that the EPA provide the translation to a statewide mass-based goals directly while others requested flexibility to translate to mass using a variety of methodologies and tools. In the context of these comments, the EPA has considered the appropriateness of rate-based and mass-based goals as an expression of BSER and their equivalence to the quantitative expression of BSER through the two CO_2 emission performance rates.

Based on the comments received, the EPA is providing a straightforward translation methodology from the CO_2 emission performance rates to yield statewide rate-based and mass-based CO_2 emission performance goals described in this section. The EPA is providing state mass-based goals in this final rule in place of having states determine the mass themselves. The mass-based goals are the result of a mathematical derivation that provides goals that are an equivalent expression of the BSER. Section VIII below discusses mechanisms for states to plan for and demonstrate achievement of the statewide CO_2 emission performance goals.

CAA section 111(d) requires states to submit a plan that establishes standards of performance for affected EGUs that implement the BSER. States meet the statutory requirements of CAA section 111(d) and the requirements of the final emission guidelines by submitting emission standards for affected EGUs that meet the performance rates, which reflect the application of the BSER as determined by the EPA. Therefore, as a first step for states that choose to submit plans that meet the rate-based or mass-based goals, the goals must be determined to have equivalence as an application of the BSER. For the rate-based and mass-based state goals provided here, this equivalence is evident in the mathematical derivation of the goals, as is described in sections VII.B and VII.C below.

Further (as described in section VIII.J), the state plan must demonstrate that it has measures in place to ensure that any alternative to the performance rates (i.e., rate-based or mass-based state goals that it uses to establish standards of performance) does not result in affected EGUs' failing to implement either the BSER measure themselves or alternative methods of compliance with emission standards that achieve equivalent reductions in emissions or carbon intensity. The EPA has identified one way in which affected EGUs could fail to meet, at a minimum, of the emission performance levels that would result from implementing the BSER, which state plans must do.

Specifically, the EPA has determined that the three building blocks are the BSER, including shifting generation from an affected EGU to a lower-emitting affected EGU or to a non-emitting EGU and that states are required to establish standards of performance that require affected EGUs to achieve, at a minimum, the emission performance levels that reflect the BSER (recognizing that affected sources may choose from a range of equivalent actions (e.g., undertaking the measures included in the building blocks, shifting generation to low-emitting or zero-emitting resources not included in the building blocks or achieving demand-side EE or transmission efficiency – either through operational undertakings, direct investment or emissions trading). Substantial shifting of generation from affected EGUs to new fossil fuel-fired EGUs, such as new NGCC units, represents a deviation from implementing the BSER or its compliance equivalent.

Since the two subcategory-specific emission performance rates represent the BSER, states that established standards of performance at or below those rates, by definition, would be implementing state plans that created no risk that affected EGUs would shift generation to new fossil-fired EGUs to an extent that would deviate from the BSER. Similarly, the EPA has determined that states using rate-based goals as the foundation for plans implementing the BSER are unlikely to foster generation shifts to new fossil fuel-fired sources to an extent that would deviate from the BSER. In contrast, however, EPA analysis has identified a concern that a mass-based state plan that failed to include appropriate measures to address leakage could result in failure to achieve emission performance levels consistent with the BSER.[759] Section VII.B. describes how the form of the rate-based state goals minimizes the risk of generation shifts to new fossil fuel-fired sources, or "leakage," by providing affected EGUs with a sufficient incentive to run, similar to the performance rates. Section VII.D. discusses how there is a potential for leakage under mass-based state goals because affected EGUs are incented to operate in a manner – in particular, by shifting generation to new NGCC units (as opposed to shifting generation as contemplated by the BSER or undertaking equivalent alternative compliance actions) –that would result in negating the equivalence with the emission performance rates and thus the BSER, and specifies that requirements are needed in mass-based implementation to assure those incentives are realigned.[760]

B. Reconstituting Statewide Rate-based CO_2 Emission Performance Goals from the Subcategory-Specific Emission Performance Rates

[759] See Chapter 3 of the Regulatory Impact Analysis for more information on this analysis, which is available in the docket.
[760] The specific mass-based plan requirements are explained in detail in section VIII.J.

In order to provide states flexibility for planning purposes, the EPA is providing a state-specific averaging of the subcategory-specific emission performance rates to determine a statewide goal. While the emission performance rates reflect the quantification of performance based on the BSER and embody the reductions estimated under building blocks 1, 2, and 3, the state goals reflect an equivalent approach through which states may choose to adopt and implement those subcategory-specific performance rates.

The EPA quantified the potential reductions of the BSER in the subcategory-specific emission performance rates established in section VI. These rates themselves reflect the reduction potential expected in emission rates under the BSER for each year from 2022 to 2030. To establish state goals, the EPA applied these rates to the baseline generation levels to estimate the affected fleet emission rate that would occur if all affected EGUs in the fleet met the subcategory-specific rates. This step respects the flexibility of sources to meet the rates in any manner that they see fit (e.g., on-site abatement technology, fuel switching, co-firing, credit purchase, etc.), and does not limit them to their building block assumptions. For example, the EPA derived the statewide rate-based CO_2 emission performance goals for 2030 by multiplying the fossil steam emission performance rate for 2030 by the baseline fossil steam generation in a state and multiplying the NGCC emission performance rate for 2030 by the baseline NGCC generation in a state. The resulting emissions for fossil steam and NGCC are then added together for each state. This emission total is divided by that state's baseline generation values from the likely affected EGUs in order to develop a state's rate-based CO_2 emission performance goal for 2030. This blended rate reflects the collective emission rate a state may expect to achieve when its baseline fleet of likely affected EGUs continues to operate at baseline levels while meeting its subcategory-specific emission performance rates reflecting the BSER. The EPA believes that using the adjusted 2012 baseline is the most appropriate way to combine the rates. First, as explained in Section VI, the EPA believes there are significant advantages to using real world data to set a baseline rather than using projected data. The adjusted 2012 data is the logical starting point because it is the data that all of the emission performance rates (discussed in Section VI) are based upon. Furthermore, it is clear that generation shifts as projected under the BSER are not the appropriate baseline. The emission performance rates already factor in the BSER assumptions about changes in generation (e.g., implementation of building block 2 significantly lowers the emission performance rate for fossil-steam units). If, on top of that, changes in generation were factored into the calculation of a combined rate, those changes in generation would be factored into the combined rate twice (once when calculating the individual emission performance rates and a second time, when incorporating those rates into a combined state rate).

This step is repeated for each year from 2022-2029 using the emission performance rates calculated for each of those years in the previous section. The EPA also repeats this step for the interim state goal using the interim subcategory rates. The EPA then averages together the annual amounts in increments of 3 years, 3 years, and 2 years for 2022-2024, 2025-2027, and 2028-2029 to estimate emission rate averages for those periods that can provide one illustrative pathway for states to consider in meeting their interim goals. These 3- and 2-year increment are not regulatory guidelines or equivalents for interim goals, but rather benchmarks for demonstrating plan performance as discussed in Section VIII.F illustrative of a potential gradual reduction compliance strategy that states may use to reach their interim and final stategoals.

As described in the steps above, the statewide goals represent an equivalent arithmetic combination of the subcategory-specific emission performance rates, weighted by the historical baseline generation levels upon which the BSER is premised. In particular, as discussed above, the method for deriving these goals assures equivalent flexibility by applying the CO_2 emission performance rates to the baseline levels, which respects the flexibility of affected EGUs to meet the rates in whatever way they wish. This corresponding treatment of affected EGUs based on the adjusted 2012 baseline ensures sufficient incentive to affected existing EGUs to generate and thus avoid leakage, similar to the CO_2 emission performance rates (this is further discussed in section VII.D below). Consequently, the statewide goals are equivalent to the CO_2 emission performance rates and are thus an equivalent expression of the BSER. The rate-based statewide goals are provided below in Table 12.

C. Quantifying Mass-based CO_2 Emission Performance Goals from the Statewide Rate-based CO_2 Emission Performance Goals

The EPA is also establishing mass-based statewide CO_2 emission performance goals for each state, which are provided below in Table 12. For state plans choosing to meet a mass-based goal, such a goal must be equivalent to the CO_2 emission performance rates in their application of the BSER, as required by the statute and the final emission guidelines. In the following discussion we describe the mathematical calculations that provide an equivalent expression of the BSER. In evaluating the equivalence of the form of mass goals, the EPA must also recognize the impact that the form of the standard has on the relative incentives that the implementation of these goals provides to affected and unaffected EGUs. This section specifies how we have established a quantitative basis for mass goals that is equivalent to CO_2 emission performance rates. The next section (section VII.D) specifies how we require state plans to ensure equivalence to the CO_2 emission performance rates through certain requirements that realign the potential difference in incentives provided to affected and unaffected EGUs to generate under a mass-based implementation compared to a rate-based implementation that could result in leakage.

The starting place for quantifying mass-based statewide CO_2 emission performance goals is the emission amounts directly represented in the numerator of the statewide rate-based CO_2 emission performance goals. Each state-specific emission amount is the product of the fossil steam emission performance rate and historical fossil steam generation, added to the product of the NGCC emission performance rate and historical NGCC generation. The resulting emission amounts for each state represent the emissions associated with rate-based compliance at historical generation levels.

However, under a rate-based state plan, all affected EGUs have the opportunity to increase utilization, provided that sufficient emission reduction measures are available to maintain the necessary ratio of emissions to generation as quantified by the subcategory-specific emission performance rates. Due to the nature of the emission performance rate methodology, which selects the highest of the three interconnection-based values for each source category as the CO_2 emission performance rate, there are cost-effective lower-emitting generation opportunities quantified under the building blocks that are not necessary for affected EGUs in the Western and Texas interconnections to demonstrate compliance at historical generation levels. The EPA recognizes that these lower-emitting generation opportunities are available to affected EGUs at a national level as a means to increase their own output (and, as a result, their own emissions) while maintaining the relevant emission performance rate. To afford affected EGUs subject to a mass-based goal similar compliance flexibility as EGUs subject to a rate-based goal, the EPA has quantified the emissions associated with the potential realization of these lower-emitting generation opportunities and incorporated those additional tons into each state's mass-based goal.[761] Because the derivation of these mass-based goals respects the arithmetic of the subcategory-specific emission performance rates and the flexibility of affected EGUs to achieve those rates while utilizing up to the full potential quantified in the building blocks, the derivation of these mass-

[761] For more detail on this methodology, please refer to the CO_2 Emission Performance Rate and Goal Computation TSD for CPP Final Rule, which is available in the docket.

based state goals offers an equivalent expression of BSER in mass form.

The mass goals for existing sources are presented in Table 13. Although their derivation is equivalent to the subcategory-specific emission performance rates, in order to maintain this equivalence in the establishment of emission standards in state plans mass goals must be implemented in combination with requirements that align the incentives provided to affected and unaffected EGUs, specifically in order to prevent leakage.

D. Addressing Potential Leakage in Determining the Equivalence of State-Specific CO_2 Emission Performance Goals

As described in section VI, the subcategory-specific emission performance rates reflect the BSER as determined by the EPA. This final rule allows states to establish emission standards that meet either rate-based or mass-based state goals. As stated above, rate-based state goals were published in the proposed rule, and commenters not only supported having the flexibility to use rate-based goals or mass-based goals as part of state plans, but also requested that the EPA include mass-based goals in this final rule. But to ensure the equivalence of mass-based state goals, we must consider how the form of the goal affects its implementation and how the incentives it provides to affected EGUs on the interstate grid affect whether or not the BSER is fully implemented.

Because of the integrated nature of the utility power sector, the form of the emission performance requirements for existing sources may ultimately impact the relative incentives to generate and emit at affected EGUs as opposed to shifting generation to new sources, with potential implications for whether a given set of standards of performance is, at a minimum, consistent with the BSER, in the context of overall emissions from the sector. In this context, we, again, define as “leakage” the potential of an alternative form of implementation of the BSER (e.g., the rate-based and mass-based state goals) to create a larger incentive for affected EGUs to shift generation to new fossil fuel-fired EGUs relative to what would occur when the implementation of the BSER took the form of standards of performance incorporating the subcategory-specific emission performance rates representing the BSER. In the proposal, the EPA recognized that the statutory construction regarding the BSER is to reduce emissions, which can be achieved through shifts of generation. Movement of generation between and among sources is needed to produce overall reductions, particularly movement from higher-emitting affected EGUs to lower-emitting affected EGUs, and from all affected EGUs to zero-emitting RE. In all of these cases, the fossil sources involved in these generation shifts are subject to obligations under this final rule.[762]

However, leakage, where shifts in generation to unaffected fossil fuel-fired sources result in increased emissions, relative to what would have happened had generation shifts consistent with the BSER occurred, is contrary to this construction. Therefore, if the form of the standard does not address leakage or incents the kinds of generation shifts that we identify as leakage, the states must otherwise address leakage in order to ensure that the standards of performance applied to the affected EGUs are, in the aggregate, at least equivalent with the emission performance rates, and therefore appropriately reflect the BSER as required by the statute. Commenters noted that shifting generation and emissions from existing sources to new sources undermined the intent of this rule and the overall emission reduction goals, and that requiring states to address leakage is consistent with the the

[762] The final rule includes state plan conditions to prevent perverse incentives that could otherwise result in greater overall emissions when generation shifts across affected EGUs. For example, states that wish to engage in rate-based trading through an emission standards plan type must adopt plans designed to achieve either a common rate-based state goal or the subcategory-specific emission performance rates (see section VIII.L). Such a state plan condition avoids encouraging generation to shift from a state with a relatively lower state goal to a state with a relatively higher state goal solely as a response to the form of CPP implementation.

obligation that states establish standards of performance that, in the aggregate, at a minimum, reflect the BSER for affected EGUs operating in the interconnected electricity sector.

This section specifically addresses the need for state plans designed to achieve either rate- or mass-based state goals to ensure that their plans succeed in implementing standards of performance that reflect the BSER by minimizing the difference in incentives provided to affected EGUs and new sources to generate in order to maintain equivalent emission performance with the CO_2 emission performance rates.

Rate-based goals do not in our view implicate leakage to an extent that would negate or limit the implementation of the BSER because under a rate-based state goal, similar to the subcategory-specific emission performance rates, existing lower-emitting affected EGUs, primarily NGCC units, are incentivized to increase their utilization in order to improve the average emission rates of affected EGUs overall. New units that are not subject to the rate-based state goal, and that are not an allowable measure for adjusting an EGU's CO_2 emission rate, will not have this incentive to increase utilization, and as a result, the imposition of a rate-based goal on affected EGUs is unlikely to encourage increased generation and emissions from unaffected new EGUs. The form of the rate-based state goals provides an equivalent or greater incentive to affected existing

EGUs as they are provided in the CO_2 emission performance rates, and similarly avoid the potential for leakage. Under both approaches, existing NGCC units can generate ERCs. These ERCs provide an economic incentive to utilize existing NGCC units rather than new NGCC units. Further, ERCs from incremental RE incentivize new renewable generation over new NGCC generation. Both of these features, which exist in the context of implementation with a state rate-based goal or CO_2 emission performance rates, provide significant incentives to ensure that, consistent with the BSER, shifting of generation does not occur between existing fossil fuel-fired units and new NGCC units.

Mass-based goals for existing sources, however, incur a leakage risk to the extent that they incent generation shifts from affected EGUs to unaffected fossil fuel-fired sources in a way that negates the reliance on the BSER. In contrast to various forms of rate-based implementation, mass-based implementation in a state plan can unintentionally incentivize increased generation from unaffected new EGUs as a substitute action for reducing emissions at units subject to the existing source mass goal in ways that would negate the implementation of the BSER and would result in increased emissions. This occurs because, unlike in a rate-based system where rate-based averaging lowers the cost of generation from existing NGCC units relative to generation from new NGCC units, in a mass-based system the allowance price increases the cost of generation from existing NGCC units relative to generation from new NGCC units. The extent to which electricity providers opt to rely on this increase in unaffected new source utilization as a substitute for improving the emissions performance across existing sources would be fundamentally inconsistent with relying on the BSER to reduce emissions as the basis of the subcategory-specific emission performance rates.

As a result, notwithstanding the fact that mass goals for existing sources are quantified in a way that is an equivalent expression of the BSER, the form of mass goals is only equivalent if leakage is satisfactorily addressed in the state plan's establishment of emission standards and implementation measures. The EPA is therefore requiring that states adopting a mass-based state plan include requirements that address leakage, or otherwise provide additional justification that leakage would not occur under the state's implementation of mass-based emission standards. This requirement enables states to establish standards of performance that meet a mass-based goal equivalent to the performance rates and therefore reflect the BSER, as required by section 111(d). The required demonstration and options for state plans to minimize leakage are discussed in detail in section VIII.J of this preamble.

Further supporting the need for this requirement, the EPA has evaluated the mass goals in concert with some of the options to minimize leakage described in that section. As mentioned above, the EPA analysis identified a concern regarding leakage in a mass-based approach, namely that the mass-based implementation without measures to address leakage produced higher generation from new NGCC units and lower emission performance when compared to a rate-based implementation. Further analysis where implementation of the mass-based goals was coupled with measures to address leakage produce utility power sector emissions performance that is similar to emissions performance under the rate goals.[763]

E. State Plan Adjustments of State Goals

The EPA notes that it is the emission performance rates in section VI that constitute the application of the BSER to the affected EGUs and serve as the chief regulatory requirement of this rulemaking. The statewide CO_2 rate-based and mass-based emission performance goals provided here are metrics that states may choose to adopt when demonstrating compliance at the state level, and states may consider these goals when determining how to set unit-level compliance requirements. The EPA believes that the regional nature of determining the emission performance

[763] See Chapter 3 of the Regulatory Impact Analysis for more information on this analysis, which is available in the docket.

rates encompasses a large population size and makes it robust against unit-level variation and unit-level inventory discrepancies. The EPA does acknowledge that state-level rate-based goals or mass-based goals may be sensitive to applicability changes within a state's affected population. In the proposal, the EPA used a baseline that aggregated data for what it believed to be affected units and asked states, companies and other stakeholders to provide corrections in their comments. We received input from many commenters and have corrected information as appropriate. Therefore, we believe the baseline to be accurate. However, if subsequent applicability review or formal applicability determinations change the status of units in regards to being affected or unaffected by this rulemaking, states can, via state plan submittal or revision, adjust their statewide rate or mass goal to reflect this change of status.

This adjustment flexibility provision is based on comments received at proposal. For example, some stakeholders noted that the affected status of particular units was unclear. The EPA recognizes that all the necessary data to determine the affected status of some units may not be available at this time. As stated above, the EPA does not believe unit-level variation or inclusion/exclusion disparities between baseline inventory and affected units will impact the regionally determined emission performance rates discussed in the previous section. However, variations in baseline data or inventory may have an impact on the *state-level* rate-based or mass-based goals provided in this section. Therefore, the EPA is allowing the flexibility for states to demonstrate the need for this type of adjustment under the justifications above and utilize an adjusted value for compliance purposes when submitting or revising its state plan. The EPA will evaluate the appropriateness of such an adjusted value based on the state's demonstration and evaluate the approvability of a plan or plan revision accordingly.

Rate-based statewide CO_2 emission performance goals are listed below in Table 12. Mass-based statewide CO_2 emission performance goals are found in Table 13.

Table 12. Statewide[764] Rate-Based CO_2 Emission Performance Goals (Adjusted Output-Weighted-Average Pounds of CO_2 Per Net MWh From All Affected Fossil Fuel-Fired EGUs)

State Name	Interim Goal - Step 1	Interim Goal - Step 2	Interim Goal - Step 3	Interim Goal	Final Goal
Alabama	1,244	1,133	1,060	1,157	1,018

* Excludes EGUs located in Indian country within the state.

F. Geographically Isolated States and Territories with Affected EGUs

Alaska, Hawaii, Guam, and Puerto Rico constitute a small set of states and U.S. territories representing about one percent of total U.S. EGU GHG emissions. Based on the current record, the EPA does not possess all of the information or the analytic tools needed to quantify the application of the BSER for these states and territories, particularly data regarding RE costs and performance characteristics needed for building block

3 of the BSER. The NREL data for RE that the EPA is relying upon for building block 3 does not cover the non-contiguous states and territories.

The EPA acknowledges that NREL has collaborated with the state of Hawaii to provide technical expertise in support of the state's aggressive goals for clean energy, including analyses of the grid integration and transmission of solar and wind resources.[765] The EPA also recognizes that there are studies and data for some renewable resources in some of the other non-contiguous jurisdictions. However, taken as a whole, the data we currently possess do not allow us to quantify the emissions reductions available from building block 3 using the same methodology used for the contiguous states encompassed by the three interconnections. Lastly, the IPM model used to support the EPA's analysis is geographically limited to the contiguous U.S. As a result of these factors, the EPA currently lacks the necessary analytic resources to set emission performance goals for these areas.

Because of the lack of suitable data and analytic tools needed to develop area-appropriate building block targets as defined in section V, the EPA is not setting CO_2 emission performance goals for Alaska, Hawaii, Guam, or Puerto Rico in

[765] Hawaii Solar Integration Study, NREL Technical Report NREL/TP-5500-57215, June 2013.

this final rule at this time. The EPA believes it is within its authority to address performance goals only for the contiguous U.S. states in this final rule. Under section 111(d), the EPA is not required, at the time that the EPA promulgates section 111(b) requirements for new sources, to promulgate emission guidelines for all of the sources that, if they were new sources, would be subject to the section 111(b) requirements if there is a reasonable basis for deferring certain groups of sources. As discussed, in this rule, the EPA has a reasonable basis for deferring setting goals for these four jurisdictions. In addition, the Courts have recognized the authority of agencies to develop regulatory programs in step-by-step fashion. As the U.S. Supreme Court noted in Massachusetts v. EPA, 549 U.S. 497, 524 (2007): "Agencies, like legislatures, do not generally resolve massive problems in one fell regulatory swoop;" and instead they may permissibly implement such regulatory programs over time, "refining their preferred approach as circumstances change and as they develop a more nuanced understanding of how best to proceed."[766]

---

[766] *See, e.g., Grand Canyon Air Tour Coalition v. F.A.A.*, 154 F.3d 455, 471 (D.C. Cir. 1998) (ordinarily, agencies have wide latitude to attack a regulatory problem in phases and that a phased attack often has substantial benefits); *National Association of Broadcasters v. FCC,* 740 F.2d 1190, 121-11 (D.C. Cir. 1984) ("We have therefore recognized the reasonableness of [an agency's] decision to engage in incremental rulemaking and to defer resolution of issues raised in a rulemaking....").

The EPA recognizes, however, that EGUs in Alaska, Hawaii, Puerto Rico, and Guam emit CO_2 and that there are opportunities to reduce the carbon intensity of generation in those areas over time. We recognize further that there are efforts underway to increase the use of RE in these jurisdictions. In particular, we recognize that Hawaii has tremendous opportunities for RE and has adopted very ambitious goals: 40 percent clean energy by 2030 and 100 percent by 2045. Since 2008, Alaska has apportioned in excess of $1.34 billion pursuing its aspirational goal of 50 percent of the state's total yearly electric load from renewable and alternative energy sources by 2025. Puerto Rico's goal is to achieve 20 percent RE sales by 2035, and the territory is working hard to meet the requirements of the Mercury and Air Toxics Standards, which will reduce emissions from its power plants substantially. Guam's RPS is to achieve 25 percent REsales by 2035.

The agency intends to continue to consider these issues and determine what the appropriate BSER is for these areas. As part of that effort, the agency will investigate sources of information and types of analysis appropriate to devise the appropriate levels for building block 3 and BSER performance levels. Because we recognize that these areas face some of the most urgent climate change challenges, severe public health problems from air pollution and some of the highest electricity rates in the U.S., the EPA is committed to obtaining the right information to quantify the emission reductions that are achievable in these four areas and putting goals in place soon.

VIII. State Plans

A. Overview

After the EPA establishes the emission guidelines that set forth the BSER, each state with one or more affected EGUs[767] shall then develop, adopt and submit a state plan under CAA section 111(d) that establishes standards of performance for the affected EGUs in its jurisdiction in order to implement the BSER. Starting from the foundation of CAA section 111(d) and the EPA's implementing regulations (40 CFR part 60 subpart B), the EPA's proposal laid out a number of options, variations and flexibilities that were intended to provide states and affected EGUs the ability to design state plans that accorded with states' specific situations and policies (now and in the future), and to ensure reliability and affordability of electricity across the system and for all ratepayers. The

---

[767] As stated previously, states with one or more affected EGUs will be required to develop and implement plans that set emission standards for affected EGUs. The CAA section 111(d) emission guidelines that the EPA is promulgating in this action apply to only the 48 contiguous states and any Indian tribe that has been approved by the EPA pursuant to 40 CFR 49.9 as eligible to develop and implement a CAA section 111(d) plan. Because Vermont and the District of Columbia do not have affected EGUs, they will not be required to submit a state plan.

proposal has prompted numerous discussions between and among stakeholders, especially states and groups of states, including state environmental and energy regulators and policy officials. The EPA has received many comments from a wide range of stakeholders seeking a final rule that afforded freedom and flexibility to consider a wide range of standards of performance to implement the BSER, but also providing significant feedback on the elements and options in the proposal and constructive suggestions for alternative approaches. The EPA has carefully considered all of this input, and is finalizing emission guidelines that continue to provide a variety of options for states to fashion their plans in ways legally supportable by the CAA, while also making certain adjustments to address key comments.

The next few paragraphs present an overview of the main features of the final emission guidelines, highlighting key changes from proposal. In the rest of this section, we describe in detail the various elements of the final emission guidelines' requirements for state plans.

The proposal contained rate-based goals for each state, reflecting a blended reduction target for that state's fossil fired EGUs, and provided that states could either meet that rate-based goal or convert it to a mass-based equivalent goal. Reflecting the final BSER described in section V and in response to many comments desirous that the EPA establish mass-based goals in the final rule, these final guidelines include three approaches that states may adopt for purposes of implementing the BSER, any one of which a state may use in its plan. These are: 1) establishing standards of performance that apply the subcategory specific CO_2 emission performance rates to their affected EGUs, 2) adopting a combination of standards and/or other measures that achieve state-specific rate-based goals that represent the weighted aggregate of the CO_2 emission performance rates applied to the affected EGUs in each state, and 3) adopting a program to meet mass-based CO_2 emission goals that represent the equivalent of the rate-based goal for each state. These alternatives, as well as the other options we are finalizing, ensure that both states and affected EGUs enjoy the maximum flexibility and latitude in meeting the requirements of the emission guidelines and that the BSER is fully implemented by each state.

In the proposal, we provided two designs for state plans: one where all the reduction obligations are placed directly on the affected EGUs and one, which we called the "portfolio approach," that could include measures to be implemented, in whole or in part, by parties other than the affected EGUs. In the final guidelines, we retain that basic choice, but with some modifications to respond to comments we received, especially on the portfolio approach. In their plans, states will be able to choose either to impose federally enforceable emission standards that fully meet the emission guidelines directly on affected EGUs (the “emission standards” approach) or to use a “state measures" approach, which would be composed, at least in part, of measures implemented by the state that are not included as federally enforceable components of the plan but result in the affected EGUs meeting the requirements of the emission guidelines. A state measures type plan must include a backstop of federally enforceable standards on affected EGUs that fully meet the emission guidelines and that would be triggered if the state measures fail to result in the affected EGUs achieving on schedule the required emission reductions.

States that choose an emission standards plan may establish as standards of performance for their affected EGUs the subcategory specific CO_2 emission performance rates, which express the BSER.[768] This would satisfy the requirement described in section VIII.D.2.a.3 that a state demonstrate its plan would achieve the CO_2 emission performance rates; in this case, no further demonstration would be necessary. Alternatively, a state may establish emission standards for affected EGUs at different levels from the uniform subcategory-specific emission

[768] Rate-based and mass-based emission standards may incorporate the use of emission trading.

performance rates, provided that when implemented, the emission standards achieve the CO_2 emission performance rates or state rate- or mass-based CO_2 emission goal set forth by the EPA for the state. States that adopt differential standards of performance among their affected EGUs must demonstrate that, in the aggregate, the differential standards of performance will result in their affected EGUs meeting the CO_2 emission performance rates, the state's rate-based CO_2 emission goal or its mass-based CO_2 emission goal.

In the proposal, we proposed that states could use the portfolio approach to meet either a rate- or mass-based goal. In these final emission guidelines, the state measures approach is available only for a state choosing a mass-based CO_2 emission goal, to provide certainty that the state measures are achieving the required emission reductions. Similar to emission standards plans with differential standards of performance, states that adopt state measures plans must demonstrate that the state measures, alone or in conjunction with any federally enforceable emission standards on affected EGUs also included in the state plan, will result in the affected EGUs in the state meeting the state's mass-based CO_2 emission goal. A "state measures" type plan must also include a backstop provision – triggered if, during the interim period, the state plan fails to achieve the emission reduction trajectory identified in the plan or if, during the final phase, the state plan fails to meet the final state mass-based CO_2 emission goal – that would impose federally enforceable emission standards on the affected EGUs adequate to meet the emission guidelines when fully implemented.

The final guidelines reflect the changes to the timing of the reductions within the interim period, which is laid out in section V as part of the determination of the BSER. States may adopt in their plans emission reduction trajectories different from the illustrative three-step trajectory included in these guidelines for purposes of creating a "glide path" between 2022 and 2029, provided that the interim and final CO_2 emission performance rates or state CO_2 emission goals are met.

We recognize that while we are establishing 2022 as the date by which the period for mandatory reductions must start as part of our BSER determination, utilities and other parties are moving forward with projects that reduce emissions of CO_2 from affected EGUs. We received numerous comments urging us to allow credit for these early actions. The final guidelines encourage those early reductions, by making clear that states may, in their plans, allow EGUs to use allowances or ERCs generated through the CEIP. The final guidelines also require that states include in their final plans a schedule of the actions they will be taking to ensure that the period for mandatory reductions will begin as required starting in 2022, and submit a progress report on those actions.

For all types of plans, the final guidelines make clear that states may adopt programs that allow trading among affected EGUs. The final guidelines retain the flexibility for states to do individual plans, or to join with other states in a multi-state plan. In addition, and in response to comments from many states and other stakeholders, the guidelines provide that states may design their programs so that they are "ready for interstate trading," that is, that they contain features necessary and suitable for their affected EGUs to engage in trading with affected EGUs in other "trading ready" states without the need for formal arrangements between individual states.

We have been mindful of the concerns raised by stakeholders about reliability. The final BSER, especially the changes in the timing of the interim period, substantially address these concerns. The flexibilities provided for the design of state plans, including the ability to use trading programs, further enhance system reliability. We have included, as an additional assurance, a reliability safety valve for use where the built-in flexibilities are not sufficient to address an immediate, unexpected reliability situation.

The EPA believes that all the flexibilities provided in the final rule are not only appropriate, but will enhance the success of the program. CO_2 is a global pollutant, and where and when the reductions occur is not as significant to the environmental outcome as compared to many other conventional pollutants. The flexibilities provided in the final guidelines will better reflect the unique interconnectedness of the electricity system, and will allow states and EGUs to reduce CO_2 emissions while maintaining reliability and affordability for all consumers.

In developing the plan, the state rulemaking process must meet the minimum public participation requirements of the implementing regulations as applicable to these guidelines, including a public hearing and meaningful engagement with all members of the public, including vulnerable communities. In the community and environmental justice considerations section, section IX of this preamble, the EPA addresses the actions that the agency is taking to help ensure that vulnerable communities are not disproportionately impacted by this rule. These actions include conducting a proximity analysis, setting expectations for states to engage meaningfully with vulnerable communities and requiring that they describe their plans for doing so as they develop their state plans, providing communities with access to additional resources, providing communities with information on federal programs and resources available to them, recommending that states take a multi-pollutant planning approach that examines the potential impacts of co-pollutants on overburdened communities, and conducting an assessment to determine if any localized air quality impacts need to be further addressed. Additionally, the EPA outlines the continued engagement that it will be conducting with states and communities throughout the state plan development process.

As discussed in more detail in section VIII.E, commenters, particularly states, provided compelling information establishing that for some, and perhaps many, states it will take longer than the agency initially anticipated to develop and submit their required plans. In response to those comments, we are finalizing a plan submittal process that provides additional time for states that need it to submit a final plan submittal to the EPA after September 6, 2016. Within the time period specified in the emission guidelines (from as early as September 6, 2016, to as late as September 6, 2018, depending on whether the state receives an extension), the state must submit its final state plan to the EPA. The EPA then must determine whether to approve or disapprove the plan. If a state does not submit a plan, or if the EPA disapproves a state's plan, then the EPA has the express authority under CAA section 111(d) to establish a federal plan for the state.[769] During and following implementation of its approved state plan, each state must demonstrate to the EPA that its affected EGUs are meeting the interim and final performance requirements included in this final rule through monitoring and reporting requirements.

This section is organized as follows. First, we discuss the timeline for state plan performance and provisions to encourage early action. Second, we describe the types of plans that states can submit. Third, we summarize the components of an approvable state plan submittal. Fourth, we address the process and timing for submittal of state plans and plan revisions. Fifth, we address plan implementation and achievement of CO_2 emission performance rates or state CO_2 emission goals for affected EGUs, and the consequences if they are not met. Sixth, we discuss general considerations for states in developing and implementing plans, including consideration of a facility's "remaining useful life" and "other factors" and electric reliability. Seventh, we note certain resources that are available to facilitate state plan development and implementation. Finally, we discuss additional considerations for inclusion of CO_2 emission reduction

[769] A federal plan may be withdrawn if the state submits, and the EPA approves, a state plan that meets the requirements of this final rule and section 111(d) of the CAA. More details regarding the federal plan are addressed in the EPA's proposed federal plan rulemaking.

measures in state plans, including: accounting for emission reduction measures in state plans; requirements for mass-based and rate-based emission trading approaches; EM&V requirements for RE and demand-side EE resources and other measures used to adjust a CO_2 rate; and treatment of interstate effects.

B. Timeline for State Plan Performance and Provisions to Encourage Early Action

This section describes state plan requirements related to the timing of achieving the emission reductions required in the guidelines and the state plan performance periods. This section also describes the CEIP the EPA is establishing to encourage early investment in certain types of RE projects, as well as in demand-side EE projects implemented in low income communities.

1. Timeline for state plan performance

The final guidelines establish three types of performance periods: 1) a final deadline by which and after which affected EGUs must be in compliance with the final reduction requirements, 2) an interim period, and 3) within that interim period, three multi-year interim step periods. As discussed below and in section V, these performance periods are consistent with our determination of the BSER and are also responsive to the key comments we received on this aspect of the state plans.

A performance period is a period for which the final plan submittal must demonstrate that the required CO_2 emission performance rates or state CO_2 emission goal will be met. The final guidelines establish 2030 as the deadline for compliance by affected EGUs with the final CO_2 emission performance rates or CO_2 rate or mass emission goal; 2030 is the beginning of the final performance period. The interim performance period is 2022 to 2029, and there are three interim step periods - 2022-2024, 2025-2027, and 2028-2029 — where increasingly stringent emission performance rates or state emission goals must be met. The state may submit a plan that incorporates alternative interim step emission performance rates or state emission goals to those provided by EPA, as long as on average or cumulatively, as appropriate, they result in the equivalent of the interim emission performance rates or state emission goals in the emission guidelines. These timelines are based on careful consideration of the substantial comments we received on both the timing of the interim period and the trajectory of compliance by affected EGUs over the interim period and our determination of the BSER, discussed in section V above. The modifications we have made to the timelines included in the proposal respond to these comments and to concerns about, among other things, reliability, feasibility, and cost.

As previously discussed, the EPA has determined that the BSER includes implementation of reduction measures over the period of 2022 through 2029, with final compliance by affected

EGUs in 2030. Therefore, the final rule requires that interim CO_2 emission performance rates or state CO_2 emission goals be met for the interim period of 2022-2029. Many commenters expressed a desire that the EPA designate steps during the interim period to create an interim goal that offered states and utilities greater flexibility and choice in determining their own emission reduction trajectories over the course of the interim period. Since our intent at proposal was to provide such flexibility and choice, and since it remains our intent to do so in this final rule, we are addressing these comments by including in the 2022-2029 interim period three interim step periods (2022-2024, 2025-2027, 2028-2029), which correspond roughly to the phasing in of the BSER. We note, however, that the final rule also allows states the flexibility to define an alternate trajectory of emission performance between 2022 and 2029, provided that 1) the state plan specifies its own interim step CO_2 emission performance rates or state CO_2 emission goals, 2) meeting the alternative interim step CO_2 emission performance rates or state CO_2 emission goals will result in the interim emission performance rates or state CO_2 emission goal being met on an 8-year average or cumulative basis, and, 3) the final CO_2 emission performance rates or state CO_2 emission goal is achieved. To be approvable, a state plan submittal must demonstrate that the emission performance of affected EGUs will meet the interim step

CO_2 emission performance rates or interim step state CO_2 emission goals over the 2022-2024, 2025-2027, and 2028-2029 periods and the final CO_2 emission performance rates or state CO_2 emission goal no later than 2030.[770]

This relatively long period – first for planning, then for implementation and achievement of the interim and final CO_2 emission performance rates or state CO_2 emission goals – provides states and utilities with substantial flexibility regarding methods and timing of achieving emission reductions from affected EGUs. The EPA believes that timing flexibility in implementing measures provides significant benefits that allow states to develop plans that will help achieve a number of goals, including, but not limited to: reducing cost, addressing reliability concerns, addressing concerns about stranded assets, and facilitating the integration of meeting the emission guidelines and compliance by affected EGUs with other air quality and pollution control obligations on the part of both states and affected EGUs. Moreover, we note that over the course of time between submittal of final plans and 2030, circumstances

[770] States are free to establish different interim step performance rates or interim step state goals than those the EPA has specified in this final rule. If states choose to determine their own interim step performance rates or state goals, the state must demonstrate that the plan will still meet the interim performance rates or state goal for 2022-2029 finalized in this action.

may change such that states may need or wish to modify their plans. The relatively lengthy performance periods provided in the final rule should help keep those situations to a minimum but will also accommodate them if necessary.[771] The EPA envisions that the agency, states and affected EGUs will have an ongoing relationship in the course of implementing this program. Since the record also indicates a high degree of interest on the part of states and stakeholders in pursuing banking and trading programs, the timing and level of stringency of the interim CO_2 performance rates or state CO_2 emission goals we are finalizing should provide states and affected EGUs with ample capacity to accommodate such changes without necessitating changes in state plans in many instances.

The timelines established in the final rule respond to the issues raised in numerous comments regarding the concept of the interim period, including comments supporting the flexibility afforded states in developing their plans and the timing necessary to meet the 2030 emission requirements. Some commenters supported beginning the interim goal plan period at 2020. Others stated that the investments necessary to meet the proposed interim emission performance goals beginning in 2020 are unachievable in that timeframe or would place too great a

[771] Modifications to state plans are addressed more specifically in section VIII.E.7 below.

burden on affected EGUs, states, and ratepayers. Some suggested that the 2020 interim goal step should be eliminated in favor of later start dates, including 2022, 2025, or other years. Some commenters urged the EPA to establish phased interim steps creating a steady downward trajectory that allowed several years for each step, compatible with the "chunkiness" of utility planning processes. Yet other commenters provided input suggesting that states be allowed to establish their own set of emission performance steps during the interim plan performance period and thereby control their own emission reduction trajectory or "glide path" for achievement of the interim goal and the 2030 goal, or that the EPA not establish any interim standards at all. Commenters also noted that for some states, there was not a significant difference between the interim and final goal, and, therefore, no glide path for those states. As discussed in previous sections, based on this input and our final determination of the BSER, the EPA has adjusted the interim period to include 2022-2029, is establishing three interim performance periods creating a reasonable trajectory from 2022 to 2030, and is also retaining the flexibility for states to establish their own emission reduction trajectory during the interim period.

As noted, the EPA has determined that the period for mandated reductions should begin in 2022, instead of 2020 as we proposed, because of the substantial amount of comment and data we received indicating that states and utilities reasonably needed that additional time to take the steps necessary to start achieving reductions. In order to assure the EPA and the public that states are making progress in implementing the plan between the time of the state plan submittal and the beginning of the interim period, and as discussed in further detail in section VIII.D, the final rule requires that the state plan submittal include a timeline with all the programmatic milestone steps the state will take between the time of the state plan submittal and 2022 to ensure the plan is effective as of 2022.

2. Provisions to encourage early action

Many commenters supported providing incentives for states and utilities to deploy CO_2-reducing investments, such as RE and demand-side EE measures, as early as possible. In the proposal, the EPA requested comment on an approach that would recognize emission reductions that existing programs provide prior to the initial plan performance period starting from a specified date. We also requested comment on options for that specified date and on conditions that should apply to counting those pre-compliance emission reductions toward a state goal. The EPA received many comments requesting that the agency recognize early actions for the emission reductions they provide prior to the performance period, that the EPA allow those pre-compliance impacts to be counted toward meeting requirements under the rule, and that certain conditions should be applied to recognition of early reductions so as to ensure the emission reductions required in the rule. We also received comments from stakeholders regarding the disproportionate burdens that some communities already bear, and stating that all communities should have equal access to the benefits of clean and affordable energy. The EPA recognizes the validity and importance of these perspectives, and as a result has determined to provide a program – called the Clean Energy Incentive Program (CEIP) – in which states may choose to participate. This section describes this program.

The CEIP is designed to incentivize investment in certain RE and demand-side EE projects that commence construction in the case of RE, or commence operation in the case of EE, following the submission of a final state plan to the EPA, or after September 6, 2018, for states that choose not to submit a final state plan by that date, and that generate MWh (RE) or reduce end-use energy demand (EE) during 2020 and/or 2021. State participation in the program is optional; the EPA is establishing this program as an additional flexibility to facilitate achievement of the CO_2 emission reductions required by this final rule, regardless of the type of state plan a state chooses to implement.

Under the CEIP, a state may set aside allowances from the

CO_2 emission budget it establishes for the interim plan performance period or may generate early action ERCs (ERCs are discussed in more detail in section VIII.K.2), and allocate these allowances or ERCs to eligible projects for the MWh those projects generate or the end-use energy savings they achieve in 2020 and/or 2021. A state implementing a mass-based plan approach, as described in section VIII.C, may issue early action allowances; a state implementing a rate-based plan approach, also described in section VIII.C, may issue early action ERCs. For each early action allowance or ERC a state allocates to such projects, the EPA will provide the state with an appropriate number of matching allowances or ERCs, as outlined below, for the state to allocate to the project. The EPA will match state-issued early action ERCs and allowances up to an amount that represents the equivalent of 300 million short tons of CO_2 emissions. The EPA intends that a portion of this pool will be reserved for eligible wind and solar projects, and a portion will be reserved for low-income EE projects. In the proposed federal plan, the EPA is taking comment on the size of each reserve, and is proposing provisions to provide that any unallocated amounts would be redistributed among participating states.

The EPA has determined that the size of this 300 million short ton CO_2-equivalent matching pool is an appropriate reflection of the CO_2 emission reductions that could be achieved by the additional early investment in RE and demand-side EE the agency expects will be incentivized by the CEIP. For example, in 2012, 13 GW of utility scale wind were deployed,[772] and, in 2014, 3.4 GW of utility-scale solar[773] plus 2-3 GW of distributed solar were deployed,[774] according to industry estimates. Assuming 19 GW per year of RE from 2017-2020 based on these historic maximums yields an installed base of 76 GW of RE potentially eligible for CEIP incentives in 2020 and/or 2021. Assuming an average capacity factor of 30 percent, this would translate into approximately 200 TWh/year of generation, which would be eligible for approximately 300 million short tons of matching allowances over the 2-year period, if the RE MWh were converted to allowances based on the 2012 carbon intensity of 0.8 short tons per MWh. This would leave the remaining half of the pool of matching federal allowances available for EE projects implemented in low-income communities, and additional growth in RE deployment beyond these historic maximums as potentially

enabled by reductions in cost and improvements in performance.

For a state to be eligible for a matching award of allowances or ERCs from the EPA, it must demonstrate that it will award allowances or ERCs only to eligible projects. These are projects that:

- Are located in or benefit a state that has submitted a final state plan that includes requirements establishing its participation in the CEIP;
- Are implemented following the submission of a final state plan to the EPA, or after September 6, 2018, for a state that chooses not to submit a complete state plan by that date;
- For RE: Generate metered MWh from any type of wind or solar resources;
- For EE: Result in quantified and verified electricity savings (MWh) through demand-side EE implemented in low-income communities; and
- Generate or save MWh in 2020 and/or 2021.

The following provisions outline how a state may award early action ERCs or allowances to eligible projects, and how the EPA will provide matching ERCs or allowances to states.

- For RE projects that generate metered MWh from any type of wind or solar resources: for every two MWh generated, the project will receive one early action ERC (or the equivalent number of allowances) from the state, and the EPA will provide one matching ERC (or the equivalent number of allowances) to the state to award to the project.

- For EE projects implemented in low-income communities: for every two MWh in end-use demand savings achieved, the project will receive two early action ERCs (or the equivalent number of allowances) from the state, and the EPA will provide two matching ERCs (or the equivalent number of allowances) to the state to award to the project.

Early action allowances or ERCs awarded by the state, and matching allowances or ERCs awarded by the EPA pursuant to the CEIP, may be used for compliance by an affected EGU with its emission standards and are fully transferrable prior to such use.

The EPA discusses the CEIP in the proposed federal plan rule, and will address design and implementation details of the CEIP, including the appropriate factor for determining equivalence between allowances and MWh and the definition of a low-income community for project eligibility purposes, in a subsequent action. Before doing so, the EPA will engage states and stakeholders to gather additional information concerning implementation topics, and to solicit information about the concerns, interests and priorities of states, stakeholders and the public.

In order for a state that chooses to participate in the CEIP to be eligible for a future award of allowances or ERCs from the EPA, a state must include in its initial submittal a non-binding statement of intent to participate in the program. In the case of a state submitting a final plan by September 6, 2016, the state plan would either include requirements establishing the necessary infrastructure to implement such a program and authorizing its affected EGUs to use early action allowances or ERCs as appropriate, or would include a non-binding statement of intent as part of its supporting documentation and revise its plan to include those requirements at a later date.

Following approval of a final state plan that includes requirements for implementing the CEIP, the agency will create an account of matching allowances or ERCs for the state that reflects the pro rata share – based on the amount of the reductions from 2012 levels the affected EGUs in the state are required to achieve relative to those in the other participating states – of the 300 million short ton CO_2 emissions-equivalent matching pool that the state is eligible to receive. Thus, states whose EGUs have greater reduction obligations will be eligible to secure a larger proportion of the federal matching pool upon demonstration of quantified and verified MWh of RE generation or demand side-EE savings from eligible projects realized in 2020 and/or 2021.

Any matching allowances or ERCs that remain undistributed after September 6, 2018,[775] will be distributed to those states with approved state plans that include requirements for CEIP participation. These ERCs and allowances will be distributed according to the pro rata method outlined above. Unused matching allowances or ERCs that remain in the accounts of states participating in the CEIP on January 1, 2023, will be retired by the EPA.

For purposes of establishing a state plan program eligible for an award of matching allowances or ERCs from the EPA, such a program must include a mechanism for awarding early action emission allowances or ERCs for eligible actions that reduce or avoid CO_2 emissions in 2020 and/or 2021, and that is implemented in a way such that the early action allowances or ERCs allocated by the state would maintain the stringency of the state's goal for emission performance from affected EGUs in the performance periods established in this rule. Specifically, the state must demonstrate in its plan that it has a mechanism in place that enables issuance of ERCs or allowances from the state to parties effectuating reductions in 2020 and/or 2021 in a manner that

[775] This may occur because not all states may elect to include requirements for CEIP participation in their state plans.

would have no impact on the aggregate emission performance of affected EGUs required to meet rate-based or mass-based CO_2 emission standards during the compliance periods.[776] This demonstration is not required to account for matching ERCs or allowances that may be issued to the state by the EPA. Participation in this program is entirely voluntary, and nothing in these provisions would have the effect of requiring any particular affected EGU to achieve reductions prior to 2022, or requiring states to offer incentives for emission reductions achieved prior to 2022.[777] These and other details will be developed in the subsequent action.

---

[776] For example, under a mass-based implementation, the state plan could include a set-aside of early action allowances from an emissions budget that itself reflects the state goals. Allocation of those early action allowances to parties effectuating reductions in 2020 and 2021 would have no impact on the total emissions budget, which sets the total allowable emissions in the compliance periods. Alternatively, under a rate-based implementation, the state plan could require that early action ERCs issued to parties effectuating reductions in 2020 and 2021 would be “borrowed” from a pool of ERCs created by the state during the interim plan performance period. States could limit the size of the “borrowed” pool of ERCs to be equivalent to the size of the federal matching pool, or could take into consideration the potential for each state’s federal matching pool to expand after a redistribution of unused credits. For every early action ERC awarded for actions in 2020 and 2021, the state would retire one ERC from the pool of ERCs created as a result of reductions achieved from 2022 onward.

[777] In addition to the CEIP, states may also offer credit for early investments in RE and demand-side EE according to the provisions of section VIII.K.1 of this final rule: a state may award ERCs to qualified providers that implement projects from 2013 onward that realize quantified and verified MWh results in 2022 and subsequent years.

The EPA is providing the CEIP as an option for states implementing plans – and is including a similar program for the federal plan proposal being issued concurrently – for several reasons. Chief among them is that offered by commenters to the effect that the overall cost of achievement of the emission performance rates or state goals could be reduced by an approach that granted some form of beneficial recognition to emissions reduction investments that both occur and yield reductions prior to the first date on which the program of the interim plan performance period. Other commenters pointed out that to the extent that states and utilities would benefit from the availability of low-cost RE and other zero-emitting generation options during the interim and final plan performance periods, the EPA should include in the final emission guidelines provisions that accelerate deployment of RE resources, since in so doing the final emission guidelines would speed achievement of expected reductions in the cost of those technologies commensurate with their accelerated deployment. In addition, the incentives and market signal generated by the CEIP can help sustain the momentum toward greater RE investment in the period between now and 2022 so as to offset any dampening effects that might be created by setting the start date 2 years later than at proposal.

The specific criteria the EPA is establishing for eligible

RE projects reflect a variety of considerations. First, the EPA seeks to preserve the incentive for project developers to execute on planned investments in all types of solar and wind technologies. Commenters raised concerns that the fast pace of reductions underlying the emission targets in the proposed rule could potentially shift investment from RE to natural gas, thus dampening the incentive to develop wind and solar projects, in particular. Second, the EPA, consistent with the CAA's directive to incentivize technology and to accelerate the decline in the costs of technology, seeks to drive the widespread development and deployment of wind and solar, as these broad categories of renewable technology are essential to longer term climate strategies. Finally, in contrast to other CO_2-reducing technologies – including other zero-emitting or RE technologies – solar and wind projects often require lead times of shorter duration, which would allow them to generate MWh beginning in 2020.

The specific criterion the EPA is establishing for eligible EE projects – namely that these projects be implemented in low-income communities - is also consistent with the technology-forcing and development purposes of section 111. The EPA believes it is appropriate to offer an additional incentive to remove current barriers to implementing demand-side EE programs in low-income communities. While the EPA acknowledges that a number of states have demand-side EE programs focused on these communities,[778] the agency also recognizes that there have been historic economic, logistical, and information barriers to implementing programs in these communities. As a result, the costs of implementing demand-side EE programs in these communities are typically higher than in other communities and stand as barrier to harvesting potentially cost effective reductions and advancing these technologies. The EPA intends for the CEIP to help incentivize increased deployment of projects that will deliver demand-side EE benefits to these communities, which will in turn lower the costs of these approaches. These lower costs will help new technologies and delivery mechanisms penetrate in the future, thus improving the cost of implementation of the emission guidelines overall, consistent with Congress' goals in the New Source Performance Standard provisions of the CAA. Further, reducing barriers to demand-side EE in low-income communities will help ensure that the benefits of the final rule are shared broadly across society and that potential adverse impacts on low-income ratepayers are avoided. It complements other steps the federal government is taking to bring clean energy technologies to these communities, as we

[778] Several of these programs are discussed in section IX of this preamble, including, for example, Maryland's EmPOWER Low Income Energy Efficiency Program (LIEEP) and New York's EmPower New York program.

discuss in section IX of this preamble.

More broadly, the CEIP responds to the urgency of meeting the challenge of climate change in two key ways. First, of course, it fosters reductions before 2022. Second, in targeting investments in wind, solar and low-income EE, it focuses on the kinds of measures and technologies that are the essential foundation of longer-term climate strategies, strategies that inevitably depend on the further development and widespread deployment of highly adaptable zero-emitting technologies.

We are not requiring that projects demonstrate to states that they are "additional" or surplus relative to a business-as-usual or state goal-related baseline in order to be eligible. At the same time, we believe that including an incentive to develop projects that benefit low-income communities will increase the likelihood of investments being made that would not have been made otherwise.

In order to be awarded matching ERCs or allowances by the EPA for projects that meet the eligibility criteria, a final state plan must have requirements establishing the appropriate infrastructure to issue early action ERCs or allowances to eligible project providers by 2020. The state must require that the state or its agent will, in accordance with state plan requirements approved as meeting the ERC issuance and EM&V requirements included in section VIII.K: (1) evaluate project proposals from eligible RE and demand-side EE project providers, including the EM&V plans that must accompany such proposals; (2) evaluate monitoring and verification reports submitted by eligible providers following project implementation, which contain the quantified and verified MWh of RE generation or energy savings achieved by the project in 2020 and/or 2021; (3) issue ERCs or allowances to eligible providers for these MWh results; (4) ensure that no MWh of renewable generation or energy savings receives early action or matching ERCs or allowances more than once.[779]

The CEIP will provide a number of benefits. First, the program will provide incentives designed to reduce energy bills early in the implementation of the guidelines through earlier and broader application of energy saving technologies, and help ensure that these benefits are fully shared by low-income communities. Second, the EPA believes that stimulating or supporting early investment in RE generation technologies could accelerate the rate at which the costs of these technologies

[779] For a state plan incorporating the use of ERCs or allowances to be approvable by the EPA, such a plan must use an EPA-approved or EPA-administered tracking system for ERCs or allowances. The EPA received a number of comments from states and stakeholders about the value of the EPA's support in developing and/or administering tracking systems to support state administration of rate-based emission trading programs. The EPA is exploring options for providing such support and is conducting an initial scoping assessment of tracking system support needs and functionality.

fall over the course of the interim performance period. Third, the CEIP will provide affected EGUs and states with additional emission reduction resources to help them achieve their state plan obligations. Finally, the program will improve the liquidity, in the early years of the program, of the ERC and allowance markets we expect to emerge for compliance with the requirements of these guidelines.[780]

The EPA is establishing this program as an option for states that wish to drive investments in RE and low-income EE that will result in actual, early reductions in CO_2 emissions from affected EGUs. States are also authorized to set their own glide path, or interim step performance rates or goals, so long as the interim and final performance rates or goals are met, and could do so in a way that takes into account the availability of the CEIP to assist affected EGUs in meeting the applicable glide path and performance rates or goals. While the EPA is not requiring states to take advantage of this program, its availability simply enhances these already-existing implementation and compliance flexibilities while at the same

[780] The CEIP is expected to provide states and affected EGUs additional flexibility in meeting the guidelines, and bears similarity in both design and purpose to the Compliance Supplement Pool, which the agency established as a part of the NO_x SIP Call. *See* 63 FR 57356, 57428-30 (Oct. 27, 1998). Certain aspects of the Compliance Supplement Pool were challenged in litigation and upheld by the D.C. Circuit Court of Appeals. *See Michigan v. EPA*, 213 F.3d 663, 694 (D.C. Cir. 2000).

time delivering meaningful benefits, particularly for low-income communities. The EPA looks forward to an upcoming public dialogue about the implementation details of the CEIP.

C. State Plan Approaches

1. Overview

Under the final emission guidelines, states may adopt and submit either of two different types of state plans. The first would apply all requirements for meeting the emission guidelines to affected EGUs in the form of federally enforceable emission standards.[781] We refer to this as an "emission standards" state

[781] 40 CFR 60.21(f) defines "emission standard" as "a legally enforceable regulation setting forth an allowable rate of emissions into the atmosphere, establishing an allowance system, or prescribing equipment specifications for control of air pollution emissions." This definition is promulgated and effective, and we note that it authorizes the use of allowance systems as a form of emission standard. To resolve any doubt that allowance systems are an acceptable form of emission standard in the final rule, we are including regulatory text in the final subpart UUUU regulations authorizing the use of allowance systems as a form of emission standard under section 111(d). Section 60.21(f) was originally amended in 2005 to include recognition of allowance systems as a form of emission standard in the Clean Air Mercury Rule (CAMR) (70 FR 28606, 28649; May 18, 2005). CAMR was vacated in its entirety in *New Jersey v. EPA*, 517 F.3d 574 (D.C. Cir. 2008). However, the reason for vacatur was wholly unrelated to the question of whether an allowance system could be a form of emission standard. In response to the *New Jersey* decision, the agency removed CAMR provisions from the Code of Federal Regulations. The agency chose to retain the language of 60.21(f) and 60.24(b)(1) generally recognizing allowance systems. This language is broader than CAMR and unrelated to the reasons for its vacatur. The EPA re-promulgated these provisions in February of 2012 (77 FR 9304, 9447; Feb. 16, 2012). Even if this were not

plan type. The second, which we refer to as a "state measures" plan type, would allow the state mass CO_2 emission goals to be achieved by affected EGUs in part, or entirely, through state measures[782] that apply to affected EGUs, other entities, or some combination thereof. The state measures plan type also includes a mandatory contingent backstop of federally enforceable emission standards for affected EGUs that would apply in the event the plan does not achieve its anticipated level of emission performance as specified in the state plan during the period that the state is relying on state measures. The inclusion of a backstop of federally enforceable emission standards in a state measures plan type is legally necessary for a state plan to meet the terms of 111(d), which specifically require a state to submit standards of performance.

These two types of state plans and their respective approaches, either of which could be implemented on a single-

---

the case, the agency would not concede that simply because "allowance systems" were not provided for in the framework regulations of subpart B, they could not be relied upon in specific emission guidelines, such as these for CO_2. The implementing regulations generally serve a gap-filling role where there are not more specific provisions laid out in the relevant emission guidelines. In order to resolve any question whether allowance systems are authorized under the final rule, we are including regulatory text in subpart UUUU to make this authorization explicit.

[782] "State measures" refer to measures that the state adopts and implements as a matter of state law. Such measures are enforceable only per state law, and are not included in and codified as part of the federally enforceable state plan.

state or multi-state basis, allow states to meet the statutory requirements of CAA section 111(d) while accommodating the wide range of regulatory requirements and other programs that states have deployed or will deploy in the electricity sector that reduce CO_2 emissions from affected EGUs. Further, as described in detail below, both types of plans are responsive to comments we received from states and other stakeholders. In addition to providing states the option of developing an emission standards or state measures type plan, the final rule makes clear that states that choose an emission standards plan can adopt either a rate-based or mass-based CO_2 emission goal.

Under these two basic plan types, the final emission guidelines provide states with a number of potential plan pathways for meeting the emission guidelines. A plan pathway represents a specific plan design approach used to meet the emission guidelines. These plan pathways are discussed in section VIII.C.2 through C.5 below, and further elaborated in sections VIII.J (for mass-based emission standards) and VIII.K (for rate-based emission standards).

The final emission guidelines provide four streamlined plan pathways. These streamlined plan pathways represent straightforward plan approaches for meeting the emission guidelines, and avoid the need to meet additional plan requirements and include additional elements in a plan submittal. The streamlined plan pathways include the following:

- Establishing federally enforceable, mass-based CO_2 emission standards for affected EGUs, complemented by state-enforceable mass-based CO_2 emission standards for new fossil fuel-fired EGUs.[783] This approach could involve an emission budget trading program that includes affected EGUs as well as new fossil fuel-fired EGUs. This approach facilitates interstate emission trading, through either a single-state "ready-for-interstate-trading" plan approach or through a multi-state plan. Under a "ready-for-interstate-trading" plan, interstate emission trading may occur without the need for a multi-state plan.[784]
- Establishing federally enforceable, mass-based CO_2 emission standards for affected EGUs.[785] This approach facilitates interstate emission trading, through either a single-state

[783] New source CO_2 emission complements are discussed in section VIII.J.2.b, which also provides EPA-derived new source CO_2 emission complements for states.
[784] Mass-based trading-ready plans are addressed in section VIII.J.3. Multi-state plans, where a group of states are meeting a joint CO_2 goal for affected EGUs, are addressed in section VIII.C.5.
[785] This plan approach would meet a state mass-based CO_2 goal for affected EGUs, or a joint multi-state mass-based CO_2 goal for affected EGUs. These plan approaches are discussed in sections VIII.J.2 and VIII.C.5, respectively.

"ready-for-interstate-trading" plan approach or through a multi-state plan. In a separate concurrent action, the EPA is proposing a model rule for states that could be used in a plan implementing this approach.[786]

- Establishing federally enforceable, subcategory-specific rate-based CO_2 emission standards for affected EGUs, consistent with the CO_2 emission performance rates in the emission guidelines. This approach provides for interstate emission trading, through either a single-state "ready-for-interstate-trading" plan approach or through a multi-state plan.[787] In a separate concurrent action, the EPA is proposing a model rule for states that could be used in a plan implementing this approach.
- Establishing federally enforceable rate-based CO_2 emission standards at a single level that applies for all affected EGUs, consistent with the state rate-based CO_2 goal for affected EGUs in the emission guidelines.[788] This approach provides for interstate emission trading, through a multi-

[786] Submission of a state plan based on the EPA's finalized model rule for a mass-based emission trading program could be considered presumptively approvable. The EPA would evaluate the approvability of such submission through an independent notice and comment rulemaking.
[787] Rate-based trading-ready plans are addressed in section VIII.K.4.
[788] This plan approach is addressed in section VIII.C.2.a.

state plan that meets a single weighted average multi-state rate-based CO_2 goal.[789]

The final emission guidelines also provide for a range of additional custom plan approaches that a state may pursue, if it chooses, to address specific circumstances or policy objectives in a state. The custom plan pathways, while viable options for meeting the emission guidelines, come with additional plan requirements and plan submittal elements. These additional plan requirements and plan submittal elements are necessary to ensure that the emission guidelines are met and that the necessary level of CO_2 emission performance is achieved by affected EGUs.

Based on this overall approach, the final emission guidelines provide for a range of state options – both easily implementable approaches that can be used to meet the emission guidelines, and more customizable approaches that can be used, if a state chooses, to address special circumstances or state policy objectives.

2. “Emission standards” state plan type

The emission standards type of state plan imposes requirements solely on affected EGUs in the form of federally enforceable emission standards. This type of state plan, as described below, may consist of rate-based emission standards

[789] This multi-state plan approach is addressed in section VIII.C.5.

for affected EGUs or mass-based emission standards for affected EGUs.

The state plan submittal for an emission standards type plan must demonstrate that these federally enforceable emission standards for affected EGUs will achieve the CO_2 emission performance rates or the applicable state rate-based or mass-based CO_2 emission goal for affected EGUs.

Both rate-based and mass-based emission standards included in a state plan must be quantifiable, verifiable, enforceable, non-duplicative and permanent. These requirements are described in more detail at section VIII.D.2.

Rate-based and mass-based emission standards may incorporate the use of emission trading, as described below. The EPA anticipates the use of emission trading in state plans, given the advantages of this approach and comments suggesting a high degree of interest on the part of states, utilities, and independent power producers in the inclusion of emission trading in state plans.[790]

The EPA notes it is proposing model rules for both mass-based and rate-based emission trading programs. States could adopt and submit the finalized model rules for either emission trading program to meet the requirements of CAA section 111(d)

---

[790] The legal basis for authorizing trading in emission standards is discussed in section VIII.C.6.

and these emission guidelines. The EPA will evaluate the approvability of such submission, as with any state plan submission, through independent notice-and-comment rulemaking. The EPA notes that state plan submittals that adopt the finalized model rule may be administratively and technically more straightforward for the EPA in evaluating approvability, as the EPA will have determined that the model rule meets the applicable requirements of the emission guidelines through the process of finalization of such rule.

a. Rate-based approach. The first type of "emission standards" plan approach a state may choose is one that uses rate-based emission standards. Under this plan approach, the plan would include federally enforceable emission standards for affected EGUs, in the form of lb CO_2/MWh emission standards.

A rate-based "emission standards" plan may be designed to either meet the CO_2 emission performance rates for affected EGUs or achieve the state's rate-based CO_2 emission goal for affected EGUs. A plan could be designed such that compliance by affected EGUs would assure achievement of either the CO_2 emission performance rates for affected EGUs or the state rate-based CO_2 emission goal. To meet the CO_2 emission performance rates for affected EGUs, a plan would establish separate rate-based emission standards for affected fossil fuel-fired electric utility steam generating units and stationary combustion turbines (in lb CO_2/MWh) that are equal to or lower than the CO_2 emission performance rates in the emission guidelines. To meet a state rate-based CO_2 goal, a plan would establish a uniform rate-based emission standard (in lb CO_2/MWh) that applies to all affected EGUs in the state. This uniform emission rate would be equal to or lower than the applicable state rate-based CO_2 goal specified in the final emission guidelines.

Under these two approaches, compliance by affected EGUs with the rate-based emission standards in a plan would ensure that affected EGUs meet the CO_2 emission performance rates in the emission guidelines or the state rate-based CO_2 goal for affected EGUs. No further demonstration would be necessary by the state to demonstrate that its plan would achieve the CO_2 emission performance rates or the state's rate-based CO_2 goal.

Alternatively, if a state chooses, it could apply rate-based emission standards to individual affected EGUs, or to categories of affected EGUs, at a lb CO_2/MWh rate that differs from the CO_2 emission performance rates or the state's rate-based CO_2 goal. In this case, compliance by affected EGUs with their emission standards would not necessarily ensure that the collective, weighted average CO_2 emission rate for these affected EGUs meets the CO_2 emission performance rates or the state's rate-based CO_2 goal.[791]

Under this type of approach, therefore, the state would be required to include a demonstration,[792] in the state plan submittal, that its plan would achieve the CO_2 emission performance rates or applicable state rate-based CO_2 goal. This demonstration would include a projection of the collective, weighted average CO_2 emission rate the fleet of affected EGUs would achieve as a result of compliance with the emission standards in the plan. Once the plan is implemented, if the CO_2 emission performance rates or applicable state rate-based CO_2 goal are not achieved, corrective measures would need to be implemented, as described in section VIII.F.3.

Under a rate-based approach, a state may include in its plan a number of provisions to facilitate affected EGU compliance with the emission standards. First, a state may encourage (or require) EGUs to undertake actions to reduce CO_2

[791] The weighted average CO_2 emission rate that will be achieved by the fleet of affected EGUs in a state that applies different rate-based emission standards to individual affected EGUs or groups of affected EGUs will depend upon the mix of electric generation from affected EGUs subject to different emission standards. For example, if a state applies higher emission standards for affected steam generating units and lower emission standards for affected NGCC units, the greater the projected amount of electric generation from steam generating units, the higher the projected weighted average emission rate that will be achieved for all affected EGUs.

[792] A demonstration of how a plan will achieve a state's rate-based or mass-based CO_2 emission goal is one of the required plan components, as described in section VIII.D.2.

emissions at the affected EGU level, such as heat rate improvements or fuel switching. These measures are discussed in section VIII.I. Second, a state may implement a market-based emission trading program, which enables EGUs to generate and procure ERCs, a tradable compliance unit representing one MWh of electric generation (or reduced electricity use) with zero associated CO_2 emissions. Considerations and requirements for rate-based trading programs are discussed in section VIII.K.

ERCs would be issued by the administering state regulatory body. The state may issue ERCs to affected EGUs that emit below a specified CO_2 emission rate, as well as for measures that provide substitute generation for affected EGUs or avoid the need for generation from affected EGUs. These ERCs may then be used to adjust the reported CO_2 emission rate of an affected EGU when demonstrating compliance with a rate-based emission standard. For each submitted ERC, one MWh is added to the denominator of the reported CO_2 emission rate, resulting in a lower adjusted CO_2 emission rate.

Eligible measures that may generate ERCs, as well as the accounting method for adjusting a CO_2 emission rate, are discussed in section VIII.K.1. Requirements for rate-based emission trading approaches are discussed in section VIII.K.2. Quantification and verification requirements for measures eligible to generate ERCs are discussed in section VIII.K.3.

(1) Rate-based emission standards based on operational or other standards. As discussed in further detail in section VIII.D.2.d.3, regarding the legal considerations and statutory language of CAA section 111(h), the EPA is finalizing that design, equipment, work practice, and operational standards cannot be considered to be "standards of performance" for this final rule. However, a state may elect to use emission standards for affected EGUs that result in a reduced CO_2 lb/MWh emission rate for affected EGUs because of operational or other standards. The state would include in its state plan an emission standard that is the rate standard that results from the applicable operational or other standard. For example, a state might choose to recognize that an individual affected EGU has plans to retire, and those plans could be codified in the state plan by adopting an emission standard of 0 CO_2 lb/MWh as of a certain date. The state would thus include in the state plan an emission standard of 0 CO_2 lb/MWh for that affected EGU that applies after a specified date.

An approvable plan could apply such emission standards to a subset of affected EGUs or all affected EGUs. As with any rate-based plan, the state would need to demonstrate that the plan would achieve the required level of emission performance for affected EGUs, in CO_2 lb/MWh. A plan could also apply such emission standards to a subset of affected EGUs in the state while applying other rate-based emission standards to the remainder of affected EGUs in the state. For example, a plan might include an emission standard of 0 CO_2 lb/MWh reflecting a retirement mandate for one or more affected EGUs in a state and apply a rate-based emission standard equal to the CO_2 emission performance rates or a state's rate-based CO_2 emission goal to the remainder of affected EGUs.

As with all emission standards, emission standards based on design, equipment, work practice, and operational standards must be quantifiable, verifiable, enforceable, non-duplicative and permanent. These requirements are described in more detail at section VIII.D.2.

(2) Additional considerations for rate-based approach. Additional considerations and requirements for rate-based emission standards state plans are addressed in section VIII.K. This includes the basic accounting method for adjusting the reported CO_2 emission rate of an affected EGU, as well as requirements for the use of measures to adjust a CO_2 emission rate, both of which are discussed in sections VIII.K.1 through 3. Such requirements include eligibility, accounting, and quantification and verification requirements (EM&V) for the use of CO_2 emission reduction measures that provide substitute generation for affected EGUs or avoid the need for generation from affected EGUs in rate-based state plans. Section VIII.K.4

addresses multi-state coordination among rate-based emission trading programs.

b. Mass-based approach. The second "emission standards" approach a state may elect to use is mass-based emission standards applied to affected EGUs. Under this approach, the plan would include federally enforceable emission standards for mass CO_2 emissions from affected EGUs. The plan would be designed to achieve the mass-based CO_2 goal for a state's affected EGUs (see section VII) or a level of CO_2 emissions equal to or less than the mass-based CO_2 goal plus the new source complement CO_2 emissions (see section VIII.J.2.b, Table 14).[793]

Under a mass-based approach, a state could require that individual affected EGUs meet a specified mass emission standard. Alternatively, a state could choose to implement a market-based emission budget trading program. The EPA envisions that the latter option is most likely to be exercised by states seeking to implement a mass-based emission standard approach, as it would maximize compliance flexibility for affected EGUs and enable the state to meet its mass goal in the most economically

[793] For example, a state plan designed to meet a state mass-based CO_2 goal for affected EGUs plus a new source complement could include a mass-based emission budget trading program that applies to both affected EGUs, as well as new fossil fuel-fired EGUs. The program requirements for affected EGUs would be federally enforceable, while the program requirements for other fossil fuel-fired EGUs would be state-enforceable. This approach is described further in section VIII.J.2.

efficient manner possible.

(1) Mass-based emission standard applied to individual affected EGUs.

One pathway a state could take to achieve its mass-based CO_2 goal would be to apply mass-based emission standards to individual affected EGUs, in the form of a limit on total allowable CO_2 emissions. These emission standards would be designed such that total allowable CO_2 emissions from all affected EGUs in a state are equal to or less than the state's mass-based CO_2 goal, or a state's mass-based CO_2 goal plus the new source complement CO_2 emissions specified in section VIII.J.2.b, Table 14. The individual affected EGUs would be required to emit at or below their mass-based standard to demonstrate compliance. Under this approach, individual affected EGUs would be required to undertake source-specific measures to assure their CO_2 emissions do not exceed their assigned emission standard. Affected EGU compliance with the emission standards prescribed under this type of mass-based approach would ensure that the affected EGUs in a state achieve the state's mass-based CO_2 goal, or mass-based CO_2 goal plus new source complement.

(2) Mass-based emission standard with a market-based emission budget trading program.

A second pathway a state could take to achieve its mass-based CO_2 goal would be to implement a market-based emission budget trading program. This type of program provides maximum compliance flexibility to affected EGUs, and as a result, may be attractive to states that choose to implement a mass-based approach in their state plan.

An emission budget trading program establishes a combined emission standard for a group of emission sources in the form of an emission budget. Emission allowances are issued in an amount up to the established emission budget.[794] Allowances may be distributed to affected emission sources (as well as to other parties) through a number of different methods, including direct allocation to affected sources or auction. These allowances can be traded among affected sources and other parties. The emission standard applied to individual emission sources is a requirement to surrender emission allowances equal to reported emissions, with each allowance representing one ton of CO_2.

The EPA views an emission budget trading program as a highly efficient, market-based approach for reducing CO_2 emissions from affected EGUs. Such programs include a limit on mass CO_2 emissions while providing both short-term and long-term price signals that encourage the owners or operators of affected EGUs, as well as other entities, to determine the most efficient

[794] An emission allowance represents a limited authorization to emit, typically denominated in one short ton or metric ton of emissions.

means of achieving the mass emission standard. Notably, such an approach incentivizes actions taken at affected EGUs to reduce CO_2 emissions, as well as the use of strategies such as RE and demand-side EE as complementary measures that reduce CO_2 emissions. However, unlike under a rate-based approach, for this latter set of measures there is no need to address and describe these state measures in a state plan submission or quantify and verify the RE and EE MWh of generation and savings. As a result, a mass-based emission budget trading program incentivizes and recognizes a wide range of emission reduction actions while being relatively simple for a state to implement and administer. Furthermore, the EPA notes that such an approach still allows for a state to address electricity load growth, as load growth can be met through low- and zero-emitting generating resources, as well as avoided through demand-side EE and demand-side management (DSM) measures.

Additional considerations and requirements for mass-based emission standards state plans are addressed in section VIII.J. This includes use of emission budget trading programs in a state plan, including provisions required for such programs (section VIII.J.2.a) and the design of such programs in the context of a state plan. Section VIII.J addresses program design approaches that ensure achievement of a state mass-based CO_2 emission goal (section VIII.J.2.c), as well as how states can use emission budget trading programs with broader source coverage and other flexibility features in a state plan, such as the programs currently implemented by California and the RGGI participating states (section VIII.J.2.d). Section VIII.J.2.e addresses other considerations for the design of emission budget trading programs that states may want to consider, such as allowance allocation approaches. Section VIII.J.3 addresses multi-state coordination among emission budget trading programs used in states that retain their individual state mass-based CO_2 goals.

(3) Mass-based emission standards based on operational or other standards.

As discussed in section VIII.C.2.a.(1) above, a state may elect to use mass-based emission standards for affected EGUs that result in a reduced total tonnage of CO_2 emissions from affected EGUs because of operational or other standards. The state would include in its state plan an emission standard that is the mass standard that results from the applicable operational or other standard. For example, a state might choose to recognize that an individual affected EGU has plans to retire, and those plans could be codified in the state plan by adopting an emission standard of 0 total tons of CO_2, as of a certain date. The state would thus include in the state plan an emission standard of 0 total tons of CO_2 for that affected EGU that applies after a specified date. Under a mass-based approach, the state could also include an emission standard (e.g., a mass limit) that reflects the result of a limit on an affected EGU's total operating hours over a specified period. Such an emission standard would be based on an affected EGU's potential to emit given a specified number of operating hours.

An approvable plan could apply such emission standards to a subset of affected EGUs or all affected EGUs. As with any mass-based plan, the state would need to demonstrate that the plan would achieve the required level of emission performance for affected EGUs, in total tons of CO_2. A plan could also apply such emission standards to a subset of affected EGUs in the state while applying other emission standards to the remainder of affected EGUs in the state. For example, a plan might include an emission standard of 0 tons of CO_2 for one or more affected EGUs, reflecting a retirement mandate for one or more affected EGUs in a state, and include the remainder of affected EGUs in an emission budget trading program.

3. "State measures" state plan type

The second type of state plan is what we refer to as a "state measures" plan. As previously discussed, the EPA believes states will be able to submit state plans under the emission standards plan type, and its respective approaches, and achieve the CO_2 emission performance rates or state rate-based or mass-based CO_2 goals by imposing federally enforceable requirements on affected EGUs. Upon further consideration of the requirements of CAA section 111(d), in consideration of the comments we received on the proposed portfolio approach and the state commitments approach, and in order to provide flexibility and choice to states that may wish to adopt a plan that does not place all the obligations on affected EGUs, the EPA is finalizing the state measures plan type in addition to the emission standards plan type. The EPA believes the state measures plan type will provide states with additional latitude in accommodating existing or planned programs that involve measures implemented by the state, or by entities other than affected EGUs, that result in avoided generation and CO_2 emission reductions at affected EGUs. This includes market-based emission budget trading programs that apply, in part, to affected EGUs, such as the programs implemented by California and the RGGI participating states in the Northeast and Mid-Atlantic, as well as RE and demand-side EE requirements and programs, such as renewable portfolio standards (RPS), EERS, and utility- and state-administered incentive programs for the deployment of RE and demand-side EE technologies and practices. The EPA believes this second state plan type will afford states with appropriate flexibility while meeting the statutory requirements of CAA section 111(d).

Measures implemented under the state measures plan type could include RE and demand-side EE requirements and deployment programs. This type of plan could align with existing state resource planning in the electricity sector, including RE and demand-side EE investments by state-regulated electric utilities. The state measures plan type also can accommodate emission budget trading programs that address a broader set of emission sources than just affected EGUs subject to CAA section 111(d), such as the programs currently implemented by California and the RGGI participating states. The EPA also notes that the state measures plan type could accommodate imposition by a state of a fee for CO_2 emissions from affected EGUs, an approach suggested by a number of commenters.

This plan type would allow the state to implement a suite of state measures that are adopted, implemented, and enforceable only under state law, and rely upon such measures[795] in achieving the required level of CO_2 emission performance from affected EGUs. The state measures under this plan type could be measures involving entities other than affected EGUs, or a combination of such measures with emission standards for affected EGUs, so long as the state demonstrates that such measures will result in achievement of a state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source complement), as discussed below. The EPA

[795] "State measures" refer to measures that the state adopts and implements as a matter of state law. Such measures are enforceable only per applicable state law, and are not included in the federally enforceable state plan.

notes that under this plan type, a state could also choose to include any emission standards for affected EGUs, which are required to be included in the plan as federally enforceable measures, to be implemented alongside or in conjunction with state measures the state would implement and enforce.

For a state measures plan to be approvable, it must include a demonstration of how the measures, whether state measures alone or state measures in conjunction with any federally enforceable emission standards for affected EGUs, will achieve the state mass-based CO_2 emission goal for affected EGUs (or mass-based CO_2 goal plus new source complement). However, because the state measures would not be federally enforceable emission standards, the plan must also include a backstop of federally enforceable emission standards for all affected EGUs, in order for the state measures plan type to satisfy the requirement of CAA section 111(d) that a state establish standards of performance for affected EGUs. This backstop would impose federally enforceable emission standards on the state's affected EGUs in the case that the state measures fail to achieve the state mass-based CO_2 goal. The backstop, discussed further below, would assure that the state CO_2 emission goal or CO_2 emission performance rates are fully achieved by affected EGUs in the form of federally enforceable emission standards.

a. Requirements for state measures under a state measures type plan. Under the state measures plan type, state measures must be satisfactorily described in the supporting material for a state plan submittal. The supporting material would need to demonstrate that the state measures meet the same integrity elements that would apply to federally enforceable emission standards. Specifically, the state plan submittal must demonstrate that the state measures are quantifiable, verifiable, enforceable, non-duplicative and permanent. These requirements are described in more detail at section VIII.D.2. Under the state measures plan, if a state chooses to impose emission standards on affected EGUs, such emission standards must be included in the federally enforceable plan as they would be under an emission standards plan.

The EPA would assess the overall approvability of a state measures plan based, in part, on the state's satisfactory demonstration that the state measures, in conjunction with any federally enforceable emission standards on the affected EGUs that might be included in the plan, would result in the state plan's achievement of the mass-based CO_2 goal for the state's affected EGUs (or mass-based CO_2 goal plus new source complement). This includes a demonstration of adequate legal authority and funding to implement the state plan and any associated measures. The EPA's determination that such a plan is satisfactory would be based in part on whether the state measures are adequately described in the supporting documentation and the plan submittal demonstrates that the state measures are quantifiable, verifiable, enforceable, non-duplicative and permanent as described above. This is necessary for the EPA to ensure that the results achieved through the plan are quantifiable and verifiable, and to assess whether the state measures are anticipated to achieve the state mass-based CO_2 goal for affected EGUs (or mass-based CO_2 goal plus new source complement).

The EPA's evaluation of the approvability of a state measures plan would also include an assessment of whether the backstop consisting of federally enforceable emission standards for the state's affected EGUs would ensure that the required emission performance level is fully achieved by affected EGUs, in the case that the state measures fail to achieve the state mass-based CO_2 goal (or mass-based CO_2 goal plus new source complement), or the state does not meet programmatic milestones during the interim period. The trigger for the backstop must also satisfactorily provide for the implementation of the backstop emission standards.

b. Considerations for the backstop included in a state measures type plan. As further discussed in section VIII.C.6.c, the EPA believes a backstop, composed of federally enforceable emission standards for the affected EGUs that are sufficient to achieve the state CO_2 emission goal or the CO_2 emission performance rates in the event that state measures do not result in the required CO_2 emission performance, is necessary for the state measures plan type to meet the requirements of CAA section 111(d). The state plan must specify the backstop that would apply federally enforceable emission standards to the affected EGUs if the state measures plan does not achieve the anticipated level of CO_2 emission performance by affected EGUs, or a state does not meet programmatic milestones during the interim period. The state plan must include promulgated regulations (or other requirements) that fully specify these emission standard requirements, which must be quantifiable, verifiable, enforceable, non-duplicative and permanent. These requirements are described in more detail at section VIII.D.2.

These federally enforceable emission standards must be designed such that compliance by affected EGUs with the emission standards would achieve the state's mass-based interim and final goals for affected EGUs. The backstop emission standards must specify CO_2 emission performance levels (in mass) that would apply for the interim plan performance period (including specifying levels for each of the interim step 1 through step 3 periods) and the final two-year plan performance periods.[796] If a state chose, these backstop emission standards could be based on a model rule or federal plan promulgated by the EPA.

The state measures plan must specify the trigger and conditions under which the backstop federally enforceable emission standards would apply that is consistent with the requirements in the emission guidelines. The trigger and attendant conditions for deployment of the backstop would address the CAA section 111(d) requirement that states submit a program that provides for the implementation of standards of performance. The state measures plan must specify the level of emission performance that will be achieved by affected EGUs as a result of implementation of the state measures plan during the interim and final plan performance periods. This includes the level of emission performance during the interim plan periods 2022-2024, 2025-2027 and 2028-2029, as well as the performance level that would be achieved during every subsequent 2-year final plan performance period (2030-2031, and subsequent 2-year periods). If actual CO_2 emission performance by affected EGUs fails to meet the level of emission performance specified in the

[796] This includes the level of emission performance during the interim plan periods 2022-2024, 2025-2027 and 2028-2029, as well as the performance level that would be achieved during every subsequent 2-year final plan performance period (2030-2031, and subsequent 2-year periods).

plan over the 8-year interim performance period (2022-2029) or for any 2-year final goal performance period, the state measures plan must require that the backstop federally enforceable emission standards would take effect and be applied to affected EGUs. Similarly, the plan must require that the backstop standards take effect if actual emission performance is deficient by 10 percent or more relative to the performance levels that the state has chosen to specify in the plan for the interim step 1 period (2022-2024) or the interim step 2 period (2025-2027). The backstop standards are also triggered if, at the time of the state's annual reports to the EPA during the interim period, the state has not met the programmatic milestones for the reporting period. The state measures plan must provide that, in the event the backstop is triggered, such emission standards would be effective within 18 months of the deadline for the state's submission of its periodic report to the EPA on state plan implementation and performance, as described in section VIII.D.2.c.[797,798]

[797] States may choose to establish an effective date for backstop emission standards that is sooner than 18 months.
[798] In the event a state does not implement the backstop as required if actual emission performance triggers the backstop, the EPA will take appropriate action. The EPA notes that as part of the proposed federal plan rulemaking, it is proposing a regulatory mechanism to call plans in the instances of substantial inadequacy to meet applicable requirements or failure to implement an approved plan.

The backstop emission standards must make up for the shortfall in CO_2 emission performance. The shortfall must be made up as expeditiously as practicable. The state may address the requirement to make up for the shortfall in CO_2 emission performance by submitting, as part of the final plan, backstop emission standards that assure affected EGUs would achieve the state's interim and final CO_2 emission goals or the CO_2 emission performance rates for affected EGUs, and then later submit appropriate revisions to the backstop emission standards adjusting for the shortfall through the state plan revision process. The state may alternately effectuate this by submitting, along with the backstop emission standards, provisions to adjust the emission standards to account for any prior emission performance shortfall, such that no modification of the emission standards is necessary in order to address the emission performance shortfall.

For example, assume a state measures plan identified a mass-based CO_2 standard for affected EGUs of 100 million tons during the interim step 1 performance period (2022-2024), 90 million tons during the interim step 2 performance period (2025-2027), and 80 million tons during the interim step 3 performance period (2028-2029). Over the entire interim plan performance period (2022-2029), the interim mass-based CO_2 goal is cumulative emissions of 270 million tons. Assume that CO_2 emissions from affected EGUs in the interim step 1 period were actually 115 million tons, triggering implementation of the backstop. In this instance, the mass-based standard for affected EGUs implemented as part of the backstop during subsequent plan performance periods would need to ensure that cumulative CO_2 emissions during the 2022-2029 interim period do not exceed 270 million tons. This could be achieved, for example, by implementing a mass standard of 75 million tons during the interim step 2 performance period (rather than the 90 million tons originally specified in the plan), or some other combination during the remaining interim step 2 and 3 performance periods.[799] The emission standards included as the backstop in the plan must specify calculations for how such adjustments will be made.

4. Summary of comments on state plan approaches

The EPA received a wide range of comments on the basic plan approaches in the proposal. Numerous commenters supported providing states with the option of implementing a rate-based or mass-based approach. Some commenters expressed concern that a rate-based approach would not reduce overall emissions, and could actually lead to increased emissions. The EPA does not

[799] In this example, states could elect to implement different combinations of mass-based standards during the remaining interim step 2 and 3 plan performance periods, provided that cumulative CO_2 emissions during the full interim plan performance period (2022-2029) do not exceed 270 million tons.

agree with this latter comment, because both approaches would result in adequate and appropriate constraints on CO_2 emissions. As documented in the RIA, a rate-based approach would result in a substantial reduction in CO_2 emissions relative to emissions under a business-as-usual case.

Numerous commenters supported allowing states to implement a rate-based emission standard approach applied to affected EGUs. There was also broad support in comments for allowing states to pursue a mass-based approach in the form of mass emission standards on affected EGUs. The EPA is finalizing both of these approaches.

The EPA received a mix of comments for and against the proposed portfolio approach, in which state requirements and other measures that apply to non-EGU entities would be part of a state's federally enforceable state plan. Multiple commenters supported the portfolio approach because it would align with existing state and utility planning processes in the electric power sector, and would maximize state discretion and flexibility in developing plans. Commenters mentioned the range of state requirements and utility programs overseen by states that could be used under a portfolio approach and result in achieving the CO_2 emission goal for affected EGUs, including state RPS, EERS and utility-administered EE programs. Commenters noted that the portfolio approach would provide states maximum flexibility to take local circumstances, economics and state policy into account when developing their plans.

By contrast, multiple commenters opposed the portfolio approach. Some commenters questioned how a portfolio approach would work, and whether the EPA had provided sufficient detail explaining how such a plan approach could be implemented by a state. In particular, multiple commenters questioned how different state programs, such as utility-administered EE programs, could be made federally enforceable in practice under CAA section 111(d).[800] Multiple commenters expressed concern about making state requirements and utility programs for RE and demand-side EE enforceable under the CAA. Some of these commenters supported the state commitments plan approach that the EPA took comment on in the proposal, which was a variant of the portfolio approach. Under the state commitment variant, measures that applied to entities other than affected EGUs would not be federally enforceable under the CAA, but state commitments to implement those measures would be federally enforceable elements of a state plan under the CAA.

After considering these comments, the EPA is not finalizing the portfolio approach or the state commitment variant. However, the EPA is finalizing the state measures plan type, as described

[800] Legal considerations with the proposed portfolio approach are explored in section VIII.C.6.d.

above, which would accommodate state choices and allow states to rely upon a variety of measures, as was envisioned under the portfolio approach, in a way that meets the statutory requirements of CAA section 111(d).

5. Multi-state plans and multi-state coordination

The EPA views the ability of a state to implement an individual plan or a multi-state plan as a significant flexibility that allows a state to tailor implementation of its plan to state policy objectives and circumstances. The EPA sees particular value in multi-state plans and multi-state coordination, which allow states to implement a plan in a coordinated fashion with other states. Such approaches can lead to more efficient implementation, lower compliance costs for affected EGUs and lower impacts on electricity ratepayers. Coordinated approaches also will help states identify and address any potential electric reliability impacts when developing plans.

The EPA received broad support in comments for allowing states to implement multi-state plan approaches, and has made multiple changes in the final rule to address many suggestions outlining different approaches states may want to take. These changes are intended to provide streamlined approaches for multi-state coordination while maintaining transparency and assuring that the CO_2 emission performance rates or state CO_2

emission goals are achieved.

The EPA is finalizing two approaches that allow states to coordinate implementation in order to meet the emission guidelines.[801]

First, states may meet the requirements of the emission guidelines and CAA section 111(d) by submitting multi-state plans that address the affected EGUs in a group of states. The EPA is finalizing the proposed approach by which multiple states aggregate their rate or mass CO_2 goals and submit a multi-state plan that will achieve a joint CO_2 emission goal for the fleet of affected EGUs located within those states (or a joint mass-based CO_2 goal plus a joint new source CO_2 emission complement).[802]

Second, the EPA is also finalizing another approach, in response to comments received on the proposed rule. This approach enables states to retain their individual state goals for affected EGUs and submit individual plans, but to coordinate plan implementation with other states through the interstate

[801] The EPA notes that in addition to these approved approaches, other types of multi-state approaches may be acceptable in an approvable plan, provided the obligations of each state under the multi-state plan are clear and the submitted plan(s) meets applicable emission guideline requirements.

[802] The concept of a new source CO_2 emission complement is addressed in section VIII.J.2.b. Table 14 provides individual state new source CO_2 emission complements. For a multi-state plan, a joint new source CO_2 emission complement would be the sum of the individual new source CO_2 emission complements in Table 14 for the states participating in the multi-state plan.

transfer of ERCs or emission allowances.[803] This approach facilitates interstate emission trading without requiring states to submit joint plans.[804] The EPA considers these to be individual state plans, not multi-state plans.

States have the option to implement this second approach in different ways, as discussed in section VIII.C.5.c. These different implementation options allow states to tailor their implementation of linked emission trading programs, based on state policy preferences, as well as economic and other considerations. These different options provide varying levels of state control over emission trading system partners and require varying levels of coordination in the course of state plan development.

In response to comments, the EPA is also further clarifying how multi-state plans with a joint goal for affected EGUs may be implemented. The EPA is clarifying that states may participate in more than one multi-state plan, if necessary, for example, to address affected EGUs in states that are served by more than one ISO or RTO. The EPA is further clarifying that a subset of affected EGUs in a state may participate in a multi-state plan.

---

[803] This approach also applies where a state plan is designed to meet a state mass-based CO_2 goal plus a state's new source CO_2 emission complement.

[804] States may submit individual plans with such linkages, or if they choose, provide a joint submittal. Forms of joint submittals are described at section VIII.E.

These clarifications are discussed in section VIII.C.5.d.

a. Summary of comments on multi-state plans. Multiple commenters supported the EPA's proposed approach that would allow states to implement a multi-state plan to meet a joint CO_2 emission goal. However, a number of states commented that states should also be allowed to coordinate without aggregating multiple individual state goals into a single joint goal. Many states questioned the incentives that a state would have to aggregate its goal with other states that have different goals, and also noted the administrative complexities presented by states seeking to formally coordinate state plans with one another.

The EPA notes that there are multiple incentives for states to collaborate by implementing a multi-state plan to meet an aggregated joint goal, regardless of the specific level of their individual goals, because states share grid regions and impacts from plan implementation will be regional in nature. Further, multiple analyses, including those by ISOs and RTOs, indicate that regional approaches could achieve state goals at lesser cost than individual state plan approaches. However, the EPA also recognizes the value in allowing for collaboration where states retain individual goals. These approaches could provide some of the benefits of a joint goal while reducing the negotiations among states necessary to develop a multi-state plan with a joint goal. As a result, the EPA has finalized the additional approaches described in section VIII.C.5 to provide for coordination while maintaining individual goals. These approaches would allow for interstate transfer of ERCs or emission allowances while retaining individual state goals.

Many commenters suggested that states should be encouraged to join or form regional market-based programs. Many commenters touted the economic efficiency benefits of such approaches, and noted that such programs have features that support electric reliability.

The EPA agrees with these comments, and notes that it encouraged such approaches in the proposal. While the EPA is not requiring states to join and/or form regional market-based programs, we note that such programs can be helpful for many reasons, including features that support reliability. Market-based programs allow greater flexibility for affected EGUs both in the short-term and long-term. Under a market-based program, affected EGUs have the ability to obtain sufficient allowances or credits to cover their emissions in order to comply with their emission standards. Additionally, we continue to encourage states to cooperate regionally. Regional cooperation in planning and reliability assessments is an important tool to meeting system needs in the most cost-effective, efficient, and reliable way.

b. Multi-state coordination through a joint emission goal. Multiple states may submit a multi-state plan that achieves an aggregated joint CO_2 emission goal for the affected EGUs in the participating states (or a joint mass-based CO_2 goal plus a joint new source CO_2 emission complement).[805] The joint emission goal approach is acceptable for both types of state plans, the "emission standards" plan type and the "state measures" plan type. However, the EPA is requiring that a joint goal may apply only to states implementing the same type of plan, either an "emission standards" plan or a "state measures" plan.[806]

[805] As a conceptual and legal matter, the relationship between states coordinating to meet a joint CO_2 emission goal under this rule is similar to the relationship between states coordinating SIP submissions to attain the NAAQS in an interstate nonattainment area. In both cases, the states coordinate their actions in a way that, cumulatively, the measures applicable in each state will lead to achievement of a common interstate goal (with the EPA evaluating the sufficiency and success of the plans on a holistic, interstate basis). Despite the shared goal, in both cases, the mere fact of coordination has no effect on each state's sovereign legal authority. For example, the legally applicable rules in a given state are adopted by that state individually, not by a joint entity or other interstate mechanism. Similarly, the fact that the states coordinate their rules does not grant them the authority to directly enforce each other's rules, or to take direct legal action against a state that is failing to implement its own rules. Although some states may jointly submit their coordinated rules to the EPA as a matter of administrative convenience, the state rules within such a plan are nothing more than reciprocal laws of the sort that states routinely enact in voluntary coordination with each other.

[806] This is necessary because if the joint goal is not achieved during a plan performance period, different remedies would apply under an emission standards plan and a state measures plan.

Under this approach, a rate-based multi-state plan would include a weighted average rate-based emission goal, derived by calculating a weighted average CO_2 emission rate based on the individual rate-based goals for each of the participating states and 2012 generation from affected EGUs. A mass-based multi-state plan would include an aggregated mass-based CO_2 emission goal for the participating states, in cumulative tons of CO_2, derived by summing the individual mass-based CO_2 emission goals of the participating states.[807]

Such plans could include emission standards in the form of a multi-state rate-based or mass-based emission trading program.[808] Alternatively, states could submit a multi-state plan

---

Under an emission standards plan, corrective measures would be triggered. Under a state measures plan, the federally enforceable backstop emission standards would be triggered. See section VIII.F.3.

[807] Where a multi-state plan is designed to meet a joint mass-based CO_2 goal plus a joint new source CO_2 emission complement, the joint new source CO_2 emission complement would be the sum of the individual new source CO_2 emission complements in section VIII.J.2.b, Table 14, for the states participating in the multi-state plan.

[808] A potential example of this approach is the method by which the states participating in RGGI have implemented individual CO_2 Budget Trading Program regulations in a linked manner using a shared emission and allowance tracking system. Each state's regulations implementing RGGI stand alone on a legal basis, but provide for the use of CO_2 allowances issued in other participating states for compliance under the state regulations. These states are not listed by name in state regulations, which instead refer to participating states that have established a corresponding CO_2 Budget Trading Program regulation. More information is available at http://www.rggi.org.

using a state measures approach.[809] Both approaches could provide for implementation of a multi-state emission trading program.

c. Multi-state coordination among states retaining individual state goals. States that do not wish to pursue a joint CO_2 emission goal with other states may pursue a second pathway to multi-state collaboration. States may submit individual plans that will meet the CO_2 emission performance rates or a state mass CO_2 goal for affected EGUs (or mass-based CO_2 goal plus the new source CO_2 emission complement), but include implementation in coordination with other state plans by providing for the interstate transfer of ERCs or CO_2 allowances, depending on whether the state is implementing a rate-based or mass-based emission trading program. This form of coordinated implementation may occur under both an "emission standards" type of plan and a "state measures" type of plan, where states are implementing emission trading programs.[810] For rate-based plans, this type of coordinated approach is limited to state plans with rate-based emission standards that are equal to the CO_2 emission performance rates in the emission guidelines.

[809] Under this approach, a state measure could include, if a state chose, a multi-state emission trading program that is enforceable at the state level.

[810] ERCs may only be transferred among states implementing rate-based emission limits. Likewise, emission allowances may only be transferred among states implementing mass-based emission limits.

Under this approach, a state plan could indicate that ERCs or CO_2 allowances issued by other states with an EPA-approved state plan could be used by affected EGUs for compliance with the state's rate-based or mass-based emission standard, respectively. Such plans must indicate how ERCs or emission allowances will be tracked from issuance through use by affected EGUs for compliance,[811] through either a joint tracking system, interoperable tracking systems, or an EPA-administered tracking system.[812]

The EPA would assess the approvability of each state's plan individually — the use of ERCs or emission allowances issued in another state would not impact the approvability of the components of the individual state plan.[813] However, the EPA would also assess linkages with other state plans, to ensure

[811] Referred to in different programs as "surrender," "retirement," or "cancellation."

[812] The EPA received a number of comments from states and stakeholders about the value of the EPA's support in developing and/or administering tracking systems to support state administration of rate-based emission trading programs. The EPA is exploring options for providing such support and is conducting an initial scoping assessment of tracking system support needs and functionality.

[813] Note that for mass-based plans, the approvability requirements for a state plan would differ, depending on the structure of the emission budget trading program included in the state plan. For example, approvability requirements and basic accounting with regard to whether a plan achieves a state's mass CO_2 goal would differ for emission budget trading programs that cover only affected EGUs subject to CAA section 111(d) vs. programs that apply to a broader set of emission sources. These considerations are addressed in section VIII.J.

that the joint tracking system or interoperable tracking systems used to implement rate-based or mass-based emission trading programs across states are properly designed with necessary components, systems, and procedures to maintain the integrity of the linked emission trading programs.

Coordinated state plan implementation among states that retain individual state mass-based CO_2 goals (or that implement individual state plans with rate-based emission standards consistent with the CO_2 emission performance rates in the emission guidelines) is discussed in more detail in sections VIII.J and K. Section VIII.J discusses coordinated implementation among states implementing individual mass-based emission budget trading programs and section VIII.K discusses coordinated implementation among states implementing individual rate-based emission trading programs.

d. Multi-state plans that address a subset of EGUs in a state. The EPA is clarifying in the final emission guidelines that a state may participate in more than one multi-state plan. Under this approach, the state would identify in its submittal the subset of affected EGUs in the state that are subject to the multi-state plan or plans. This could involve a subset of affected EGUs that are subject to a multi-state plan, with the remainder of affected EGUs subject to a state's individual plan. Alternatively, different affected EGUs in a state may be subject to different multi-state plans. In all cases, the state would need to identify in each specific plan which affected EGUs are subject to such plan, with each affected EGU subject to only one multi-state plan or subject only to the state's individual plan (if relevant).

These scenarios may occur where a state chooses to cover affected EGUs in different ISOs or RTOs in different multi-state plans. This will provide states with flexibility to participate in multi-state plans that address the affected EGUs in a respective grid region, in the case where state borders cross grid regions.

These scenarios may also occur where a state is served by multiple vertically integrated electric utilities with service territories that cross state lines. This will provide states with flexibility to participate in multi-state plans that address the affected EGUs owned and operated by a utility with a multi-state service territory.

6. Legal bases and considerations for state plan types and approaches

a. Legal basis for emission standards approach. The emission standards approach is consistent with the requirements of CAA section 111(d). If a state simply adopts the CO_2 emission performance rates, then the corresponding rate-based emission standards in the state plan establish standards of performance for affected EGUs as required under section 111(d)(1)(A). Similarly, if a state chooses to achieve the rate-based CO_2 emission goal through rate-based emission standards applicable only to affected EGUs, or to achieve the mass-based CO_2 emission goal through mass-based emission standards applicable only to affected EGUs (or, alternatively, to achieve the mass CO_2 goal and a new source CO_2 emission complement through federally enforceable mass-based emission standards in conjunction with state enforceable emission standards on new sources), then the set of rate-based emission standards or the set of mass-based emission standards in the state plan establishes standards of performance for affected EGUs as required under section 111(d)(1)(A). The EPA has the authority to approve emission standards for affected EGUs as part of a state plan under all three cases (as long as such emission standards meet the requirements of CAA section 111(d) and the final emission guidelines), thereby making such emission standards federally enforceable upon approval by the EPA. In all three cases, the emission standards must be quantifiable, verifiable, enforceable, non-duplicative and permanent; this ensures that the plan provides for implementation and enforcement of the standards of performance (i.e. the emission standards) as required by section 111(d)(1)(B). Finally, as described in section VIII.B.7.b below, standards of performance may include emission trading. Thus, the credit and allowance trading that is allowed under the emission standards approach is consistent with the statutory requirement that the plan establish standards of performance.

We note that the standard the statute provides for the EPA's review of a state plan is whether it is "satisfactory." We interpret a "satisfactory" plan as one that meets all applicable requirements of the CAA, including applicable requirements of these guidelines. Some commenters suggested that "satisfactory" should be taken to mean something less (such as mostly or substantially meeting requirements) but the structure of 111(d) shows otherwise. When a state plan is unsatisfactory, section 111(d)(2) gives the EPA the "same" authority to promulgate a federal plan as the EPA has under section 110(c). Under section 110(c), the EPA has authority to promulgate a federal implementation plan if a SIP does not comply with all CAA requirements (see sections 110(k)(3) and 110(l)).

For example, if an emission standards type plan includes an emission standard that is unenforceable due to defective rule language, then the plan is not satisfactory because it does not comply with the guideline requirement that emission standards must be enforceable. On the other hand, if a state plan complies with all applicable requirements of the CAA (including these guidelines), then the EPA must approve it as satisfactory. This is true even if the emission standards in the state plan are more stringent than the minimum requirements of these guidelines, or the state plan achieves more emission reductions than required by these guidelines. This follows from section 116 of the CAA as interpreted by the U.S. Supreme Court in *Union Elec. Co. v. EPA*, 427 U.S. 246, 263-64 (1976).

b. Legal basis for emissions trading in state plans. There are three legal considerations with respect to emissions trading in state plans. First, we explain how the definition of "standard of performance" in section 111(a)(1) allows section 111(d) plans to include standards of performance that authorize emissions trading. Second, we explain how the EPA interprets the phrase "provides for implementation and enforcement of [the] standards of performance" in the context of a rate-based ERC trading program. Third, we give a similar explanation of the EPA's interpretation of the same phrase in the context of a mass-based allowance trading program.

(1). In the proposal, the EPA proposed that CAA section 111(d) plans may include standards of performance that authorize emissions averaging and trading. 79 FR 34830, 34927/1 (June 18, 2014). We are finalizing that states may include the use of emission trading in approvable state plans.

For purposes of this legal discussion, in the case of an emission limitation expressed as an emission rate, trading takes the form of buying or selling ERCs that an affected EGU may generate if its actual emission rate is lower than its allowed emission rate or that an eligible resource may generate. In the case of an emission limitation expressed as a mass-based limit, trading takes the form of buying or selling allowances.

To reiterate for convenience, the definition of "standard of performance" under CAA section 111(a)(1) is:

> The term 'standard of performance' means a standard for emissions of air pollutants which reflects the degree of emission limitation achievable through the application of the best system of emission reduction which (taking into account the cost of achieving such reduction and any nonair quality health and environmental impact and energy requirements) the Administrator determines has been adequately demonstrated.

Both an emission rate that may be met through tradable ERCs, and a mass limit requirement that emissions not exceed the number of tradable allowances surrendered by an affected source, qualify as a "standard for emissions." The term "standard" is not defined, but its everyday meaning is a rule or requirement,[814] which, under the only (or at least a permissible) reading of the provision, would include an emission rate that may be met through tradable ERCs and a requirement to retire tradable allowances.

Treating a tradable emission rate or mass limit requirement as a "standard of performance" is consistent with past EPA practice. In the Clean Air Mercury Rule, promulgated in 2005, the EPA established tradable mass limits as the emission guidelines for certain air pollutants from fossil fuel-fired EGUs, and explained that a tradable mass limit qualifies as a "standard for emissions."[815] In addition, in the 1995 Municipal Solid Waste (MSW) Combustor rule the EPA authorized emission trading by sources.[816]

It should be noted that CAA section 302(l) includes another definition of "standard of performance," which is "a requirement of continuous emission reduction, including any requirement relating to the operation or maintenance of a source to assure continuous emission reduction." As described above, section 111(d) contains its own, more specific definition of "standard

[814] E.g., "Something that is set up and established by authority as a rule for the measure of quantity, weight, value, or quality." Webster's Third New International Dictionary 2223 (1967); see also The American College Dictionary (C.L. Barnhart, ed. 1970) ("an authoritative model or measure").
[815] 70 FR 28606, 28616-17 (May 18, 2005).
[816] 60 FR 65387, 6540/2 (Dec. 19, 1995).

of performance," which a tradable emission rate or mass limit satisfies. Whether or not section 302(l) applies in light of section 111(d)'s more specific definition, a tradable emission rate or mass limit also meets section 302(l)'s requirements. A tradable emission rate applies continuously in that the source is under a continuous obligation to meet its emission rate, and that is so regardless of the averaging time, e.g., a rate that must be met on an annual basis. Similarly, a mass limit requirement implemented through the use of allowances applies continuously in that the source is continuously under an obligation to assure that at the appropriate time, its emissions will not exceed the allowances it will surrender. In this respect, a tradable emission rate or mass limit requirement is similar to a non-tradable emission rate that must be met over a specified period, such as one year. In all of these cases, a source is continuously subject to its requirement although it may be able to emit at different levels at different points in time. It should also be noted that a tradable emission rate or mass limit requirement is appropriate for CO_2 emissions, the air pollutant covered by this rule, because the environmental effects of CO_2 emissions are not dependent on the location of the emissions.

(2). In our final rule, we are prescribing certain specific requirements for trading systems for ERCs in a rate-based approach. These specific requirements are in addition to the generic requirements for any state plan (see section VIII.D.2.d below for the legal basis for the generic components for state plans) and are intended to ensure the integrity of the ERC trading system. The integrity of the trading system is key to ensuring that a state plan provides for implementation and enforcement of the standards of performance, as required by section 111(d)(1)(B). Requirements relating to ERCs in a rate-based trading system, and allowances in a mass-based system, must also be submitted as federally enforceable components of the state plan, as such requirements provide for the implementation and enforcement of a tradable emission rate or mass limit for an affected EGU.

However, as described in section VIII.C.6.d, the EPA has legal concerns regarding whether federally enforceable requirements under a CAA section 111(d) state plan can be imposed on entities other than affected EGUs. It is important to note that the use of ERCs and inclusion of state plan requirements regarding a rate-based trading system, and the use of allowances and inclusion of state plan requirements regarding a mass-based trading system, does not run afoul of these legal concerns, as neither the requirements of section 111(d) nor of the federally enforceable state plan in either case extend to non-EGU generators or third-party verifiers of such compliance units.

(3). In our final rule, we are prescribing certain specific requirements for trading systems for allowances in a mass-based approach. These specific requirements are in addition to the generic requirements for any state plan (see section VIII.D.2.d below for the legal basis for the generic requirements for state plans) and are intended to ensure the integrity of the allowance trading system. The integrity of the trading system is key to ensuring that a state plan provides for implementation and enforcement of the standards of performance.

Our interpretation of the phrase "provides for implementation and enforcement of [the] standards of performance" in the context of the integrity of a trading system for allowances under a mass-based approach is further explained in the Legal Memorandum.

c. <u>Legal basis for state measures plan type</u>. The EPA believes the state measures plan type is consistent with CAA section 111(d). Section 111(d)(1) requires a state to submit a plan that "(A) establishes standards of performance for any existing source for [certain] air pollutant[s] ... and (B) provides for the implementation and enforcement of such standards of performance." Section 111(d)(2)(A) indicates that the EPA must approve the state plan if it is "satisfactory."

For states that choose to adopt and submit a state measures plan, such state must submit a state plan that includes standards of performance for CO_2 emissions from affected EGUs in the form of a federally enforceable backstop in order to meet the requirements of section 111(d). Section 111(d) unambiguously requires a state to submit a plan that establishes standards of performance for certain sources, but does not mandate when such standards of performance must be in effect or implemented in order to meet applicable compliance deadlines. Instead, Congress has delegated to the EPA the determination of the appropriate effective date of standards of performance submitted under state plans to meet the requirements of section 111(d). In other words, where the statute is silent, the EPA has authority to provide a reasonable interpretation. The EPA's interpretation is that for states that submit state plans establishing standards of performance under section 111(d), the effective date of such standards of performance may be later in time, perhaps indefinitely, for a number of reasons and under certain conditions. A key condition is that the state plan provides for the achievement of the required reduction by means other than the standards of performance on the timetable required by the BSER, with provision for federally enforceable standards of performance to be implemented if those other means fall short. The EPA believes it is reasonable to defer the effective date for standards of performance for affected EGUs as long as affected EGU CO_2 emissions are projected to achieve, and do achieve, the requisite state goal.

Additionally, under the state measures plan type, if a state chooses to impose emission standards for the affected EGUs in conjunction with state measures that apply to other entities for any period prior to the triggering of the backstop, this final rule requires such emission standards to be submitted as federally enforceable measures included in the state plan. The EPA believes this is appropriate to help ensure the performance of a state measures plan will meet the requirements of this final rule. Section 111(d) clearly authorizes states to impose, and the EPA to approve, federally enforceable emission standards for affected EGUs. Though federally enforceable emission standards for affected EGUs in a state measures plan themselves would not necessarily achieve the requisite state goals, the EPA is authorized to approve state plans when they satisfactorily meet applicable requirements. The EPA can evaluate whether a state measures plan is satisfactory by determining whether any federally enforceable emission standards for affected EGUs in conjunction with state measures on other entities will result in the achievement of the requisite emissions performance level. As previously explained in this final rule, the performance rates and the state goals are the arithmetic expression of BSER as applied across affected EGUs in a state as a source category. In a state measures plan, the evaluation of whether a state measures plan is satisfactory goes to evaluating both the state measures and any federally enforceable emission standards on the affected EGUs to determine whether the plan as a whole will result in the affected EGUs achieving the applicable goals that reflect BSER.

Section 111(d)(1)(B) also requires a state to submit a program that provides for the implementation and enforcement of the applicable standards of performance. Under the state measures approach, this requirement regarding implementation is satisfied in part by the submission of an approvable trigger mechanism for the backstop and appropriate monitoring, reporting and recordkeeping requirements. The trigger mechanism provides for the "implementation" of the backstop, i.e., the standards of performance, by putting the backstop into effect once the associated trigger is deployed. In other words, when the CO_2 performance level under a state plan exceeds the trigger as described in section VIII.C.4.b, the emission standards that were submitted as the federally enforceable backstop and any attendant requirements must be implemented and in effect. The statutory requirement under CAA section 111(d)(2) regarding enforcement is also satisfied under the state measures plan type by the state submitting standards of performance sufficient to meet the requisite emission performance rates or state goal, in the form of the backstop, for inclusion as part of the federally enforceable state plan.

Additionally, by requiring states that choose to impose emission standards on affected EGUs under the state measures approach to submit such emission standards for inclusion in the federally enforceable plan, this requirement further provides for implementation and enforcement as required by the statute. Regulating the affected EGUs through federally enforceable emission standards themselves in conjunction with any state measures the state chooses to rely upon further assures the likelihood of the affected EGUs achieving the state goals as required under this rule and section 111(d).

The state measures plan is a variation of the proposed portfolio approach in that both plan types allow the state to rely upon measures that impose requirements on sources other than affected EGUs in meeting the requisite state CO_2 emission goal. The state measures plan type is also a variation of the proposed state commitment approach in that the measures involving entities other than affected EGUs are not included as part of the federally enforceable 111(d) state plan, but the state may rely upon such measures that have the effect of reducing CO_2 emissions from affected EGUs as a matter of state law. The EPA took comment on the proposed portfolio approach and state commitment approach, and on the utilization of measures on entities other than affected EGUs in meeting the requirements of the emission guidelines and CAA section 111(d). With respect to the proposed state commitment approach, the EPA received comments recommending that the EPA require a federally enforceable backstop with emission standards sufficient to achieve the requisite CO_2 emission performance. The backstop component the EPA is finalizing as part of the state measures plan type is consistent with the EPA's statements in the proposal regarding states' obligations under section 111(d) to establish emission standards for affected EGUs, as the backstop contains federally enforceable emission standards for affected EGUs that will achieve the requisite CO_2 emission performance, and is consistent with comments received regarding the proposed state commitment approach.

The state measures plan type the EPA is finalizing is also a logical outgrowth of the comments received on the proposed portfolio approach. As further explained below, legal questions remain as to whether state plans under section 111(d) can include federally enforceable measures that impose requirements on sources other than affected EGUs. However, a number of commenters and stakeholders expressed robust support for the ability to rely on measures and programs that do not impose requirements on affected EGUs themselves through plan types such as the proposed portfolio and state commitment approaches. The

EPA is reasonably interpreting 111(d) as authorizing the state measures plan type, and believes this plan type is also responsive to, and accommodating of, states and stakeholders who have expressed the importance of being able to rely upon various measures that have the effect of reducing CO_2 emissions from affected EGUs. The EPA is finalizing the state measures plan type upon careful consideration of statutory requirements and comments received based on the proposed portfolio approach and state commitment approach.

The EPA additionally notes that the state measures plan type is not precluded by the recent Ninth Circuit Court of Appeals' decision in *Committee for a Better Arvin et al. v. US EPA et al.*, Nos. 11-73924 and 12-71332 (May 20, 2015). The court held that the EPA violated the CAA by approving a California SIP which relied on emission reductions from state-only mobile source standards ("waiver measures") without including those standards in the SIP. The court first looked at the plain language of section 110(a)(2)(A) of the CAA, which states that SIPs "shall include" the emission limitations and other control measures on which a state relies to comply with the CAA. The court then stated that the EPA's action was also inconsistent with the structure of the CAA. The EPA has the primary responsibility to protect the nation's air quality, but in the court's view, the EPA itself would be unable to enforce the state-only standards. In addition, the court stated that the EPA's action was inconsistent with citizens' right to enforce SIP provisions under section 304.

There are a number of reasons why this decision does not preclude the state measures plan type. The Ninth Circuit's textual analysis does not apply here, as the language of section 110(a)(2)(A) does not control for 111(d) state plans. Section 111(d)(1) requires state plans to "establish standards of performance" and to "provide for implementation and enforcement" of the standards of performance, but, unlike section 110(a)(2)(A), section 111(d) does not specifically say that every emission reduction measure must be "included" in the state plan and be made federally enforceable. Even if section 111(d) did impose such requirements, the state measures approach satisfies them because the trigger is included in the plan as a federally enforceable implementation measure, and the backstop included in the plan also contains standards of performance that reflect the BSER and are federally enforceable once they are triggered.

The Ninth Circuit's structural analysis also does not apply. The availability of the trigger and backstop gives the EPA and citizens a federally enforceable route to ensure that all necessary emission reductions take place in order to achieve the standards of performance. This is markedly different than the state-only standards, where according to the Ninth Circuit, the EPA and citizens had no route to ensure that all necessary emission reductions took place in order to attain the NAAQS. In addition, case law suggests that federal enforceability for every requirement may not be necessary when there are sufficient federally enforceable requirements to satisfy the statute, see *National Mining Ass'n v. United States EPA*, 59 F.3d 1351 (D.C. Cir. 1995); in this case federal enforceability for the state-only measures is not necessary to meet the statutory requirements of section 111(d)(1) as the federally enforceable trigger and backstop are sufficient.

d. Legal considerations with proposed portfolio approach. The EPA is not finalizing the portfolio approach that was included in the proposed rulemaking, 79 FR 34830, 34902 (June 18, 2014). In the proposal, the EPA noted that the portfolio approach raised legal questions. 79 FR 34830, 34902-03. A number of commenters stated that the portfolio approach is unlawful because it exceeds the limitations that section 111(d)(1) places on state plans. Upon further review, we agree with these comments.

Section 111(d)(1) provides that state plans shall "establish[] "standards of performance for any existing source" and "provide[] for the implementation and enforcement of . . . standards of performance" under CAA section 111(d)(1). Although in the proposal we identified possible interpretations of section 111(d)(1) that could justify the proposed portfolio approach, after reviewing the comments, we are not adopting those interpretations. Because section 111(d)(1) specifically requires state plans to include only (A) standards for emissions imposed on affected sources and (B) measures that implement and enforce such standards,[817] we interpret it as allowing federal enforceability only of requirements or measures that are in those two specifically required provisions. We therefore do not interpret the term "implementation of ... such standards of performance" to authorize the EPA to approve state plans with obligations enforceable against the broad array of non-emitting entities that would have been implicated by the portfolio approach. Thus, the EPA is not finalizing the portfolio approach, and in the event that states submit such measures to the EPA for inclusion in the state plan, the EPA would not approve them into the state plan and therefore would not make them federally enforceable.

We note that section 111(d) limits on federal enforceability of requirements against non-affected sources do not imply that the BSER cannot be based on actions by non-affected sources. As discussed in section V, the BSER may be

[817] Such measures include, for example, in this rule, requirements for ERCs.

based on the ability of owners/operators of affected sources to engage in commercial relationships with a wide range of other entities, from the vendors, installers, and operators of air pollution control equipment to, in this rulemaking, owners/operators of RE.

The EPA notes it is also not finalizing the proposed state commitment approach or state crediting approach. The EPA believes the finalized state measures plan type provides states with the same flexibilities as would have been allowed under these two proposed approaches, and does so in a way that is legally supportable by the CAA. Therefore, the EPA does not believe it necessary to finalize the state commitment approach or state crediting approach.

e. Legal basis for multi-state plans. While nothing in section 111(d)(1) explicitly authorizes either states to adopt and submit multi-state plans, or the EPA to approve them as satisfactory, nothing in section 111(d)(1) explicitly prohibits it, either. In addition, nothing in section 111(d)(2)(A)'s standard of "satisfactory" prohibits the EPA from considering multi-state plans as satisfactory. There is thus a gap that the EPA may reasonably fill.

In light of the purpose of these emission guidelines, to reduce emissions of a pollutant that globally mixes in the stratosphere, and the mechanisms to reduce those emissions, which may have beneficial effects across state lines, it is reasonable to allow for multi-state plans. Thus, our gap-filling interpretation of section 111(d) in this context is reasonable.

D. State Plan Components and Approvability Criteria

1. Approvability criteria

In the "Criteria for Approving State Plans" section of the preamble to the June 2014 proposal (section VIII.C), the EPA proposed the following as necessary components of an approvable state plan:

1. The plan must contain enforceable measures that reduce EGU CO_2 emissions;

2. The projected CO_2 emission performance by affected EGUs must be equivalent to or better than the required CO_2 emission performance level in the state plan;

3. The EGU CO_2 emission performance must be quantifiable and verifiable;

4. The plan must include a process for state reporting of plan implementation, CO_2 emission performance outcomes, and implementation of corrective measures, if necessary.

After reviewing the comments we received concerning the approvability criteria, the EPA has decided against maintaining the four proposed approvability criteria separately from the list of components required for an approvable plan, which may be confusing and potentially redundant. The EPA has determined that a satisfactory state plan that meets the required plan components discussed below will inevitably meet the proposed approvability criteria. The EPA, therefore, has incorporated the proposed approvability criteria into the section titled "Components of a state plan submittal" (section VIII.D.2 below). There is no functional change in the approvability criteria or the components of a state plan addressed in the proposal; they are simply combined and this change does not have a substantive effect on state plan development or approval.

Under the proposed "Enforceable Measures" criterion (section VIII.C.1 of the proposal preamble), the EPA specifically requested comment on the appropriateness of applying existing EPA guidance on enforceability to state plans under CAA section 111(d), considering the types of entities that might be included in a state plan.[818]

The EPA also requested comment on whether the agency should provide guidance on enforceability considerations related to requirements in a state plan for entities other than affected

[818] The existing guidance documents referenced were: (1) September 23, 1987 memorandum and accompanying implementing guidance, "Review of State Implementation Plans and Revisions for Enforceability and Legal Sufficiency," (2) August 5, 2004 "Guidance on SIP Credits for Emission Reductions from Electric-Sector Energy Efficiency and Renewable Energy Measures," and (3) July 2012 "Roadmap for Incorporating Energy Efficiency/Renewable Energy Policies and Programs into State and Tribal Implementation Plans, Appendix F."

EGUs, and if so, what types of entities. Comments received strongly suggested that the EPA provide guidance on enforceability considerations for non-EGU affected entities, particularly for RE and EE. Comments also requested additional guidance specific to this rulemaking, including examples of enforceable measures for specific activities, such as solar thermal technologies, waste heat recovery, net-metering energy savings and state RPS.

These enforcement considerations arose primarily under the proposed portfolio approach for state plans, which would have allowed state plans to include federally enforceable measures that apply to entities that are not affected EGUs. In this action, the EPA is finalizing the state measures approach instead of the portfolio approach, under which a state can rely upon measures that are not federally enforceable as long as the plan also includes a backstop of federally enforceable emission standards that apply to affected EGUs. As explained in depth in section VIII.C, if the state is adopting the state measures approach, the state plan submittal will need to specify, in the supporting materials, the state-enforceable measures that the state is relying upon, in conjunction with any federally enforceable emission standards for affected EGUs, to meet the emission guidelines. As part of the state measures approach, the EPA is finalizing a requirement for a federally enforceable backstop, which requires the affected EGUs to meet emission standards that fully achieve the CO_2 emission performance rates or the state's CO_2 emission goal if the state measures do not meet the intended emission performance levels. Because the EPA is not finalizing the portfolio approach, which would have allowed states to include federally enforceable measures in a state plan that apply to entities that are not affected EGUs, the agency is not providing additional guidance on federal enforceability of measures that might apply to such entities. As proposed, we are requiring that state plans include a demonstration that plan measures are enforceable, which for emission standards plan types is discussed in section VIII.D.2.b.3 below and for state measures plan types is discussed in section VIII.D.2.c.6 below.

Commenters also requested that the EPA allow states to rely on provisions with flexible compliance mechanisms in state plans and clarify how to address flexible compliance mechanisms when demonstrating achievement of a state CO_2 emission goal. Additionally, a commenter requested that the enforceability mechanisms that the EPA requires in state plans should support existing programs, as well as new programs in other states, by minimizing program changes required purely to conform with federal requirements, while still providing enough additional program review and accounting to ensure that CO_2 emission reductions are achieved. These and related comments contributed to the EPA's decision to finalize the option for states to submit a state measures plan, which would be comprised, at least in part, of measures implemented by the state that are not included as federally enforceable components of the plan, with a backstop of federally enforceable emission standards for affected EGUs that fully meet the emission guidelines and that would be triggered if the plan failed to achieve the CO_2 emission performance levels specified in the plan on schedule. For more information on the state measures plan approach, see section VIII.C.3 of this preamble above.

2. Components of a state plan submittal

In this action, the EPA is finalizing that a state plan submittal must include the components described below. As a result of constructive comments received from many commenters and additional considerations, the EPA is finalizing state plan components that are responsive to that input and are appropriate for the types of state plans allowed in the final emission guidelines. A state plan submittal must also be consistent with additional specific requirements elsewhere in this final rule and with the EPA implementing regulations at 40 CFR 60.23-60.29, except as otherwise specified by this final rule. These requirements apply to both individual state plan submittals and multi-state plan submittals. When a state plan submittal is approved by the EPA, the EPA will codify the approved CAA section 111(d) state plan in 40 CFR part 62. Section VIII.D.3 discusses the components of a state plan submittal that would be codified as the state CAA section 111(d) plan when the state plan submittal is approved by the EPA.

The EPA is finalizing that states can choose to meet the emission guidelines through one of two types of state plans: an emission standards plan type or a state measures plan type. A state pursuing the emission standards plan type may opt to submit a plan that meets the CO_2 emission performance rates for affected EGUs or meets the state rate-based or mass-based CO_2 emission goal for affected EGUs. A state implementing a state measures approach plan type must submit a plan that meets the state mass-based CO_2 goal for affected EGUs. The content of the state plan submittal will vary depending on which plan type the state decides to adopt. States that choose to participate in multi-state plans must adequately address plan components that apply to all participating states in the multi-state plan.

The rest of this section covers components that are required for all types of plans, as well as components specific to each specific type of plans. Section VIII.D.2.a addresses the components required for all plan submittals. Section VIII.D.2.b addresses the additional components required for submittals under the emission standards plan type. Section VIII.D.2.c addresses additional components required for submittals under the state measures plan type.

a. <u>Components required for all state plan submittals</u>. The EPA is finalizing requirements that a final plan submittal must contain the following components, in addition to those in either section VIII.D.2.b (for the emission standards plan type) or VIII.D.2.c (for the state measures plan type) of this section.

(1) <u>Description of the plan approach and geographic scope</u>.

The description of the plan type must indicate whether the state will meet the emission guidelines on an individual state basis or jointly through a multi-state plan, and whether the state is adopting an emission standards plan type or a state measures plan type. For multi-state plans this component must identify all participating states and geographic boundaries applicable to each component in the plan submittal. If a state intends to implement its individual plan in coordination with other states by allowing for the interstate transfer of ERCs or emission allowances, such links must also be identified.[819]

(2) <u>Applicability of state plans to affected EGUs</u>.

The state plan submittal must list the individual affected EGUs that meet the applicability criteria of 40 CFR 60.5845 and

[819] If applicable, this plan component must also identify if the plan is being submitted as a "ready-for-interstate-trading" plan, as discussed in section VIII.J.3 and VIII.K.4.

provide an inventory of CO_2 emissions from those affected EGUs for the most recent calendar year prior to plan submission for which data are available.

(3) Demonstration that a state plan will achieve the CO_2 emission performance rates or state CO_2 emission goal.

A state plan submittal must demonstrate that the federally enforceable emission standards for affected EGUs and/or state measures are sufficient to meet either the CO_2 emission performance rates or the state's CO_2 emission goal for affected EGUs in the emission guidelines for the interim and final plan performance periods. This includes during the interim period of 2022-2029, including the interim step 1 period (2022-2024); interim step 2 period (2025-2027); and interim step 3 period (2028-2029) period, as well as during the final period of 2030-2031 and subsequent 2-year periods.[820] A demonstration of CO_2 emission performance is required through 2031. For the post-2031 period, the demonstration requirement may be satisfied by showing that emission standards or state measures on which the

[820] State plans may meet the CO_2 emission performance rates in the emission guidelines during the interim plan performance step periods, or assign different interim step CO_2 emission performance rates, provided the CO_2 emission performance rates in the emission guidelines are achieved during the full interim period. Likewise, a state plan may meet the interim step state CO_2 emission goals in the emission guidelines or establish different interim step CO_2 emission levels, provided the state interim CO_2 goal is achieved during the full interim period.

demonstration through 2031 is based are permanent and will remain in place. As discussed in more detail in section VIII.J, states adopting a plan based upon a mass-based state CO_2 emission goal must demonstrate that they have addressed the risk of potential emission leakage in their mass-based state plan.

The type of demonstration of CO_2 emission performance and documentation required for such a demonstration in a state plan submittal will vary depending on how the CO_2 emission standards for affected EGUs and/or state measures in a state plan are applied across the fleet of affected EGUs in a state, as discussed below.[821]

(a) State plan type designs that require a projection of CO_2 emission performance. Whether a projection of affected EGU CO_2 emission performance must be included in a state plan submittal depends on the design of the state plan. The following plan designs do not require a projection of CO_2 emission performance by affected EGUs under the state plan because they ensure that the CO_2 emission performance rates or state rate-based or mass-

[821] For simplicity, the EPA refers here to state measures under a state measures plan as being included "in the state plan" although such state-enforceable measures are not codified as part of the federally enforceable approved state plan. However, the approval of a state measures plan is dependent on a demonstration in the state plan submittal that those state-enforceable measures meet the requirements in the emission guidelines and that those state measures, alone or in combination with federally enforceable emission standards for affected EGUs, will meet the mass-based CO_2 goal.

based CO_2 goals are achieved when affected EGUs comply with the emission standards:

- State plan establishes separate rate-based CO_2 emission standards for affected fossil fuel-fired electric utility steam generating units and stationary combustion turbines (in lb CO_2/MWh) that are equal to or lower than the CO_2 emission performance rates in the emission guidelines during the interim and final plan performance periods.
- State plan establishes a single rate-based CO_2 emission standard for all affected EGUs that is equal to or lower than the state's rate-based CO_2 goal in the emission guidelines during the interim and final plan performance periods.
- State plan establishes mass-based CO_2 emission standards for affected EGUs that cumulatively do not exceed a state's mass-based CO_2 goal in the emission guidelines during the interim and final plan performance periods.
- State plan establishes mass-based CO_2 emission standards for affected EGUs that, together with state enforceable limits on mass emissions from new EGUs, cumulatively do not exceed the state's EPA-specified mass CO_2 emission

budget[822] in the emission guidelines during the interim and final plan performance periods.

All other state plan designs must include a projection of CO_2 emission performance by affected EGUs under the state plan. For example, if a state chooses to apply rate-based CO_2 emission standards to individual affected EGUs, or to subcategories of affected EGUs (such as fossil fuel-fired electric utility steam generating units and stationary combustion turbines), at a lb CO_2/MWh rate that differs from the CO_2 emission performance rates or the state's rate-based CO_2 goal in the emission guidelines, then a projection is required. Also, if a state chooses to implement a mass-based program including both affected EGUs and new EGUs, but with total allowable emissions in excess of the presumptively approvable EPA-specified mass CO_2 emission budget for that state, the state must provide a projection of CO_2 emission performance. Likewise, if a state chooses a state measures state plan approach, a projection of CO_2 emission performance is required.

(b) Methods and tools. A satisfactory demonstration of the future CO_2 emission performance of affected EGUs must use technically sound methods that are reliable and replicable. A

[822] A state's EPA-specified mass CO_2 emission budget is the state's mass-based CO_2 goal for affected EGUs plus the EPA-specified new source CO_2 emission complement. See section VIII.J.2.b.

state plan submittal must explain how the projection method and/or tool works and why the method and/or tool chosen is appropriate considering the type of emission standards and/or state measures included (or relied upon, in the case of state measures) in a state plan. The results of the demonstration must be reproducible using the documented assumptions described in the state plan submittal. The method and projection of EGU generation and CO_2 emissions can differ from the EPA's forecast in the RIA. The EPA received comments on whether it would require specific modeling tools and input assumptions. Commenters raised concerns that the EPA may require states to use proprietary models, and that states do not have the financial resources to use such models. The EPA is not requiring a specific type of method or model, as long as the one chosen uses technically sound methods and tools that establish a clear relationship between electricity grid interactions and the range of factors that impact future EGU economic behavior, generation, and CO_2 emissions. The EPA will assess whether a method or tool is technically sound based on its capability to represent changes in the electric system commensurate to the set of emission standards and state measures in a state plan while accounting for the key parameters specified in section VIII.D.2.a.(3)(c) below. Including a base case CO_2 emission projection in the state plan submittal (i.e., one that does not include any federally enforceable CO_2 emission standards included in a plan or state-enforceable measures referenced in a plan submittal), will help facilitate the EPA's assessment of the CO_2 emission performance projection. Methods and tools could range from applying future growth rates to historical generation and emissions data, using statistical analysis, or electric sector energy modeling.

(c) Required documentation of projections. When required to provide a CO_2 emission performance projection, the state must also provide comprehensive documentation of analytic parameters for the EPA to assess the reasonableness of the projection. The analytic parameters, when considered as a whole, should reflect a logically consistent future outlook of the electric system. Refer to the Incorporating RE and Demand-side EE Impacts into State Plan Demonstrations TSD of the final rule for further details on quantifying impacts of eligible RE and demand-side EE measures.

The CO_2 emission performance projection documentation must include:

- Geographic representation, which must be appropriate for capturing impacts and/or changes in the electric system
- Time period of analysis, which must extend through 2031
- Electricity demand forecast (MWh load and MW peak demand)

at the state and regional level. If the demand forecast is not from NERC, an ISO or RTO, EIA, or other publicly available source, then the projection must include justification and documentation of underlying assumptions that inform the development of the demand forecast, such as annual economic and demand growth rate, population growth rate.

- Planning reserve margins
- Planned new electric generating capacity
- Analytic treatment of the potential for building unplanned new electric generating capacity
- Wholesale electricity prices
- Fuel prices, when applicable;
- Fuel CO_2 content
- Unit-level fixed operations and maintenance costs, when applicable;
- Unit-level variable operations and maintenance costs, when applicable;
- Unit-level capacity
- Unit-level heat rate
- If applicable, EGU-specific actions in the state plan designed to meet the required CO_2 emission performance, including their timeline for implementation

- If applicable, state-enforceable measures, with electricity savings and renewable electricity generation (MWhs) expected for individual and collective measures, as applicable. Quantification of MWhs expected from EE and RE measures will involve assumptions that states must document, as described in the Incorporating RE and Demand-side EE Impacts into State Plan Demonstrations TSD.
- Annual electricity generation (MWh) by fuel type and CO_2 emission levels, for each affected EGU
- ERC or emission allowance prices, when applicable

The state must also provide a clear demonstration that the state measures and/or federally enforceable emission standards informing the projected achievement of the emission performance requirements will be permanent and remain in place.

The EPA encourages participation in regional modeling efforts which are designed to allow sharing of data and help promote consistent approaches across state boundaries. A state that submits a single-state plan must consider interstate transfer of electricity across state boundaries, taking into account other states' plan types reflecting the best available information at the time of the CO_2 emission performance projection. Projections of CO_2 emission performance for multi-state plans and single-state plans that include multi-state coordination must either use a single (regional) electricity demand forecast or must document the use of electricity demand forecasts from different information sources and demonstrate how any inconsistencies between the individual electricity demand forecasts have been reconciled.

(d) Additional projection requirements under a rate-based emission standards plan. For an emission standards plan that applies rate-based CO_2 emission standards to individual affected EGUs, or to subcategories of affected EGUs, at a lb CO_2/MWh rate that differs from the CO_2 emission performance rates or the state’s rate-based CO_2 goal in the emission guidelines, a projection of affected EGU CO_2 emission performance is required. The state must demonstrate that the weighted average CO_2 emission rate of affected EGUs, when weighted by generation (in MWh) from affected EGUs subject to the different rate-based emission standards, will be equal to or less than the CO_2 emission performance rates or the state's rate-based CO_2 emission goal during the interim and final plan performance periods.

The projection will involve an analysis of the change in generation of affected EGUs given the compliance costs and incentives under the application of different emission rate standards across affected EGUs in a state. It must accurately represent the emission standards in the plan, including the use of market-based aspects of the emission standards (if applicable), such as use of ERCs or emission allowances as compliance instruments.

In addition to the elements described in the previous section (c), the projection under this plan design must include:

- The assignment of federally enforceable emission standards for each affected EGU;
- A projection showing how generation is expected to shift between affected EGUs and across affected EGUs and non-affected EGUs over time;
- Underlying assumptions regarding the availability and anticipated use of the MWh of electricity generation or electricity savings from eligible measures that can be issued ERCs;
- The specific calculation (or assumption) of how eligible MWh of electricity generation or savings that can be issued ERCs are being used in the projection to adjust the reported CO_2 emission rate of affected EGUs, consistent with the accounting methods for adjusting the CO_2 emission rate of an affected EGU specified in section VIII.K.1 of the emission guidelines, if applicable;
- ERC prices, if applicable;
- If a state plan provides for the ability of RE resources

located in states with mass-based plans to be issued ERCs for use in adjusting the reported CO_2 emission rates of affected EGUs, consideration in the projection that such resources must meet geographic eligibility requirements, based on power purchase agreements or related documentation, consistent with the requirements at section VIII.K.1 and section VIII.L; and

- Any other applicable assumptions used in the projection.

(e) Additional projections requirements for a state measures plan. For a state measures plan, a projection of affected EGU CO_2 emission performance must demonstrate that the state measures, whether alone or in conjunction with any federally enforceable CO_2 emission standards for affected EGUs, will achieve the state's mass-based CO_2 goals in the emission guidelines for the interim and final periods. The projection must accurately represent individual state-enforceable measures (or bundled measures) and timing for implementation of these state measures.

A state must demonstrate that its state-enforceable measures, along with any federally enforceable CO_2 emission standards for affected EGUs included in a state plan, will achieve the state mass-based CO_2 goal. In addition to the elements described in section VIII.D.2.a.(3).(c), the state must clearly document, at a minimum:

- the assignment of federally enforceable emission standards for each affected EGUs, if applicable; and

- the individual state measures, including their projected impacts over time.

Because different types of state measures could have varying degrees of impact on reducing or avoiding CO_2 emissions from affected EGUs, and different state measures may interact with one another in terms of CO_2 emission reduction impacts, the method and tools a state uses to project CO_2 emissions impacts must have the capability to project how the combined set of state-enforceable measures are likely to impact CO_2 emissions at affected EGUs. If a state chooses to use an emission budget trading program as a mass-based state measure, for example, the state must choose an analytic method or tool that can account for and properly represent any program flexibilities that impact CO_2 emissions from affected EGUs, such as use of out-of-sector GHG offsets and cost-containment provisions. The state would show that the emissions budget trading program included in the state measures plan, as well as any other state measures, ensure that the sum of emissions at all affected EGUs will be lower than or equal to the state's CO_2 emission goal in the time periods specified in these guidelines. All flexibilities must be clearly documented in the demonstration.

(4) Monitoring, reporting and recordkeeping requirements for affected EGUs.

The state plan submittal must specify how each emission standard is quantifiable and verifiable by describing the CO_2 emission monitoring, reporting and recordkeeping requirements for affected EGUs. The applicable monitoring, recordkeeping and reporting requirements for affected EGUs are outlined in section VIII.F.

In the June 2014 proposal, the EPA proposed that states must include in their state plans a record retention requirement for affected EGUs to maintain records for at least 10 years following the date of each occurrence, measurement, maintenance, corrective action, report or record. Commenters requested clarification of the record retention requirements for states as compared to for affected EGUs and also requested that the EPA clarify onsite versus offsite record maintenance requirements for affected EGUs. The EPA is finalizing that states must include in their plans a record retention requirement for affected EGUs of not less than 5 years following the date of each compliance period, compliance true-up period, occurrence, measurement, maintenance, corrective action, report, or record, whichever is latest. Affected EGUs must maintain each record onsite for at least 2 years after the date of the occurrence of each record and may maintain records offsite and electronically for the remaining years. Each record must be in a form suitable and readily available for expeditious review. The EPA finds that these final recordkeeping requirements are appropriate and consistent with the requirements for other CAA section 111(d) emission guidelines.

(5) State reporting and recordkeeping requirements.

A state plan submittal must contain the process, content and schedule for state reporting to the EPA on plan implementation and progress toward meeting the CO_2 emission performance rates or state CO_2 emission goal.

The EPA requested comments on whether full reports containing all of the report elements should only be required every 2 years and on the appropriate frequency of reporting of the different proposed elements, considering both the goals of minimizing unnecessary burdens on states and ensuring program transparency and effectiveness. Commenters recognized that different reporting frequencies may be appropriate for different types of state plans. The EPA agrees with the commenters and is finalizing state reporting requirements based on the type of plan the state chooses to adopt and implement. These state reporting requirements and reporting periods are discussed in section VIII.D.2.b (for emission standards plan types) and VIII.D.2.c (for state measures plan types). The EPA finalizes that each state report is due to the EPA no later than the July 1 following the end of each reporting period. The EPA recognizes the multiple comments received recommending extending the state report due date from July 1 to a later date or to allow the states the flexibility to propose an alternative report submittal date. The EPA is not pursuing these recommendations due to the implications of the state reports’ due date and the trigger and schedule for implementation of corrective measures (for the emission standards approach) or the backstop federally enforceable emission standards (for the state measures approach). The EPA believes the July 1 deadline for states to submit reports to the EPA on plan implementation is feasible given that the information required to be included in the reports will be available per the reporting requirements for affected EGUs in state plans.

In addition to the state reporting requirements discussed in section VIII.D.2.b (for emission standards approach) and VIII.D.2.c (for state measures approach) and as discussed below, states must include in the supporting material of a final state plan submittal a timeline with all the programmatic milestone steps the state will take between the time of the final state plan submittal and 2022 to ensure the plan is effective as of 2022. The EPA is also finalizing a requirement that states must submit a report to the EPA in 2021 that demonstrates that the state has met the programmatic milestone steps that the state indicated it would take from the submittal of the final plan through the end of 2020, and that the state is on track to implement the approved state plan as of January 1, 2022. A final state plan submission must include a requirement for the state to submit this report to the EPA no later than July 1, 2021. This report will help the EPA further assist and facilitate plan implementation with states as part of an ongoing joint effort to ensure the necessary reductions are achieved.

The EPA is finalizing the requirement that submissions related to this program be submitted electronically. Specifically, this includes negative declarations, state plan submittals (including any supporting materials that are part of a state plan submittal), any plan revisions, and all reports required by the state plan. The EPA is developing an electronic system to support this requirement that can be accessed at the EPA’s Central Data Exchange (CDX) (http://www.epa.gov/cdx/). See section VIII.E.8 for additional information on electronic submittal requirements.

In the June 2014 proposal, the EPA proposed that states must keep records, for a minimum of 20 years, of all plan components, plan requirements, plan supporting documentation and status of meeting the plan requirements, including records of all data submitted by each affected EGU used to determine compliance with its emission standards. The EPA received multiple comments recommending that the EPA reduce recordkeeping requirements due to the burden in expenditure of resources and manpower to maintain records for at least 20 years. Commenters recommended that recordkeeping requirements be reduced to 5 years consistent with emission guidelines for other existing sources.

After considering the comments received, this final rule requires that a state must keep records of all plan components, plan requirements, supporting documentation, and the status of meeting the plan requirements defined in the plan for the interim plan period from 2022-2029 (including interim steps 1, 2 and 3). After 2029, states must keep records of all information relied upon in support of any continued demonstration that the final CO_2 emission performance rates or goals are being achieved. The EPA agrees with comments that a 20-year record retention requirement could be unduly burdensome, and has reduced the length of the record retention requirement for the final rule. During the interim period, states must keep records for 10 years from the date the record is used to determine compliance with an emission standard, plan requirement, CO_2 emission performance rate or CO_2 emission goal. During the final period, states must keep records for 5 years from the date the date the record is used to determine compliance with an emission standard, plan requirement, CO_2 emission performance rate or CO_2 emissions goal. All records must be in a form suitable and readily available for expeditious review. States must also keep records of all data submitted by each affected EGU that was used to determine compliance with each affected EGU's emission standard, and such data must meet the requirements of the emission guidelines, except for any information that is submitted to the EPA electronically pursuant to requirements in 40 CFR part 75. If the state is adopting and implementing the state measures approach, the state must also maintain records of all data regarding implementation of each state measure and all data used to demonstrate achievement of the CO_2 emission goal and such data must meet the requirements of the emission guidelines. The EPA finds that these final recordkeeping requirements balance the need to maintain records while reducing the strain on state resources.

(6) Public participation and certification of hearing on state plan.

A robust and meaningful public participation process during state plan development is critical. For the final plan submittal, states must meaningfully engage with members of the public, including vulnerable communities, during the plan development process. This section describes how the EPA will evaluate a state plan for compliance with the minimum required elements for public participation provided in the existing implementing regulations as well as recommendations for other steps the state can take to assure robust and inclusive public participation.

The existing implementing regulations regarding public participation requirements are in 40 CFR 60.23(c)-(f). Per the implementing regulations, states must conduct a public hearing on a final state plan before such plan is adopted and submitted. State plan development can be enhanced by tapping the expertise and program experience of several state government agencies. The EPA encourages states to include utility regulators (e.g. the PUCs) and state energy offices as appropriate early on and throughout in the development of the state plan.[823] The EPA notes that utility regulators and state energy offices have the opportunity during the public participation processes required for state plans to provide input as well. The EPA also encourages states to conduct outreach meetings (that could include public hearings or meetings) with vulnerable communities on its initial submittal before the plan is submitted. In its final plan submittal, a state must provide certification that the state made the plan submittal available to the public and gave reasonable notice and opportunity for public comment on the state plan submittal. The state must demonstrate that the public hearing on the state plan was held only after reasonable notice,

[823] While we specifically encourage state environmental agencies and utility regulators to consult here, we note that, under CAA programs, state agencies have a history of consultation with one another as appropriate.

which will be considered to include, at least 30 days prior to the date of such hearing, notice given to the public by prominent advertisement announcing the date(s), time(s) and place(s) of such hearing(s). For each hearing held, a state plan submittal must include in the supporting documentation the list of witnesses and their organizational affiliations, if any, appearing at the hearing, and a brief written summary of each presentation or written submission pursuant to the requirements of the implementing regulations at 40 CFR 60.23. Additionally, the EPA recommends that states work with local municipalities, community-based organizations and the press to advertise their state public hearing(s). The EPA also encourages states to provide background information about their proposed final state plan or their initial submittal in the appropriate languages in advance of their public hearing and at their public hearing. Additionally, the EPA recommends that states provide translators and other resources at their public hearings, to ensure that all members of the public can provide oral feedback.

As previously discussed in this rule, recent studies also find that certain communities, including low-income communities and some communities of color (more specifically, populations defined jointly by ethnic/racial characteristics and geographic location) are disproportionately affected by certain climate change related impacts.[824] Also as discussed in this rule, effects from this rule can be anticipated to affect vulnerable communities in various ways. Because certain communities have a potential likelihood to be impacted by state plans, the EPA believes that the existing public participation requirements under 40 CFR 60.23 are effectuated for the purposes of this final rule by states engaging in meaningful, active ways with such communities.

In addition, certain communities whose economies are significantly dependent on coal, or whose economies may be affected by ongoing changes in the utility power and related sectors, may be particularly concerned about the final rule. The EPA encourages states to make an effort to provide background information about their proposed initial submittal and final state plans to these communities in advance of their public hearing. In particular, the EPA encourages states to engage with workers and their representatives in the utility and related sectors, including the EE sector.

The EPA notes that meaningful public involvement goes beyond the holding of a public hearing. The EPA envisions meaningful engagement to include outreach to vulnerable communities,

---

[824] USGCRP 2014: Melillo, Jerry M., Terese (T.C.) Richmond, and Gary W. Yohe, Eds., 2014: *Climate Change Impacts in the United States: The Third National Climate Assessment.* U.S. Global Change Research Program, 841 pp.

sharing information and soliciting input on state plan development and on any accompanying assessments, such as those described in section IX. The agency uses the terms "vulnerable" and "overburdened" in referring to low-income communities, communities of color, and indigenous populations that are most affected by, and least resilient to, the impacts of climate change, and are central to our community and environmental justice considerations. In section VIII.E, the EPA provides states with examples of resources on how they can engage with vulnerable communities in a meaningful way. With respect specifically to ensuring meaningful community involvement in their public hearing(s), however, the EPA recommends that states have both a website and toll-free number that all stakeholders, including overburdened communities, labor unions, and others can access to get more information regarding the upcoming hearing(s) and to get their questions related to upcoming hearings answered. Furthermore, the EPA recommends that states work with their local government partners to help them in reaching out to all stakeholders, including vulnerable communities, about the upcoming public hearing(s).

(7) Supporting documentation.

The state plan submittal must provide supporting material and technical documentation related to applicable components of the plan submittal.

(a) Legal authority.

In its submittal, a state must adequately demonstrate that it has the legal authority (regulations/legislation) and funding to implement and enforce each component of the state plan submittal, including federally enforceable emission standards for affected EGUs and state measures. A state can make such a demonstration by providing supporting material related to the state's legal authority used to implement and enforce each component of the plan, such as copies of statutes, regulations, PUC orders, and any other applicable legal instruments. For states participating in a multi-state plan, the submittal(s) must also include as supporting documentation each state's necessary legal authority to implement the portion of the plan that applies within the particular state, such as copies of state regulations and statutes, including a showing that the states have the necessary authority to enter into a multi-state agreement.

(b) Technical documentation.

As applicable, the state submittal must include materials necessary to support the EPA's evaluation of the submittal including analytical materials used in the calculation of interim goal steps (if applicable), analytical materials used in the multi-state goal calculation (if multi-state plan), analytical materials used in projecting CO_2 emission performance that will be achieved through the plan, relevant implementation materials and any additional technical requirements and guidance the state proposes to use to implement elements of the plan.

(c) Programmatic milestones and timeline.

As part of the state plan supporting documentation, the state must include in its submittal a timeline with all the programmatic milestone steps the state will take between the time of the state plan submittal and 2022 to ensure the plan is effective as of January 1, 2022. The programmatic milestones and timeline should be appropriate to the overall state plan approach included in the state plan submittal.

(d) Reliability.

As discussed in more detail in section VIII.G.2, each state must demonstrate as part of its state plan submission that it has considered reliability issues while developing its plan.

b. Additional components required for the emission standards plan type. The EPA is finalizing requirements that a final plan submittal using the emission standards plan type must contain the following components, in addition to the components discussed in the preceding section VIII.D.2.a.

(1) Identification of interim period emission performance rates or state goal (for 2022-2029), interim step performance rates or interim state goals (2022-2024; 2025-2027; 2028-2029) and final emission performance rates or state goal (2030 and

beyond).

The state plan submittal must indicate whether the plan is designed to meet the CO_2 emission performance rates or the state CO_2 emission goal. As noted in the emission guidelines, the EPA is finalizing CO_2 emission performance rates for fossil fuel-fired steam generating units and for stationary combustion turbines. The EPA has translated the source category-specific CO_2 emission performance rates into equivalent state-level rate-based and mass-based CO_2 goals in order to maximize the range of choices that states will have in developing their plans. The state may choose to develop a state plan that meets the CO_2 performance rates for the two subcategories of affected EGUs or develop a plan that adopts either the rate-based or the mass-based state CO_2 emission goal provided in the emission guidelines.

Each state plan must identify the emission performance rates or rate-based or mass-based CO_2 emission goal that must be achieved through the plan (expressed in numeric values, including the units of measurement, such as pounds of CO_2 per net MWh of useful energy output or tons of CO_2). The plan submittal must identify the CO_2 interim period performance rates or state goal (for 2022-2029), interim step performance rates or state goals (interim step performance rates or state goal 1 for 2022-2024; interim step performance rates or state goal 2 for 2025-

2027; interim step performance rates or state goal 3 for 2028-2029) and final CO_2 emission performance rates or state goal of 2030 and beyond.

The EPA has finalized an interim performance rates or state goal for the interim period of 2022-2029 and a final performance rates or state goal to be met by 2030. For the interim period, the EPA has also finalized three interim step performance rates or state goals: interim step 1 performance rates or state goal for 2022-2024, interim step 2 performance rates or state goal for 2025-2027 and interim step 3 performance rates or state goal for 2028-2029.[825] States are free to establish different interim step performance rates or interim step state goals than those the EPA has specified in this final rule. If states choose to determine their own interim step performance rates or state goals, the state must demonstrate that the plan will still meet the interim performance rates or state goal for 2022-2029 finalized in the emission guidelines and the plan submittal must include in its supporting documentation a description of the analytic process, tools, methods, and assumptions used to make this demonstration.

For states participating in a multi-state plan with a joint

[825] In this action, the EPA is providing interim state goals in the form of a CO_2 emission rate (emission rate-based goal) and in the form of tonnage CO_2 emissions (mass-based goal).

goal (for interim and final periods), the individual state goals in the emission guidelines would be replaced with an equivalent multi-state goal for each period (interim and final). For a rate-based multi-state plan this would be a weighted average rate-based emission goal, derived by the participating states, by calculating a weighted average CO_2 emission rate based on the individual rate-based goals for each of the participating states and 2012 generation from affected EGUs. For a mass-based multi-state plan, the joint goal would be a sum of the individual mass-based goals of the participating states, in tons of CO_2. The plan submittal must include in its supporting documentation a description of the analytic process, tools, methods, and assumptions used to calculate the joint multi-state goal.

(2) Identification of federally enforceable emission standards for affected EGUs.

The state plan submittal for an emission standards plan type must include federally enforceable emission standards that apply to affected EGUs. The emission standards must meet the requirement of component (3) of this section, "Demonstrations that each emission standard is quantifiable, non-duplicative, permanent, verifiable, and enforceable." The plan must identify the affected EGUs to which these standards apply. The compliance periods for each emission standard for affected EGUs, on a calendar year basis, must be as follows for the interim period:

January 1, 2022 – December 31, 2024; January 1, 2025 – December 31, 2027; and January 1, 2028 – December 31, 2029. Starting on January 1, 2030, the compliance period for each emission standard is every 2 calendar years. States can choose to set shorter compliance periods for the emission standards than the compliance periods the EPA is finalizing in this rulemaking, but cannot set longer periods. As discussed in more detail in section VIII.F, the EPA recognizes that the compliance periods provided for in this rulemaking are longer than those historically and typically specified in CAA rulemakings. The EPA determined that the longer compliance periods provided for in this rulemaking are acceptable in the context of this specific rulemaking because of the unique characteristics of this rulemaking, including that CO_2 is long-lived in the atmosphere, and this rulemaking is focused on performance standards related to those long-term impacts.

For state plans in which affected EGUs may rely upon the use of ERCs for meeting a rate-based federally enforceable emission standard, the emission standards in the state plan must include requirements addressing the issuance, tracking and use for compliance of ERCs consistent with the requirements in the emission guidelines. These requirements are discussed in sections VIII.K.1-2. The state plan must also demonstrate that the appropriate ERC tracking infrastructure that meets the requirements of the emission guidelines will be in place to administer the state plan requirements regarding ERCs and document the functionality of the tracking system. State plan requirements must include provisions to ensure that ERCs are properly tracked from issuance to submission for compliance. The state plan must also demonstrate that the MWh for which ERCs are issued are properly quantified and verified, through plan requirements for EM&V and verification that meet the requirements in the emission guidelines. EM&V requirements are discussed in section VIII.K.3. Rate-based emission standards must also include monitoring, reporting, and recordkeeping requirements for CO_2 emissions and useful energy output for affected EGUs; and related compliance demonstration requirements and mechanisms. These requirements are discussed in more detail in sections VIII.F and VIII.K.

For state plans using a mass-based emission trading program approach, the state plan must include implementation requirements that specify the emission budget and related compliance requirements and mechanisms. These requirements must include: CO_2 emission monitoring, reporting, and recordkeeping requirements for affected EGUs; provisions for state allocation of allowances; provisions for tracking of allowances, from issuance through submission for compliance; and the process for affected EGUs to demonstrate compliance (allowance "true-up" with reported CO_2 emissions).

(3) Demonstration that each emission standard is quantifiable, non-duplicative, permanent, verifiable and enforceable.

The plan submittal must demonstrate that each emission standard is quantifiable, non-duplicative, permanent, verifiable and enforceable with respect to an affected EGU, as outlined below.

An emission standard is quantifiable if it can be reliably measured, using technically sound methods, in a manner that can be replicated.[826]

An emission standard is non-duplicative with respect to an affected EGU if it is not already incorporated in another state plan, except in instances where incorporated as part of a multi-state plan. An example of a duplicative emission standard would occur, for example, where a quantified and verified MWh from a wind turbine could be applied in more than one state's CAA

[826] A CO_2 continuous emissions monitoring system (CEMS) is the most technically reliable method of emission measurement for EGUs. A CEMS provides a measurement method that is performance based rather than equipment specific and is verified based on NIST traceable standards. A CEMS provides a continuous measurement stream that can account for variability in the fuels and the combustion process. Reference methods have been developed to ensure that all CEMS meet the same performance criteria, which helps to ensure a level playing field and consistent, accurate data.

section 111(d) plan to adjust the reported CO_2 emission rate of an affected EGU (e.g., through issuance and use of an ERC), except in the case of a multi-state plan where CO_2 emission performance is demonstrated jointly for all affected EGUs subject to the multi-state plan or where states are implementing coordinated individual plans that allow for the interstate transfer of ERCs.[827] This does not mean that measures used to comply with an emission standard cannot also be used for other purposes. For example, a MWh of electric generation from a wind turbine could be used by an electric distribution utility to comply with state RPS requirements and also be used by an affected EGU comply with emission standard requirements under a state plan. Another example is when actions taken pursuant to CAA section 111(d) requirements can satisfy other CAA program requirements (e.g., Regional Haze requirements, MATS).

An emission standard is permanent if the emission standard must be met for each applicable compliance period.

[827] For example, an ERC that is issued by a state under its rate-based emission standards may be used only once by an affected EGU to adjust its reported CO_2 emission rate when demonstrating compliance with the emission standards. However, an ERC issued in one state could be used by an affected EGU to demonstrate compliance with its emission standard in another state, where states are collaborating in the implementation of their individual emission trading programs through interstate transfer of ERCs, or participating in a multi-state plan with a rate-based emission trading program. These coordinated multi-state approaches are addressed in sections VIII.C.5, VIII.J.3, and VIII.K.4.

An emission standard is verifiable if adequate monitoring, recordkeeping and reporting requirements are in place to enable the state and the Administrator to independently evaluate, measure, and verify compliance with it.

An emission standard is enforceable if: (1) it represents a technically accurate limitation or requirement and the time period for the limitation or requirement is specified; (2) compliance requirements are clearly defined; (3) the entities responsible for compliance and liable for violations can be identified; and (4) each compliance activity or measure is enforceable as a practical matter in accordance with EPA guidance on practical enforceability,[828] and the Administrator, the state, and third parties, maintain the ability to enforce against affected EGUs for violations and secure appropriate corrective actions, in the case of the Administrator pursuant to CAA sections 113(a)-(h), in the case of a state, pursuant to its state plan, state law or CAA section 304, as applicable, and in the case of third parties, pursuant to CAA section 304.

[828] The EPA guidance on enforceability includes: (1) September 23, 1987, memorandum and accompanying implementing guidance, "Review of State Implementation Plans and Revisions for Enforceability and Legal Sufficiency," (2) August 5, 2004, "Guidance on SIP Credits for Emission Reductions from Electric-Sector Energy Efficiency and Renewable Energy Measures," and (3) July 2012 "Roadmap for Incorporating Energy Efficiency/Renewable Energy Policies and Programs into State and Tribal Implementation Plans, Appendix F."

In developing its CAA section 111(d) plan, to ensure that the plan submittal is enforceable and in conformance with the CAA, a state should follow the EPA's prior guidance on enforceability.[829] These guidance documents serve as the foundation for the types of monitoring, reporting, and emission standards that the EPA has found can be, as a practical matter, enforced.

In the proposed regulatory text describing the enforcing measures that states must include in state plans, the EPA inadvertently excluded a required demonstration that states and other third parties can enforce against affected EGUs for violations of an emission standard included in a state plan via civil action pursuant to CAA section 304. Commenters noted the EPA's intent to require this demonstration based on statements in both the proposal preamble text and "State Plan Considerations" TSD[830] and based on the requirements of CAA section 304. We are finalizing a requirement for a demonstration that states and other third parties can enforce against affected EGUs for violations of an emission standard included in a state plan via civil action as part of the required plan component

[829] See prior footnote.
[830] State Plan Considerations technical support document for the Clean Power Plan Proposed Rule: http://www2.epa.gov/carbon-pollution-standards/clean-power-plan-proposed-rule-state-plan-considerations.

demonstrating enforceability. We are finalizing this requirement as a logical outgrowth of proposal preamble text, the proposal preamble citation to existing enforceability guidance documents that discuss this requirement, comments received, and the clear statutory foundation.

(4) State reporting requirements.

After consideration of the comments received regarding state reporting requirements, the EPA is finalizing for state plans using the emission standards approach that a state report is due to the EPA no later than the July 1 following the end of each reporting period. Within the interim period (2022-2029) the EPA is finalizing the following interim reporting periods: interim step 1 covers the three calendar years 2022-2024, interim step 2 covers the three calendar years 2025-2027, and interim step 3 covers the two calendar years 2028-2029. A biennial state report is required starting in 2030 and beyond covering the two calendar years of each reporting period. This final reporting schedule reduces the reporting frequency for states implementing the emission standards approach and is responsive to comments received that different reporting frequencies may be appropriate for different type of state plans. The EPA believes that because of the federally enforceable emission standards that apply to affected EGUs and their corresponding monitoring, reporting and recordkeeping requirements under the emission standards plan type, a lesser frequency of reporting by the state is warranted.

The state must include in each report to the EPA the status of implementation of emission standards for affected EGUs under the state plan, including current aggregate and individual CO_2 emission performance by affected EGUs during the reporting period. The state report must include compliance demonstrations for affected EGUs and identify whether affected EGUs are on schedule to meet the applicable CO_2 emission performance rate or emission goal during the performance periods and compliance periods, as specified in the state plan. For rate-based emission trading programs, the report must also include for EPA review the state's review of the administration of their state rate-based emission trading program, as discussed in section VIII.K.2.g.

As discussed in more detail in section VIII.F, the state must include an interim performance check in the report submitted after each of the first two interim step periods. The interim performance check will compare the CO_2 emission performance level identified in the state plan for the applicable interim step period with the actual CO_2 emission performance achieved by affected EGUs during the period. In the report due to the EPA on July 1, 2030, the state must include a comparison of the actual CO_2 emission performance achieved by affected EGUs for the interim period (2022-2029) with the interim CO_2 emission performance rates or state rate-based or mass-based CO_2 interim goal, as applicable. The report due on July 1, 2030, must also include the actual CO_2 emission performance achieved by affected EGUs during the interim step 3 period (2028-2029). Starting in 2032, the biennial state report must include a final performance check to demonstrate that the affected EGUs continue to meet the final CO_2 emission performance rates or state rate-based or mass-based CO_2 goal.

For state plans that use the emission standards approach and are subject to the corrective measures provisions in the emission guidelines, if actual CO_2 emission performance (i.e., the emissions or emission rate) of affected EGUs exceeds the specified level of CO_2 emission performance in the state plan by 10 percent or more during the interim step 1 or step 2 reporting periods, the state report must include a notification to the EPA that corrective measures have been triggered. The same notification is required if actual CO_2 emission performance fails to meet the specified level of emission performance in the state plan for the 8-year interim performance period or any final plan reporting period. Corrective measures are discussed in detail in section VIII.F.

c. Additional components required for the state measures approach. The EPA is finalizing requirements that a final plan submittal using the state measures approach must contain the following components, in addition to the components discussed in section VIII.D.2.a. We note again that states choosing the state measures plan type must use a mass-based state goal.

(1) Identification of interim state mass goal (for 2022-2029), interim step state mass goals (2022-2024; 2025-2027; 2028-2029) and final state mass goal (2030 and beyond).

The state plan submittal must identify the mass-based CO_2 emission goal that must be achieved through the plan (expressed in tons of CO_2). The plan submittal must identify the state CO_2 interim period goal (for 2022-2029), interim step goals (interim step goal 1 for 2022-2024; interim step goal 2 for 2025-2027; interim step goal 3 for 2028-2029) and final CO_2 emission goal of 2030 and beyond.

For each state, the EPA has finalized an interim goal for the interim period of 2022-2029 and a final goal to be met by 2030. For the interim period, the EPA has also finalized three interim step goals: interim step 1 goal for 2022-2024, interim step 2 goal for 2025-2027 and interim step 3 goal for 2028-2029.[831] States are free to establish different interim step goals than those the EPA has specified in this final rule. If

[831] In this action, the EPA is providing interim state goals in the form of a CO_2 emission rate (emission rate-based goal) and in the form of tonnage CO_2 emissions (mass-based goal).

states choose to determine their own interim step goals, the state must demonstrate that it will still meet the interim goal for 2022-2029 finalized in this action and the plan submittal must include in its supporting documentation a description of the analytic process, tools, methods, and assumptions used to make this demonstration.

For states participating in a multi-state plan with a joint goal (for interim and final periods), the individual state goals in the emission guidelines would be replaced with an equivalent multi-state goal for each period (interim and final). The joint goal would be a sum of the individual mass-based goals of the participating states, in tons of CO_2. The plan submittal must include in its supporting documentation a description of the analytic process, tools, methods, and assumptions used to calculate the joint multi-state goal.

(2) Identification of federally enforceable emission standards for affected EGUs (if applicable).

If applicable, the state plan submittal must include any federally enforceable CO_2 emission standards that apply to affected EGUs, and demonstrate that those emission standards meet the requirements that apply in the context of an emission standards approach, discussed in the preceding section VIII.D.2.b. Specifically, the state plan submittal must demonstrate that each federally enforceable emission standard is quantifiable, non-duplicative, permanent verifiable, and enforceable. If a state measures plan type includes CO_2 emission standards that apply to affected EGUs, these emission standards must be federally enforceable.

(3) Identification of backstop of federally enforceable emission standards.

A state measures plan must include a backstop of federally enforceable emission standards for affected EGUs that fully achieve the interim and final CO_2 emission performance rates or the state's interim and final CO_2 emission goal if the state plan fails to achieve the intended level of CO_2 emission performance. The backstop emission standards could be based on the finalized model rule that the EPA is proposing in a separate action. For the federally enforceable backstop, the state plan submittal must identify the federally enforceable emission standards for affected EGUs, demonstrate that those emission standards meet the requirements that apply in the context of an emission standards approach, discussed in the preceding section, identify a schedule and trigger for implementation of the backstop that is consistent with the requirements in the emission guidelines as discussed in section VIII.C.3.b and identify all necessary state administrative and technical procedures for implementing the backstop (e.g. how and when the state would notify affected EGUs that the backstop has been triggered). Aspects of the backstop are discussed in detail in section VIII.C.3.b.

(4) Identification of state measures.

A state adopting a state measures plan type must provide as a part of the supporting documentation of its plan submittal, a description of all the state enforceable measures the state will rely upon to achieve the requisite state mass-based goal, the applicable state laws or regulations related to such measures, and identification of parties or entities implementing or complying with such state measures. The state must also include in its supporting documentation the schedule and milestones for the implementation of the state measures, showing that the measures are expected to achieve the mass-based CO_2 emission goal for the interim period (including the interim step periods) and meet the final goal by 2030. A state measures plan submittal that relies upon state measures that include RE and demand-side EE programs and projects must also demonstrate in its supporting documentation that the minimum EM&V requirements in the emission guidelines apply to those programs and projects as a matter of state law.

(5) State reporting requirements.

After consideration of the comments received regarding state reporting requirements, the EPA is requiring in this final rule for states using the state measures approach that an annual state report is due to the EPA no later than July 1 following the end of each calendar year during the interim period. This annual state report must include the status of implementation of federally enforceable emission standards (if applicable) and state measures, and must include a report of the periodic programmatic milestones to show progress in program implementation. The programmatic milestones with specific dates for achievement should be appropriate to the state measures included in the state plan submittal. The EPA believes that annual state reporting is appropriate for state measures approach due to the flexibility inherent to the approach described in section VIII.C.3 including the potential use by the state of a wider variety of state measures, responsible parties, etc. This reporting frequency will also increase the degree of certainty on plan performance for states pursuing the state measures approach.

As discussed in section VIII.F, for states using the state measures approach, the EPA is finalizing that at the end of the first two interim step periods, the state must also include in their annual report to the EPA the corresponding emission performance checks. The interim performance checks will compare the CO_2 emission performance level identified in the state plan for the applicable interim step period versus the actual CO_2 emission performance achieved by the aggregate of affected EGUs. In the report submitted to the EPA on July 1, 2030, the state must also report the actual CO_2 performance check for the interim period (2022-2029) with the interim mass-based CO_2 goal, as well as the actual CO_2 emission performance achieved by affected EGUs during the interim step 3 period (2028-2029).

Beginning with the final period, the state must submit biennial reports no later than July 1 after the end of each reporting period that includes an actual performance check to demonstrate that the state continues to meet the final state CO_2 goal.

If, at the time of the state report to the EPA, the state has not met the programmatic milestones for the reporting period, or the performance check shows that the actual CO_2 emission performance of affected EGUs warrants implementation of backstop requirements,[832] the state must include in the state report a notification to the EPA that the backstop has been triggered and describe the steps taken by the state to inform the affected EGUs that the backstop has been triggered. In the

[832] As explained in section VIII.C.3.b, state plans subject to the backstop requirement must require the backstop to take effect if actual CO_2 emission performance by affected EGUs fails to meet the level of emission performance specified in the plan over the 8-year interim performance period (2022-2029), or for any 2-year final goal performance period. The plan also must require the backstop to take effect if actual emission performance is deficient by 10 percent or more relative to the performance levels that the state has chosen to specify in its plan for the interim step 1 period (2022-2024) or the interim step 2 period (2025-2027).

event of such an exceedance under the state measures approach, the backstop federally enforceable emission standards for the EGUs must be effective within 18 months of the deadline for the state reporting to the EPA on plan implementation and progress toward the meeting the state CO_2 emission goal. For example, if a state report due on July 1, 2025, shows that actual CO_2 emission performance of affected EGUs is deficient by 10 percent or more relative to the specified level of emission performance for 2022-2024 in the state plan, the backstop federally enforceable emission standards for affected EGUs must be effective as of January 1, 2027.

(6) Supporting documentation.

(a) Demonstration that each state measure is quantifiable, non-duplicative, permanent, verifiable and enforceable.

A state using the state measures approach, in support of its plan, must also include in the supporting documentation of the state plan submittal the state measures[833] that are not federally enforceable emission standards, and describe how each state measure is quantifiable, non-duplicative, permanent, verifiable, and enforceable with respect to an affected entity.

[833] "State measures" refer to measures that the state adopts and implements as a matter of state law. Such measures are enforceable only per applicable state law, and are not included in the federally enforceable state plan.

A state measure is quantifiable if it can be reliably measured, using technically sound methods, in a manner that can be replicated.

A state measure is non-duplicative with respect to an affected entity if it is not already incorporated as a state measure or an emission standard in another state plan or state plan supporting material, except in instances where incorporated in another state as part of a multi-state plan. This does not mean that measures in a state measure cannot also be used for other purposes. For example actions taken pursuant to CAA section 111(d) requirements can satisfy other CAA program requirements (e.g., Regional Haze requirements, MATS) and state requirements (e.g., RPS).

A state measure is permanent if the state measure must be met for each applicable compliance period.

A state measure is verifiable if adequate monitoring, recordkeeping and reporting requirements are in place to enable the state to independently evaluate, measure and verify compliance with it.

A state measure is enforceable[834] if: (1) it represents a technically accurate limitation or requirement and the time period for the limitation or requirement is specified; (2)

[834] Under the state measures approach, state measures are enforceable only per applicable state law.

compliance requirements are clearly defined; (3) the affected entities responsible for compliance and liable for violations can be identified; and (4) each compliance activity or measure is practically enforceable in accordance with EPA guidance on practical enforceability,[835] and the state maintains the ability to enforce against affected EGUs for violations and secure appropriate corrective actions pursuant to its plan or state law.

The EPA will disapprove a state plan if the documentation is not sufficient for the EPA to be able to determine whether the state measures are expected to yield CO_2 emission reductions sufficient to result in the necessary CO_2 emission performance from affected EGUs for the state CO_2 emission goal to be achieved.

d. Legal basis for the components.

(1) General legal basis.

[835] The EPA's prior guidance on enforceability serves as the foundation for the types of measures that the EPA has found can be, as a practical matter, enforced. The EPA's guidance on enforceability includes: (1) September 23, 1987, memorandum and accompanying implementing guidance, "Review of State Implementation Plans and Revisions for Enforceability and Legal Sufficiency," (2) August 5, 2004, "Guidance on SIP Credits for Emission Reductions from Electric-Sector Energy Efficiency and Renewable Energy Measures," and (3) July 2012 "Roadmap for Incorporating Energy Efficiency/Renewable Energy Policies and Programs into State and Tribal Implementation Plans," Appendix F.

Under section 111(d), state plans must "provide for the implementation and enforcement of [the] standards of performance." Similar language occurs elsewhere in the CAA. First, for SIPs, section 110(a)(1) requires SIPs to "provide for implementation, maintenance, and enforcement" of the NAAQS. However, section 110(a)(2), unlike 111(d), details a number of specific requirements for SIPs that, in part, speak exactly to how a SIP should "provide for implementation, maintenance, and enforcement" of the NAAQS. We note that section 111(d) provides explicitly only that the "procedures," and not the substantive requirements, for section 111(d) state plans should be "similar" to those in section 110, and thus a substantive requirement in section 110(a)(2) is not an independent source of authority for the EPA to require the same for section 111(d) plans. However, when there is a gap for the EPA to fill in interpreting how a section 111(d) plan should "provide for implementation and enforcement of the] standards of performance," and Congress explicitly addressed a similar gap in section 110, then it may be reasonable for the EPA to fill the gap in section 111(d) using an analogous mechanism to that in section 110(a)(2), to the extent that the section 110(a)(2) requirement makes sense and is reasonable in the context of section 111(d). On the other hand, that Congress did not explicitly provide such details as are found in section 110(a)(2) indicates that Congress intended to give the EPA considerable leeway in interpreting the ambiguous phrase "provides for implementation and enforcement of [the] standards of performance."

For example, section 110(a)(2)(E)(i) explicitly requires states to provide necessary assurances that they have adequate personnel, funding and authority to carry out the SIP. Section 111(d), on the other hand, does not explicitly contain this requirement. Thus, there is a gap to fill with respect to this issue when the EPA interprets section 111(d)'s requirement that plans "provide for implementation and enforcement" of the standards of performance, and it is reasonable for the EPA to fill the gap by requiring adequate funding and authority, both because adequate funding and authority are fundamental prerequisites to adequate implementation and enforcement of any program, and because Congress has explicitly recognized this fundamental nature in the section 110 context.[836]

We note two other places where the CAA requires a state program to satisfy similar language regarding implementation and enforcement. First, section 112(l)(1) allows states to adopt and

[836] On the other hand, there are specific requirements in 110(a)(2) that are fundamental for SIPs, but would not make sense in the 111(d) context. For example, the specific requirement for an ambient air quality monitoring network in 110(a)(2)(B) is irrelevant in the 111(d) context. For a detailed discussion of the specific legal basis for each component, please see the Legal Memorandum for this final rule.

submit a program for "implementation and enforcement" of section 112 standards. Section 112(l)(5) further provides that the program must (among other things) have adequate authority to enforce against sources, and adequate authority and resources to implement the program. Second, section 111(c) provides that, if a state develops and submits "adequate procedures" for "implementing and enforcing" section 111(b) standards of performance for new sources in that state, the Administrator shall delegate to the state the Administrator's authority to "implement and enforce" those standards. The EPA has interpreted these ambiguous provisions in the EPA's "Good Practices Manual for Delegation of NSPS and NESHAPS" and recommended (in the context of guidance) that state programs have a number of components, such as source monitoring, recordkeeping, and reporting, in order to adequately implement and enforce section 111(b) or 112 standards. This again indicates it is reasonable for the EPA to fill a gap in section 111(d)'s language and similarly require source monitoring, recordkeeping, and reporting, as these are fundamental to implementing and enforcing standards of performance that achieve the state performance rates or goals.

Some commenters argued that states have primary authority over the content of state plans and that the EPA lacks authority to disapprove a state plan as unsatisfactory simply because it lacks one or more of these components. We disagree. The EPA has the authority to interpret the statutory language of section 111(d) and to make rules that effectuate that interpretation. With respect to the components of an approvable plan, we are interpreting the statutory phrase "provide for implementation and enforcement" and making rules that set out the minimum elements that are necessary for a state plan to be "satisfactory" in meeting this statutory requirement. This does not in any way intrude on the state's ability to decide what mix of measures should be used to achieve the necessary emission reductions. Nor does it intrude in any way on the state's ability to decide how to satisfy a component. For example, for legal authority, we are not dictating which state agencies or officials must specifically have the necessary legal authority; that is entirely up to the state so long as the fundamental requirement to have adequate legal authority to implement and enforce the plan is met.

In addition, the EPA has already determined in the 1975 implementing regulations that certain components, such as monitoring, recordkeeping, and reporting, are necessary for implementation and enforcement of section 111(d) standards of performance. 40 FR 53340, 53348/1 (Nov. 17, 1975). Thus, EPA's position here is hardly novel. The EPA notes in discussing the implementing regulations, nothing in this final rule reopens provisions or issues that were previously decided in the original promulgation of the regulations unless otherwise explicitly reopened for this rule.

(2) Legal considerations with changes to affected EGUs.

In the proposed rulemaking, the EPA proposed the interpretation that if an existing source is subject to a section 111(d) state plan, and then undertakes a modification or reconstruction, the source remains subject to the state plan, while also becoming subject to the modification or reconstruction requirements. 79 FR 34830, 34903-4. The EPA is not finalizing a position on this issue in this final rule, and is re-proposing and taking comment on this issue through the federal plan rulemaking being proposed concurrently with this action. The EPA's deferral of action on this issue does not impact states' and affected EGUs' pending obligations under this final rule relating to plan submission deadlines, as this issue concerns potential obligations or impacts after an existing source is subject to the requirements of a state plan. The EPA will propose and finalize its position on this issue through the federal plan rulemaking, which will be well in advance of the plan performance period beginning in 2022, at which point state plan obligations on existing sources are effectuated.

(3) Legal considerations regarding design, equipment, work practice or operational standards.

In the proposal, the EPA asked for comment on three approaches to inclusion of design, equipment, work practice and operational standards in section 111(d) plans. 79 FR 34830, 34926/3 (June 18, 2014). Under the first approach, states would be precluded from including these standards in section 111(d) plans unless the design, equipment, work practice or operational standard could be understood as a "standard of performance" or could be understood to "provide for implementation and enforcement" of standards of performance. We also asked, for the first approach, whether it was even possible, given the statutory language of 111(h), to consider a design, equipment, work practice or operational standard as a "standard of performance." Under the second approach, states could include design, equipment, work practice or operational standards in the event that it could be shown a "standard of performance" was not feasible, as set out in section 111(h). Under the third approach, a state could include design, equipment, work practice and operational standards in a 111(d) plan without any constraints. We also asked whether, if there was legal uncertainty as to the status of these standards, the EPA should authorize states to include them in their 111(d) plans with the understanding that if the EPA's authorization were invalidated by a court, states would have to revise their plans accordingly.

The EPA is finalizing the first approach. Specifically, a state’s standards of performance (in other words, either the federally enforceable backstop under the state measures approach or the emission standards under the emission standards approach) cannot consist of (in whole or part) design, equipment, work practice or operational standards. A state may include such standards in a 111(d) plan in order to implement the standards of performance. For example, a state taking a mass-based approach may include in its 111(d) plan a limit on hours of operation on a particular affected EGU, but that operational standard itself cannot substitute for a mass-based emission standard on the affected EGU.[837]

This follows from the statute. First, section 111(h)(1) authorizes the Administrator, when it is not feasible for certain reasons (specified in 111(h)(2)) to prescribe or enforce a standard of performance, to instead promulgate a design, equipment, work practice or operational standard. If a standard of performance could include design, equipment, work practice or operational standards, such authority would be unnecessary. Second, 111(h)(5) states that design, equipment, work practice or operational standards “described in” 111(h) shall be treated as standards of performance for the purposes of the CAA. This

[837] In particular, a state may include in its 111(d) state plan an emission standard that is reflective of the CO_2 performance resulting from operational standards the state imposes on an affected EGU.

creates a strong inference that standards of performance otherwise should not include design, equipment, work practice, or operational standards. Finally, the general definition of "standard of performance" in section 302(l) is similar to the definition of "emission limitation" (or "emission standard") in section 302(k), with the exception that the definition of "emission limitation" explicitly includes design, equipment, work practice and operational standards, but the definition of "standard of performance" omits them. Thus, as with our discussion of the term "standard of performance" above in VIII.C.6.b, even if the general definition of "standard of performance" in 302(l) applies to 111(d), the omission of design, equipment, work practice, and operational standards in 302(l) confirms our interpretation that they cannot be a 111 "standard of performance" (except under the limited circumstances in 111(h)). We conclude that it is reasonable, and perhaps compelled, to interpret the term "standards of performance" in 111(d) to not include design, equipment, work practice and operational standards.

However, section 111(d) requires plans to "provide for implementation and enforcement of [the] standards of performance." This language does not explicitly prohibit a plan from including design, equipment, work practice and operational standards, and allows for them to be included so long as they are understood to provide for implementation of the standards of performance. If they are included, the 111(d) plan must still be "satisfactory" in other respects, in particular in establishing standards of performance that are not in whole or in part design, equipment, work practice, and operational standards.

(4) <u>Legal basis for engagement with communities</u>.

As previously discussed, section 111(d)(1) requires the EPA to promulgate procedures "similar" to those in section 110 under which states adopt and submit 111(d) plans. Section 110(a)(1) requires states to adopt and submit implementation plans "after reasonable notice and public hearings." The implementing regulations under 40 CFR 60.27 reflect similar public participation requirements with respect to section 111(d) state plans. The EPA is sensitive to the legal importance of adequate public participation in the state plan process, including public participation by affected communities. As previously discussed in this rule, recent studies also find that certain communities, including low-income communities and some communities of color, are disproportionately affected by certain climate change-related impacts. Because certain communities have a potential likelihood to be impacted by state plans for this rule, the EPA believes that the existing public participation requirements under 40 CFR 60.23 are effectuated for the purposes of this final rule by states engaging in meaningful, active ways with such communities. By requiring states to demonstrate how they have meaningfully engaged with vulnerable communities potentially impacted by state plans as part of the state plan development process, states meeting this requirement will satisfy the applicable statutory and regulatory requirements regarding public participation.

3. Components of the federally approved state plan

In this action the EPA finalizes that, to be fully approved, a state plan submittal must meet the criteria and include the required components described above. The EPA will propose and take final action on each state plan submittal in the *Federal Register* and provide an opportunity for notice and comment. When a state plan submittal is approved by the EPA, the EPA will codify the approved 111(d) state plan in 40 CFR part 62. The following components of the state plan submittal will become the federally enforceable state 111(d) plan:

- Federally enforceable emission standards for affected EGUs
- Federally enforceable backstop of emission standards for affected EGUs
- Implementing and enforcing measures for federally enforceable emission standards including EGU monitoring, recordkeeping and reporting requirements
- State recordkeeping and reporting requirements

E. State Plan Submittal and Approval Process and Timing

1. Overview

In this action the EPA is finalizing that state plan submittals are due on September 6, 2016, with the option of an extension to submit final state plans by September 6, 2018, which is 3 years after finalization of this rule. The compelling nature of the climate change challenge, and the need to begin promptly what will be a lengthy effort to implement the requirements of these guidelines, warrant this schedule. The EPA also believes, for reasons further described in the next section, why this schedule is achievable for states to submit final plans. We discuss the timing of state plans in more detail in this section below.

Discussed in the following sections are state plan submittal and timing, required components for initial submittals and the 2017 update, multi-state plan submissions, process for EPA review of state plans, failure to submit a plan, state plan modifications (including modifications to interim and final CO_2 emission goals), plan templates and electronic submittal, and legal bases regarding state plan process.

2. State plan submittal and timing

The implementing regulations (40 CFR 60.23) require that state plans be submitted to the EPA within 9 months of promulgation of the emission guidelines, unless the EPA specifies otherwise.[838] For these 111(d) guidelines, the EPA is finalizing that each state must by September 6, 2016, either submit a final plan submittal or seek an extension to submit a final plan by September 6, 2018. In the case of a state electing to participate in the CEIP, this 2016 submittal must include a non-binding statement of intent to participate in the program. To seek an extension of the September 6, 2016 deadline until no later than September 6, 2018, a state must submit an initial submittal by September 6, 2016, that addresses three required components sufficiently to demonstrate that a state is able to undertake steps and processes necessary to timely submit a final plan by the extended date of September 6, 2018. If an extension is requested and granted, states must also submit a 2017 update by September 6, 2017, that documents the state's continued progress towards meeting the September 6, 2018 final plan submittal deadline.

In the proposal, EPA proposed a 13 month final state plan submittal deadline, with a 1 year possible extension for states submitting individual state plans and a 2 year possible extension for states submitting multi-state plans as part of a multi-state region. The EPA received substantive comment on the achievability of these proposed deadlines for state plan

[838] 40 CFR 60.23(a)(1).

submittals. Multiple commenters expressed concern that due to timing of legislative cycles (some of which are every 2 years), regulatory processes, and other necessary tasks, states would find it extremely difficult to submit plans in 1 or 2 years, whether or not they were planning to submit as part of a multi-state region. The EPA agrees based on this input that a schedule shorter than 3 years will be challenging for many — though not all - states. In light of the comments received and in order to provide maximum flexibility to states while still taking timely action to reduce CO_2 emissions, in this final rule the EPA is allowing for a 2 year extension until September 6, 2018, for both individual and multi-state plans, to provide a total of 3 years for states to submit a final plan if an extension is received. Based on comments received, information the EPA has regarding steps states have already begun taking towards plan development, and extensive experience with similar state plan submission deadlines under CAA section 110 SIPs, the EPA believes states will be able to submit final plans within 3 years by September 6, 2018, in the event states are not required to submit a final plan by September 6, 2016. We address the substantive requirements of initial submittals and the 2017 update in the next section. States that receive 2-year extensions may submit the final plan earlier than September 6, 2018, if they so choose.

The EPA highlights one purpose of the initial submittal is to encourage and potentially facilitate states to do necessary planning and engagement with stakeholders so states are able to submit an approvable final state plan by the extended deadline of September 6, 2018. Some states have well-developed existing programs and the attendant legal authority underpinning such programs to more easily meet the September 6, 2016 deadline by submitting a final plan which largely contains or relies upon such existing programs.[839] Based on comments and stakeholder feedback, however, the EPA anticipates that many states intending to develop and submit a final plan will seek the optional extension given the time it may take to undergo necessary legislative, stakeholder, and planning processes. The EPA acknowledges that the initial submittal of September 6, 2016, is not essential to the ability for states to submit final plans by September 6, 2018, so that even without this 2016 deadline, the EPA could require states to meet the 2018 deadline. Even so, this earlier date in the 3 year planning process serves as a useful “check-in” that provides several significant advantages. First, this earlier date provides all states an opportunity to understand what approaches other states

[839] Based on comments received, we understand that the Northeast and Mid-Atlantic states that participate in RGGI may be in this position.

are considering. Because there are significant benefits to regional cooperation, the EPA believes that a formal process to collect and then provide this information will help all states develop better plans. Second, because the guidelines provide significant flexibility, the ability for the EPA to provide early input to states who may be pursuing more innovative approaches will help ensure that all state plans are ultimately approvable. The EPA therefore believes the initial submittal is an appropriate means by which to offer the optional extension, and for reasons further described in section VIII.E.3, that the requirements of the initial submittal are achievable by September 6, 2016, so states will be able to develop and submit a plan that meets the requirements of the final emission guidelines and section 111(d) of the CAA by the extended date.

Additionally, some states may not submit a state plan as required by the final emission guidelines and section 111(d) of the CAA. For states that do not submit a state plan, the CAA gives the EPA express authority to implement a federal plan for sources in that state upon determination by the EPA that a state has failed to submit a state plan by the required date. For states that do not intend to submit a state plan to meet the obligations of this final rule, by promulgating a federal plan for affected EGUs in states that do not submit a plan by September 6, 2016, such affected EGUs would have an additional 2 years to plan for and determine compliance strategies than had promulgation of a federal plan been predicated on states failing to submit a plan by September 6, 2018. The EPA also notes that this final rule affords states and affected EGUs with many implementation flexibilities and approaches for state plans that the EPA itself may not have the authority to implement through a federal plan. Therefore, affected EGUs subject to a federal plan promulgated for a state that refuses to submit a state plan may benefit from an additional 2 years to plan for compliance with a federal plan with potentially fewer flexibilities.

If no affected EGU is located within a state, the state must submit a letter to the EPA certifying that no such facilities exist by September 6, 2016.[840] The EPA will publish a notice in the *Federal Register* to notify the public of receipt of such letters. If an affected EGU is later found to be located in that state, the state must submit a final plan addressing such affected EGU or the EPA will determine the state has failed to submit a plan as required by the emission guidelines and CAA section 111(d), and begin the process of implementing a federal plan for that affected EGU.

In the case of a tribe that has one or more affected EGUs located in its area of Indian country, if the tribe either does

---

[840] 40 CFR 60.23(b).

not submit a CAA section 111(d) plan or does not receive EPA approval of a submitted plan, the EPA has the responsibility to establish a CAA section 111(d) plan for that area if it determines that such a plan is necessary or appropriate to protect air quality.[841] See the proposed federal plan rulemaking for further information.

The EPA notes that the current implementing regulations at 40 CFR part 60 do not specify who has the authority to make a formal submission of the state plan to the EPA for review. In order to clarify who on behalf of a state is authorized to submit an initial submittal, 2017 update, final state plan (or negative declaration, if applicable), and any revisions to an approved plan, the EPA has included a requirement in this final rule mirroring that of the requirement in 40 CFR part 51 App. V.2.1.(a) with respect to SIPs that identifies the Governor of a state as the authorized official for submitting the state plan to the EPA. If the Governor wishes to designate another responsible official the authority to submit a state plan, the EPA must be notified via letter from the Governor prior to the 2016 deadline for plan submittal so that they have the ability to submit the initial submittal or final plan in the State Plan Electronic Collection System (SPeCS). If the Governor has

[841] See 40 CFR 49.1 to 49.11.

previously delegated authority to make CAA submittals on the Governor’s behalf, a state may submit documentation of the delegation in lieu of a letter from the Governor. The letter or documentation must identify the designee to whom authority is being designated and must include the name and contact information for the designee and also identify the state plan preparers who will need access to SPeCS discussed in section VIII.E.8. A state may also submit the names of the state plan preparers via a separate letter prior to the designation letter from the Governor in order to expedite the state plan administrative process. Required contact information for the designee and preparers includes the person’s title, organization and email address. The EPA recommends this information be submitted early in the state planning process to allow sufficient time for completion of SPeCS registration so that those authorized to use the system are provided access.

3. Components of an initial submittal and 2017 update

As noted, states may request a 2-year extension to submit a final plan through making an initial submittal by September 6, 2016. For the extension to be granted, the EPA is finalizing that the initial submittal must address three required components sufficiently to demonstrate that a state is able to undertake steps and processes necessary to timely submit a final plan by the extended date of September 6, 2018:[842]

- An identification of final plan approach or approaches under consideration, including a description of progress made to date.
- An appropriate explanation for why the state requires additional time to submit a final plan by September 6, 2018.
- Demonstration or description of opportunity for public comment on the initial submittal and meaningful engagement with stakeholders,[843] including vulnerable communities, during the time in preparation of the initial submittal and plans for engagement during development of the final plan.

During the public comment period, multiple commenters stated that the proposed timeframe for states to submit an initial submittal was not achievable, citing, among other things, the number of decisions needed to be made by a state or states, and that the EPA needed to clarify the requirements for an initial submittal. Multiple commenters also expressed concern

[842] As stated previously, in the case of a state electing to participate in the CEIP, this 2016 submittal must include a non-binding statement of intent to participate in the program.
[843] Such stakeholders may include labor unions and workers that have an interest in the state plan, and communities whose economies are dependent on coal.

that the requirements for an initial submittal required final decisions to be made by states, and that the initial submittal deadline was not enough time for states to make these decisions.

It is important to note that the EPA is not requiring the adoption of any enforceable measures or final decisions in order for the state to address any of the initial submittal components by September 6, 2016. The EPA believes the absence of requiring enforceable measures to be included with the initial submittal greatly supports the ability of states intending to develop a final state plan to submit an initial submittal by September 6, 2016. States are required to submit enforceable measures supported by technically complex documentation, such as modeling, and adopted through state public participation and regulatory or legislative processes as part of SIPs under other parts of the CAA within timeframes comparable to the time the EPA is providing for initial submittals.[844]

In order to further address the commenters’ concerns regarding possible ambiguity of the requirements for an initial submittal so that an extension is granted, the EPA is providing

---

[844] For example, 13 states were required to submit SIP revisions sufficient to regulate GHGs under the Prevention of Significant Deterioration (PSD) permitting requirements of the CAA within either 3 weeks or 12 months in response to the EPA’s SIP call. *See* “Action To Ensure Authority To Issue Permits Under the Prevention of Significant Deterioration Program to Sources of Greenhouse Gas Emissions: Finding of Substantial Inadequacy and SIP Call”, 75 FR 77698, (December 13, 2010).

clarity regarding the required components for an initial submittal. Regarding the component that states address an appropriate explanation for an extension, the EPA proposed that appropriate explanations for seeking an extension beyond 2016 for submitting a final plan include: a state's required schedule for legislative approval and administrative rulemaking, the need for multi-state coordination in the development of an individual state plan, or the process and coordination necessary to develop a multi-state plan. In this final rule, the EPA is finalizing these as appropriate explanations for seeking an extension beyond 2016, but makes clear — as explained further below — that other appropriate explanations will be acceptable as well. It is important to note that the initial submittal does not require legislation and/or regulations to be passed prior in order for the state to be granted an extension, but the initial submittal should describe any concrete steps the state has already taken on legislation and/or administrative rulemaking and detail what the remaining steps are in those processes before a final plan can be submitted. The EPA also sought comment on other circumstances for which an extension of time would be appropriate, and also whether some explanations for extensions should not be permitted. Commenters stated that states should be able to seek extensions whenever an extension can be reasonably justified, and that the EPA should take at face value states' good faith efforts by accepting any state assertion that more time is needed to develop a plan unless there is clear evidence to the contrary. The EPA believes there may be appropriate explanations states may submit in addition to the ones described in this final rule sufficient to demonstrate that a state is able to undertake steps and processes necessary to timely submit a final plan by the extended date of September 6, 2018. Given the opportunity for states to submit appropriate explanations other than the ones detailed here, the EPA believes addressing this component requiring an appropriate explanation for an extension is easily achievable by September 6, 2016.

In order to additionally clarify the required components of the initial submittal, the following are types of explanations of information states may provide as part of the initial submittal to sufficiently address each of the three required components for getting an extension:

- Details on whether a state is considering a single or multi-state plan, a plan that meets the CO_2 emission performance rates or state CO_2 rate or mass emission goal, and/or an emission standards or state measures plan type.
- A description of how the state intends to address development of the required components of the final state

plan, including describing what actions have already been taken, what steps remain, and the schedule for completing those steps.

- A commitment to maintain any existing measures the state intends to rely upon for its final plan in order to achieve the necessary reductions once the performance period begins.
- Describing public participation opportunities such as stakeholder and community meetings, or public hearings, throughout the 3 year plan development process. This could also include leverage of public participation approaches that states already use to identify and engage potentially affected communities.

The EPA emphasizes the required initial submittal components are intended to provide a reasonable pathway for states to demonstrate whether they will be able to submit an approvable plan by the extended date of September 6, 2018. The EPA also anticipates that through the requirement to address these components, the initial submittal will also facilitate state planning and stakeholder engagement, particularly as one component requires the public and stakeholders to have an opportunity to comment on the initial submittal. As previously described, these components do not require final decisions to be made by states, and this is further illustrated by the clarifications on how states may meet each of the three required components. Accordingly, the EPA believes none of these components is onerous for states to address in an initial submittal by the September 6, 2016 deadline. To further underscore this point, the EPA is further explaining the clarifying examples listed above of how states may address the three required components, and highlighting the achievability of these examples for states to address through the initial submittal by September 6, 2016.

For identification of the final plan approach or approaches the state is considering, and description of progress made to date, states could identify whether the state is considering the option of the CO_2 emission performance rates, a rate-based CO_2 goal, or a mass-based CO_2 goal, and whether the state is intending to pursue a single-state or multi-state plan. Stakeholders commented that states will not be far enough along in the rule development process to have made these decisions. Commenters also stated that many state legislatures would need to pass legislation giving state environmental agencies legal authority and direction before they could begin to make decisions such as rate or mass-based approach or single or multi-state plan submittal. In order to address the commenters' concerns, the EPA wishes to clarify that state approaches identified in the initial submittal do not need to be final and/or formalized through a state legislature, and that states may opt to identify pursuit of more than one approach at the same time, or to indicate the status of the deliberation of this issue within the state.

The EPA received substantive comment regarding the potential adverse consequences for states pursuing a multi-state approach and receiving an extension until 2018, where, for various reasons, a state or states then decide(s) to pursue the single state approach. Commenters viewed this as being potentially problematic since, as proposed, a single state could only receive an extension until 2017, and if a multi-state plan effort does not work out the deadline for seeking the extension until 2017 would have passed. The EPA notes finalizing a 2 year extension that is available for any state, whether they are pursuing an individual state plan or a multi-state plan resolves the commenters' concern about conflicting extension deadlines if states involved in a multi-state effort decide not to pursue the multi-state approach. Importantly, such identification in an initial submittal does not obligate the state to then actually adopt that approach in their final plan as the EPA acknowledges that based on state processes and public input through plan development during the extended submission period, a state may end up adopting a state plan approach more suitable to the needs of that state and its affected EGUs than previously identified in the initial submittal.

States can also describe progress made to date by identifying steps already taken to address development of the final state plan, as the EPA recognizes that states in general have already taken a number of steps to prepare for state plan development to meet the obligations of this rule. For example, since proposal, states have: begun exploring tradeoffs among various state plan approaches such as individual versus multistate coordination, increased utilization of demand-side EE and RE programs, and implementing rate-based versus mass-based programs; increased their understanding of existing state programs and policies that reduce carbon emissions; built relationships and communications between key state institutions such as environmental agencies, PUCs, governors' offices, and energy regulators; hosted public stakeholder meetings to educate and solicit input from the public; and begun discussing state processes for developing potential state plans. States may meet the first required component by describing steps such as these already undertaken.

The EPA underscores that states may easily address the first component of the initial submittal by describing such steps, and also address the second required component by identifying next steps (which may be a natural extension of these already implemented activities), and laying out a schedule for development of a final plan. States that have taken these steps would especially be able to address the component regarding an appropriate explanation for an extension as the EPA recognizes the substantial work such states have begun to put towards development of state plans, and the continuation of this work justifies additional time to complete necessary steps to result in an approvable state plan. The EPA emphasizes that for states who intend to submit a final plan and need an extension, the components of the initial submittal are not intended to require burdensome final action by states by September 6, 2016, but to identify a viable path to completing a final plan by September 6, 2018.

An initial submittal that contains a commitment to maintain any existing measures the state intends to rely upon for its final plan in order to get the necessary reductions once the performance period begins (e.g. RE standards and demand-side EE programs the state intends to rely upon through a state measures plan type), at least until the final plan is approved, also addresses the requirement that states provide an appropriate explanation for an extension. Given the state's request for additional time prior to putting in place enforceable measures to reduce CO_2, it would be reasonable and appropriate, and in keeping with the goals of 111(d) to ensure that any existing CO_2

reduction measures that the state intends to rely upon remain in place while the state is developing a final plan. Such commitment would demonstrate that the state is taking substantive steps towards successful development of a final plan within 3 years.

Regarding the required public participation component of the initial submittal, the EPA believes this requirement is both achievable for states to submit an initial submittal by the September 6, 2016 deadline, and provides a benefit in facilitating state plan development so that states are more likely to be able to submit a final plan within 3 years if the extension is granted. The EPA can use a comment opportunity on the initial submittal to advise the state whether aspects of the draft initial submittal and overall plan development are appropriate for purposes of meeting the requirements of the final rule so that the state will be able to procure the extension through an acceptable initial submittal and submit a final plan by the extended deadline. The EPA notes the comment period on the initial submittal is only one opportunity the EPA has to assist a state in the state plan development process. The EPA has historically worked with states throughout the state plan development process to help ensure that the state plan is approvable once submitted to the EPA, and expects this level of engagement with states to continue throughout the plan development process. This requirement will also facilitate early identification of concerns stakeholders and the public may have with aspects of a final plan the state is considering. As states have longtime and extensive experience with responding to public comments in numerous contexts, including in the context of other CAA programs such as section 110 SIP development and in permit issuance under NSR and Title V, the EPA anticipates states will be able to timely address the initial submittal public participation.

As previously discussed, because certain communities have a potential likelihood to be impacted by state plans, the EPA believes that the existing public participation requirements under 40 CFR 60.23 are effectuated for the purposes of this final rule by states engaging in meaningful, active ways with such communities. Therefore, the public participation component of the initial submittal includes meaningful engagement with vulnerable communities, throughout the state plan development process and including through the initial submittal. In order to demonstrate to the EPA that states are actively engaging with communities, states could provide in their initial submittal a summary of steps they have already taken to engage the public and how they intend to continue meaningful engagement, including with vulnerable communities, during the additional time (if an extension is granted) for development of the final plan. In addition to approaches that states already use to identify and engage potentially affected communities, the EPA encourages states to use the proximity analysis conducted for this rulemaking (which is described in section IX.A) as a tool to help them identify overburdened communities that could be potentially impacted by their plans. Other tools, such as EJ screen, can also be helpful. The EPA in its continued outreach with states during the implementation phase will also provide resources to assist them in engaging with communities. The EPA believes that through the provision of these resources states will also more easily be able to address this required component of the initial submittal regarding public engagement, including with vulnerable communities, by September 6, 2016.

In addition to the resources the EPA intends to provide to states, there are existing resources states can take advantage of to address this component as well. On the steps that states could take to engage vulnerable communities in a meaningful way, the Agency recommends that states consult the EPA's May 2015 *Guidance on Considering Environmental Justice During the Development of Regulatory Actions*. In this document, the EPA defines meaningful involvement as ensuring that "potentially affected community members have an appropriate opportunity to participate in decisions about a proposed activity (i.e., rulemaking) that may affect their environment and/or health; the population’s contribution can influence the EPA’s [regulatory authority’s] rulemaking decisions; the concerns of all participants involved will be considered in the decision-making process; and the EPA [decision-makers] will seek out and facilitate the involvement of those potentially affected by the EPA’s [or other regulatory authority’s] rulemaking process.”[845] Additionally, this guidance document also encourages those writing rules to consider the positive impacts that a rulemaking will have on communities).[846] Another resource that the EPA recommends that states consult when devising their state plans is the document “Considering Environmental Justice in Permitting” available on the agency’s website.[847] Both of the resources discussed above can add to what states may already have in place to effectively engage vulnerable communities in the rulemaking process.

The EPA recommends that as part of their meaningful engagement with vulnerable communities, states work with communities to ensure that they have a clear understanding of the benefits and any potential adverse impacts that a state plan

[847] Considering Environmental Justice in Permitting. http://www.epa.gov/environmentaljustice/plan-ej/permitting.html#actions.

might have on their overburdened communities and that there is a clear process for states to respond to input from communities.

If a state seeks an extension by submitting an appropriate initial submittal addressing the three required components as described above by September 6, 2016, the EPA will grant the extension. If the state does not submit an initial submittal by September 6, 2016, that contains the three required components, the EPA will notify the state by letter, within 90 days, that the agency cannot grant the extension request based the state's initial submittal. The EPA will notify a state by letter only if the initial submittal does not address the three required components. An extension for submitting a final plan will be deemed granted if the EPA does not deny the extension request based on the initial submittal. The EPA has determined this approach is authorized by, and consistent with, 40 CFR 60.27(a) of the implementing regulations.

For states that request and receive a 2-year extension, the state must submit an update halfway through that extension, by September 6, 2017. In the proposal the EPA included a requirement regarding a 2017 check in. Because the EPA is finalizing that states are able to get a 2-year extension regardless of whether they are submitting an individual or multi state final plan, the EPA believes it appropriate to ensure through the 2017 update that the state is making continuous progress on its initial submittal and that it is on track to meet the final plan submittal deadline of September 6, 2018. The EPA will also be able to use the information provided through the 2017 update to further assist states in plan development.

The final rule requires that states address in the 2017 update the following components:

- A summary of the status with respect to required components of the final plan, including a list of which components are not yet complete.
- A commitment to a plan approach (e.g., single or multi-state, rate or mass emission performance level), including draft or proposed legislation and/or regulations.
- An updated comprehensive roadmap with a schedule and milestones for completing the plan, including progress to date in developing a final plan and steps taken in furtherance of actions needed to finalize a final plan.

In order to assess whether a state is on track to submit a final plan by the 2018 extension deadline, the EPA is requiring that the 2017 update must contain a progress update on components from the initial submittal and a list of which final plan components are still not complete. This progress update must demonstrate that state is meeting any steps and schedule it outlined in its initial submittal.

The EPA is also requiring that the 2017 update include a commitment to the type of plan approach the state will take in the final plan submittal. During the public comment period, many commenters stated that legislative action would be required to enact this final rule at the state level, and that the proposal did not provide enough time for legislative action or other regulatory actions needed for a state to be granted an extension. In order to respond to these comments, the EPA is clarifying that proposed or passed legislation or regulations are not required in the initial submittal due by September 6, 2016. While a state may indicate consideration of multiple state plan approaches in the initial submittal, the EPA is requiring that the state commit to one approach in the 2017 update. This commitment must include draft or proposed legislation or regulations that must become final at the state level prior to submitting a final plan submittal to the EPA. While commenters expressed concern with not being able to have legislation enacted in time to receive an extension until 2018, the EPA has determined that 2 years is a reasonable timeframe for a state to decide on the type of approach it will take in the final plan submittal and to draft legislation or regulations for this approach in order to timely meet the extended September 6, 2018 deadline.

4. Multi-state plan submittals

For states wishing to participate in a multi-state plan, the EPA is finalizing three forms of submittal that states may choose for the submittal of a multi-state plan.

First, the EPA is finalizing its proposed approach where one multi-state plan submittal is made on behalf of all participating states. The joint submittal must be signed by authorized officials for each of the states participating in the multi-state plan and would have the same legal effect as an individual submittal for each participating state. The joint submittal must adequately address plan components that apply jointly for all participating states and for each individual state in the multi-state plan, including necessary state legal authority to implement the plan, such as state regulations and statutes. Because the multi-state plan functions as a single plan, each of the required plan components (e.g., plan emission goals, program implementation milestones, emission performance checks, and reporting) would be designed and implemented by the participating states on a multi-state basis.

The EPA received comments from states requesting flexibility for multi-state plan submittals. In response to these comments, the EPA is also finalizing two additional options on which it solicited comment. First, states participating in a multi-state plan can provide a single submittal — signed by authorized officials from each participating state — that addresses common plan elements. This option requires individual participating states to provide supplemental individual submittals that provide state-specific elements of the multi-state plan. The common multi-state submittal must address all relevant common plan elements and each individual participating state submittal must address all required plan components (including common plan elements, even if only through cross reference to the common plan submittal). Under this approach, the combined common submittal and each of the individual participating state submittals would constitute the multi-state plan submitted for EPA review. The joint common submittal must be signed by authorized officials for each of the states participating in the multi-state plan and would have the same legal effect as an individual submittal for each participating state.

Second, the EPA is finalizing an approach where all states participating in a multi-state plan separately make individual submittals that address all elements of the multi-state plan. These submittals would need to be materially consistent for all common plan elements that apply to all participating states, and would also address individual state-specific aspects of the multi-state plan. Each individual state plan submittal would need to address all required plan components. The EPA encourages states participating in this type of multi-state plan to use as much common material as possible to ease review of the state plans.

These approaches will provide states with flexibility in addressing contingencies where one or more states submit plan components that are not approvable. In such instances, these options simplify the EPA's approval of remaining common or individual portions of a multi-state plan and help address contingencies during plan development where a state fails to finalize its participation in a multi-state plan, with minimal disruption to the submittals of the remaining participating states. These additional submittal approaches also facilitate multi-state plans where the participating states are coordinating the implementation of their plans but are not taking on a joint multi-state emission goal for affected EGUs. For example, states may seek to engage in a multi-state approach that links rate-based or mass-based emission trading programs through appropriate authorizations (e.g. reciprocity agreements, or state regulations) that allow affected EGUs to use emission allowances or RE/EE credits issued in one state for compliance with an emission standard in another state.

In order to avoid a multi-state plan becoming unapprovable due to one state submitting an unapprovable portion of a multi-state plan, withdrawing from the multi-state plan, or failing to implement the multi-state plan, states may include express severability clauses if their multi-state plan is able to stand without further revision if one of the situations described above occurs. The severability clause must specify how the remainder of the multi-state plan or individual state plan would continue to function with the withdrawal of a state or states, and may also include pre-specified revisions. The EPA will evaluate the appropriateness of such a clause as part of its review of the multi-state plan submittal.

5. Process for EPA review of state plans

Our proposal laid out the basic steps for the EPA's review and action on submitted state plans and, at some length, discussed the required components of state plans, as further described in the preceding sections. We received a number of thoughtful and helpful comments on these issues. We are finalizing the basic requirements in this rule and are proposing, in the companion proposed federal plan under section 111(d), some additional procedural elements we believe will be helpful to states, stakeholders and the EPA moving forward.

Following the September 6, 2016 deadline for state plan submittals, the EPA will review plan submittals. For a state that submits an initial submittal by September 6, 2016, and requests an extension of the deadline for the submission of a final state plan submittal, the EPA will determine if the initial submittal meets the minimum requirements for an initial submittal. If the state does not submit an initial submittal by September 6, 2016, that contains the three required components, the EPA will notify the state by letter, within 90 days, that the agency cannot grant the extension request based the state's initial submittal. If the initial submittal meets the minimum requirements specified in the emission guidelines, the state's request for a deadline extension to submit a final plan submittal will be deemed granted, and the final plan submittal must be submitted to the EPA by no later than September 6, 2018.

After receipt of a final plan submittal, the EPA will review the plan submittal and, within 12 months, approve or disapprove the plan through a notice-and-comment rulemaking process publicized in the *Federal Register*, similar to that used for acting upon SIP submittals under section 110 of the CAA. The implementing regulations currently provide for the EPA to act on a final plan within 4 months after the deadline for submission, which is consistent with versions of section 110 prior to the 1990 Amendments to the CAA. 40 CFR 60.27(b). To be consistent with the current version of section 110, the EPA intends to adopt a timeline of 12 months to review final plan submittals upon receipt of complete submittals, as is generally consistent with the timing requirements of section 110 with respect to complete SIP submittals. Such a timeline would also provide the

EPA with adequate time for review and rulemaking procedures, and ensuring an opportunity for public notice and opportunity for comment. We note, however, that we proposed this timeline for review and action on state plans in our proposal, but our proposal was specific to the timeline for state plans submitted pursuant to this rule rather than for state plans submitted under 111(d) generally.[848] We are finalizing as part of this rule that state plans submitted to meet the requirements of this rule will be reviewed and acted upon by the EPA within 12 months of submission. Because such timeline would be appropriate to be made to 111(d) state plans more generally, we are also proposing the appropriate revisions to the implementing regulations as part of the federal plan proposal for section 111(d).

In addition, while the proposal and this final rule lay out in considerable detail the required components of a state plan, the EPA believes that it would also be helpful to include in the rule a completeness determination process, similar to that used for SIP submittals under section 110, which will allow the EPA to determine whether a final plan submittal contains the components necessary to enable the EPA to determine through notice and comment rulemaking whether such submittal complies

[848] The EPA proposed 12 months after the date required for submission of a plan or plan revision to approve or disapprove such plan or revision or each portion thereof.

with the requirements of section 111(d). This is a procedural requirement under CAA section 110(k)(1) for SIPs, and the EPA believes this requirement is appropriate to establish under section 111(d)'s direction to the EPA to prescribe through regulations a procedure similar to that provided by section 110. However, because the EPA did not propose such regulations as part of the proposal for this action, the EPA is proposing such regulations as part of the federal plan proposal for section 111(d). The EPA notes that this preamble (in section VIII.D) and final rule lay out required components of state plans and all the requirements for a state plan submittal, and therefore states have the necessary information at this time to develop state plans. The upcoming completeness criteria will not add to or change these required components, but only add a procedural step that allows the EPA to identify whether there are absent or insufficient components in the plan submittal that would render the EPA unable to act on such submittal because it is incomplete. As we further explain in the federal plan proposal, a determination by the EPA that a plan submittal is incomplete has the effect of a state having a still-pending statutory obligation to submit a plan that meets the requirements of section 111(d).

The EPA is planning to propose an amendment to the section 111(d) implementing regulations that will add the partial approval/disapproval and conditional approval mechanisms in section 110(k)(3) and (4) to the procedure for acting on section 111(d) plans. The input the agency received in response to the proposal for these guidelines indicated that the flexibility provided by these mechanisms could be useful getting state plans in place. The EPA agrees, and is proposing to amend the implementing regulations as part of the rulemaking for the federal 111(d) plan. The EPA is not taking final action on these changes in this action.

The later timing for our action on partial approval/disapproval and conditional procedures does not create any issue with finalizing this rule. These procedural adjustments will only come into play after states have submitted their plans and the EPA is required to act on them, and we intend to finalize these procedural changes prior to September 6, 2016, when the first plan submittals would occur. Until then, the EPA believes that every plan is submitted with the intent to be fully approvable and there is no need for states to rely on the possibility of these procedures when developing their plans. Conditional approval and partial approval/disapproval should be used to deal with approvability issues that arise despite the best efforts of states and the EPA to work together to make sure a submittal in the first instance is fully approvable. The EPA plans to finalize any changes in the implementing regulations before the EPA is required to act on state submittals, so that the EPA and states will have appropriate flexibility in the plan approval process.

6. Failure to submit a plan

If a state does not submit a final plan submittal by the applicable deadline, or submits a final plan the EPA determines to be incomplete, the EPA will notify the state by letter of its failure to submit. The EPA will publish a *Federal Register* notice informing the public of its finding of failure to submit. Upon a finding of failure to submit for a state, a statutory clock will run requiring the EPA to promulgate a federal plan for such state no later than 1 year after the EPA makes the finding unless the state submits, and the EPA approves, a state plan during this time. Refer to the federal plan proposal for more details on how and when a federal plan would be triggered.

7. State plan modifications

a. Modifications to an approved state plan. During the course of implementation of an approved state plan, a state may wish to update or alter one or more of the enforceable measures in the state plan, or replace certain existing enforceable measures with new measures. The EPA received broad support for allowing states to submit modifications to approved state plans, and we agree that this is an important aspect of this program. In this rulemaking, therefore, the EPA is finalizing that a state may revise its state plan, and states in a multi-state plan may revise their joint plan. Consistent with the timing for final plan submittals originally submitted by states, the EPA will act on state plan revisions within 12 months of a complete submittal. The EPA expects that the long plan performance timeframes in this final rule and flexibility provided to states in developing state plans will lessen the need for modifications to approved state plans.

A state may enter or exit a multi-state plan through a plan modification, with certain limitations. Multiple commenters stated that the EPA should clarify the plan modification process in such instances.

Where a state with a single-state approved plan seeks to join a multi-state plan, the state may submit a modification of its plan indicating that it is joining the multi-state plan and including the necessary plan components under the multi-state plan. The current participants of the multi-state plan will also need to submit a plan modification, to acknowledge the new state participant and to recalculate the multi-state rate-based or mass-based CO_2 goal. Functionally, both the modification of the single-state plan of the new participant and the multi-state plan of the current plan participants could be addressed through the same plan modification submittal or addressed under a plan modification submittal comparable to the alternate formats for multi-state plan submittals addressed in section VIII.E.4.

The entry or exit of a state to/from a multi-state plan involves the recalculation of the multi-state rate-based or mass-based CO_2 goal for affected EGUs in the participating states. The recalculated multi-state rate-based or mass-based CO_2 goal must take into account and ensure achievement of the individual state rate-based or mass-based CO_2 goal for any state that is joining the multi-state plan. If implementation of the individual state plan has triggered corrective measures or backstop emission standards prior to the plan modification, as described in Section VIII.F.3, the modification must take into account the need to make up for any shortfall in CO_2 emission performance in the individual state plan prior to joining the multi-state plan. Where one or more states are leaving a multi-state plan through a plan modification, the process is similar and the same considerations must be taken into account in connection with the states that are leaving the multi-state plan.

As a result of these requirements and considerations, the EPA is finalizing certain requirements for multi-state plan modifications. A multi-state plan modification may be submitted to the EPA at any time. However, an approved multi-state plan modification may only take effect at the beginning of a new interim or final plan performance period. These requirements are necessary to ensure that state rate-based or mass-based CO_2 goals in the emission guidelines are achieved. In addition, such requirements for the timing of the effective date of multi-state plan modifications are necessary for coordination of the implementation of multi-state plans, especially where such plans include a multi-state emission trading approach. This approach is also consistent with the approach the EPA is proposing for the implementation of federal plan, where relevant for a state(s).

The EPA solicited comment on whether, for new projections of emission performance included in a submitted plan modification, the projection methods, tools, and assumptions used should match those used for the projection in the original demonstration of plan performance, or should be updated to reflect the latest data and assumptions, such as assumptions for current and future economic conditions and technology cost and performance. Comments received on this topic were generally supportive of allowing the use of updated data in state plan modifications, citing that states should have the ability to determine whether the original data and assumptions or updated data and assumptions are appropriate. The EPA is finalizing that new projections of emission performance, the projection methods, tools, and assumptions do not have to match those used for the projection in the original demonstration of plan performance;

they can be updated to reflect the latest data and assumptions, such as assumptions for current and future economic conditions and technology cost and performance.

As discussed in more detail in section VIII.G.2, the final rule has several measures to ensure that it does not interfere with the industry's ability to maintain reliability. One such measure is that if a state cannot address a reliability issue in accordance with an approved state plan, the state can submit a request to the EPA to modify the state plan. See section VIII.G.2 for a more detailed discussion of this issue.

The EPA is not finalizing any circumstances under which a state may or may not revise its state plan, with the exception that a state may not revise its state plan in a way that results in the affected EGU or EGUs not meeting the requisite CO_2 emission performance levels.

b. Modifications to interim and final CO_2 emission goals. As discussed in section VII, the final rule specifies that the state interim and final CO_2 emission goals for affected EGUs in a state may be adjusted to address changes within a state's fleet of affected EGUs. If these changes occur before a state submits its initial submittal or final plan, the state should indicate in its submittal the circumstance that necessitates the goal adjustment and the revised interim or final CO_2 emission goal. If the circumstances occur after a state has an approved plan, a state must submit a modification to its approved plan. The plan revision submittal must indicate the circumstance that necessitates the goal adjustment, the revised interim and/or final CO_2 emission goal, and the adjustments to the enforceable measures in the plan.

8. Plan templates and electronic submittal

The EPA is finalizing the requirement that submissions related to this program be submitted electronically. Specifically, that includes negative declarations, state plan submittals (including any supporting materials that are part of a state plan submittal), any plan revisions, and all reports required by the state plan. The rule provides that files that are submitted to the EPA in an electronic format may be maintained by states in an electronic format. The submission of the information by the authorized official must be in a non-editable format. In addition to the non-editable version, the EPA is also requiring that all plan components designated as federally enforceable must be submitted in an editable version as well, as discussed below.

a. <u>Submittal of an editable version of federally enforceable plan components</u>. To ensure that the EPA has the ability to identify, evaluate, merge, update and track federally enforceable plan components in a timely and comprehensive manner, the EPA is requiring states to submit an editable copy of the specific plan components in their submittals that are designated as federally enforceable, either effective upon the EPA plan approval or as a state plan backstop measure. The editable version is in addition to the non-editable version. Examples of editable file formats include Microsoft Word, Apple Pages and WordPerfect.

b. <u>Revisions to an approved plan</u>. States shall provide the EPA with both a non-editable and editable copy of any submitted revision to existing approved federally enforceable plan components, including state plan backstop measures. The editable copy of any such submitted plan revision must indicate the changes made, if any, to the existing approved federally enforceable plan components, using a mechanism such as redline/strikethrough. This approach to identifying the changes made to the existing federally enforceable plan components is consistent with the criteria for determining the completeness of SIP submissions set forth in Section 2.1(d) of Appendix V to 40 CFR part 51.

c. <u>Electronic submittal</u>. It is the EPA's experience that electronic submittal of information has increased the ease and efficiency of data submittal and data accessibility. The EPA is developing the SPeCS, a web accessible electronic system to support this requirement that will be accessed at the EPA's Central Data Exchange (CDX) (http://www.epa.gov/cdx/). The EPA will pre-register authorized officials and plan preparers in CDX. See section VIII.E.2 for additional information on the pre-registration process for authorized officials and plan preparers. Detailed instructions for accessing CDX and SPeCS will be outlined in the "111(d) SPeCS User Guide: How to submit state 111(d) plan material to EPA" which will be available on the EPA's Clean Power Plan Toolbox for States. The EPA will provide SPeCS training for states prior to the state plan submittal due date.

Once in CDX, SPeCS can be selected from the Active Program Service List. The preparer (e.g., state representative compiling a state plan submittal) assembles the submission package. The preparer can upload files and complete electronic forms. However, the preparer may not formally submit and sign packages. Only registered authorized officials may submit and sign for the state with the exception of draft submittals. The EPA's intent is to allow submittal of draft plans or parts of plans for early EPA review prior to formal submission by the authorized official and will allow preparers, as well as authorized officials, to submit draft documents. The authorized official will be able to assemble submission packages and will be able to modify submission packages that a preparer has assembled. The key difference between the preparer and the authorized official is that the authorized official can submit and sign a package for formal EPA review using an electronic signature. In the case of a multi-state plan, each participating state's authorized official must provide an electronic signature.

The process has been designed to be compliant with the Cross-Media Electronic Reporting Rule (CROMERR), under 40 CFR part 3, which provides the legal framework for electronic reporting under all of the EPA's environmental regulations. The framework includes criteria for assuring that the electronic signature is legally associated with an electronic document for the purpose of expressing the same meaning and intention as would a handwritten signature if affixed to an equivalent paper document. In other words, the electronic signature is as equally enforceable as a paper signature. For more information on CROMERR, see the Web site: http://www.epa.gov/cromerr/. States who claim that a state plan submittal or supporting documentation includes confidential business information (CBI) must submit that information on a compact disc, flash drive, or other commonly used electronic storage media to the EPA. The electronic media must be clearly marked as CBI and mailed to U.S. EPA/OAQPS/CORE CBI Office, Attention: State and Local Programs Group, MD C539-01, 4930 Old Page Rd., Durham, NC 27703.

The EPA received a number of comments on the electronic submittal of state plans. Some commenters preferred the option to submit electronically rather than the requirement to do so.

In the final rule, for the reasons discussed below, the EPA is requiring electronic submittal of state plans and not allowing alternate options for plan submittal (e.g. paper submittal).

Requiring electronic submittal is in keeping with current trends in data availability and will result in less burden on the regulated community. Electronic submittal will facilitate two-way business communication between states and the EPA, will guide states through the submittal process to ensure submission of all required plan components, and will enable states to submit proposed plans to the EPA electronically for early EPA comments. Electronic submittal will also facilitate, expedite and promote national consistency in the EPA's review of state plans and promote transparency by providing stakeholder-specific access to updated information on state plan status and posting of plan requirements for viewing by the public, government regulators and regulated entities. The EPA recently implemented an electronic submittal process for SIPs under CAA section 110 and continues to explore opportunities to increase the ease and efficiency with which states and the regulated community can meet regulatory data submittal requirements. In summary, the EPA believes electronic submittal will be enormously beneficial in terms of improving coordination and cooperation between the EPA and its state partners in developing approvable state plans. We note, however, that there may be some circumstances where having paper copies of the plan is needed to facilitate public engagement, and encourage states to take those considerations into account.

d. Plan templates. In the proposal, the EPA requested comment on the creation of templates for initial submittals and final state plan submittals. Multiple commenters requested the EPA provide state plan templates. One commenter requested templates for different plan designs (e.g. a mass-based trading framework, a rate-based trading framework, multi-state compliance and a utility-based portfolio approach) and for specific plan components (e.g. how to incorporate a state RE standard and an EE program into a state plan, how to assess the emission reductions delivered by RE and EE). The EPA has determined that the broad range of approaches states may take in preparing individual or multi-state plans makes the development of specific templates challenging and likely not useful to states. However, concurrent with this final rule, the EPA is proposing model rules for both rate- and mass-based programs in conjunction with the proposed federal plan. These effectively can serve as a template for states when preparing their state plan submittals. The EPA will continue extensive outreach to states and work closely with them on the need for additional tools and guidance to facilitate the development of approvable state plans.

9. Legal basis regarding state plan process

Section 111(d)(1) requires the EPA to promulgate procedures "similar" to those in section 110 under which states adopt and submit 111(d) plans. The EPA has interpreted this provision previously in the implementing regulations found in 40 CFR part 60 subpart B. As discussed above, the EPA intends that planned revisions to the part 60 implementing regulations will clarify (among other things) whether certain procedures are appropriate for the EPA's action on 111(d) state plans, and if so, precisely how those procedures should apply. The EPA is proposing these revisions to the 111(d) implementing regulations in the notice of proposed rulemaking for the federal plan being issued concurrently with this final rule. In this section we discuss the legal basis for procedures that the EPA is finalizing in this action: initial submittals, extensions, and plan revisions.

First, by using the ambiguous word "similar," Congress delegated authority to the EPA to determine precisely what procedures would govern 111(d) plans. "Similar" does not have an identical meaning as the word "same." One definition of "similar" is "having likeness or resemblance, especially in a general way." The American College Dictionary 1127 (C.L. Barnhart, ed. 1970). On the other hand, "same" is defined as "alike in kind, degree, quality; that is, identical" or "unchanged in character." *Id.* at 1073.

Had Congress intended that the procedures for section 111(d) plans be indistinguishable from those in section 110, Congress knew how to say so. *See, e.g.*, 36 U.S.C. § 2352(b)(2)(B) ("same procedures"). And had Congress intended that the procedures for section 111(d) plans be as close as possible to those in section 110, Congress knew how to say that. *See, e.g.*, 38 U.S.C. § 4325(c) (agency "shall ensure, *to the maximum extent practicable, that the procedures are similar* to" certain other procedures). Therefore, Congress must have intended to give the EPA leeway to create procedures for section 111(d) state plans that somewhat vary from those in section 110, so long as the section 111(d) procedures are reasonably tied to the purpose and text of section 111(d). In other words, "similar" creates a gap in the statute that the EPA may reasonably fill.

a. <u>Initial submittals and extensions</u>. Initial submittals in this instance are a reasonable gap-filling procedural step. As explained in our proposal, certain aspects of section 111(d) plan development for these particular guidelines warrant our creation of this procedural step, even though section 110 does not provide for initial submittals. As explained above, though, we are not bound under section 111(d)(1) to follow exactly the same procedures.

With respect to the timing of initial submittals, final submittals, and extensions, we note that section 111 does not prescribe any particular deadlines, instead leaving it to EPA's discretion to establish "similar" procedures to section 110. The implementing regulations for section 111(d) plans require state plans to be submitted within 9 months of finalization of emission guidelines. Section 110(a)(1) provides that states should adopt and submit SIPs that provide for implementation, maintenance, and enforcement of the NAAQS within 3 years, or such shorter period as the Administrator may prescribe.[849] As further explained in Section VIII.E., the EPA is providing states with up to 3 years to submit a final plan under this rule, contingent upon the grant of an extension through an initial submittal due by September 6, 2016. Section 110(a)(1) does not provide any particular factors for the Administrator to consider in prescribing a shorter period. Thus, the EPA's prescription of a shorter period for either an initial submittal or a final plan submittal is consistent with the discretion granted in section 110(a)(1). We further discuss why the September 6, 2016 initial submittal deadline is reasonable in Section VIII.E., and such deadline is achievable by states seeking to submit a final plan within 3 years. We also note that

[849] Under this grant of authority to prescribe shorter deadlines, the EPA has in a number of occasions required SIPs to be submitted in 1 year.

section 110(b) provides for extensions of 2 years for plans to implement secondary NAAQS, that other provisions in part D provide for extensions of due dates of attainment plans in certain circumstances, and that the section 111(d) implementing regulations provide for extensions generally. We conclude, in view of the above discussion of "similar," that the approach of initial submittals and extensions of due dates as proposed are reasonable procedures that, while not identical to the procedures in section 110, are still similar.

Some commenters argued that the 1-year period for initial submittals and, even assuming an extension, the additional 1- to 2-year period for final submittals were unreasonably short, particularly in light of the possibility that some state legislatures might need to act to provide adequate legal authority for these particular plans. We are not finalizing the 1-year extension for single state submittals, and we have addressed concerns about legal authority for the initial submittals by allowing states to identify remaining legislative action in those submittals.

With respect to the overall period of up to 3 years for submittals, we continue to find it reasonable and consistent with other deadlines in the CAA. First, section 110(a)(1) requires states to submit a plan for implementation, maintenance, and enforcement of new NAAQS within 3 years of promulgation of that NAAQS. This is true even if the EPA promulgates a NAAQS for a previously non-criteria pollutant. In that case, it is possible and even likely that at least some state agencies will lack statutory authority to regulate the new pollutant. Nonetheless, Congress dictated that states should submit section 110(a)(1) plans within 3 years.

Furthermore, we note that under subpart 1 of Part D of Title 1, attainment plans are generally due no later than 3 years after designation of a nonattainment area, and under other subparts of Part D, plans are due even more quickly. For example, under subpart 4, attainment plans for particulate matter are generally due 18 months after designation, and under subpart 5, the same deadline applies for attainment plans for sulfur oxides, nitrogen dioxide and lead. Developing attainment plans may or may not require states to seek additional legislative authority, but certainly in terms of complexity they are similar to section 111(d) plans for this guideline. In general, attainment plans must contain (among other things) a comprehensive inventory of sources of the relevant pollutant and its precursors (which in populated areas can be very numerous), control measures for those sources (including individualized control measures for the larger sources), and modeled demonstrations of attainment (which in some instances requires photochemical grid modeling). Thus, it is reasonable to have the same timeline for these section 111(d) plans as Congress generally provided for attainment plans in section 172(b).

b. State plan modifications. Section 110(l) provides for states to revise their SIPs, as does 40 CFR 60.28 for section 111(d) plans. Section 110(l) also sets out a standard for revisions: it prohibits the EPA from approving a SIP revision that would interfere with any applicable requirement concerning attainment or reasonable further progress, or any other applicable requirement of the CAA. Under the existing section 111(d) implementing regulations, the Administrator will disapprove section 111(d) plan revisions as unsatisfactory when they do not meet the requirements of subpart B to part 60. See 40 CFR 60.27(c)(3). However, the implementing regulations do not set forth a substantive standard like that in section 110(l).

Section 111(d)(1) does not mention revisions (except indirectly through the reference to section 110) and, therefore, does not explicitly provide any substantive requirements for them. There is, therefore, a gap in the statute that the EPA may reasonably fill, since many stakeholders commented on the desirability of states being able to modify their plans, and the EPA agrees. It is reasonable, at a minimum, that the state plan as revised should continue to provide for implementation and enforcement of the standards of performance, and to achieve the CO_2 emission performance rates or state CO_2 emission performance goal. This is analogous to the substantive requirements of section 110(l), which as explained above for section 110(a)(2), we may consider in determining how to reasonably fill statutory gaps for section 111(d) plans.

In our proposal, we stated that certain revisions to state plans under these emission guidelines, those that revised enforceable measures for affected EGUs, should satisfy some additional conditions. First, the state should demonstrate that the plan continues to achieve the CO_2 emission performance rates or state CO_2 emission performance goal. We proposed that this demonstration might be simple for minor revisions, but for major revisions a more complete demonstration may be required. We are finalizing this proposal. As legal basis for this position, we note that a demonstration is necessary to show that a state plan provides for implementation of standards of performance that achieve the CO_2 emission performance rates or state CO_2 emission performance goal, and as explained above we can reasonably require the same of revisions.

It is also reasonable to tailor the requirements of the demonstration to the magnitude of the revision. The EPA has taken a similar approach to tailoring the requirements for a technical demonstration that, under section 110(l), a SIP revision does not interfere with any applicable requirement concerning attainment of the NAAQS. If a SIP revision does not relax the stringency of any SIP measure, then the demonstration is simple. If the SIP revision does relax the stringency of SIP measures, then a qualitative or quantitative analysis may be necessary to show non-interference, depending on the nature of the revision, the current air quality in the area, and other factors.

Finally, we proposed that revisions "should not result in reducing the required emission performance for affected EGUs specified in the original approved plan. In other words, no 'backsliding' on overall plan emission performance through a plan modification would be allowed." 79 FR 34917/1. We received adverse comments that this standard did not have a basis in section 111(d). According to commenters, since the standard for EPA approval of a section 111(d) plan is whether the plan is satisfactory in establishing and providing for implementation and enforcement of standards of performance that achieve the emission performance rates or goal, the same standard should apply to revisions. In other words, the standard for revisions should be whether the plan as revised is satisfactory. We believe that our proposal was unclear as to this point, and we agree that the same standard for revisions should be the same as for submittals. We have finalized this position.

F. State Plan Performance Demonstrations

This section describes state plan requirements related to compliance periods, monitoring and reporting for affected EGUs; plan performance demonstrations; consequences if the CO_2 emission performance rates or state CO_2 emission goals are not met; and out-year requirements.

1. Compliance periods, monitoring and reporting requirements for affected EGUs

For plans that include emission standards on affected EGUs, the EGU emission standards for the interim period must have schedules of compliance for each interim step 1, 2 and 3 for the calendar years 2022-2024, 2025-2027 and 2028-2029, respectively. For the final period, EGUs must have emission standards that have schedules of compliance for each 2 calendar years starting in 2030 (i.e., 2030-2031, 2032-2033, 2034-2035, etc.). If a backstop is triggered for a state measures plan, the schedule of compliance for the federally enforceable emission standards must begin no later than 18 months after the backstop is triggered and end at the end of the same compliance period. For example, if a backstop is triggered on July 1, 2025, the compliance period for the backstop emission standards must begin no later than January 1, 2027, and end on December 31, 2027. The next compliance period for the backstop emission standards would be January 1, 2028-December 31, 2029.

In the June 2014 proposal, the EPA proposed that the appropriate averaging time for any rate-based emission standard for affected EGUs be no longer than 12 months within a plan performance period and no longer than 3 years for a mass-based standard. The EPA solicited comments on longer and shorter averaging times for emission standards included in state plans. The EPA received comments stating that the proposed 12-month averaging was too short and that there was no reason why the compliance period under a rate-based plan should be different from a mass-based plan. Comments stated that a multi-year averaging period is appropriate for rate-based and mass-based plans to account for variations that can occur in a single year, allowing operators the flexibility they need to manage unforeseen events. The commenters also recommended that the final rule use discrete 3-year periods for compliance reconciliation instead of the rolling-average approach proposed.

The EPA has considered all comments received on this matter and is finalizing the compliance periods specified above, which respond to the comments by applying to both rate- and mass-based programs, providing compliance periods longer than 1 year, and establishing block compliance periods rather than a rolling average approach. We agree with comments that longer averaging periods allow for operational and seasonal variability to even out. The EPA finalizes that states can choose to set shorter compliance periods for their emission standards but none that are longer than the compliance periods the EPA is finalizing in this rulemaking. If a state chooses to set shorter compliance periods, we urge them to make efforts to be cognizant of other deadlines facing EGUs to assure that there will not be conflicts. The EPA recognizes that the compliance periods provided for in this rulemaking are longer than those historically and typically specified in CAA rulemakings. "The time over which [the compliance standards] extend should be as short term as possible and should generally not exceed one month." See e.g., June 13, 1989 "Guidance on Limiting Potential to Emit in New Source Permitting" and January 25, 1995 "Guidance on Enforceability Requirements for Limiting Potential to Emit through SIP and §112 Rules and General Permits." However, the EPA has determined that the longer compliance periods provided for in this rulemaking are acceptable in the context of this specific rulemaking because of the unique characteristics of this rulemaking, including that CO_2 is long-lived in the atmosphere, and this rulemaking is focused on performance standards related to those long-term impacts. The distinction between these unique characteristics and the EPA's general practice regarding compliance periods is bolstered by the EPA guidance on appropriate averaging periods for emission limitations in NAAQS implementation. For example, the EPA guidance has stated that in implementation of the ozone standards, which have a short averaging period, the averaging period for VOC emission limitations should be correspondingly short. See 51 FR 43857. A longer averaging period for VOC emission limitations (VOCs are one of the key precursors to ozone formation) can allow spikes in emissions that adversely impact ambient air and violate the short term ozone standards. This is precisely the opposite of the unique characteristics cited above: the long-lived persistence of CO_2 in the stratosphere and the intent of these guidelines to address the long-term impacts.

State plans must contain requirements for tracking and reporting actual plan performance during implementation, which includes reporting of CO_2 emissions from affected EGUs. Affected EGUs must comply with emissions monitoring and reporting requirements that are largely incorporated from 40 CFR part 75 monitoring and reporting requirements. The majority of affected EGUs are already familiar with the reporting requirements of part 75, and because of this, the EPA has chosen to streamline the applicable reporting requirements for affected EGUs under the state plans in the final rule. States must require all affected EGUs to monitor and report hourly CO_2 emissions and net energy output (including total net MWh output that is comprised of generation, and where applicable, useful thermal output converted to net MWhs) on a quarterly basis in accordance with 40 CFR part 75. Note that this requirement applies for all types of state plans, regardless of whether the state chooses the option of the CO_2 emission performance rates, a state rate-based CO_2 emission goal, or a state mass-based CO_2 emission goal.

In the June 2014 proposal, the EPA proposed that state plans must include monitoring, reporting and recordkeeping requirements for useful energy output from affected EGUs. Multiple commenters questioned whether gross rather than net electrical production should be reported by affected EGUs and recommended that the EPA should utilize gross rather than net generation. Many commenters recommended electricity be reported in the form used in the 111(b) rules for consistency between reporting requirements and simplification of calculation of emission limitations between new and old sources. Commenters also stated that to the extent the EPA seeks to provide guidance to states regarding its preferred monitoring and reporting procedures, the EPA should encourage states to avoid imposing additional monitoring and reporting burdens by taking advantage of the monitoring requirements that already exist to the greatest extent possible. For example, the commenters noted that the 40 CFR part 75 monitoring procedures used to comply with other programs, such as the Title IV Acid Rain Program, provide much of the data that would be needed to demonstrate compliance under the rule. Comments stated that the June 2014 proposal appeared to mandate a monitoring approach that would eliminate key flexibilities provided in the part 75 regulations, thus requiring utilities to maintain separate document collection and reporting procedures and potentially eliminating important alternative monitoring options intended to ensure representative, cost-effective monitoring approaches are available. The commenters asked the EPA to revise its proposal to make clear that the procedures established under part 75 will suffice or explain the need for any exceptions. Commenters indicated that the rule should require all affected EGUs to monitor CO_2 emissions and net hourly electric output under 40 CFR part 75, and report the data using the EPA's Emission Collection and Monitoring Plan System (ECMPS) assuring a more uniform monitoring and reporting process for all EGUs. The EPA believes that the final monitoring and reporting requirements (via ECMPS) address the issue of duplicative requirements and alleviate concern about lost flexibility raised by commenters.

2. Plan performance demonstrations

The state plan must include emission performance checks, and for state measures plans, periodic program implementation milestones. The state plan must provide for tracking of emission performance, and for measures to be implemented if the emission performance of affected EGUs in the state does not meet the applicable CO_2 emission performance rates or state CO_2 emission goal during a performance period.

As discussed above in section VII, the agency is finalizing CO_2 emission performance rates or state-specific CO_2 emission goals that represent emission levels to be achieved by 2030 and emission levels to be achieved over the 2022-2029 interim period, and over three interim steps of 2022-2024, 2025-2027 and 2028-2029. A state may choose to define different interim step emission levels for achieving its required 2022-2029 average performance rate. The EPA recognizes the importance of ensuring that, during the 8-year interim period (2022-2029) for the interim performance rates or interim state goal, a state is making steady progress toward achieving the required level of emission performance. For both emission standards plans and state measures plans, the final rule requires periodic checks on overall emission performance leading to corrective measures or implementation of the backstop, if necessary, as described in section VIII.F.3 below. States must demonstrate that the interim steps were achieved at the end of the first two interim step periods.

In 2032 and every 2 years thereafter, states must demonstrate that affected EGUs achieved the final performance rates or state goal on average or cumulatively, as appropriate, during each 2-year reporting period (i.e., 2030-31, 2032-33, 2034-2035 etc.). The multi-year performance periods for measuring actual plan performance against the performance rates or state goals allow states some flexibility that accounts for seasonal operation of affected EGUs, and inclusion of RE and demand-side EE efforts.

For a rate-based plan, emission performance is an average CO_2 emission rate for affected EGUs representing cumulative CO_2 emissions for affected EGUs over the course of each reporting period divided by cumulative MWh energy output[850] from affected EGUs over the reporting period, with rate adjustments for qualifying measures, such as RE and demand-side EE measures. For a mass-based plan, emission performance is total tons of CO_2 emitted by affected EGUs over the reporting period.

For emission standards plans, as discussed in section VIII.D, the state must submit a report to the EPA containing the emissions performance comparison for each reporting period no later than the July 1 following the end of each reporting period (i.e., by July 1, 2025; July 1, 2028; July 1, 2030; July 1, 2032; and so on). As discussed in section VIII.D, the emission comparison required in the July 1, 2030 report must compare the actual emissions from affected EGUs over the interim period (2022-2029) with the interim CO_2 emission performance rates or state CO_2 emission goal. The report is not required to include a

[850] For EGUs that produce both electric energy output and other useful energy output, there would also be a credit for non-electric output, expressed in MWh.

comparison for the interim step 3 period, but must include the actual emissions from affected EGUs during the interim step 3 period.

The EPA notes that for certain types of emission standards plans, with mass-based emission standards in the form of an emission budget trading program, achievement of a state's mass-based CO_2 goal (including interim step goals and final goal) will be assessed by the EPA based on compliance by affected EGUs with their emission standards under the program, rather than CO_2 emissions during a specific interim step period or final period. This approach is limited to plans with emission budget trading programs where compliance by affected EGUs with the emission standards will ensure that, on a cumulative basis, the state interim and final mass-based CO_2 goals are achieved.[851] This approach allows for CO_2 allowance banking across plan performance periods, including from the interim period to the final period. As a result, CO_2 emissions by affected EGUs could differ from the state mass-based CO_2 goal during an individual plan performance period, but on a cumulative basis CO_2 emissions from affected EGUs would not exceed what is allowable if the interim and final

[851] Emission budget trading programs in such plans establish CO_2 emission budgets equal to or less than the state mass CO_2 goal, as specified for the interim plan performance period (including specified levels in interim steps 1 through 3) and the final 2-year plan performance periods.

CO_2 goals are achieved.

Also as discussed in section VIII.D, states that choose a state measures plan must submit an annual report no later than July 1 following the end of each calendar year in the interim period. This annual report must include the status of the implementation of programmatic milestones identified in the state plan submittal. The annual report that follows the end of each reporting period (i.e., 2022-2024, 2025-2027, and 2028-2029) must also include an emissions performance comparison for the reporting period, as described above for the emission standards plan. As discussed in section VIII.D, the emission comparison required in the July 1, 2030 report must compare the actual emissions from affected EGUs over the interim period (2022-2029) with the interim CO_2 emission performance rates or state CO_2 emission goal. The report is not required to include a comparison for the interim step 3 period, but must include the actual emissions from affected EGUs during the interim step 3 period. Beginning with the final period of 2030 and onward, states using a state measures plan must submit a biennial report no later than July 1 following the end of each reporting period with an emission performance comparison for each reporting period, consistent with the reporting requirements for emission standards plans.

In the June 2014 proposal, the EPA proposed that a state report is due to the EPA no later than July 1 of the year immediately following the end of each reporting period. The EPA requested comment on the appropriate frequency of reporting of the different proposed reporting elements, considering both the goals of minimizing unnecessary burdens on states and ensuring program effectiveness. In particular, the agency requested comment on whether full reports containing all of the elements should only be required every 2 years rather than annually and whether these reports should be submitted electronically, to streamline transmission.

The EPA mainly received adverse comments for requiring annual state reporting; commenters stated that this requirement was too burdensome for both states and the EPA. Commenters also requested that the EPA extend the due date of the annual report from July 1 to at least December 31. Commenters stated that because of the timing of current data collection and the need to leave time to organize and submit the reports, allowing only 6 months after the close of the year is problematic. Commenters asked that the EPA consider reducing the amount of data required if annual reporting was required.

Considering the comments received and the goals of minimizing unnecessary burdens on states and ensuring program effectiveness, the EPA has reduced the frequency of reporting of emissions data to every 3 years for the first two interim steps and every 2 years thereafter. However, the EPA is finalizing that state reports are due to the EPA no later than July 1 following the end of each reporting period. The EPA believes states can design their state plans to receive the data and information needed for these reports in a timely manner so that this requirement can be met. Furthermore, some of the state reporting requirements, such as reporting of EGU emissions, can be met through existing reporting mechanisms (ECMPS) and would not place additional burdens on states.

3. Consequences if actual emission performance does not meet the CO_2 emission performance rates or state CO_2 emission goal

The EPA recognizes that, under certain scenarios, an approved state plan might fail to achieve a level of emission performance that meets the emission guidelines or the level of performance established in a state plan for an interim milestone. Despite successful implementation of certain types of plans, emissions under the plan could turn out to be higher than projected at the time of plan approval because actual conditions vary from assumptions used when projecting emission performance. Emissions also could theoretically exceed projections because affected entities under a state plan did not fulfill their responsibilities, or because the state did not fulfill its responsibilities.

The final rule specifies the consequences in the event that actual emission performance under a state plan does not meet, or is not on track to meet, the applicable interim and interim step CO_2 emission performance rates or state goals in 2022-2029, or does not meet the applicable final CO_2 emission performance rates or state CO_2 emission goal in 2030-2031 or later. The determination that a state is not on track to meet the applicable interim goal or interim step goals in 2022-2029 or the applicable final goal in 2030-2031 or later, or the CO_2 emission performance rates, will be made through the actual performance checks to be included in state reports of performance data described in section VIII.D.2.a above.

For emission standards plans, the final rule specifies that corrective measures must be enacted once triggered. Corrective measures apply only to emission standard plans in which full compliance by affected EGUs would not necessarily lead to achievement of the emission performance rates or CO_2 emission goals.[852] For such plans, corrective measures are triggered if actual CO_2 emission performance by affected EGUs is deficient by

[852] To be specific, corrective measures requirements apply to all emission standard plan designs that do not mathematically assure that the plan performance level will be achieved when all affected EGUs are in compliance with their emission standards, regardless of electricity production and electricity mix. Corrective measures requirements apply, for example, to emission standards plans that include standards on affected EGUs that differ from the emission performance rates in the guidelines. Backstop requirements apply to state measures plans.

10 percent or more relative to the specified level of emission performance in the state plan for the step 1 or step 2 interim performance periods. Corrective measures also are triggered if actual emission performance fails to meet the specified level in the plan for the 8-year interim period 2022-2029, or for any 2-year final goal performance period (beginning in 2030). In such cases, the state report must include a notification to the EPA that corrective measures have been triggered. If, in the event of such an exceedance, the EPA determines that corrective measures have been triggered and the state has failed to notify the EPA, the EPA will inform the affected EGUs that corrective measures have been triggered.[853]

When corrective measures are triggered, if the state plan does not already contain corrective measures, the state must submit to the EPA a plan revision including corrective measures that adjust requirements or add new measures. The corrective measures must both ensure future achievement of the CO_2 emission performance rates or state CO_2 emission goal and achieve additional emission reductions to offset any emission performance shortfall that occurred during a performance period. The shortfall must be made up as expeditiously as practicable.

[853] The EPA notes that as part of the proposed federal plan rulemaking, it is proposing a regulatory mechanism to call plans in the instances of substantial inadequacy to meet applicable requirements or failure to implement an approved plan.

The state plan revision submission must explain how the corrective measures both make up for the shortfall and address the state plan deficiency that caused the shortfall. The state must submit the revised plan to the EPA as expeditiously as practicable and within 24 months after submitting the state report indicating the exceedance. The 24-month time period allows time to identify corrective measures and make rule changes through state regulatory processes. The EPA will then act on the plan revision within 12 months, consistent with other plan revisions and with the timing for final plan submittals originally submitted by states. The state must implement corrective measures within 6 months of the EPA's approval of a plan revision adding them.

For states using the state measures approach, the EPA is finalizing the backstop requirement as described in section VIII.C.3 of this preamble. As discussed in section VIII.D.2, the determination that a state using the state measures approach is not on track to meet the applicable interim goal or interim step goals in 2022–2029, or the applicable final goal in 2030–2031 or later, is based on checks that must be included in state reports that must be submitted annually during the interim period and biennially during the final period. The state must annually report on its progress in meeting its programmatic milestones during the interim period. In addition, the state must report actual emission performance checks, similar to the requirements discussed above for emission standards plans, in 2025, 2028, 2030, and every 2 years thereafter. If, at the time of the state report to the EPA, the state did not meet the programmatic milestones for the reporting period, or the performance check shows that the plan's actual CO_2 emission performance warrants implementation of backstop requirements,[854] the state must include in the state report a notification to the EPA that the backstop has been triggered. If, in the event of such an exceedance, the EPA determines that the backstop has been triggered and the state has failed to notify the EPA, the EPA will inform the affected EGUs that the backstop has been triggered.[855]

For multi-state plans, corrective measure or backstop provisions would be required for the same plan approaches for which those provisions are required in individual state plans.

---

[854] As explained in section VIII.C.3.b., state measures plans must require the backstop to take effect if actual CO_2 emission performance fails to meet the level of emission performance specified in the plan over the 8-year interim performance period (2022-2029), or for any 2-year final goal performance period. The plan also must require the backstop to take effect if actual emission performance is deficient by 10 percent or more relative to the performance levels that the state has chosen to specify in its plan for the interim step 1 period (2022-2024) or the interim step 2 period (2025-2027).

[855] The EPA notes that as part of the proposed federal plan rulemaking, it is proposing a regulatory mechanism to call plans in the instances of substantial inadequacy to meet applicable requirements or failure to implement an approved plan.

For multi-state plans using plan approaches to which corrective measures or backstop requirements apply, all states that are party to the multi-state plan would be subject to corrective action or backstop requirements, and requirements to make up the past CO_2 emission performance shortfall, if those requirements were triggered. This is because multi-state plans are joint plans (even if created through separate state submittals). That would not be the case for coordinated individual state plans linked through interstate ERC or emission allowance trading. In the case of coordinated individual state plans, for plan types subject to corrective measure or backstop requirements, the state where the CO_2 emission performance deficiency occurs would be required to implement corrective measures or backstop requirements for affected EGUs, as applicable, and remedy the past CO_2 emission performance shortfall.

Multiple commenters requested that corrective measures not be required in the case of a catastrophic, uncontrollable event. We recognize that there are potential system emergencies that cannot be anticipated that could cause a severe stress on the electricity system for a length of time such that the multi-year requirements in a state plan may not be achievable by certain affected EGUs without posing an otherwise unmanageable risk to reliability. We are finalizing a reliability safety valve, which includes an initial period of up to 90 days during which a reliability-critical affected EGU or EGUs will not be required to meet the emission standard established for it under the state plan but rather will meet an alternative standard. While the initial 90-day period is in use, the emissions of the affected EGU or EGUs that exceed their obligations under the approved state plan will not be counted against the state's overall goal or emission performance rate for affected EGUs and will not be counted as an exceedance that would otherwise trigger corrective measures under an emission standard plan type or an exceedance that would trigger a backstop under a state measures plan type. Use of the reliability safety valve will not alter or abrogate any other obligations under the approved state plan. After the initial period of up to 90 days, the reliability-critical affected EGU is required to continue to operate under the original state plan emission standard or an alternative standard as part of the reliability safety valve, and the state must revise its plan to accommodate changes needed to respond to ongoing reliability requirements and to ensure than any emissions excess of the applicable state goals or performance rates occurring after the initial period of up to 90 days are accounted for and offset. See section VIII.G.2.e of this preamble.

Multiple commenters supported the inclusion of strong enforcement measures for ensuring the interim and final goals are met, including the required use of corrective measures when triggered. Other commenters provided feedback as to the percentage that actual emission performance would need to exceed the level of emission performance specified in the statewide plan to trigger corrective measures. Some commenters supported the trigger that we are finalizing (actual emissions or emission rate performance that is 10 percent or more than the specified level of emission performance in the state plan for the interim step 1 or step 2 performance periods), while some recommended a lower or higher trigger.

The agency is finalizing the trigger at the level of 10 percent for the interim step 1 or step 2 performance periods. Ten percent is a reasonable level to ensure that when deficiencies in state plan performance begin to emerge, corrective measures (or backstop requirements) will be implemented promptly to avoid emissions shortfalls (or minimize the extent of shortfalls) relative to the 8-year interim goal and the final goal, which reflect the BSER. The 10 percent figure also provides latitude for a state's emission improvement trajectory during the interim period to deviate a bit from its planned path without triggering these requirements, as the state initiates or ramps up programs to meet the 8-year interim goal and final goal.

The EPA requested comment on whether the agency should promulgate a mechanism under CAA section 111(d) similar to the SIP call mechanism in CAA section 110. Under this approach, after the agency makes a finding of the plan's failure to achieve the CO_2 emission performance rates or state CO_2 emission goal during a performance period, the EPA would require the state to cure the deficiency with a new plan within a specified period of time. If the state still lacked an approved plan by the end of that time period, the EPA would have the authority to promulgate a federal plan under CAA section 111(d)(2)(A). 79 FR 34830, 34908/1-2 (June 18, 2014).

The EPA intends that planned revisions to the part 60 implementing regulations will clarify (among other things) whether the EPA has authority to call for plan revisions under section 111(d) when a state's plan is not complying with the requirements of this guideline, and if so, precisely what procedures should apply. The EPA is proposing these revisions to the 111(d) implementing regulations in the notice of proposed rulemaking for the federal plan. The EPA is not taking final action now on this issue or the related change to the implementing regulations.

a. Legal basis for corrective measures. The EPA discussed the concept of corrective measures in our 1992 General Preamble for the Implementation of Title I of the CAA Amendments of 1990. 57 FR 13498 (Apr. 16, 1992). The General Preamble sets out four general principles that apply to all SIPs, "including those involving emissions trading, marketable permits and allowances." *Id.* at 13568. The fourth principle, accountability, means (among other things) that "the SIP must contain means … to track emission changes at sources and provide for corrective action if emissions reductions are not achieved according to the plan." In the General Preamble, we noted that Part D of Title I explicitly provided for this in certain instances by requiring milestones and contingency measures.

Some commenters noted that the contingency measures explicitly required by part D are required to be adopted in the attainment plan and ready to implement when a milestone is not achieved or the area fails to attain the relevant NAAQS. These commenters therefore concluded that corrective measures for 111(d) plans should likewise already be adopted in the 111(d) plan and ready to implement. We disagree. Under Part D, contingency measures are not expected to fully bring the area into attainment. In fact, this would not be possible given the difficulty of predicting in advance exactly what measures would be needed to fully attain. A better analogue in Part D for the corrective measures in these guidelines is the primary way Part D addresses failure to attain: the state is required to revise its plan in various ways within a certain time in order to bring about attainment. See, e.g., section 179(d). This is analogous to what we are requiring for corrective measures. Thus, part D contingency measures are unlike the corrective measures in this rule.

However, the requirement to revise an attainment plan in response to failure to attain differs somewhat from the corrective measures in these guidelines. Under these guidelines, the corrective measures must make up the difference by which the plan fell short of the goal, including any prior shortfall that had accumulated if the plan fell short of the goal in prior years. There is no corresponding requirement in attainment planning to increase the stringency of the plan by an amount that somehow makes up for any shortfall in attainment from prior years; instead the revised plan must demonstrate attainment going forward, and other more stringent requirements (such as requirements for best available control measures) may be triggered.

This distinction is the natural result of the difference between these guidelines and NAAQS attainment planning. In this case, we are finalizing guidelines representing technology-based standards for a pollutant with cumulative and long-lasting effects. If a plan falls short of a performance goal, then in effect the standards of performance in the plan have failed to reflect the BSER over the corresponding period. Due to the cumulative effects of CO_2, it is possible to remedy this failure by requiring the plan to be revised in such a way that the standards of performance in the revised plan will reflect the BSER over the cumulative plan period, and this can be done by requiring the revised plan to make up the shortfall from the previous period. In short, the flexibility that these guidelines provide should not come at the cost of allowing the standards of performance to reflect less than the BSER over the long run.[856]

Some commenters noted that 111(d) does not contain explicit provisions regarding corrective measures, and they therefore inferred that the EPA is not authorized to require them. That inference is mistaken. The requirement for 111(d) plans to "provide for implementation and enforcement" of the standards of performance is ambiguous and does not directly speak to whether corrective measures should or should not be required. There is therefore a gap for the EPA to fill. While the discussion above about Part D does not independently provide any authority to fill this gap, the fact that Congress created a scheme with stages of planning in Part D suggests that it would be reasonable, if appropriate, to fill this gap in 111(d) in a similar way.

In this guideline, it is appropriate for emission standards

[856] Similar considerations apply to the requirement under the state measures approach to revise the plan to make up the shortfall.

plans to fill this gap with corrective measures if triggered. There are two ways an emission standards plan can provide for implementation of standards of performance that achieve the CO_2 emission performance rates or requisite state CO_2 emission performance goal. First, the state can set emission standards that necessarily achieve the performance rates or goal, even if the affected EGUs in the future vary in their relative amounts of electricity generated. Second, the state can set emission standards that are demonstrated to achieve the performance rates or goal based on assumptions about the relative amounts of electricity generated, but which may turn out to not actually achieve the goal even if all affected EGUs comply. This is analogous to an attainment plan that demonstrated attainment by the applicable attainment date, but due to unpredicted economic changes actually failed to attain. In this second case, the EPA interprets the ambiguous language "provide for implementation . . . of standards of performance" in the context of achieving the performance rate or emissions goal, to mean that at the time the plan is submitted it must contain some mechanism to check the progress of the plan and correct course. The EPA has determined that, for this particular rule, the minimum mechanism is the set of milestones and provisions for corrective measures specified in this rule. Indeed, not requiring corrective measures in the case of deficient plan performance would undercut the viability of state plan options other than emission standard plans with uniform rates applied to all affected EGUs within the state.

4. Out-year requirements: Maintaining or improving the level of emission performance required by the emission guidelines

The agency is determining CO_2 emission performance rates and state CO_2 emission goals for affected EGU emission performance based on application of the BSER during specified time periods. This raises the question of whether affected EGU emission performance should be maintained at the 2030 level – or instead should be further improved - once the final CO_2 emission performance rate or state CO_2 emission goal is met in 2030. This involves questions of performance rate and goal-setting as well as questions about state planning. The EPA believes that Congress either intended the emission performance improvements required under CAA section 111(d) to be maintained or, through silence, authorized the EPA to reasonably require maintenance. Other CAA section 111(d) emission guidelines set emission limits that do not expire. Therefore, the EPA is finalizing that the level of emission performance for affected EGUs represented by the final CO_2 emission performance rates or state CO_2 emission goal must continue to be maintained in the years after 2030.

As noted above, the state plan must demonstrate that plan measures are projected to achieve the final emission performance level by 2030. In addition, the state plan must identify requirements that continue to apply after 2030 and are likely to maintain affected EGU emission performance meeting the final goal. The state plan would be considered to provide for maintenance of emission performance consistent with the final goal if the plan measures used to demonstrate projected achievement of the final goal by 2030 will continue in force and not sunset. After implementation, the state is required to compare actual plan performance against the final goal on a 2-year average basis starting in 2030, and to implement corrective measures or a backstop if triggered.

In the proposal, the EPA noted that "CAA section 111(b)(1)(B) calls for the EPA, at least every eight years, to review and, if appropriate, revise federal standards of performance for new sources" in order to assure regular updating of performance standards as technical advances provide technologies that are cleaner or less costly. The proposal "requests comment on the implications of this concept, if any, for CAA section 111(d)." 79 FR 34830, 34908/3 (June 18, 2014).

We acknowledge the obligation to review section 111(b) standards as stated. The EPA is not finalizing any position with respect to any implications of this concept for section 111(d). We are promulgating rules for section 111(d) state plans that will establish standards of performance for existing sources to which a section 111(b) standard of performance would apply if such sources were new sources, within the definition in section 111(a)(2) of "new source." It is not necessary to address at this time whether subsequent review and/or appropriate revision of the corresponding section 111(b) standard of performance have any implications for review and/or revision of this rule.

a. Legal basis for maintaining emission performance. In the proposal, the EPA proposed "that the level of emission performance for affected EGUs represented by the final goal should continue to be maintained." The EPA explained that "Congress either intended the emission performance improvements required under CAA section 111(d) to be permanent or, through silence, authorized the EPA to reasonably require permanence. Other CAA section 111(d) emission guidelines set emission limits to be met permanently." 79 FR 34830, 34908/2 (June 18, 2014). We also requested comment on whether "we should establish BSER-based state performance goals that extend further into the future (e.g. beyond the proposed planning period), and if so, what those levels of improved performance should be." *Id.* at 34908/3.

We received adverse comment on establishing BSER-based state performance goals beyond the proposed planning period. Commenters argued that we did not have a sufficient basis at this time to determine what those future goals should be. We agree and have decided not to establish such goals. We are finalizing, though, that the level of emission performance for affected EGUs represented by the final goal should continue to be maintained, for the reasons given in our proposal and quoted above.

The general structure of the CAA supports our interpretation. Section 111(d) plans establish standards of performance that reflect the BSER, a technology-based standard. Generally speaking, in the future technology will only improve, and correspondingly the CAA does not provide explicit processes to relax technology-based standards. In contrast, the provisions in Part D of title I that address attainment of health-based standards, the NAAQS, explicitly provide that once the NAAQS are attained, emission reduction measures may be relaxes so long as the NAAQS are maintained. The absence in section 111(d) of explicit provisions for future relaxation of emission reduction measures, as compared to Part D, supports our interpretation that the emission reductions continue to be on-going after the CO_2 emission performance rates or state CO_2 emission goals are achieved in 2030. This is consistent with our past practice for section 111(d) rules, which do not contain any provision that in the future removes or relaxes the promulgated guidelines. In light of the persistence of CO_2 as a pollutant and its long-term impacts, it is particularly critical in these guidelines to explicitly provide for continuing emission reductions.

G. Additional Considerations for State Plans

1. Consideration of a facility's "remaining useful life" and "other factors"

This section discusses the way in which the final emission guidelines address the CAA section 111(d)(1) provision requiring the Administrator, in promulgating 111(d) regulations, to "permit the State in applying a standard of performance to any particular source under a [111(d)] plan . . . to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."

The final guidelines permit a state, in developing its state plan, to fully consider and take into account the remaining useful life of an affected EGU and other factors in establishing the requirements that apply to that EGU, as discussed further below. Therefore, consideration of facility-specific factors and in particular, remaining useful life, does not justify a state making further adjustments to the performance rates or aggregate emission goal that the guidelines define for affected EGUs in a state and that must be achieved by the state plan. Thus, these guidelines do not provide for states to make additional goal adjustments based on remaining useful life and other facility-specific factors because they can fully consider these factors in designing their plans.

a. <u>Statutory and regulatory backdrop</u>. This section describes the statutory and existing regulatory background concerning facility-specific considerations in implementation of section 111(d).

Section 111(d)(1)(A) requires states to submit a plan that "establishes standards of performance" for existing sources. Under section 111(d)(1)(B), the plan must also "provide for implementation and enforcement of such standards of performance." Finally, the last sentence of section 111(d)(1) provides: "Regulations of the Administrator under this paragraph shall permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."

The EPA's 1975 implementing regulations[857] addressed a number of facility-specific factors that might affect requirements for an existing source under section 111(d). Those regulations provide that for designated pollutants, standards of performance in state plans must be as stringent as the EPA's emission guidelines. Deviation from the standard might be appropriate where the state demonstrates with respect to a specific facility (or class of facilities):

(1) Unreasonable cost of control resulting from plant

[857] 40 FR 53340 (Nov. 17, 1975).

age, location, or basic process design;

(2) Physical impossibility of installing necessary control equipment; or

(3) Other factors specific to the facility (or class of facilities) that make application of a less stringent standard or final compliance time significantly more reasonable.

This provision was amended in 1995 (60 FR 65387, December 19, 1995), and is now prefaced with the language "Unless otherwise specified in the applicable subpart on a case-by-case basis for particular designated facilities or classes of facilities." 40 CFR 60.24(f).

b. <u>Our proposal regarding the implementing regulations</u>. Our proposal stated that the reference to "[u]nreasonable cost of control resulting from plant age" in 60.24(f) "implements" the statutory provision on remaining useful life. We also stated that the implementing regulations "provide the EPA's default structure for implementing the remaining useful life provision of CAA section 111(d)." We noted that the prefatory language "unless otherwise specified in the applicable subpart" gives the EPA discretion to alter the extent to which the implementing rules applied if appropriate for a particular source category and guidelines. We requested comment on our analysis of the existing implementing regulations and any implications for our regulatory text in respect to how these guidelines relate to those regulations.

Commenters stated, among other things, that the sentence concerning "remaining useful life" was added in the 1977 CAA Amendments and that therefore it could not be said that provisions from the 1975 implementing regulations "implement" the sentence. The EPA does not think as a general matter that it is necessarily impossible that a pre-statutory amendment rule could continue to serve as a reasonable implementation of a post-statutory amendment provision. However, we also think it is appropriate, as we suggested in the June 2014 proposal, to specify in the applicable subpart for these guidelines that the provisions in 60.24(f) should not apply to the class of facilities covered by these guidelines. As a result, regardless of whether the implementing regulations appropriately implement the "remaining useful life" provision in general, the relevant consideration is that, as we now explain, these particular guidelines "permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies."

c. <u>How these emission guidelines permit states to consider remaining useful life and other facility-specific factors</u>. The EPA notes that, in general, the implementing regulation provisions for remaining useful life and other facility-specific factors are relevant for emission guidelines in which the EPA specifies a presumptive standard of performance that must be fully and directly implemented by each individual existing source within a specified source category. Such guidelines are similar to a CAA section 111(b) standard in their form. For example, the EPA emission guidelines for sulfuric acid plants, phosphate fertilizer plants, primary aluminum plants, Kraft pulp plants, and municipal solid waste landfills specify emission limits for sources.[858] In the case of such emission guidelines, some individual sources, by virtue of their age or other unique circumstances, may warrant special accommodation.

In these final guidelines for state plans to limit CO_2 from affected EGUs, however, the agency does not specify presumptive performance rates that each individual EGU is to achieve in the absence of trading. Instead, these guidelines provide collective performance rates for two classes of affected EGUs (steam generating units and stationary combustion turbines), and give

[858] See "Phosphate Fertilizer Plants; Final Guideline Document Availability," 42 FR 12022 (Mar. 1, 1977); "Standards of Performance for New Stationary Sources; Emission Guideline for Sulfuric Acid Mist," 42 FR 55796 (Oct. 18, 1977); "Kraft Pulp Mills, Notice of Availability of Final Guideline Document," 44 FR 29828 (May 22, 1979); "Primary Aluminum Plants; Availability of Final Guideline Document," 45 FR 26294 (Apr. 17, 1980); "Standards of Performance for New Stationary Sources and Guidelines for Control of Existing Sources: Municipal Solid Waste Landfills, Final Rule," 61 FR 9905 (Mar. 12, 1996).

states the alternative of developing plans to achieve a state emission goal for the collective group of all affected EGUs in a state. Providing states with the ability to consider facility-specific factors such as remaining useful life in designing their state plans is one of the fundamental reasons that the EPA designed the final rule in this way. In addition, the significant revisions since proposal to address achievability concerns (e.g., moving the start date from 2020 to 2022, and other changes in interim and final state goals summarized in the next section) will help to ensure that states in practice can consider remaining useful life and other facility-specific factors in setting EGU requirements. Of course, EGUs vary considerably in age, so remaining useful life is potentially relevant to regulation of some units and not others.

The guidelines capitalize on the inherent flexibility offered by the CO_2 emission performance rates and by the state CO_2 emission goals approach, allowing states flexibility on the form of the EGU standards that they include in CAA section 111(d) plans. A state could select a form of standards (e.g., marketable credits or permits, retirement of certain older facilities after their useful life, etc.) that avoids or diminishes concerns about facility-specific factors such as remaining useful life. If a state adopted the CO_2 emission performance rates for fossil fuel-fired electric utility steam generating units and stationary combustion turbines in conjunction with rate-based trading, though, the state would be taking remaining useful life into consideration by allowing affected EGUs to comply using ERCs. In effect, under a trading program with repeating compliance periods, a facility with a short remaining useful life has a total outlay that is proportionately smaller than a facility with a long remaining useful life, simply because the first facility would need to comply for fewer compliance periods and would need proportionately fewer ERCs than the second facility. Buying ERCs would avoid excessive up-front capital expenditures that might be unreasonable for a facility with a short remaining useful life, and would reduce the potential for stranded assets.

In addition to providing states with flexibility on the form of the standards of performance in their plans, the guidelines leave to each state the design of the specific requirements that fall on each affected EGU in applying those standards. To the extent that an emission standard that a state may wish to adopt for affected EGUs raises facility-specific issues, the state may make adjustments to a particular facility's requirements on facility-specific grounds, so long as any such adjustments are reflected (along with any necessary compensating emission reductions to meet the state goal) in the state's CAA section 111(d) plan submission.

Finally, we note that these guidelines permit states to use a rate or mass CO_2 emission goal, and that each of these pathways allow states multiple design choices. Under either pathway states can take into consideration remaining useful life and seek to avoid stranded assets.

The EPA believes that this approach to permitting states to consider remaining useful life is appropriate because it reflects, and is compatible with, the interconnected nature of the electricity system.

Although this discussion emphasizes state flexibility on plan design, it is important to note that the main intended beneficiaries of state flexibility are the affected EGUs themselves. As a key case in point, the EPA has endeavored to craft the final guidelines to support and facilitate state plans that include trading systems, including interstate trading systems that can help EGUs continue to operate with the flexibility that they currently enjoy on regional grid levels.

Trading can provide affected EGUs that have a limited remaining useful life with the flexibility to comply through purchasing allowances or ERCs, thereby avoiding major capital expenditures that would create long-term debt. By buying allowances or ERCs, affected EGUs with a limited remaining useful life contribute to achieving emission reductions from the source category during the years that they operate. During its lifetime, a facility with a short remaining useful life will need fewer total credits or allowances than an otherwise comparable facility with a long remaining useful life, but the annualized cost to the two facilities is the same.[859]

In part to help states address remaining useful life considerations, the final guidelines facilitate state plans that employ trading in multiple ways:

- By allowing trading under emission standards plans and state measures plans, and under rate-based plans and mass-based plans;
- By defining national EGU performance rates that make it easier for states to set up rate-based trading regimes that allow for interstate trading of ERCs;
- By clearly defining the requirements for mass-based and rate-based trading systems to ensure their integrity; and
- By providing information on potential allocation approaches for mass-based trading.

In addition, the EPA is separately proposing model trading rules for rate-based and mass-based trading to assist states with

---

[859] Trading of course has other benefits beyond helping to address remaining useful life concerns. For example, trading can lower costs of achieving a given level of emission reduction and can provide economic incentives for innovation and development of cleaner technologies.

design of these programs in the section 111(d) context.

d. Why remaining useful life and other facility-specific factors do not warrant adjustments in the guidelines' performance rates and state goals. Under the final guidelines, remaining useful life and other facility-specific considerations do not provide a basis for adjusting the CO_2 emission performance rates, or the state's rate-based or mass-based CO_2 emission goals, nor do they affect the state's obligation to develop and submit an approvable CAA section 111(d) plan that adopts the CO_2 emission performance rates or achieves the goal by the applicable deadline. After considering public comments discussed below and in the response to comments document, the EPA has retained this aspect of the proposed rule for the reasons described below.

As noted above, the final guidelines provide aggregate emission goals for affected EGUs in each state, in addition to the CO_2 emission performance rates. The guidelines also reflect a number of changes from proposal to address concerns about achievability of proposed state goals that were raised in public comments, many of which were explicitly prompted by consideration of the remaining useful life issue. The result is to afford states with broad flexibility to design requirements for affected EGUs to achieve the CO_2 emission performance rates or state CO_2 emission goals in ways that avoid requiring major capital expenditures, or imposing unreasonable costs, on those affected EGUs that have a limited remaining useful life. State plans may use any combination of the emissions reduction methods represented by the building blocks, and may also choose to employ emission reduction methods that were not assumed in calculating state goals.

To be more specific, the EPA notes that a state is not required to achieve the same level of emission reductions with respect to any one building block as assumed in the EPA's BSER analysis. A state may use any combination of measures, including those not specifically factored into the BSER by the EPA. The EPA has estimated reasonable rather than maximum possible implementation levels for each building block in order to establish EGU emission rates and state goals that are achievable while allowing states to take advantage of the flexibility to pursue some building blocks more aggressively, and others less aggressively, than is reflected in the agency's computations, according to each state's needs and preferences. The guidelines provide further flexibility by allowing state plans to use emission reduction methods not reflected in the BSER. A description of multiple emission reduction methods is provided in sections VIII.I-K.

e. <u>Response to key comments on remaining useful life</u>. In response to the proposed guidelines, some commenters said that the proposed state goals were unachievable and therefore too stringent to provide states, as a practical matter, with the flexibility to consider remaining useful life for individual units. These commenters said the result would be premature retirements and stranded assets.

In the final guidelines, the EPA has addressed the comments about lack of practical flexibility to consider remaining useful life by revising key elements of the guidelines in ways that will ensure that the CO_2 emission performance rates and state CO_2 emission goals are achievable considering cost. At the same time, the final guidelines maintain the broad flexibility of each state to design its own compliance pathway, taking into account any facility-level concerns – including remaining useful life – in designing EGU requirements.

The changes to the BSER and goal-setting methodologies include:

- Starting the interim goal period in 2022 rather than 2020, which allows more lead time for states and regulated entities and helps to ensure that the interim goal is achievable
- Revising the goal-setting formula and the state goals themselves
- Updating analyses of achievable levels of improvement through the building blocks that together represent the

BSER, while keeping them at reasonable, rather than maximum, levels (thus creating headroom which can, and is intended to, help to accommodate the range of ages of different facilities)

- Providing an explicit phase-in schedule for meeting the revised interim goals, while also allowing a state the option of choosing its own emission reduction trajectory

The final guidelines also contain changes to avoid certain inconsistencies between the goal-setting methodology and accounting of reductions under state plans that could have made state goals less achievable for some states.

Together, the changes described above help to ensure that the CO_2 emission performance rates and state CO_2 emission goals established in the final guidelines are achievable, and leave states with the practical ability to issue rules that take into account the remaining useful life of affected EGU.

As explained in the Legal Memorandum accompanying this rule, the EPA believes that Congress intended the remaining useful life provision to provide a mechanism for states to avoid the imposition of unreasonable retrofit costs on existing sources with relatively short remaining useful lives, a scenario that could result in stranded assets. However, commenters on the proposed rule raised a different stranded assets concern not primarily related to retrofit costs -- a concern that the proposed rule could cause changes in economic competitiveness of particular EGUs that would prompt their retirement before the end of their economically useful lives. These commenters said the proposed state goals were so stringent that states would have no choice but to adopt requirements that would result in retirements of coal-fired capacity that had been built relatively recently or had recently made pollution control investments. In response to these comments, the EPA has conducted a stranded assets analysis which demonstrates that the CO_2 emission performance rates and state goals in the final guidelines provide sufficient flexibility to states to address stranded asset concerns. The EPA shares the goal of minimizing stranded assets. Although nothing in section 111(d) explicitly bars a guideline that results in some facilities becoming uneconomic before the end of their useful lives, the EPA nonetheless has striven to design the guidelines so as to give states flexibility to develop plans that include, for example, differential treatment of affected EGUs or opportunities to rely on emissions trading, to allow power companies to recover their investments in generation units.

For purposes of the stranded assets analysis, the EPA considered a potential “stranded asset” to be an investment in a coal-fired EGU (or in a capital-intensive pollution control installed at such an EGU) that retires before it is fully depreciated. Book life is the period over which long-lived assets are depreciated for financial reporting purposes. The agency estimated typical book life by researching financial statements of utility and merchant generation companies in filings to the Securities and Exchange Commission. The agency estimated the book life of coal-fired EGUs to be 40 years, and assumed a 20-year book life for pollution control retrofits. The book life of coal-fired EGUs (coal steam and IGCC) is twice as long as the debt life and the depreciation schedule used for federal tax purposes. Although the book life for environmental retrofits is often 15 years, the agency conservatively assumed 20 years in this analysis.

The analysis examined coal generation in the three large regional interconnections of the U.S. The analysis found that in both 2025 and 2030, for each region, the amount of 2012 coal generation included in the final guidelines' emission performance rate calculation -- specifically, the generation remaining after the BSER calculation -- is greater than the amount of 2012 generation from coal-fired EGUs that are not fully depreciated in those years under the book life assumptions described above. This shows that the final rule allows flexibility for states to preserve these units as part of their plans.

To put this analysis in perspective: The EPA's role is to set emission guidelines that meet the statutory requirements, which includes consideration of cost in identifying the BSER, as the EPA has done in these guidelines. States have a broad degree of flexibility to design plans to achieve the rates in the emission guidelines in a manner that meets their policy priorities, including ensuring cost-effective compliance. Although not a required component of the EPA's consideration of cost, this analysis shows that the CO_2 emission performance rates in the final guidelines can be met without the retirement of affected EGUs before the end of their book life, and without the retirement of affected EGUs before the end of the book life of capital-intensive pollution control retrofits installed on those EGUs. Thus, according to this analysis, the CO_2 emission performance rates and state CO_2 emission goals need not result in stranded assets. The EPA recognizes that power plant economics are determined by many aspects of markets that are outside of the EPA's control, such as wholesale power prices and capacity prices, and that the compliance path of least cost may involve retiring assets that have not fully depreciated. Nonetheless, this analysis further demonstrates the extent of flexibility available to states in designing their plans to best serve the policy priorities of the state. Details are available in a memo to the docket.[860]

Several commenters said that the statute does not authorize the EPA to require other facilities to achieve greater reductions to compensate for a facility that warrants relief based on remaining useful life. One said that consideration of remaining useful life and other relevant factors is a one-way ratchet that provides relief to sources that cannot achieve the BSER, and that the EPA turns that approach on its head by prohibiting a state from providing such relief to a specific facility unless it can identify another facility to "punish" by requiring additional emissions reductions to offset that relief.

The EPA disagrees with these comments, which proceed from an incorrect premise. The EPA is not determining a BSER-based emission level achievable by each individual facility without trading, and then requiring better-than-BSER from some facilities to make up to worse-than-BSER performance that a state authorizes for other facilities because of a short remaining useful life. Rather, as previously noted, the guidelines set CO_2 emission performance rates and state CO_2 emission goals that represent the average or aggregate emission

[860] Memorandum to Clean Power Plan Docket titled "Stranded Assets Analysis" dated July 2015.

level achievable by affected EGUs based on regional average estimates of the impact of applying the BSER to collective groupings of affected EGUs.[861] In estimating the amount of improvement achievable through each building block (e.g., improvement in heat rate or amount of generation shift to lower-emitting EGUs), the EPA has estimated the average level achievable by EGUs in a region rather than attempting to estimate the level achievable by each and every affected EGU in the absence of trading. Thus, the fact that an individual facility may be unable, for example, to achieve the average level of heat rate improvement assumed in goal-setting is consistent with the EPA's analysis, and does not undermine the EPA's determination of CO_2 emission performance rates and state CO_2 emission goals. The Legal Memorandum discusses additional reasons that the agency disagrees with comments that the guideline must permit adjustments in the guidelines' CO_2 emission performance rates and state CO_2 emission goals based on remaining useful life considerations.

An additional reason that the EPA believes that

[861] The EPA expects that states that choose to adopt the national CO_2 emission performance rates for all of their EGUs would permit ERC trading, rather than requiring each facility to meet the applicable rate without trading. In effect, the presence of trading means that the EGU performance rates will be achieved on average by the EGUs involved in trading, rather than be achieved by each facility in the absence of trading.

consideration of remaining useful life and other facility-specific factors does not warrant adjustments to state goals is that the design of the guidelines does not mandate that states impose requirements that would call for substantial capital investments at affected EGUs late in their useful life. Multiple methods are available for reducing emissions from affected EGUs that do not involve capital investments by the owner/operator of an affected EGU. For example, generation shifts among affected EGUs, and addition of new RE generating capacity do not generally involve capital investments by the owner/operator at an affected EGU. Additional emission reduction methods available to states that do not entail significant capital costs at affected EGUs are discussed elsewhere in this preamble.

Heat rate improvements at affected EGUs do require capital investments. However, states have flexibility to design their plan requirements; they are not required to mandate heat rate improvements at plants that have limited remaining useful life. In fact, a state can choose whether or not to require heat rate improvements at all. The agency also notes that capital expenditures for heat rate improvements would be much smaller than capital expenditures required for example, for purchase and installation of scrubbers to remove SO_2; a fleet-wide average cost for heat rate improvements based primarily on best practices at coal-fired generating units would not likely exceed

\$100/kW, compared with a typical SO_2 wet scrubber cost of \$500/kW (costs vary with unit size).[862] Even if a state did choose to adopt requirements for heat rate improvements, the proposed guidelines would allow states to regulate affected EGUs through flexible regulatory approaches that do not require affected EGUs to incur large capital costs (e.g., averaging and trading programs). Under the EPA's final approach - establishing state goals and providing states with flexibility in plan design – states have flexibility to make exactly the kind of judgments necessary to avoid requiring capital investments that would result in stranded assets.

Remaining useful life and other factors, because of their facility-specific nature, are potentially relevant as states determine requirements that are directly applicable to affected EGUs. If relief is due a particular facility, the state has an available toolbox of emission reduction methods that it can use to develop a section 111(d) plan that will achieve the CO_2 emission performance rates or state CO_2 emission goals on time. The EPA therefore concludes that the remaining useful life of affected EGUs, and the other facility-specific factors

---

[862] Heat rate improvement methods and related capital costs are discussed in the GHG Mitigation Measures TSD; SO_2 scrubber capital costs are from the documentation for the EPA's IPM Base Case v5.13, Chapter 5, Table 5-3, available at http://www.epa.gov/airmarkets/documents/ipm/Chapter_5.pdf.

identified in the existing implementing regulations, should not be regarded as a basis for adjusting the CO_2 emission performance rates or a state CO_2 emission goal, and should not relieve a state of its obligation to develop and submit an approvable plan that achieves that goal on time.

f. <u>Legal considerations regarding remaining useful life</u>. Section 111(d)(1) requires the EPA in promulgating section 111(d) regulations to "permit the State in applying a standard of performance to any particular source under a plan submitted under this paragraph to take into consideration, among other factors, the remaining useful life of the existing source to which such standard applies." Here, we discuss the legal basis for determining that the emission guidelines are consistent with this statutory requirement. For details, please see the Legal Memorandum.

Section 111(d)(1) only requires that EPA emission guidelines permit states to take into account remaining useful life (among other factors), but section 111(d)(1) does not specify how the EPA must permit that. In other words, the meaning of the provision and the way that the EPA is to implement it in promulgating guidelines are not specified further in the provision. The provision is ambiguous and capable of implementation in several ways, and therefore the EPA has discretion to interpret and apply it. Furthermore, section

111(d)(1) does not suggest that states must be given carte blanche to consider remaining useful life in any way that can be imagined. As detailed above in sections VIII.G.1.c-e, these guidelines permit states to take into account remaining useful life in a number of reasonable ways and thus the guidelines satisfy the statutory obligation.

The phrase "remaining useful life" also appears in the visibility provisions of section 169A. There, in determining best available retrofit technology (BART), the state (or the EPA) must take into consideration (among other factors) "the remaining useful life of the source." 42 USC 7491(g)(2); see also *id.* (g)(1) (reasonable progress). In the context of the visibility program, we have interpreted this provision to mean that the remaining useful life should be considered when calculating the annualized costs of retrofit controls. *See* 40 CFR Pt. 51, App. Y, IV.D.4.k.1. This annualized cost is then used to determine a cost effectiveness, in dollars per ton of pollutant removed on an annual basis. As a result, a technology with a large initial capital cost that might have a reasonable cost-effectiveness for a facility with a long remaining useful life would have a much higher and possibly unreasonable cost-effectiveness for a facility with a short remaining useful life.

Although section 111(d)(1) is different than section 169A(g)(2) and need not be interpreted in the same way, we would note (as discussed in detail in sections VIII.G.1.c-e, section 5.11 of the Response to Comments document, and the Legal Memorandum) that (for example) a trading program under these section 111(d) guidelines only requires compliance on a periodic basis and does not require any initial capital expenditures. Thus, over the life of the facility, a facility with a short remaining useful life will need fewer total credits or allowances than an otherwise comparable facility with a long remaining useful life, but the annualized cost to the two facilities is the same. In other words, under a trading program remaining useful life of a source is automatically accounted for in the way it is accounted for under the visibility program.

Some commenters stated that the EPA's interpretation of remaining useful life is impermissible. These commenters claimed that states, if they wish to take into account remaining useful life at one affected EGU, must relax the stringency of the emission standard for that EGU. Then, the state would be compelled to increase the stringency of emission standards at other affected EGUs in order to achieve the state performance goal. According to these commenters, section 111(d) does not allow this outcome.

First, the commenters are mistaken in their premise. As discussed in section VIII.G.1, section 5.11 of the Response to Comments document, the Legal Memorandum, and in the example immediately above, states can impose the exact same emission standards on two affected EGUs and still take into account remaining useful life through the availability of trading. In other words, states need not relax an emission standard here and strengthen an emission standard there in order to take into account remaining useful life. Thus, these guidelines permit states to take into account remaining useful life without any of the effects commenters are concerned about.

Second, even if states decide to relax emission standards at one EGU, on the basis of remaining useful life or any other factor, nothing in the last sentence of section 111(d)(1) prohibits these guidelines from requiring the state plan to still meet the CO_2 emission performance rates or state CO_2 emission goal. In fact, that sentence is completely silent on the issue. Thus, the EPA has the discretion to determine what should be the concomitant effects if a state chooses to consider remaining useful life in a particular way. In this case the concomitant effect of a state relaxing one emission standard may be that the state must make up for it elsewhere in order to meet the goal, but nothing in section 111(d)(1), including the statutory requirement to permit consideration of remaining useful life, prohibits that outcome.

2. Electric reliability

The final rule features overall flexibility, a long planning and implementation horizon, and a wide range of options for states and affected EGUs to achieve the CO_2 emission performance rates or state CO_2 emission goal. This design reflects, among other things, the EPA's commitment to ensuring that compliance with the final rule does not interfere with the industry's ability to maintain the reliability of the nation's electricity supply. Comments from state, regional and federal reliability entities, power companies and others, as well as consultation with the Department of Energy (DOE) and Federal Energy Regulatory Commission (FERC), helped inform a number of changes made in this final rule to address reliability. In addition, FERC conducted one national and three regional technical conferences on the proposed rule in which the EPA participated and at which the issue of reliability was raised by numerous participants.

As discussed throughout the preamble and TSDs, the electricity sector is undergoing a period of intense change. While the change in the resource mix has accelerated in recent years, wind, solar, other RE, and EE resources have been reliably participating in the electric sector for a number of years. Many of the potential changes to the electric system that the final rule may encourage, such as shifts to cleaner sources of power and efforts to reduce electricity demand, are already well underway in the electric industry. To the extent that the final rule accelerates these changes, there are multiple features well embedded in the electricity system that ensure that electric system reliability will be maintained. Electric system reliability is continually being considered and planned for. For example, in the Energy Policy Act of 2005, Congress added a section to the Federal Power Act to make reliability standards mandatory and enforceable by FERC and the North American Electric Reliability Corporation (NERC), the Electric Reliability Organization which FERC designated and oversees. Along with its standards development work, NERC conducts annual reliability assessments via a 10-year forecast and winter and summer forecasts; audits owners, operators, and users for preparedness; and educates and trains industry personnel. Numerous other entities such as FERC, DOE, state PUCs, ISOs/RTOs, and other planning authorities also consider the reliability of the electric system. There are also numerous remedies that are routinely employed when there is a specific local or regional reliability issue. These include transmission system upgrades, installation of new generating capacity, calling on demand response, and other demand-side actions.

Additionally, planning authorities and system operators constantly consider, plan for, and monitor the reliability of the electricity system with both a long-term and short-term perspective. Over the last century, the electric industry’s efforts regarding electric system reliability have become multidimensional, comprehensive, and sophisticated. Under this approach, planning authorities plan the system to assure the availability of sufficient generation, transmission, and distribution capacity to meet system needs in a way that minimizes the likelihood of equipment failure.[863] Long-term system planning happens at both the local and regional levels with all segments of the electric system needing to operate together in an efficient and reliable manner. In the short-term, electric system operators operate the system within safe operating margins and work to restore the system quickly if a disruption occurs.[864] Mandatory reliability standards apply to how the bulk electric system is planned and operated. For example, transmission operators and balancing authorities have to develop, maintain, and implement a set of plans to mitigate operating emergencies.[865]

As the electricity market changes and new challenges emerge, electric system regulators and industry participants make changes to how the electric system is designed and operated

[863] Casazza, J. and Delea, F., *Understanding Electric Power Systems: An Overview of the Technology, the Marketplace, and Government Regulations*, IEEE Press, at 160 (2010).
[864] *Id.*

to respond to these challenges. For example, expressing reliability and rate concerns about fuel assurance issues, FERC recently issued an order requiring ISOs/RTOs to report on the status of their efforts to address market and system performance associated with fuel assurance.[866] In February of 2015, Midcontinent Independent System Operator (MISO), California Independent System Operator Corporation (CAISO), New York Independent System Operator (NYISO), Southwest Power Pool (SPP), ISO New England (ISO-NE), and PJM Interconnection (PJM) each filed a report with FERC highlighting their efforts to respond to fuel assurance concerns.[867] This is just one of many examples where electric system regulators and industry participants recognize a potential reliability issue and are proactively searching for solutions.

---

[866] *Centralized Capacity Markets in Regional Transmission Organizations and Independent System Operators*, 149 FERC ¶ 61,145 (2014). FERC generally defines fuel assurance as "generator access to sufficient fuel supplies and the firmness of generator fuel arrangements". *Id.* P 5.

[867] For example, ISO-NE and PJM each filed "pay-for-performance" proposals to address fuel assurance in their regions. FERC recently acted on ISO-NE market rule changes providing increased market incentives in capacity, energy, and ancillary services markets for generators to be available to meet their obligations during reserve shortages. *ISO New England Inc.*, 147 FERC ¶ 61,172 (2014). Additionally, FERC conditionally approved a PJM "pay-for-performance" proposal that creates a new capacity product to provide greater assurance of delivery of energy and reserves during emergency conditions, establishing credits for superior performance and charges for poor performance. *PJM Interconnection, L.L.C.*, 151 FERC ¶ 61,208 (2015).

The EPA's approach in this final rule is consistent with our commitment to ensuring that compliance with the final rule does not interfere with the industry's ability to maintain the reliability of the nation's electricity supply. Many aspects of the final rule's design are intended to support system reliability, especially the long compliance period and the basic design that allows states and affected EGUs flexibility to include a large variety of approaches and measures to achieve the environmental goals in a way that is tailored to each state's and utility's energy resources and policies. Despite the flexibility built into the design of the proposal, and the long emission reduction trajectory, many commenters expressed concerns that the proposed rule could jeopardize electric system reliability. We note that the EPA has received similar comments in EPA rulemakings dating as far back as the 1970s. The EPA has always taken and continues to take electric system reliability comments very seriously. These reoccurring comments with regard to reliability notwithstanding, the electric industry has done an excellent job of maintaining reliability, including when it has had to comply with environmental rules with much shorter compliance periods and much less flexibility than this final rule provides. Now, more than ever, the electric industry has tools available to maintain reliability, including mandatory and enforceable reliability standards.[868]

As with numerous prior CAA regulations affecting the electric power sector, environmental requirements for this industry are accommodated within the existing extensive framework established by federal and state law to ensure that electricity production and delivery are balanced on an ongoing basis and planned sufficiently to ensure reliability and affordability into the future. In addition, changes that the EPA is making in this final rule respond directly to the comments and the suggestions that we received on reliability and provide further assurance that implementation of the final rule will not

[868]For example, Andrew Ott, then Executive Vice President-Markets and current President of PJM, an RTO with a substantial amount of coal-fired capacity and generation, discussed the success of PJM's market design in assuring that PJM met and exceeded target reserve margins while MATS was being implemented. *See* Statement of Andrew Ott, PJM Executive Vice President-Markets, FERC Technical Conference on Centralized Capacity Markets in Regional Transmission Organizations and Independent System Operators, AD13-7-000, at 3, 7 (Sept. 25, 2013), *available at* http://www.ferc.gov/EventCalendar/EventDetails.aspx?ID=6944&CalType= &CalendarID=116&Date=09/25/2013&View=Listview. At the FERC national Clean Power Plan Technical Conference, Michael J. Kormos, PJM Executive Vice President-Operations, said that PJM's markets have proven, "resilient enough to respond to different policy initiatives. . . Whether it is the Sulfur Dioxide Trading Program of the 1990s, the MATS rule or individual state RPS initiatives, the markets have been able to send the appropriate price signals that produce competitive outcomes." *See* Michael J. Kormos, PJM Executive Vice President, Statement at FERC Technical Conference on EPA's Clean Power Plan, AD15-4-000, at 3 (Feb. 19, 2015), *available at* http://www.ferc.gov/CalendarFiles/20150213081650-Kormos,%20PJM.pdf.

create reliability concerns.

First, the final rule allows significant flexibility in how the applicable CO_2 emission performance rates or the statewide CO_2 goals are met. Given the differing characteristics of the electric grid within each state and region, there are many paths to meeting the final rule's requirements that can be taken while continuing to maintain a reliable electricity supply. As further described elsewhere in section VIII, states can develop plans to meet the CO_2 emission performance rates or state CO_2 emission goals by choosing from a variety of state plan types and approaches that afford states and affected EGUs appropriate flexibility. EE and other measures that were not included in the determination of the BSER can strengthen a state's ability to establish a plan to meet the CO_2 emission performance rates or state CO_2 emission goals by providing a considerable amount of headroom above the levels of the rates and goals. EE especially, because it reduces load, can provide assurance that reliability can and will be maintained. Additionally, the final rule offers opportunities for trading among affected EGUs within and between states, and other multi-state approaches that will further support electric system reliability.

Second, the final rule provides sufficient time to ensure system reliability. The final rule retains the 2030 date for the final period, which commenters largely supported as reasonable and not a concern for reliability, and addresses one of the key issues that commenters pointed to as a reliability-related concern by both moving the start of the interim period from 2020 to 2022 and adjusting the interim goals to provide a more gradual phasing-in of the initial reduction requirement and thus a more gradual emissions reduction trajectory or glide path to the final 2030 goals. These changes deliver on the intent of the proposal to afford states and affected EGUs the latitude to determine their own emissions reduction schedules over the interim period. Both FERC's May 15, 2015 letter[869] and the comment record made it clear that providing sufficient time for planning and implementation is essential to ensuring electric system reliability. The EPA has responded by providing additional time to allow for planning and implementation of the final rule requirements, while at the same time allowing enough time between the beginning of the interim period and 2030 to achieve state goals or emission performance rates. We note that the final rule does not require that all states have met their interim goal or performance rate by 2022 but rather that they meet it on average or cumulatively, as appropriate, during the 2022 to 2029 period.

---

[869] On May 15, 2015, the five FERC Commissioners sent a letter to Acting Assistant Administrator Janet McCabe regarding the EPA's Clean Power Plan proposal. *See* FERC letter, *available at* http://ferc.gov/media/headlines/2015/ferc-letter-epa.pdf.

As a result of these changes, the states themselves will have a meaningful opportunity – which, again, many commenters suggested the timing and stringency of the proposal failed to create despite our intent to do so – to determine the timing, cadence and sequence of actions needed for states and sources to meet final rule requirements while accommodating the ongoing activity needed to ensure system reliability. The final rule provides more than 6 years before reductions are required and an 8-year period from 2022 to 2029 to meet interim goals. Moreover, while the final rule requires each state to submit a plan by September 6, 2016, we recognize that some states may need more than 1 year to complete all of the actions needed for their final state plans, including consideration of reliability. Therefore, states have the opportunity to receive an extension for submitting a final plan. If the state needs additional time to submit a final plan, then the state may submit an initial submittal by September 6, 2016, that must address three required components sufficiently to demonstrate that a state is able to undertake steps and processes necessary to timely submit a final plan by the extended date of September 6, 2018.

Third, we are including in the final rule a requirement that each state demonstrate in its final state plan submittal that it has considered reliability issues in developing its plan. This was suggested by a number of commenters, and we agree that it is a useful element to state plan development.

Fourth, the final rule provides a mechanism for a state to seek a revision to its plan in order to address changes in circumstances that could have reliability impacts if not accommodated in the plan. The long compliance timeframe, with several interim steps, naturally provides opportunities for states, working with their utilities and reliability entities, to assess how implementation is proceeding, identify unforeseen changes that may warrant plan revisions, and work with the EPA to make necessary revisions. Similarly, the ready availability of emissions trading as a compliance tool affords EGUs ample flexibility to integrate compliance with both routine and critical reliability needs.

Fifth, in response to a variety of comments, we are providing a reliability safety mechanism that provides a path for a state to come to the EPA during an immediate, unforeseen, emergency situation that threatens reliability to notify the EPA that an affected EGU or EGUs may need to temporarily comply with modified emission standards to respond to this kind of reliability concern.

Sixth and finally we are committed to maintaining an ongoing relationship with FERC and DOE as this final rule is implemented to help ensure continued reliable electric generation and transmission.

We provide more details about these various elements of the final rule, as well as other features of the rule that support system reliability, below.

a. Summary of key comments. The EPA received a number of comments regarding the proposed rule and electric reliability. Many commenters provided specific, useful ideas regarding changes that could be made to the proposal to specifically address their reliability concerns. For example, many commenters state that allowing additional time to comply could help in meeting the final rule requirements while addressing their reliability concerns. Some commenters suggest that additional time would allow them to evaluate potential reliability impacts and system changes that need to be made to comply with final rule requirements while allowing affected EGUs time to meet interim CO_2 emissions goals. The EPA also received comment that market-based approaches have features that could help support reliability, and therefore we should encourage states to join or form regional market-based programs. Commenters also stated that the EPA should require states to consult with grid operators who would analyze the impact of state plans on reliability. A number of commenters also suggested that the EPA should include some sort of reliability safety valve in the final rule. We note that many participants at the FERC technical conferences on the proposed rule also discussed a reliability safety valve in great detail with many suggestions for how such a reliability mechanism could be designed. The EPA appreciates these and all the comments we received regarding the interaction of the proposal and electric reliability. We have carefully considered all comments, consulted further with FERC and incorporated many of the suggested changes in this final rule.

b. Final rule flexibility. In issuing this final rule, the EPA considered public comments on the potential interaction between the proposal and electric reliability. While we have made every effort to develop guidelines that would allow states and utilities to steer clear of potential reliability disruptions, a number of commenters argued that the possibility of an unanticipated reliability event cannot be entirely eliminated. It is important to note that there are many factors that influence system reliability and, given the complexity of the electric grid, electric system planners and operators likely will not completely avoid reliability issues, even in the absence of these guidelines. The EPA designed the final rule to ensure to the greatest extent possible that actions taken by states and affected EGUs to comply with the final rule do not increase potential reliability issues or complicate their resolution. In fact, to the extent that meeting final rule requirements results in the reduction of demand, upgrades in transmission efficiency and infrastructure, and investment in new, more efficient technologies, the outcome could be that the system is more robust and faces fewer risks to electric reliability.

One specific concern raised by many commenters is that the proposed plan development schedule may not leave sufficient time to conduct reliability planning between the development of state plans and the proposed start of the interim period in 2020. To address these concerns and to support a more effective reliability planning process, the EPA is moving the start of the interim period from 2020 to 2022 and adjusting the interim goals to provide a gradually phased-in initial reduction requirement and a more gradual glide path to the final 2030 goals. This more gradual application of the BSER over the 2022-2029 interim period provides the state with substantial latitude in selecting the emission reduction glide path for affected EGUs over that period. As noted above, the final rule also provides states with up to 3 years to adopt and submit their final state plans, and afterwards states can, if necessary, revise their plans, as discussed in section VIII.E.7. This timing gives system planners and operators the opportunity to do what they have already been doing; looking ahead to forecast potential contingencies that pose reliability risks and identifying those actions needed to mitigate those risks. The final rule allows states to develop a pathway over the interim period that reflects their own circumstances, such as reflecting planned additions and changes in generation mix and potentially taking advantage of opportunities for trading of credits or allowances by affected EGUs within and between states. Because achievement of the emission rates or goals can be demonstrated over several years, state plans can accommodate situations where, for example, it may take time to develop new generation, pipelines, or transmission while still providing many options for meeting the final rule requirements and planning for the reliability of the system.

c. Considering reliability during state plan development process. Under CAA section 111(d)(1)(B), state plans must provide for the implementation and enforcement of standards of performance for affected EGUs. The EPA does not believe a state that establishes standards of performance for affected EGUs without taking reliability concerns into consideration satisfactorily provides for the implementation of such standards of performance as required by CAA section 111(d)(1)(B), as a serious reliability issue would disrupt the state's implementation of the state plan. Therefore, the EPA is requiring that each state demonstrate as part of its final state plan submission that it has considered reliability issues while developing its plan in order to ensure that standards of performance can be implemented and enforced as required by the

CAA. If system reliability is threatened, the ability of affected EGUs to meet the requirements of this final rule could be compromised if they are required to operate beyond the emission standards established in state plans in order to maintain the reliability of the electric grid. The requirement that states consider reliability as part of the development of state plans is therefore designed to ensure that state plans are flexible enough to avoid this kind of potential conflict between maintaining reliability and providing for the implementation of emission standards for affected EGUs as required by the CAA.

A number of commenters, notably ISOs and RTOs, also discussed reliability concerns in the context of state plans and pointed out that planning and anticipation of change are among the essential ingredients of ensuring the ongoing reliability of the electricity system. To that end, they recommended that as states are developing state plans, their activity include the consideration of the reliability needs of the region in which affected EGUs operate and of the potential impact of actions to be taken in compliance with state plans. Therefore, we are requiring that each state demonstrate in its final state plan submittal that it has considered reliability issues in developing its plan. One particularly effective way in which states can make this demonstration is by consulting with the relevant ISOs/RTOs or other planning authorities as they develop their plans and documenting this consultation process in their state plan submissions. If a state chooses to consider reliability through consultation with the ISO/RTO or other planning authority, the EPA recommends that the state request that the planning authority review the state plan at least once during the plan development stage and provide its assessment of any reliability implications of the plan. Additionally, we encourage states that are considering reliability through an ISO/RTO or other planning authority consultation process to have a continuing dialogue with those entities during development of their final state plan. While following the recommendations of the planning authority would not be mandatory, the state should document its consultation process, any response and recommendations from the planning authority, and the state’s response to those recommendations in its final state plan submittal to the EPA. This consultation is designed to inform how the state might adjust its plan for meeting the CO_2 reduction requirements under this guideline; the consultation is not a basis for relaxing that requirement. While we consider this process to be an effective way for a state to demonstrate that it considered reliability in developing its final state plan, a state may provide other comparable support for a demonstration that it has considered reliability during the state plan development process.[870] Also as discussed elsewhere in this preamble, the EPA encourages states to include state utility regulators and the state energy offices in the development of the state plan. These agencies have expertise that can help to assure that state plans complement the state's power sector. The EPA believes that this requirement to demonstrate consideration of reliability will provide an effective reliability evaluation in the state plan development process. It should further help states avoid any conflicts between state plans and the maintenance of reliability during implementation of the state plan and associated emission standards. Finally, we also encourage states as they develop their plans to consider, to the extent possible, other potential issues that may impact affected EGUs. For example, an affected EGU may be in an ISO/RTO that puts certain deadlines on generators that may not line up perfectly with state plan deadlines.

d. <u>State plan modifications</u>. If, during the implementation of a state plan, a reliability issue cannot be addressed within the range of actions or mechanisms encompassed in an approved state plan, the state can submit a plan revision to the EPA to amend its plan. In such a circumstance, the state plan may need to be

[870] While the EPA is requiring that the states demonstrate that they have considered reliability in developing their plans, state plan submissions will not be evaluated substantively regarding reliability impacts.

adjusted to enable affected EGUs to continue to meet final rule requirements without causing an otherwise unmanageable reliability threat. In all cases the plan revision must still ensure the affected EGUs meet the emission performance level set out in the 111(d) final rule. Whether or not these circumstances occur will depend in part upon how each state designs its state plan. States that design plans with a high level of flexibility, such as market-based plans or multi-state plans, are less likely to face a potential conflict between state plan requirements and the maintenance of reliability. States that participate in multi-state programs will be better able to weather unexpected reliability risks.

Events not anticipated at the time of the final plan submittal - such as the retirement of a large low- or zero-emitting unit - may trigger the request for state plan revisions. It may also be the case that affected EGU-specific emission standards in a state plan are proving to be too inflexible to allow the plan to accommodate market or other changes in the power sector. In such instances, there should be a lead time between the announced retirement of the unit and the need to amend the state plan. Therefore, the state should be able to utilize the revisions process that the EPA provides.

The EPA will review a plan revision per the implementing regulation requirements of 40 CFR part 60.28. If the state's request for a state plan revision must be addressed in an expedited manner to assure a reliable supply of electricity, the state must document the risks to reliability that would be addressed by the plan revision by providing the EPA with a separate analysis of the reliability risk from the ISO/RTO or other planning authority. This analysis should be accompanied by a statement from the ISO/RTO or other planning/reliability authority that there are no practicable alternative resolutions to the reliability risk. In this case, the EPA will conduct an expedited review of the state plan revision.[871]

e. <u>Reliability safety valve</u>. In this section we describe a reliability safety valve, available to states with affected EGUs providing reliability-critical generation in emergency circumstances. Specifically and as discussed below the reliability safety valve provides i) a 90-day period during which the affected EGU will not be required to meet the emission standard established for it under the state plan but rather will meet an alternative standard, and ii) a period beginning after the initial 90 days during which the reliability-critical affected EGU may be required to continue to operate under an alternative standard rather than under the original state plan

[871] The EPA will still undertake notice and comment rulemaking per the requirements of the Administrative Procedures Act when acting on such state plan revision, but intends to prioritize review of plan revisions needed to address reliability concerns.

emission standard, as needed in light of the emergency circumstances, and the state must during this period revise its plan to accommodate changes needed to respond to ongoing reliability requirements. Any emissions in excess of the applicable state goals or performance rates occurring after the initial 90-day period must be accounted for and offset.

Many commenters expressed concerns that a serious, unforeseen event could occur during the final rule implementation period that would require immediate reliability-critical responses by system operators and affected EGUs that would result in unplanned or unauthorized emissions increases. After reviewing the comments, we believe that it is highly unlikely that there would be a conflict between activities undertaken under an approved state plan and the maintenance of electric reliability, except in the case of a state plan that puts relatively inflexible requirements on specific EGUs. While some have pointed out that severe weather or other short-term events could potentially conflict with state plans, we note that most of those events are of short duration and would not require major – if any - adjustments to emission standards for affected EGUs or to state plans. For example, during an event like the extreme cold experienced in periods of the winter of 2013-2014, affected EGUs may need to run at a higher level for a short period of time to accommodate increased demand and/or short-term unavailability of other generators. However, because compliance by affected EGUs will be demonstrated over 2-3 years, such a short-term event would not cause affected EGUs to be out of compliance with their applicable emission standards. States can also ensure that this is true by developing plans that allow adequate compliance flexibility to accommodate such short-term events. We note that we have included in this final rule a number of different features designed to facilitate emissions trading between and among EGUs on an interstate basis – and have done so, in no small part, in response to comments from states and stakeholders seeking to put in place or operate under state-level and interstate emissions trading regimes. Affected EGUs operating in those circumstances and operating, in addition, subject to state plans that incorporate flexible glide paths and trading would be able to accommodate an unanticipated reliability event.

We recognize, however, that affected EGUs operating in a state with a relatively inflexible state plan could face unanticipated system emergencies that could cause a severe stress on the electricity system for a length of time such that the requirements in that state’s plan may not be achievable by certain affected EGUs without posing an otherwise unmanageable risk to reliability. In particular, there could be extremely serious events, outside the control of affected EGUs, that would require an affected EGU or EGUs operating under an inflexible state plan to temporarily operate under modified emission standards to respond to this kind of reliability concern. Examples of such an event could include, a catastrophic event that damages critical or vulnerable equipment necessary for reliable grid operation; a major storm that floods and causes severe damage to a large NGCC plant so that it must shut down; or a nuclear unit that must cease generating unexpectedly and therefore other affected EGUs need to run so as to exceed their requirements under the approved state plan. This is not an all-inclusive list, but the examples illustrate several key attributes of the kinds of circumstances in which the reliability safety valve would apply. First, the event creating the reliability emergency would be unforeseeable, brought about by an extraordinary, unanticipated, potentially catastrophic event. Second, the relief provided would be for EGUs compelled to operate for purposes of providing generation without which the affected electricity grid would face some form of failure. Third, the EGU or EGUs in question would be subject to the requirements of a state plan that imposes emissions constraints such that the EGU or EGUs' operation in response to the reliability emergency resulted in levels of emissions that violated those constraints. We do not anticipate that EGUs operating under a plan that permitted emissions trading would meet these criteria.

The final guidelines provide a reliability safety valve for these types of situations. If an emergency situation arises, the state must submit an initial notification to the appropriate EPA regional office within 48 hours that it is necessary to modify the emission standards for a reliability-critical affected EGU or EGUs for up to an initial 90 days. The notification must include a full description, to the extent it is known at the time, of the emergency situation that is being addressed. It must also identify with particularity the affected EGU or EGUs that are required to run to assure reliability. It must also specify the modified emission standards at which the affected EGU or EGUs will operate. The EPA will consider this notification to be an approved short-term modification to the state plan, allowing the EGU to operate at an emission standard that is an alternative to the emission standard originally specified in the relevant state plan, subject to confirmation by the further documentation described below.[872]

Within 7 days of submitting the initial notification, the state must submit a second notification providing documentation

[872] The EPA reserves the right to review such notification, and in the event that the EPA finds such notification is improper, the EPA may disallow the short-term modification and affected EGUs must continue to operate under the original approved state plan emission standards.

to the appropriate EPA regional office that includes a full description of the reliability concern and why an unforeseen, emergency situation that threatens reliability requires the affected EGU or EGUs to operate under modified emission standards (including discussion of why the flexibilities provided under the state's plan are insufficient to address the concern). The state must also describe in its documentation how it is coordinating or will coordinate with relevant reliability coordinators and planning authorities to alleviate the problem in an expedited manner, and indicate the maximum time that the state anticipates the affected EGU or EGUs will need to operate in a manner inconsistent with its or their obligations under the state's approved plan, and the modified emission standards or levels at which the affected EGU or EGUs will be operating at during this period if it has changed from the initial notification. The documentation must also include a written concurrence from the relevant reliability coordinator and/or planning authority confirming the existence of the imminent reliability threat and supporting the temporary modification request or an explanation of why this kind of concurrence cannot be provided. Additionally, if the relevant planning authority has conducted a system-wide or other analysis of the reliability concern, the state must include that information in its request. If the state fails to submit this documentation on a timely basis, the EPA will notify the state, which must then notify the affected EGU(s) that they must operate or resume operations under the original approved state plan emission standards.

It is important to note that the affected EGUs must continue to monitor and report their emissions and generation pursuant to requirements in this final rule and under the state plan during any short-term modification. For the duration of the up to 90-day short-term modification, the emissions of the affected EGU or EGUs that exceed their obligations under the approved state plan will not be counted against the state's overall goal or emission performance rate for affected EGUs. Such a modification will not alter or abrogate any other obligations under the approved state plan.

During this short term modification period, the EPA expects that the source, the state and the relevant reliability coordinator and/or planning authority will assess whether the reliability issue can be addressed in a way that would allow the EGU or EGUs to resume operating under the original approved state plan within the 90-day period or whether revisions to the state plan need to be made to address the unexpected circumstances for the longer term (the unexpected unavailability of a nuclear unit, for example).

The EPA recognizes that an emergency may persist past 90 days. At least 7 days before the end of the initial 90-day reliability safety valve period, the state must notify the appropriate EPA regional office whether the reliability concern has been addressed and that the EGU or EGUs can resume meeting the original emission standards established in the state plan prior to the short-term modification.

If there still is a serious, ongoing reliability issue at the end of the short-term modification period that necessitates the EGU or EGUs to emit beyond the amount allowed under the state plan, the state must provide to the EPA a notification that it will be submitting a state plan revision and submit the plan revision as expeditiously as possible, specifying in the notice the date by which the revision will be submitted. The state must document the ongoing emergency with a second written concurrence from the relevant reliability coordinator and/or planning authority confirming the continuing urgent need for the EGU or EGUs to operate beyond the requirements of the state plan and that there is no other reasonable way of addressing the ongoing reliability emergency but for the EGU or EGUs to operate under an alternative emission standard than originally approved under the state plan. In this event, the EPA will work with the state on a case-by-case basis to identify an emission standard for the affected EGU or EGUs for the period before a new state plan revision is approved. After the initial 90-day period, any excess emissions beyond what is authorized in the original approved state plan will count against the state's overall goal or emission performance rate for affected EGUs.

The EPA intends for this reliability safety valve to be used only in exceptional situations. In addition, this reliability safety valve applies only to this final rule and has no effect on CAA requirements to which the state or the affected EGUs are otherwise subject. As discussed earlier, we are providing states with the flexibility to design programs that incorporate the level of flexibility that allow affected EGUs to meet compliance obligations while responding to reliability needs, even in emergency situations. This flexibility means that a conflict between the requirements of the state plan and maintenance of reliability should be extremely rare. We recognize, however, that a state with an inflexible plan could be faced with more than one emergency and in this case the reliability safety valve may be used more than once. If the state finds that a second reliability emergency arises that conflicts with the state plan, the state must submit a revision to its state plan so that the state plan is flexible enough to assure that such conflicts do not recur and that the state is providing for the implementation of the standards of performance for affected EGUs as required by the CAA.

f. Coordination among federal partners. The EPA, DOE, and FERC have agreed to coordinate efforts to help ensure continued reliable electricity generation and transmission during the implementation of the final rule. The three agencies have developed a coordination strategy that reflects their joint understanding of how they will work together to monitor final rule implementation, share information, and resolve any difficulties that may be encountered. This strategy is based on the successful working relationship that the three agencies established in their joint effort to work together to monitor reliability during MATS implementation.

g. <u>Analyses of the reliability impacts of the proposal</u>. The EPA appreciates that a large number of entities from many different industry perspectives have published reports and analysis with respect to electric reliability and the 111(d) proposed rule. We take concerns about reliability very seriously, and we appreciate the attention given to this issue in the comments and shared with us in public forums. It is important to note that these studies were conducted prior to promulgation of this final rule, and thus were only able to consider electric reliability with respect to the proposal. The EPA has made changes and improvements to the proposal in response to comments and new information, and some of the changes are relevant to the final rule's potential effect on electric reliability. One notable change pertains to the start of the interim period, which is now 2022 rather than 2020. Another important change to the final rule is a more gradual phase-in of the BSER for affected EGUs over the interim period (from 2022 through 2029). The final rule also provides considerable flexibility and multiple pathways to states, including allowing their EGUs to use multi-state trading and other approaches, which would allow essential units to continue to meet their compliance obligation while generating even at unplanned but reliability-critical levels. In addition, we have included in the final rule a reliability safety valve provision that can be utilized in certain emergency situations. These changes, in addition to already existing industry mechanisms and planning requirements, will help to ensure that industry will be able to maintain electric reliability. The EPA is confident that the final rule will cut harmful electric power plant pollution while maintaining a reliable electric grid because the final rule provides industry with the time and flexibility needed to continue its current and ongoing planning and investing to modernize and upgrade the electric power system.

In June of 2015, M.J. Bradley & Associates issued a report that enumerated a set of useful guiding principles for studying and evaluating the reliability impacts of the final rule.[873] The

[873] M.J. Bradley & Associates, *Guiding Principles for Reliability Assessments Under EPA's Clean Power Plan* (June 3, 2015), *available at* http://www.mjbradley.com/node/295.

report enumerated six principles: (1) a study should be transparent about the assumptions and data used; (2) a study should accurately reflect the existing status of the grid in its modeling assumptions; (3) a study should clearly identify the base case and not confuse what will happen as a result of the final rule with what would have happened anyway; (4) where possible, a study should contain sensitivities and probabilities as they are looking into the future which is necessarily uncertain; (5) a study should reflect the flexibility provided to states to allow them to design compliance approaches to maximize reliability; and (6) a study should provide realistic and reliability-focused results. These principles are helpful to keep in mind when reviewing recent studies.

NERC published its analyses of the proposed rule in November 2014 and again in April 2015.[874] The EPA appreciates NERC's attention to, and interest in, the proposed rule. However, we note that like some other studies, NERC assumes

---

[874] North American Electric Reliability Corporation, *Potential Reliability Impacts of EPA's Proposed Clean Power Plan* (Nov. 5, 2014), *available at* http://www.nerc.com/news/Pages/Reliability-Review-of-Proposed-Clean-Power-Plan-Identifies-Areas-for-Further-Study,-Makes-Recommendations-for-Stakeholders.aspx; North American Electric Reliability Corporation, *Potential Reliability Impact of EPA's Proposed Clean Power Plan: Phase 1* (Apr. 21, 2015), *available at* http://www.nerc.com/news/Pages/Assessment-Uses-Scenario-Analysis-to-Identify-Potential-Reliability-Risks-from-Proposed-Clean-Power-Plan.aspx.

considerably less flexibility than actually is provided to states and EGUs in this final rule. The final rule provides states with considerable time and latitude in designing plans that are tailored to the system in which their EGUs operate, which should be reflected in any reliability analysis. Also, the NERC study does not fully reflect the current electric grid. For example, the amount of RE generation that NERC assumes for 2020 is similar to levels of generation that we see today whereas projections for 2020 are considerably higher.[875] Further, NERC conflates retirements that may happen as a result of the rule with those that are already planned. The Brattle Group has also reviewed NERC's November 2014 initial analysis of the proposed rule, noting that it is important to distinguish between concerns about the building blocks and reliability concerns about compliance with state plans.[876] The Brattle Group concluded that there are real world solutions to NERC's concerns. These include making use of the many flexible options available to states under the rule to mitigate reliability risks.

Multiple ISOs/RTOs also provided analyses of the proposed

rule, including MISO, PJM, ERCOT, and SPP.[877] For example, MISO conducted an analysis of coal units at risk for retirement, finding that 14 GW of coal may be at risk.[878] SPP performed a resource adequacy analysis that assumes planned retirements plus the EPA's projected retirements, but did not similarly account for the building of new generation capacity.[879] While we appreciate MISO's and SPP's concerns regarding retirements and the potential that reserves will fall below reserve requirement levels, it is important to consider the many ways in which states can develop plans that account for their potential reliability concerns. The final rule continues to give states

significant flexibility in how they comply with requirements, including both BSER measures and measures that were not included in the determination of the BSER as a means to comply. For example, demand-side EE measures can greatly assist states and affected EGUs in meeting the standards and/or state plan. Many studies assume that state plans will simply apply the BSER and do not recognize the large number of compliance approaches and opportunities that states and affected EGUs have available to them. The Analysis Group recently analyzed reliability considerations in MISO as the region considers how to comply with the final rule.[880] The Analysis Group found that despite the large amount of coal-fired generating capacity that will likely be retired in MISO in the coming years, the entities responsible for electric system reliability in MISO are prepared to collaboratively address any reliability issues that arise and that there is a "strong tool kit for managing 'Essential Reliability Services' needed to assure high-quality electric service."[881]

ERCOT also performed an analysis, modeling numerous scenarios.[882] ERCOT stated that its modeling identified two potential reliability problems – impacts of units retiring and increased levels of renewable generation on the ERCOT grid.[883] As noted above, the final rule gives additional time for compliance, providing needed time to obtain new or replacement generation necessary as some existing generators retire. Moreover, affected EGUs needed for reliability should be able to employ the flexibilities afforded to them as they seek lower and zero-emitting generation. Finally, we note that ERCOT has a history of notable success in integrating RE into its electric grid, giving ERCOT significant expertise regarding challenges that may arise with the addition of new RE in order to comply with the final rule. In fact, a recent Brattle Group report used ERCOT as a case study for how to effectively integrate a large number of RE into the electric grid.[884]

[884] Brattle Group, *Integrating Renewable Energy Into the Electricity Grid: Case Studies Showing How System Operators are Maintaining Reliability* (June 2015), *available at* http://info.aee.net/integrating-renewable-energy-into-the-electricity-grid.

PJM conducted its own analysis at the request of the Organization of PJM States (OPSI).[885] This analysis is consistent with many of the M.J. Bradley guiding principles. PJM designed various scenarios to capture the impact of the proposed rule under a series of assumptions. Because the EPA had not yet issued the final rule, PJM cautioned against using the report as a reliability analysis or predictor of the future. PJM stated that, since 2007, PJM's capacity markets have helped to attract 35,000 MWs of additional generation. Even though 26,000 MWs will retire between 2009 and 2016, the PJM capacity market has procured sufficient resources to maintain reliability.

WECC also produced a study which is part of a longer-term, phased effort.[886] The assumptions, methodology, and limitations were all clearly presented, and there was extensive involvement by a range of stakeholders. WECC stated that it is embarking on a phased-study process that seeks to "provide the industry with unbiased and independent analysis of this issue."[887] WECC

concluded that the effects of the proposal on resource adequacy may be minimal but that resource adequacy cannot be fully assessed without realistic and/or proposed compliance scenarios.[888]

Analysis Group analyzed the proposed rule, finding that it provides states and affected EGUs with a wide range of options and operational discretion that can prevent reliability issues while also reducing carbon pollution and costs.[889] Analysis Group noted that some of the concerns raised by stakeholders about the proposed rule assume "inflexible implementation, are based upon worst-case scenarios, and assume that policy makers, regulators, and market participants will stand on the sidelines until it is far too late to act" to ensure reliability.[890] It stated that these assumptions are not consistent with past actions.

We appreciate the time that multiple entities took to analyze and consider the potential impacts of the proposed rule. As we issue the final rule and states draft plans to implement the rule, we look forward to further analysis by these and other groups. Such analysis can provide states with needed resources to help them design state plans that will augment the efforts of the industry to maintain electric reliability.

3. Consideration of effects on employment and economic development

States in designing their state plans should consider the effects of their plans on employment and overall economic development to assure that the opportunities for economic growth and jobs that the plans offer are manifest. To the extent possible, states should try to assure that any communities that can be expected to experience job losses can also take advantage of the opportunities for job growth or otherwise transition to healthy, sustainable economic growth. The EPA’s illustrative analysis indicates that there may be some additional job losses in sectors related to coal extraction and generation that are attributable to implementation of this rule. At the same time, the EPA’s illustrative analysis indicates that there may be new jobs in the utility power sector associated with both improving the efficiency of fossil fuel-fired power plants, construction and operation of new natural gas-fired and RE production, and actions to increase demand-side EE. Consideration of these effects in the context of the particulars of the state plan can help states craft plans that, to the extent possible, meet multiple environmental, economic, and workforce development goals.

The Partnerships for Opportunity and Workforce and Economic Revitalization (POWER) Initiative is a new interagency effort led by the Economic Development Administration in the Department of Commerce. POWER was launched to respond to current trends in the power sector: "The United States is undergoing a rapid energy transformation, particularly in the power sector. This transformation is producing cleaner air and healthier communities, and spurring new jobs and industries. At the same time, it is impacting workers and communities who have relied on the coal industry as a source of good jobs and economic prosperity, particularly in Appalachia, where competition with other coal basins provides additional pressure."[891] The POWER Initiative aligns, leverages, and targets economic and workforce development assistance to communities and workers affected by changes in the coal industry and the utility power sector. The POWER Initiative is competitively awarding planning assistance and implementation grants with funding from the Department of

[891] http://www.eda.gov/power/.

Commerce, Department of Labor, Small Business Administration, and the Appalachian Regional Commission to partnerships anchored in impacted communities. These grants will help communities organize themselves, develop comprehensive strategic plans that chart their economic future, and execute coordinated economic and workforce development activities based on their strategic plans.[892]

In addition to POWER, however, the EPA encourages states to use economic and labor market analysis to identify where they can deploy strategies to: 1) provide a range of employment and training assistance to workers, and economic development assistance to communities affected by the rapid changes underway in the power sector and closely related industries, to diversify their economies, attract new sources of investment, and create new jobs; and 2) mobilize existing education and training resources, including those of community and technical colleges and registered apprenticeship programs, to ensure that both incumbent and new workers are trained for the skills necessary to meet employer demand for new workers in the utility, construction and related sectors, that such training includes career pathways for members of low-income communities and other

[892] https://www.whitehouse.gov/the-press-office/2015/03/27/fact-sheet-partnerships-opportunity-and-workforce-and-economic-revitaliz.

vulnerable communities to attain employment in these sectors, and that such training results in validated skill certifications for workers.

4. Workforce considerations

Some stakeholders commented that, to ensure that emission reductions are realized, it is important that construction, operations and other skilled work undertaken pursuant to state plans is performed to specifications, and is effective, safe, and timely. A good way to ensure a highly proficient workforce is to require that workers have been certified by: 1) an apprenticeship program that is registered with the U.S. DOL, Office of Apprenticeship or a state apprenticeship program approved by the DOL; 2) a skill certification aligned with the U.S. DOE Better Building Workforce Guidelines and validated by a third party accrediting body recognized by DOE; or 3) other skill certification validated by a third party accrediting body.

5. Tenth Amendment legal considerations

Some commenters have raised concerns that the emission guidelines and requirements for 111(d) state plans violate principles of federalism embodied in the U.S. Constitution, particularly the Tenth Amendment. These commenters claim that states will be unconstitutionally “coerced” or “commandeered” into taking certain actions in order to avoid the prospect of either a federal 111(d) plan applying to sources in the state, or of losing federal funds.

We disagree on both fronts. First, the prospect of a federal plan applying to sources in a state does not "coerce" or "commandeer" that state into submitting its own satisfactory plan. Far from violating principles of federalism, this rule provides states with the initial opportunity to submit a satisfactory state plan, and provides states flexibility in developing that plan. If a state declines to take advantage of that opportunity, affected EGUs in that state will instead be subject to a federal plan that satisfies statutory requirements.[893] This approach is consistent with ordinary cooperative federalism regimes that federal courts have routinely upheld against Tenth Amendment challenges.[894]

---

[893] Among other things, a federal plan will implement standards of performance subject to specific statutory requirements. *See* 42 U.S.C. § 7411(a)(1). The APA and CAA would prohibit the imposition of any federal plan that is "arbitrary, capricious, an abuse of discretion, or otherwise not in accordance with law." 5 U.S.C. § 706(2)(a). Particularly given these independent constraints on the EPA's authority with respect to any potential federal plan, the prospect of any such plan would not commandeer states or coerce them into submitting their own state plans.

[894] *See, e.g.*, *Hodel v. Va. Surface Mining & Reclamation Ass'n, Inc.*, 452 U.S. 264, 283–93 (1981); *Texas v. EPA*, 726 F.3d 180, 196–97 (D.C. Cir. 2013) (noting that "Supreme Court precedent repeatedly affirm[s] the constitutionality of federal statutes that allow States to administer federal programs but provide for direct federal administration if a State chooses not to administer it").

Second, states that decline to take certain actions under this rule will not face the prospect of sanctions, such as withdrawn federal highway funds. CAA section 111 does not contain sanctions provisions, and we are finalizing revisions to these emission guidelines making explicit that the EPA will not withhold federal funds from a state on account of that state's failure to submit or implement an approvable 111(d) state plan.

Some commenters pointed to section 110(m) as a possible source of the EPA's sanction authority.[895] Section 110(m) grants the EPA discretionary authority to withhold some federal highway funds under certain conditions. However, section 110(m) requires the EPA to adopt regulations to "establish criteria for exercising" this discretionary authority, and the only EPA regulations implementing section 110(m) apply to SIPs submitted under section 110.[896]

The EPA never intended to even imply that we would contemplate using this authority to encourage state participation in this rule under section 111. To the contrary, we believe that imposition of a federal plan rather than sanctions is the appropriate path in the context of this

---

[895] Other commenters point to CAA section 179 as a possible direct source of this sanctions authority. However, the mandatory sanctions outlined in section 179 clearly apply only in the contexts of nonattainment SIPs and responses to SIP Calls made under CAA section 110(k)(5). *See* 42 U.S.C. § 7509(a).
[896] 40 CFR 52.30 (defining "plan or plan item").

program. Accordingly, regardless of whether the EPA could theoretically apply discretionary sanctions against states in the section 111(d) context, the final rule forbids the agency from exercising any such authority. We have included in this rule a provision that prohibits the agency from imposing sanctions in the event that a state fails to submit or implement a satisfactory plan under this rule. As states consider whether to take advantage of the opportunity to develop state plans, they can be assured that the EPA will not withdraw federal funding should they decline to participate.

6. Title VI

States that are recipients of EPA financial assistance must comply with all federal nondiscrimination statutes that together prohibit discrimination on the bases of race, color, national origin (including limited-English proficiency), disability, sex and age. These laws include: Title VI of the Civil Rights Act of 1964; Section 504 of the Rehabilitation Act of 1973; Section 13 of the Federal Water Pollution Control Act Amendments of 1972; Title IX of the Education Act Amendments of 1972; and the Age Discrimination Act of 1975. Compliance with these nondiscrimination statutes is a recipient's separate and distinct obligation from compliance with environmental regulations. In other words, all recipients are required to ensure that all aspects of their state plans do not violate any of the federal nondiscrimination statutes, including Title VI.

The EPA's Office of Civil Rights (OCR) is responsible for carrying out compliance with these federal nondiscrimination statutes and does so through a variety of means including: complaint investigation; agency-initiated compliance reviews; pre-grant award assurances and audits; and technical assistance and outreach activities. Anyone who believes that any of the federal nondiscrimination laws enforced by OCR have been violated by a recipient of EPA financial assistance may file an administrative complaint with the EPA's OCR.

H. Resources for States to Consider in Developing Plans

As part of the stakeholder outreach and comment processes, the EPA asked states what the agency could do to facilitate state plan development and implementation. In addition, after the comment period closed, the EPA continued to consult with state organizations including the Association of Air Pollution Control Agencies (AAPCA), Environmental Council of the States (ECOS), National Association of Clean Air Agencies (NACAA), National Association of Regulatory Utility Commissioners (NARUC), National Association of State Energy Officials (NASEO) and the National Governors Association (NGA).

Some states indicated that they wanted the EPA to create resources to assist with state plan development, especially resources related to accounting for RE and demand-side EE in state plans. They requested clear methodologies for estimating emission reductions from RE and demand-side EE policies and programs so that these could be included as part of their compliance strategies. Stakeholders said that these tools and metrics should build upon the EPA’s “Roadmap for Incorporating Energy Efficiency/Renewable Energy Policies and Programs into State and Tribal Implementation Plans,” as well as the State Energy Efficiency Action Network’s “Energy Efficiency Program Impact Evaluation Guide.” In addition, stakeholders requested clear guidance on how to measure the impacts of RE and demand-side EE programs using established EM&V protocols.

The EPA also heard that states would like guidance on plan development to be released at the same time as this final rule. This guidance should include allowable programs and policies for compliance, examples of compliance pathways, clear information on multi-state plan development, and identification of tools.

As a result of this feedback, in consultation with U.S. DOE and other federal agencies, the EPA continued to refine its toolbox of decision support resources at: http://www2.epa.gov/www2.epa.gov/cleanpowerplantoolbox. The site includes information on regulatory requirements, including state plan guidance and state plan decision support. The state plan guidance section serves as a central repository for the final emission guidelines, RIA, guidance documents, TSDs and other supporting materials. The state plan decision support section includes information to help states evaluate different approaches and measures they might consider as they initiate plan development. This section includes, for example, a summary of existing state climate and RE and demand-side EE policies and programs, information on electric utility actions that reduce CO_2, and tools and information to estimate the emissions impact of RE and demand-side EE programs.

The EPA notes that our inclusion of a measure in the toolbox does not mean that a state plan must include that measure. In fact, inclusion of measures provided at the website does not necessarily imply the approvability of an approach or method for use in a state plan. States will need to demonstrate that any measure included in a state plan meets all relevant criteria and adequately addresses elements of the plan components discussed in section VIII.D of this preamble.

I. Considerations for CO_2 Emission Reduction Measures that Occur at Affected EGUs

This section describes a range of emission reduction actions that may be taken at affected EGUs that reduce CO_2 emissions from an affected EGU and/or improve its CO_2 emission rate, and the accounting treatment for these actions in a state plan. Some of these actions do not necessitate additional accounting, monitoring or reporting requirements. Such actions are discussed in section VIII.I.1 below, and include heat rate improvements, fuel switching from one fossil fuel to another, integration of RE into EGU operations, and combined heat and power (CHP) expansion or retrofit. Other actions, however, do necessitate additional accounting, monitoring, or reporting requirements. These include use of CCS, CCU and biomass, as discussed in section VIII.I.2 below.

The discussion in this section applies for both rate-based and mass-based plans. Additional accounting considerations for mass-based plans are discussed in section VIII.J. Additional accounting considerations for rate-based plans, including how actions that substitute for generation from affected EGUs or avoid the need for generation from affected EGUs may be used in a state plan to adjust the CO_2 emission rate of an affected EGU, are discussed in section VIII.K.

1. Actions without additional accounting and reporting requirements

Many actions will reduce the reported CO_2 emissions or CO_2 emission rate of an affected EGU, without the need for additional accounting or monitoring and reporting requirements beyond the required CEMS tracking of actual stack CO_2 emissions and tracking of actual energy output.[897] The effect of these actions will result in changes in reported CO_2 emissions and/or energy output by an affected EGU. These actions include:

- heat rate improvements;
- fuel switching to a fossil fuel with lower carbon content (e.g., from coal to natural gas);
- integrated RE;[898] and
- CHP, including retrofit of an affected EGU to a CHP configuration, or revising the useful energy outputs (electrical and thermal) at an affected EGU already operating in a CHP configuration.[899]

Heat rate improvements, fuel switching, integrating RE and CHP would not require any additional accounting or monitoring

---

[897] Monitoring and reporting requirements for affected EGU CO_2 emissions and useful energy output are addressed in section VIII.F.

[898] "Integrated RE" refers to RE that is directly incorporated into the mechanical systems and operation of the EGU. An example is a solar thermal energy system used to preheat boiler feedwater. Such approaches reduce the amount of fossil fuel heat input per unit of useful energy output.

[899] The emission reduction potential from CHP stems from the unit using less fuel for producing useful electrical and thermal outputs than would be required to run separate electrical and thermal units. The emission reduction would depend on the type of affected EGU and available steam hosts in the vicinity of the affected EGU. A conventional combustion turbine generator, for example, converted into a CHP unit could effectively result in a reduction of 25 percent or more in the reported CO_2 emission rate. The potential retrofitted EGU CHP market consists of converted simple cycle turbines, older steam plants in urban areas, and combined cycle units near beneficial thermal loads.

and reporting, because under the emission guidelines affected EGUs are already required to monitor and report CO_2 emissions at the stack level, and to monitor and report useful energy outputs. Stack monitoring would reflect reductions in CO_2 emissions from efficiency improvements, changes in fuel use (including incorporation of RE), and other on-site changes.

2. Actions with additional accounting and reporting requirements

Certain actions that may be taken at an affected EGU to reduce CO_2 emissions, specifically application of CCS and CCU, and use of biomass, require additional accounting and reporting.

a. Application of CCS. Affected EGUs may utilize retrofit CCS technology to reduce reported stack CO_2 emissions from the EGU.[900] Affected EGUs that apply CCS under a state plan must meet the same monitoring, recordkeeping and reporting requirements for sequestered CO_2 as new units that implement CCS to meet final standards of performance under CAA section 111(b) for new EGUs.[901] Specifically, the final CAA section 111(b) rule for new sources requires that, if a new affected EGU uses CCS to meet

[900] Addition of retrofit CCS technology should not trigger CAA section 111(b) applicability for modified or reconstructed sources. Pollution control projects do not trigger NSPS modifications and addition of CCS technology does not count toward the capital costs of reconstruction for NSPS.

[901] Standards of Performance for Greenhouse Gas Emissions from New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units.

the applicable CO_2 emission limit, the EGU must report in accordance with 40 CFR part 98 subpart PP (Suppliers of Carbon Dioxide), and the captured CO_2 must be injected at a facility or facilities that report in accordance with 40 CFR part 98 subpart RR (Geologic Sequestration of Carbon Dioxide).[902,903] See 40 CFR part 60.46Da(h)(5) and part 60.5555(d). Taken together, these requirements ensure that the amount of captured and sequestered CO_2 will be tracked as appropriate at project- and national-levels, and that the status of the CO_2 in its sequestration site will be monitored, including air-side monitoring and reporting. As detailed in the preamble for the CAA section 111(b) standards for new EGUs, the EPA found that there is ample evidence that CCS is technically feasible and that partial CCS can be implemented at a new fossil fuel-fired steam generating EGU at a cost that is reasonable and that is consistent with the cost of

---

[902] The final CAA section 111(b) rule finalizes amendments to subpart PP reporting requirements, specifically requiring that the following pieces of information be reported: (1) the electronic GHG Reporting Tool identification (e-GGRT ID) of the EGU facility from which CO_2 was captured, and (2) the e-GGRT ID(s) for, and mass of CO_2 transferred to, each GS site reporting under subpart RR. As noted, the final 111(b) rule also requires that any affected EGU unit that captures CO_2 to meet the applicable emission limit must transfer the captured CO_2 to a facility that reports under 40 CFR part 98 subpart RR.

[903] Under final requirements in the CAA 111(b) NSPS, any well receiving CO_2 captured from an affected EGU, be it a Class VI or Class II well, must report under subpart RR. A UIC Class II well’s regulatory status does not change because it receives such CO_2, nor does it change by virtue of reporting under subpart RR.

other dispatchable, non-NGCC generating options. In the June 2014 proposal, the EPA noted that CCS technology at existing EGUs would entail additional considerations beyond those at issue for newly constructed EGUs. Specifically, the cost of integrating a retrofit CCS system into an existing facility may be expected to be substantial, and some existing EGUs may have space limitations and thus may not be able to accommodate the expansion needed to install the equipment to implement CCS. Further, the EPA noted that aggregated costs of applying CCS as a component of the BSER for the large number of existing fossil fuel-fired steam EGUs would be substantial and would be expected to affect the cost and potentially the supply of electricity on a national basis. Because there are lower-cost systems of emission reduction available to reduce emissions from existing plants, the EPA did not propose nor finalize CCS as a component of the BSER for existing EGUs.

However, the EPA noted that CCS may be a viable CO_2 mitigation technology at some existing sources and that it would be available to states and to sources as a compliance option. Numerous commenters agreed with the EPA's proposed determination that CCS technology is not part of the BSER building blocks for existing EGUs. Other commenters opposed inclusion of CCS requirements in state plans and provided specific reasons why CCS would not be applicable in certain states. Many commenters felt that CCS technology is not adequately demonstrated and is not economically practical at this time. Other commenters argued that CCS is an available technology and that it can be implemented at more EGUs than predicted by EPA modeling.

Some commenters noted that there are opportunities to reduce the cost of CCS implementation by selling the captured CO_2 for use in Enhanced Oil Recovery (EOR) operations. One commenter expressed concern that federal requirements under the Greenhouse Gas Reporting Program – specifically the requirement (mentioned above) to report under 40 CFR part 98 subpart RR – would foreclose, rather than encourage, the use of captured CO_2 for EOR. The EPA received similar public comments on the CAA 111(b) proposal for new EGUs. The EPA disagrees with the commenters' assertions and addressed those in the preamble for the final standards of performance and in the Response-to-Comments (RTC) document for the CAA 111(b) NSPS rulemaking. The EPA noted that the cost of compliance with subpart RR is not significant enough to offset the potential revenue for the EOR operator from the sale of produced oil for CCS projects that are reliant on EOR. The costs associated with subpart RR are relatively modest, especially in comparison with revenues from an EOR field.

After consideration of the variety of comments we received on this issue, we are confirming our proposal that CCS is not an element of the BSER, but it is an available compliance measure for a state plan. EGUs implementing CCS would need to follow reporting requirements established in the final CAA section 111(b) rule for new affected EGUs.

b. Application of CCU. The EPA received comments suggesting that carbon capture and utilization (CCU) technologies should also be allowed as a CO_2 emission rate adjustment measure for affected EGUs.

Potential alternatives to storing CO_2 in geologic formations are emerging and may offer the opportunity to offset the cost of CO_2 capture. For example, captured anthropogenic CO_2 may be stored in solid carbonate materials such as precipitated calcium carbonate (PCC) or magnesium or calcium carbonate, bauxite residue carbonation, and certain types of cement through mineralization. The carbonate materials produced can be tailored to optimize performance in specific industrial and commercial applications. For example, these carbonate materials have been used in the construction industry and, more recently and innovatively, in cement production processes to replace Portland cement.

The Skyonics Skymine® project, which opened its demonstration project in October 2014, is an example of captured CO_2 being used in the production of carbonate products. This plant converts CO_2 into commercial products. It captures over 75,000 tons of CO_2 annually from a San Antonio, Texas, cement plant and converts the CO_2 into other products including sodium carbonate and sodium bicarbonate.[904] Other companies – including Calera[905] and New Sky[906] – also offer commercially available technology for the beneficial use of captured CO_2. These processes can be utilized in a variety of industrial applications – including at fossil fuel-fired power plants.

However, consideration of how these emerging alternatives could be used to meet CO_2 emission performance rates or state CO_2 emission goals would require a better understanding of the ultimate fate of the captured CO_2 and the degree to which the method permanently isolates the captured CO_2 or displaces other CO_2 emissions from the atmosphere.

Several commenters also suggested that algae-based CCU (i.e., the use of algae to convert captured CO_2 to useful products – especially biofuels) should be recognized for its potential to reduce emissions from existing fossil-fueled EGUs.

Unlike geologic sequestration, there are currently no uniform monitoring and reporting mechanisms to demonstrate that these alternative end uses of captured CO_2 result in overall reductions of CO_2 emissions to the atmosphere. As these alternative technologies are developed, the EPA is committed to

[904] http://skyonic.com/technologies/skymine.
[905] http://www.calera.com/beneficial-reuse-of-co2/process.html.
[906] http://www.newskyenergy.com/index.php/products/carboncycle.

working collaboratively with stakeholders to evaluate the efficacy of alternative utilization technologies, to address any regulatory hurdles, and to develop appropriate monitoring and reporting protocols to demonstrate CO_2 reductions.

In the meantime, state plans may allow affected EGUs to use qualifying CCU technologies to reduce CO_2 emissions that are subject to an emission standard, or those that are counted when demonstrating achievement of the CO_2 emission performance rates or a state rate-based or mass-based CO_2 emission. State plans must include analysis supporting how the proposed qualifying CCU technology results in CO_2 emission mitigation from affected EGUs and provide monitoring, reporting, and verification requirements to demonstrate the reductions. The EPA would then review the appropriateness and basis for the analysis and the verification requirements in the course of its review of the state plan.

c. <u>Application of biomass co-firing and repowering</u>. The EPA received multiple comments supporting the use of biomass feedstocks as a means of reducing CO_2 emissions within state plans. Several commenters also asserted that states should be able to determine how biomass can be used in their plans. Additionally, the EPA received a range of comments regarding the valuation of CO_2 emissions from biomass combustion. Some argued that all biomass feedstocks should be considered "carbon neutral," while others maintained that only the full stack emissions from biomass combustion should be counted. As discussed in the next section, the revised *Framework for Assessing Biogenic Carbon Dioxide for Stationary Sources*[907] and 2012 Science Advisory Board peer review of the *2011 Draft Framework* find that it is not scientifically valid to assume that all biogenic feedstocks are "carbon neutral, but that the net biogenic CO_2 atmospheric contribution of different biomass feedstocks can vary and depends on various factors, including feedstock type and characteristics, production practices, and, in some cases, the alternative fate of the feedstock.[908] Other comments focused on the use of sustainably-derived agricultural and forest biomass feedstocks, including stakeholders who supported and those against such feedstocks as approvable elements, and those who wanted further definition of these feedstocks. As discussed above and in more detail below, these final guidelines provide that states can include qualified biomass in their plans and include provisions for how qualified biomass feedstocks or feedstock categories will be determined. The EPA will review the appropriateness and basis for determining qualified biomass feedstocks or feedstock categories in its review of the approvability of a state plan.

---

[907] www.epa.gov/climatechange/downloads/Framework-for-Assessing-Biogenic-CO2-Emissions.pdf.
[908] www.epa.gov/climatechange/ghgemissions/biogenic-emissions.html.

(1) Considerations for use of biomass in state plans.

The EPA recognizes that the use of some biomass-derived fuels can play a role in controlling increases of CO_2 levels in the atmosphere. The use of some kinds of biomass has the potential to offer a wide range of environmental benefits, including carbon benefits. However, these benefits can typically only be realized if biomass feedstocks are sourced responsibly and attributes of the carbon cycle related to the biomass feedstock are taken into account.

In November 2014, the agency released a second draft of the technical report, *Framework for Assessing Biogenic Carbon Dioxide for Stationary Sources*. The revised *Framework,* and the EPA's Science Advisory Board (SAB) peer review of the *2011 Draft Framework*, finds that it is not scientifically valid to assume that all biogenic feedstocks are "carbon neutral" and that the net biogenic CO_2 atmospheric contribution of different biogenic feedstocks generally depends on various factors related to feedstock characteristics, production, processing and combustion practices, and, in some cases, what would happen to that feedstock and the related biogenic emissions if not used for energy production.[909] The revised Framework also found that the

[909] Specifically, the SAB found that "There are circumstances in which biomass is grown, harvested and combusted in a carbon neutral fashion but carbon neutrality is not an appropriate a

production and use of some biogenic feedstocks and subsequent biogenic CO_2 emissions from stationary sources will not inevitably result in increased levels of CO_2 to the atmosphere, unlike CO_2 emissions from combustion of fossil fuels.

The SAB peer review panel agreed that the use of biomass feedstocks derived from the decomposition of biogenic waste in landfills, compost facilities or anaerobic digesters did not constitute a net contribution of biogenic CO_2 emissions to the atmosphere. And further, information considered in preparing the second draft of the Framework, including the SAB peer review and stakeholder input, supports the finding that use of waste-derived feedstocks[910] and certain forest-derived industrial byproducts (such as those without alternative markets) are likely to have minimal or no net atmospheric contributions of biogenic CO_2 emissions, or even reduce such impacts, when

---

priori assumption; it is a conclusion that should be reached only after considering a particular feedstock's production and consumption cycle. There is considerable heterogeneity in feedstock types, sources and production methods and thus net biogenic carbon emissions will vary considerably." www.epa.gov/climatechange/ghgemissions/biogenic-emissions.html.

[910] Types of waste-derived biogenic feedstocks may include: landfill gas generated through the decomposition of MSW in a landfill; biogas generated from the decomposition of livestock waste, biogenic MSW, and/or other food waste in an anaerobic digester; biogas generated through the treatment of waste water, due to the anaerobic decomposition of biological materials; livestock waste; and the biogenic fraction of MSW at waste-to-energy facilities.

compared with an alternate fate of disposal.

In addition, as detailed in the President's Climate Action Plan,[911] part of the strategy to address climate change includes efforts to protect and restore our forests, as well as other critical landscapes including grasslands and wetlands, in the face of a changing climate. This country's forests currently play a critical role in addressing carbon pollution, removing more than 13 percent of total U.S. GHG emissions each year.[912] Conservation and sustainable management can help ensure our forests and other lands will continue to remove carbon from the atmosphere while also improving soil and water quality, reducing wildfire risk and enhancing forests' resilience in the face of climate change.

Many states have recognized the importance of forests and other lands for climate resilience and mitigation, and have developed a variety of sustainable forestry policies, RE incentives and standards, and GHG accounting procedures. Some states, for example Oregon and California, have programs that recognize the multiple benefits that forests provide, including biodiversity and ecosystem services protection as well as

---

[911] www.whitehouse.gov/sites/default/files/image/president27sclimateactionplan.pdf.

[912] www.epa.gov/climatechange/Downloads/ghgemissions/US-GHG-Inventory-2015-Chapter-6-Land-Use-Land-Use-Change-and-Forestry.pdf.

climate change mitigation through carbon storage. Oregon has several programs focused on best forest management practices and sustainability, including the Oregon Indicators of Sustainable Forests, that promote environmentally, economically and socially sustainable management of state forests. California's Forest Practice Regulations support sustained production of high-quality timber while considering ecological, economic and social values, and the state's Greenhouse Gas Reduction Fund provides resources for forestry projects to improve forest health, maintain carbon storage and avoid GHG emissions from pests, wildfires and conversion to non-forest uses.

Several states focus on sustainable bioenergy, as seen with the sustainability requirements for eligible biomass in the Massachusetts RPS, which, among other requirements, limits old growth forest harvests. Many states employ complementary programs that together work to address sustainable forestry practices. For example, Wisconsin uses a state forest sustainability framework that provides a common system to measure the sustainability of the state's public and private forests, in conjunction with a series of voluntary best management guideline manuals for sustainable woody biomass and agriculturally-derived biomass. In addition to state-specific programs, some states also actively participate in sustainable forest management or certification programs through third-party entities such as the Sustainable Forestry Initiative (SFI) and the Forest Stewardship Council (FSC). For example, in addition to other state sustainability programs, New York has certified more than 780,000 acres of state forestland to both SFI and FSC's sustainable forest management programs. SFI and FSC have certified more than 63 and 35 million acres of forestland across the U.S., respectively.

These examples demonstrate how states already use diverse strategies to promote sustainable forestry and agricultural management while realizing their unique economic, environmental and RE goals. As states evaluate options for meeting the emission guidelines, they may consider how sustainably-derived biomass and sustainable forestry and agriculture programs, such as the examples highlighted above, may help them control increases of CO_2 levels in the atmosphere. In addition, the EPA's work on assessing biogenic CO_2 emissions from stationary sources may also help inform states' efforts to assess the role of different biogenic feedstocks in their plans and broader climate strategies.[913]

The EPA is engaging in a second round of targeted peer review on the revised Framework with the SAB in 2015.[914] As part

[913] As highlighted in a November 2014 memorandum to the EPA's Regional Air Division Directors. www.epa.gov/climatechange/ghgemissions/biogenic-emissions.html.
[914] www.epa.gov/sab.

of this technical process, and as the EPA and states implement these emission guidelines, the EPA will continue to assess and closely monitor overall bioenergy demand and associated landscape conditions for changes that might have negative impacts on public health or the environment.

(2) Additional considerations and requirements for biomass fuels.

The EPA anticipates that some states may consider the use of certain biomass-derived fuels used in electricity generation as a way to control increases of CO_2 levels in the atmosphere, and will include them as part of their state plans to meet the emission guidelines. Not all forms of biomass are expected to be approvable as qualified biomass (i.e., biomass that can be considered as an approach for controlling increases of CO_2 levels in the atmosphere). Affected EGUs may use qualified biomass in order to control or reduce CO_2 emissions that are subject to an emission standard requirement, or those that are counted when demonstrating achievement of the CO_2 emission performance rates or a state rate-based or mass-based CO_2 emission goal.

State plan submissions must describe the types of biomass that are being proposed for use under the state plan and how those proposed feedstocks or feedstock categories should be considered as “qualified biomass” (i.e., a biomass feedstock that is demonstrated as a method to control increases of CO_2

levels in the atmosphere). The submission must also address the proposed valuation of biogenic CO_2 emissions (i.e., the proposed portion of biogenic CO_2 emissions from use of the biomass feedstock that would not be counted when demonstrating compliance with an emission standard, or when demonstrating achievement of the CO_2 emission performance rates or a state rate-based or mass-based CO_2 emission goal).

With regard to assessing qualified biomass proposed in state plans, the EPA generally acknowledges the CO_2 and climate policy benefits of waste-derived biogenic feedstocks and certain forest- and agriculture-derived industrial byproduct feedstocks, based on the conclusions supported by a variety of technical studies, including the revised *Framework for Assessing Biogenic Carbon Dioxide for Stationary Sources.* The use of such waste-derived and certain industrial byproduct biomass feedstocks would likely be approvable as qualified biomass in a state plan when proposed with measures that meet the biomass monitoring, reporting and verification requirements discussed below and other measures as required elsewhere in these emission guidelines.

Given the importance of sustainable land management in achieving the carbon goals of the President's Climate Action Plan, sustainably-derived agricultural and forest biomass feedstocks may also be acceptable as qualified biomass in a state plan, if the state-supplied analysis of proposed qualified feedstocks or feedstock categories can adequately demonstrate that such feedstocks or feedstock categories appropriately control increases of CO_2 levels in the atmosphere and can adequately monitor and verify feedstock sources and related sustainability practices. Information in the revised Framework, the second SAB peer review process, and the state and third party programs highlighted in the previous section can assist states when considering the role of qualified biomass in state plan submittals.

Regardless of what biomass feedstocks are proposed, state plans must specify how biogenic CO_2 emissions will be monitored and reported, and identify specific EM&V, tracking and auditing approaches for qualified biomass feedstocks. As discussed in section VIII.D.2, state plan submittals must include CO_2 emission monitoring, reporting and recordkeeping measures. In the case of sustainably-derived forest- and agriculture-derived feedstocks, this will also include measures for verifying feedstock type, origin and associated sustainability practices. Section VIII.K describes how state plan submittals must specify the requirements and procedures that EM&V measures must meet. As discussed in section VIII.K, the EPA is addressing potential EM&V measures for qualified biomass in EPA's model trading rule and draft EM&V guidance, such as measures that would ensure that biomass-related biogenic CO_2 benefits are quantifiable, verifiable, non-duplicative, permanent and enforceable.

State plan submittals must ensure that all biomass used meets the state plan requirements for qualified biomass and associated biogenic CO_2 benefits, such as using robust, independent third party verification and establishing measures to maintain transparency, including disclosure of relevant documentation and reports. State plan submittals must include measures for tracking and auditing performance to ensure that biomass used meets the state plan requirements for qualified biomass and associated biogenic CO_2 benefits. Details on how to adjust CO_2 rates through the use of qualified biomass feedstocks are provided in section VIII.K.1.

The EPA will review the appropriateness and basis for proposed qualified biomass and biomass treatment determinations and related accounting, monitoring and reporting measures in the course of its review of a state plan. The EPA's determination that a state plan satisfactorily proves that proposed biomass fuels qualify would be based in part on whether the plan submittal demonstrates that proposed state measures for qualified biomass and related biogenic CO_2 benefits are quantifiable, verifiable, enforceable, non-duplicative and permanent. The EPA recognizes that CCS technology (described above in section VIII.I.2.a) could be applied in conjunction with the use of qualified biomass.

(3) Biomass co-firing.

Affected EGUs may use qualified biomass co-fired with fossil fuels at an affected EGU. As discussed above in this section, not all forms of biomass are expected to be approvable and states should propose biomass feedstocks and treatment of biogenic CO_2 emissions in state plans, along with supporting analysis where applicable. The EPA will review the appropriateness and basis for such determinations and accounting measures in the course of its review of a state plan.

An affected EGU using qualified biomass as a fuel must monitor and report both its overall CO_2 emissions and its biogenic CO_2 emissions. If biomass is to be used as means to control increases of CO_2 levels in the atmosphere in a state plan, the plan must specify requirements for reporting biogenic CO_2 emissions from affected EGUs.

(4) Biomass repowering.

Affected EGUs could fully repower to use primarily qualified biomass. The characteristics of affected EGUs, as discussed in section IV.D, include the use of at least 10 percent fossil fuel for applicability of these emission guidelines. An EGU repowering with at least 90 percent biomass fuels instead of fossil fuels becomes a non-affected EGU.[915] An EGU repowering with less than 90 percent biomass would remain an affected EGU and therefore need to propose biomass feedstocks and treatment of biogenic CO_2 emissions in state plans, along with supporting analysis where applicable.

J. Additional Considerations and Requirements for Mass-Based State Plans

This section discusses considerations and requirements for different types of mass-based state plans. This includes mass-based state plans using emission budget trading programs, and coordination among such programs where states retain individual mass CO_2 emission goals. CAA section 111(d) requires states to submit, in part, a plan that establishes standards of performance for affected EGUs which reflect the BSER. The state plan must be satisfactory with respect to this requirement in order for the EPA to approve the plan. As previously described, states meet the statutory requirements of 111(d) and the requirements of the final emission guidelines by establishing emission standards for affected EGUs that meet the performance rates, which reflect the application of BSER as determined by

[915] For such an EGU to be considered non-affected, the EGU must be subject to a federally enforceable or practically enforceable condition, expressed in (for example) a construction permit or otherwise, that limits the amount of fossil fuel that may be used to 10 percent or less.

the EPA. This final rule allows states to alternatively establish emission standards that meet rate-based or mass-based goals. The state goals must be equivalent to the performance rates in order to reflect the application of the BSER as required by the statute and the final emission guidelines. Therefore, a state choosing a mass-based implementation must address leakage as part of its mass-based plan in order to satisfactorily establish emission standards for affected EGUs that reflect the BSER as set by the EPA.

1. Accounting for CO_2 emission reduction measures in mass-based state plans

As discussed in section VIII.I, measures that occur at affected EGUs will result in CO_2 emission reductions that are automatically accounted for in reported CO_2 emissions. Other measures that provide substitute generation for affected EGUs or avoid the need for generation from affected EGUs, such as demand-side EE, are automatically accounted for under a mass-based plan to the extent that these measures reduce reported CO_2 emissions from affected EGUs. Unlike under a rate-based plan, no additional accounting is necessary in order to recognize these emission reductions.

2. Use of emission budget trading programs

This section addresses the use of emission budget trading programs in a mass-based state plan, including provisions required for such programs and the design of such programs in the context of a state plan. This includes program design approaches that ensure achievement of a state mass-based CO_2 emission goal (or mass-based CO_2 goal plus new source CO_2 emission complement) (section VIII.J.2.b), as well as how states can use emission budget trading programs with broader source coverage and other flexibility features in a state plan, such as the programs currently implemented by California and the RGGI participating states (section VIII.J.2.c). Section VIII.J.2.d addresses other considerations for the design of emission budget trading programs that states may want to consider, such as allowance allocation approaches. Section VIII.J.3 addresses multi-state coordination among emission budget trading programs used in states that retain their individual state mass-based CO_2 goals.

a. <u>State plan provisions required for a mass-based emission budget trading program approach</u>.For a mass-based emission trading program approach, the state plan would include as its federally enforceable emission standards requirements that specify the emission budget and related compliance requirements and mechanisms. These requirements would include: CO_2 emission monitoring, reporting, and recordkeeping requirements for affected EGUs; provisions for state allocation of allowances; provisions for tracking of allowances, from issuance through submission for compliance; and the process for affected EGUs to demonstrate compliance (allowance "true-up" with reported CO_2 emissions). Mass-based emission standards that take the form of an emission budget trading program must be quantifiable, verifiable, enforceable, non-duplicative and permanent. These requirements are described in more detail at section VIII.D.2.

Where a state plan establishes mass-based emission standards for affected EGUs only, the emission standards and the implementing and enforcing measures may be included in the state plan as the full set of requirements implementing the emission budget trading program. Where an emission budget trading program in a state plan addresses affected EGUs and other fossil fuel-fired EGUs or emission sources, pursuant to the approaches described in sections VIII.J.2.b-d below, the requirements that must be included in the state plan are the federally enforceable emission standards in the state plan that apply specifically to affected EGUs, and the requirements that specifically require affected EGUs to participate in and comply with the requirements of the emission budget trading program. This includes the requirement for an affected EGU to surrender emission allowances equal to reported CO_2 emissions, and meet monitoring and reporting requirements for CO_2 emissions, among other requirements. These requirements may be submitted as part of the federally enforceable state plan through mechanisms with the appropriate legal authority and effect, such as state regulations, Title V permit requirements for affected EGUs, and other possible instruments that impose these requirements specifically with respect to affected EGUs. Under this approach, the full set of regulations establishing the emission budget trading program that applies to affected EGUs and other fossil fuel-fired EGUs and other emission sources (if relevant) must be described as supporting documentation in the state plan submittal for EPA to evaluate the approvability of the plan by determining whether the affected EGUs will achieve the requisite goal.

b. Requirement for emission budget trading programs to address potential leakage. In Section VII.D, the EPA specifies that potential emission leakage must be addressed in a state plan with mass-based emission standards. The EPA received comments suggesting various solutions to this concern, such as the inclusion of new sources under the rule and quantitative adjustments to mass CO_2 goals for affected EGUs. In response to this issue, the EPA has sought to give states flexibility in how they meet this requirement and base the acceptable solutions on what will best suit a state's unique characteristics and state plan structure.

To address the potential for emission leakage to new sources under a mass-based plan approach, which could prevent a mass-based program from successfully achieving a mass-based CO_2 goal consistent with BSER, the EPA is requiring that a state submitting a plan that is designed to meet a state mass-based CO_2 goal for affected EGUs demonstrate that the plan addresses and mitigates the risk of potential emission leakage to new sources. The following options provide sufficient demonstration that potential emission leakage has been addressed in a mass-based state plan:[916]

1. Regulate new non-affected fossil EGUs as a matter of state law in conjunction with emission standards for affected EGUs in a mass-based plan. If a state adopts an EPA-provided mass budget[917] that includes the state mass-based CO_2 goal for affected EGUs plus a new source CO_2 emission complement, this option could be presumptively approvable.
2. Use allocation methods in the state plan that counteract incentives to shift generation from affected EGUs to unaffected fossil-fired sources. If a state adopts allowance set-aside provisions exactly as they are outlined in the finalized model rule, this option could

[916] The first two options need not be mutually exclusive; they can both be implemented as part of a mass-based plan.
[917] In Table 14, we have provided a mass budget for each state that includes the state mass-based CO_2 goal and a projection for a new source CO_2 emission complement.

be presumptively approvable.

3. Provide a demonstration in the state plan, supported by analysis, that emission leakage is unlikely to occur due to unique state characteristics or state plan design elements that address and mitigate the potential for emission leakage.

In the first option, states may choose to regulate new non-affected fossil fuel-fired EGUs, as a matter of state law, in conjunction with federally enforceable emission standards for affected EGUs under a mass-based plan. This regulation of both new and existing sources, as part of a state plan approach, is conceptually analogous to a method that has been adopted by the mass-based systems adopted by California and the RGGI participating states. To address potential emission leakage under this option, the mass-based plan includes federally enforceable emission standards for affected EGUs, and the supporting documentation for the plan describes state-enforceable regulations for, at a minimum, all new grid-connected fossil fuel-fired EGUs that meet the applicability standards for EGUs subject to CAA section 111(b). States have the option of regulating a wider array of sources if they choose, as a matter of state law.

For this option, a state must adopt, as a matter of state law, a mass CO_2 emission budget of sufficient size to cover both affected EGUs under the existing source mass CO_2 goal provided in this final rule, along with sufficient CO_2 emission tonnage to cover projected new sources. There are two pathways that states can use for adopting such an emission budget that applies to both affected EGUs and new sources. The EPA is providing a mass budget for each state that account for the state's mass CO_2 goal for affected EGUs and a complementary emission budget for new sources, referred to as the new source CO_2 emission complement. States that both adopt the EPA-provided mass budget, based on the state mass-based CO_2 goal for affected EGUs plus the new source CO_2 emission complement, and regulate new sources under this emission budget as a matter of state law, in conjunction with federally enforceable emission standards for affected EGUs as part of the mass-based state plan may be able to submit a presumptively approvable plan. Such a plan would include federally enforceable emission standards for affected EGUs, and in the supporting documentation of the plan, would describe that the state is regulating new sources under a mass CO_2 emission budget that is equal to or less than the state mass-based CO_2 goal for affected EGUs plus the EPA-specified CO_2 emission complement, in conjunction with the federally enforceable emission standards for affected EGUs. If the state plan is designed to achieve the EPA provided mass budget, plan performance will be evaluated based on whether the existing affected EGUs, regulated under the federally enforceable state plan, and new sources regulated as a matter of state law, together meet the total mass budget that includes the state's mass CO_2 goal for affected EGUs and a complementary emission budget for new sources.

EPA-specified mass CO_2 emission budgets for each state, including the state's mass CO_2 goal and a new source CO_2 emission complement, are provided in Table 14 below. The derivation of the new source CO_2 emission complements is explained in a TSD titled New Source Complements to Mass Goals, which is available in the docket.

Table 14. New Source Complements to Mass Goals

State	**New Source Complements (Short Tons of CO_2)**		**Mass Goals[918] + New Source Complements (Short Tons of CO_2)**	
	Interim	**Final**	**Interim**	**Final**
Alabama	856,524	755,700	63,066,812	57,636,174
Arizona	1,424,998	2,209,446	34,486,994	32,380,196
Arkansas	411,315	362,897	34,094,572	30,685,529
California	2,846,529	4,413,516	53,873,603	52,823,635
Colorado	1,239,916	1,922,478	34,627,799	31,822,874
Connecticut	135,410	119,470	7,373,274	7,060,993

States can, in the alternative, provide their own projections for a new source CO_2 emission complement to their mass-based CO_2 goals for affected EGUs. In the supporting documentation for the state plan submittal, the state must specify the new source budget, specify the analysis used to derive such a new source CO_2 emission complement, and the state must demonstrate that under the state plan affected EGUs in the state will meet the state mass-based CO_2 goal for affected EGUs as a result of being regulated under the broader CO_2 emission cap that applied to both affected EGUs and new sources. Such a projection should take into account the mass goal quantification method outlined in section VII.C and the CO_2 Emission Performance Rate and Goal Computation TSD, including the fact that the mass-based state goals already incorporate a significant growth in generation from historical levels. The EPA will evaluate the approvability of the plan based on whether the federally enforceable emission standards for affected EGUs in conjunction with the state-enforceable regulatory requirements for new sources will result in the affected EGUs meeting the state mass-based CO_2 goal. If, rather than designing a plan to achieve the EPA provided mass budget, the state uses its own projections for a new source complement and the plan is approved to meet this new source complement, plan performance will be evaluated based on whether the existing affected EGUs, regulated under the federally enforceable state plan, meet the state's mass CO_2 goal for affected EGUs.

The second demonstration option allows states to use allowance allocation methods that counteract incentives to shift generation from affected EGUs to unaffected fossil-fired sources. These allocation approaches must be specified in state plans as part of the provisions for state allocation of allowances required under a mass-based plan approach (see section VIII.J.2.a). The EPA is proposing the inclusion of two allocation strategies as part of the mass-based approach in the proposed federal plan and model rule: updating output-based allocations and an allowance set-aside that targets RE. These options are described in more detail below. If a state were to adopt allowance set-aside provisions exactly as they are outlined in the finalized model rule, they could be considered presumptively approvable. The allowance allocation alternative for addressing leakage was chosen for the federal plan and model rule proposal because EPA does not have authority to extend regulation of and federal enforceability to new fossil fuel-fired sources under CAA section 111(d), and therefore we cannot include them under a federal mass-based plan approach.

An updating output-based allocation method allocates a portion of the total CO_2 emission budget to affected EGUs based, in part, on their level of electricity generation in a recent period or periods. Therefore, the total allocation to an EGU that is eligible to receive allowances from an output-based allowance set-aside is not fixed, but instead depends on its generation. Under this approach, each eligible affected EGU may receive a larger allowance allocation if it generates more. Therefore, eligible affected EGUs will have an incentive to generate more in order to receive more allowances, aligning their incentive to generate with new sources.

This allocation method can be implemented through the creation of a set-aside that reserves a subset of the total allowances available to sources, and distributes them based upon the criteria described above. Because the total number of allowances is limited, this allocation approach will not exceed the overall state mass-based CO_2 goal for affected EGUs. Instead, it merely modifies the distribution of allowances in a manner designed to mitigate potential emission leakage.

The other allocation strategy included as part of the mass-based approach in the proposed federal plan and model rule is a set-aside of allowances to be allocated to providers of incremental RE. A set-aside can also be allocated to providers of demand-side EE, or to both RE and demand-side EE. The increased availability of RE generation can serve as another source of generation to satisfy electricity demand. Increased demand-side EE will reduce the demand that sources need to meet.

Therefore, both RE and demand-side EE can serve to reduce the incentive that new sources have to generate, and therefore align their incentives with affected EGUs. Thus, increased RE and demand-side EE, supported by a dedicated set-aside, can also serve to address potential emission leakage.

If a state is submitting a plan with an allocations approach that differs from that of the finalized model rule, the state should also provide a demonstration of how the specified allocation method will provide sufficient incentive to counteract potential emission leakage.

Finally, a state can provide a demonstration that emission leakage is unlikely to occur, without implementing either of the two strategies above, as a result of unique factors, such as the presence of existing state policies addressing emission leakage or unique characteristics of the state and its power sector that will mitigate the potential for emission leakage. This demonstration must be supported by credible analysis. The EPA will determine if the state has provided a sufficient demonstration that potential emission leakage has already been adequately addressed, or if additional action is required as part of the state plan.

Aside from the possible incentives for emission leakage addressed in this section, there may be other potential generation incentives across states and unit subcategories that could increase CO_2 emissions, particularly in an environment where various states are implementing a variety of state plan approaches in a shared grid region. Some examples of these incentives, particularly those that were specified by commenters, are discussed in section VIII.L. That section also describes how the EPA has structured this final rule to either prevent or minimize the potential for foregone emission reductions from differential incentives that may result from state plan implementation. These safeguards include placing restrictions on interstate trading when there could be a risk of such differential incentives. Additionally, the nature of the CO_2 emission performance rates and state rate-based CO_2 goals helps to minimize these potential effects, as does the MWh-accounting method for adjusting the CO_2 emission rates of affected EGUs under rate-based plans.

However, without a better understanding of the different mechanisms that states may ultimately choose to meet the emission guidelines, and how different requirements in different states may interact, the EPA cannot project every potential differential incentive that could lead to a loss of CO_2 emission reductions. Therefore, once program implementation begins, the EPA will assess how emission performance across states may be affected by the interaction of different regulatory structures implemented through state plans. Based upon that evaluation, the

EPA will determine whether there are potential concerns and what course of action may be appropriate to remedy such concerns.

c. Emission budget trading programs that ensure achievement of a state CO_2 goal. A mass-based emission budget trading program can be designed such that compliance by affected EGUs will achieve the state mass-based CO_2 goal. Under this approach, a state plan would establish CO_2 emission budgets for affected EGUs during the interim and final plan performance periods that are equal to or lower than the applicable state mass-based CO_2 goals specified in section VII. A mass-based emission budget trading program can also be designed such that compliance by affected EGUs in conjunction with new fossil fuel-fired EGUs meeting applicable requirements under state law will achieve a mass-based CO_2 goal plus new source CO_2 emission complement. Under this approach, a state would establish CO_2 emission budgets under state law for affected EGUs plus new sources during the interim and final plan performance periods that are equal to or lower than the applicable state mass-based CO_2 emission goal plus the new source CO_2 emission complement specified in Table 14 in section VIII.J.2.b above, and describe such emission budgets in the supporting documentation of the state plan. Under either program, compliance periods for affected EGUs (or for affected EGUs plus new fossil fuel-fired EGUs meeting applicable requirements under state law) would also be aligned with the interim and final plan performance periods. This approach would limit total CO_2 emissions from affected EGUs (or total CO_2 emissions from affected EGUs and new fossil fuel-fired EGUs meeting applicable requirements under state law) during the interim and final plan performance periods to an amount equal to or less than the state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement).

Under this approach, compliance by affected EGUs with the mass-based emission standards in a plan would ensure that the state achieves its mass-based CO_2 goal for affected EGUs (or mass-based CO_2 goal plus new source CO_2 emission complement). No further demonstration would be necessary by the state to demonstrate that its plan would achieve the state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement).

For this type of plan, where the emission budget is equal to or less than the state mass CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement),[919] the EPA would assess achievement of the state goal based on compliance by affected EGUs with the mass-based emission standards, rather than reported CO_2 emissions by affected EGUs during the interim plan

[919] As specified for the interim plan performance period (including specified levels in interim steps 1 through 3) and the final two-year plan performance periods.

performance periods and final plan performance periods. This approach would allow for allowance banking between performance periods, including the interim and final performance periods outlined in this final rule.

Banking provisions have been used extensively in rate-based environmental programs and mass-based emission budget trading programs. This is because banking reduces the cost of attaining the requirements of the regulation. The EPA has determined that the same rationale and outcomes apply under a CO_2 emission rate approach, in that allowing banking will reduce compliance costs. Banking encourages additional emission reductions in the near-term if economic to meet a long-term emission rate constraint, which is beneficial due to social preferences for environmental improvements sooner rather than later. It is also beneficial when addressing pollutants that are long-lived in the atmosphere, such as CO_2, and where increasing atmospheric concentration of the pollutant leads to increasing adverse atmospheric impacts.

Banking also provides long-term economic signals to affected emission sources and other market participants where actions taken today will have economic value in helping meet tighter emission constraints in the future, provided those emission sources expect that the banked ERCs or emission allowances may be used for compliance in the future. Linking short-term and long-term economic incentives, which allows owners or operators of affected EGUs and other market participants to assess both short-term and long-term incentives when making decisions about compliance approaches or emission reduction investments, reduces long-term compliance costs for affected EGUs and ratepayer impacts. In addition, the increased temporal flexibility provided by banking would further help address potential electric reliability concerns, as banked ERCs can be used to meet emission standard requirements for an affected EGU.

d. Addressing emission budget trading programs with broader source coverage and other flexibility features. As described in section VIII.C above, under the emission standards plan type, a mass-based emission budget trading program with broader source coverage and other flexibility features may be designed such that compliance by affected EGUs (or compliance by affected EGUs plus new fossil fuel-fired EGUs meeting applicable requirements under state law) would assure achievement of the applicable state mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement).[920]

However, emission budget trading programs, including those

[920] Section VIII.J.2.a describes how state plan submittals must include as requirements, or describe as part of supporting documentation, relevant aspects of such emission budget trading programs.

currently implemented by California and the RGGI participating states, include a number of different design elements that functionally expand the emission budget under certain circumstances. If a state chose, it could apply such mass-based emission standards, in the form of an emission budget trading program that differs in design from that outlined in section VIII.J.2.c above. These types of emission budget trading programs must be submitted as a part of a state measures plan type. Where an emission budget trading program addresses affected EGUs and other fossil fuel-fired EGUs, the requirements that must be included in the state plan are the federally enforceable emission standards in the state plan that apply specifically to affected EGUs, and the requirements that specifically require affected EGUs to participate in and comply with the requirements of the emission budget trading program. This includes the requirement for an affected EGU to surrender emission allowances equal to reported CO_2 emissions, and meet monitoring and reporting requirements for CO_2 emissions, among other requirements. These requirements may be submitted as part of the federally enforceable state plan through mechanisms with the appropriate legal authority and effect, such as state regulations, relevant Title V permit requirements for affected EGUs, and other possible instruments that impose these requirements specifically with respect to affected EGUs.[921] Under this approach, the full set of regulations establishing the emission budget trading program that applies to affected EGUs and other fossil fuel-fired EGUs and other mission sources (if relevant) must be described as supporting documentation in the state plan submittal. This structure is appropriate to ensure that states with an emission budget trading program that addresses both affected EGUs and other fossil fuel-fired EGUs do not inappropriately submit requirements regarding entities other than affected EGUs for inclusion in the federally enforceable state plan.

Such state programs could include a number of different design elements. This includes broader program scope, where a program includes other emission sources beyond affected EGUs subject to CAA section 111(d) and new fossil fuel-fired EGUs, such as industrial sources. Programs might also include design elements that make allowances available in addition to the established emission budget. This includes project-based offset allowances or credits from GHG emission reduction projects outside the covered sector and cost containment reserve

[921] This approach for establishing federally enforceable emission standards based on requirements for affected EGUs subject to a broader emission budget trading program that also covers non-affected emission sources is addressed in section VIII.J.2.d. above.

provisions that make additional allowances available at specified allowance prices.[922]

In the case where an emission budget trading program contains elements that functionally expand the emission budget in certain circumstances, compliance by affected EGUs with the mass-based emission standards would not necessarily ensure that CO_2 emissions from affected EGUs do not exceed the state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement). However, states could modify such programs to remove flexibility mechanisms that functionally expand the emission budget, such as out-of-sector offsets and certain cost containment reserve mechanisms, and submit the program under an emission standards plan type.

Where a state chooses to retain such flexibility mechanisms as part of an emission budget trading program, the program may only be implemented as part of a state measures plan type because these state flexibility mechanisms would not assure CO_2 emissions from affected EGUs do not exceed the state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2

[922] For example, both the California and RGGI programs allow for the use of allowances awarded to GHG offset projects to be used to meet a specified portion of an affected emission source's compliance obligation. The RGGI program contains a cost containment allowance reserve that makes available additional allowances up to a certain amount, at specified allowance price triggers.

emission complement). A description of the state measures plan type and related requirements is provided in section VIII.C.3.

Under this type of approach, the state would be required to include a demonstration,[923] in its state plan submittal, of how its plan would achieve the state mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement). This demonstration would include a projection of the total CO_2 emissions from the fleet of affected EGUs that would occur as a result of compliance with the emission standards in the plan. Section VIII.D.2 discusses how such demonstrations could address design elements of emission budget trading programs with broader scope and additional compliance flexibility mechanisms, such as those included in the California and RGGI programs. Once the plan is implemented, if the mass-based CO_2 goal is not achieved during a plan performance period, the backstop federally enforceable emission standards included in the state plan that apply to affected EGUs would be implemented, as described in section VIII.C.3.b.[924]

---

[923] A demonstration of how a plan will achieve a state's rate-based or mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) is one of the required plan components, as described in section VIII.D.2.

[924] Achievement of the state mass-based CO_2 goal would be determined based solely on stack CO_2 emissions from affected EGUs. Where a state program includes the ability of an affected emission source to use GHG offsets to meet a portion of its allowance compliance obligation, no "credit" is applied to

e. Considerations for mass-based emission budget trading programs. The EPA notes that while an emission budget trading program included in an emission standards plan must be designed to achieve a state mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement), states have wide discretion in the design of such programs, provided the emission standards included in the plan are quantifiable, verifiable, enforceable, non-duplicative, and permanent.

(1) Allowance allocation. A key example is state discretion in the CO_2 allowance allocation methods included in the program.[925] This includes the methods used to distribute CO_2 allowances and the parties to which allowances are distributed. For example, if a state chose, it could include CO_2 allowance allocation provisions that provide incentives for certain types of complementary activities, such as RE generation, that help achieve the overall CO_2 emission limit for affected EGUs established under the program. In addition, a state could use its allocation provisions to encourage investments in RE and

reported CO_2 emissions by the affected EGU. The use of offset allowances or credits in such programs merely allows an affected EGU to emit a ton of CO_2 in the amount of submitted offset allowances or credits. In all cases, there is no adjustment applied to reported stack emissions of CO_2 from an affected EGU when determining compliance with its emission limit.

[925] Allowance allocation refers to the methods used to distribute CO_2 allowances to the owners or operators of affected EGUs and/or other market participants.

demand-side EE in low-income communities. States could also use CO_2 allowance allocation provisions to provide incentives for early action, such as RE generation or demand-side EE savings that occur prior to the beginning of the interim plan performance period in 2022. For example, a state could include CO_2 allowance allocation provisions where CO_2 allowances are distributed to RE generators based on MWh of RE generation that occurs prior to 2022. Such provisions might be addressed through a finite set-aside of CO_2 allowances that are available for allocation under these provisions. This set-aside could be additional to a set-aside created by the state for the CEIP discussed in section VIII.B.2.

(2) Facility-level compliance. If a state chose, it could evaluate compliance (i.e., allowance true-up) under its emission budget trading program at the facility level, rather than at the individual unit level. The EPA has adopted facility-level compliance in the emission budget-trading programs it administers, including the Acid Rain Program (70 FR 25162), Clean Air Interstate Rule (70 FR 25162), and Cross-State Air Pollution Rule (76 FR 48208). Under this approach, states would still track reported unit-level CO_2 emissions – while evaluating compliance at the facility level – allowing them to track increases and decreases of CO_2 emissions at individual EGUs.

3. Multi-state coordination: mass-based emission trading

programs.

An individual state may provide for the use of CO_2 allowances issued by another state(s) for compliance with the mass-based emission standards in its plan. This type of state plan would include regulatory provisions that enable affected EGUs to use allowances issued in other states for compliance under the state's emission budget trading program. This type of state plan must also indicate how CO_2 allowances will be tracked from issuance through use for compliance, through either a joint tracking system, interoperable tracking systems, or use of an EPA-administered tracking system.[926]

Two different implementation approaches could be used to create such links. A state could submit a "ready-for-interstate-trading" plan using an EPA-approved tracking system, but the plan would not identify links with other states. A state could also submit a plan with specified bilateral or multilateral links that explicitly identify partner states.

Interstate allowance linkages would not affect the approvability of each state's individual plan. However,

---

[926] The emission standards in each individual state plan must include regulatory provisions that address the issuance of CO_2 allowances and tracking of CO_2 allowances from issuance through use for compliance. The description here addresses how those regulatory provisions will be implemented through the use of a joint tracking system, interoperable tracking systems, or an EPA-administered tracking system.

different considerations apply for the approvability of an individual plan with such links, based on whether the emission budget trading program in the plan applies only to affected EGUs or includes other emission sources, and if the plan is designed to meet a state mass-based CO_2 goal for affected EGUs only or to meet a mass-based CO_2 goal plus a new source CO_2 emission complement).

Under the first "ready-for-interstate-trading" implementation approach, a state would indicate in its state plan that its emission budget trading program will be administered using an EPA-approved (or EPA-administered) emission and allowance tracking system.[927] State plans using a specified EPA-approved tracking system would be deemed by the EPA as ready for interstate linkage upon approval of the state plan. No additional EPA approval would be necessary for states to link their emission budget trading programs, and affected EGUs in those states could engage in interstate trading subsequent to EPA plan approval.

A state would indicate in its plan submittal that its emission budget trading system will use a specified EPA-approved

[927] The EPA would designate tracking systems that it has determined adequately address the integrity elements necessary for the issuance and tracking of emission allowances. Under this approach, a state could include in its plan such a designated tracking system, which has already been reviewed by the EPA.

tracking system. The state would also indicate in the regulatory provisions for its emission budget trading program that it would recognize as usable for compliance any emission allowance issued by any other state with an EPA-approved state plan that also uses the specified EPA-approved tracking system.

States could also adopt such a collaborative emission trading approach over time (through appropriate state plan revisions if the plan is not already structured as ready-for-interstate-trading), without requiring all of the original participating states to revise their EPA-approved plans.

Under the second implementation approach, a state could specify the other states from which it would recognize issued emission allowances as usable for compliance with its emission budget trading program. The state would indicate in the regulatory provisions for its emission budget trading program that emission allowances issued in other identified partner states may be used by affected EGUs for compliance. Such plans must indicate how allowances will be tracked from issuance through use for compliance, through either a joint tracking system, interoperable tracking systems, or EPA-administered tracking system. The EPA would assess the design and functionality of this tracking system(s) when reviewing individual submitted state plans.

Under this approach, states could also join such a collaborative emission trading approach over time. However, all participating states would need to revise their EPA-approved plans. If the expanded linkage is among previously approved plans with mass-based emission standards, approval of the plan revision would be limited to assessing the functionality of the shared tracking system or interoperable tracking systems in order to maintain the integrity of the linked programs.[928]

a. Considerations for linked emission budget trading programs. For individually submitted plans, interstate emission allowance linkages would not affect the approvability of each state's plan. However, approvability of an individual linked plan would differ based on the structure of the emission budget trading program included in the plan. These differences for plan approvability address distinctions among programs that include only affected EGUs and programs that cover a broader set of emission sources, as well as if the plan is designed to meet a state mass-based CO_2 goal for affected EGUs only or to meet a mass-based CO_2 goal plus a new source CO_2 emission complement. Differences in approval criteria are necessary to ensure that each individual state plan demonstrates it will achieve a

[928] Depending on the specific regulatory provisions in the emission standards in their approved state plans, participating states may also need to revise their implementing regulations (and by extension their state plans) to accept CO_2 emission allowances issued by new partner states as usable for compliance with their mass-based emission standards.

state's mass-based CO_2 emission goal for affected EGUs (or mass-based CO_2 goal plus new source CO_2 emission complement). The accounting applied to individual plans to assess whether a state achieves its mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) will also differ, based on whether an emission budget trading program includes only affected EGUs (or affected EGUs and applicable new fossil fuel-fired EGUs) or a broader set of emission sources. These considerations are addressed below, for both types of emission budget trading programs.

(1) <u>Links among emission budget trading programs that only include affected EGUs</u> or affected EGUs and applicable new fossil fuel-fired EGUs. Where the emission budget trading programs in each plan apply only to affected EGUs subject to the final rule (or emission budget trading programs that apply to affected EGUs under the state plan and applicable new fossil fuel-fired EGUs under state law), and include compliance timeframes for affected EGUs that align with the interim and final plan performance periods, both plans would functionally be meeting an aggregated multi-state mass-based goal (or aggregated mass-based CO2 goal plus new source CO2 emission complement), but without formally aggregating the goal (or aggregated mass-based CO2 goal plus new source CO2 emission complement). CO2 emissions from affected EGUs in both states could not exceed the total combined CO2

emission budgets under the emission standards in the two states. A net "import" of CO2 allowances from one state would mean that allowable CO2 emissions in the other net "exporting" state are less than that state's established emission budget. On a multi-state basis, CO2 emissions from affected EGUs could not exceed the sum of the states' emission budgets.

Under this approach, if the emission budget for the mass-based emission standard in each plan is equal to or lower than the state's mass-based CO_2 goal (or aggregated mass-based CO_2 goal plus new source CO_2 emission complement, if applicable), compliance by affected EGUs with the mass emission standard in a state[929] would ensure that cumulatively the mass CO_2 goals (or mass-based CO_2 goals plus new source CO_2 emission complements) of the linked states are achieved. As a result, achievement of an individual state's mass CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) would be assessed by the EPA based on compliance by affected EGUs with the mass-based emission standards in the state plan, rather than reported CO_2 emissions by affected EGUs in the state.[930]

---

[929] Compliance by an affected EGU with the emission standard is demonstrated based on surrender to the state of a number of CO_2 allowances equal to its reported CO_2 emissions.
[930] This approach is warranted because under such linked programs, CO_2 emissions from affected EGUs in one state that exceed a state's mass CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) would be accompanied by CO_2

The same accounting approach will apply for such plans in all cases, even if the state is linked to another state emission budget trading program that includes a broader set of emission sources (e.g., sources beyond affected EGUs, or beyond affected EGUs plus applicable new fossil fuel-fired EGUs), as described below. In all cases, where a state plan includes an emission budget trading program that applies only to affected EGUs (or beyond affected EGUs plus applicable new fossil fuel-fired EGUs), and includes compliance timeframes that align with plan performance periods, achievement of a state mass CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) will be assessed by the EPA based on whether affected EGUs comply with the mass-based emission standard, rather than reported CO_2 emissions from affected EGUs.

(2) <u>Links with emission budget trading programs that include a broader set of emission sources</u>. State plans may involve emission budget trading programs that include affected EGUs, applicable new fossil fuel-fired EGUs if a plan includes a new source CO_2 emission complement, and other non-affected emission sources.[931]

---

emissions from affected EGUs in another linked state that are below that state's mass CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement).

[931] This may apply under both an emission standards plan and a state measures plan. Section VIII.J.2.a describes how state plan

Generally, such plans must demonstrate that the mass-based CO_2 goal for affected EGUs (or mass-based CO_2 goal plus new source CO_2 emission complement) in a state will be achieved, as a result of implementation of the emission budget trading program.[932] Where a program includes other non-affected emission sources (i.e., non-affected emission sources that are not subject to a new source CO_2 emission complement) and is linked with other programs,[933] the state plan submittal must include a demonstration that the mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) will be achieved, considering the emission allowance links with other programs. The EPA, in determining the approvability of each state's plan under this approach, would evaluate the linkages between plans. Specifically, the EPA would evaluate whether the linkages would

submissions must include as requirements, or describe as part of supporting documentation, relevant aspects of such emission budget trading programs.

932 Under a program that applies to affected EGUs and other emission sources, compliance by affected EGUs with the emission standard – a requirement to surrender emission allowances equal to reported emissions – will not assure that a state's CO_2 mass goal (or mass-based CO_2 goal plus new source CO_2 emission complement) is achieved. As a result, a further demonstration is required in the plan that compliance by affected EGUs with the program will result in CO_2 emissions from affected EGUs that are at or below a state's CO_2 mass goal (or mass-based CO_2 goal plus new source CO_2 emission complement).

933 Section VIII.J.2.a describes how state plan submittals must include as requirements, or describe as part of supporting documentation, relevant aspects of such emission budget trading programs.

enable the affected EGUs (or affected EGUs in conjunction with applicable new fossil fuel-fired EGUs) in each participating state to meet the state's applicable mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement).

During plan implementation, the EPA would assess whether the affected EGUs in a state achieved the state's mass-based CO_2 goal (or mass-based CO_2 goal plus new source CO_2 emission complement) as follows. Reported CO_2 emissions from affected EGUs under such plans must be at or below a state's mass-based CO_2 emission goal (or mass-based CO_2 goal plus new source CO_2 emission complement) during an identified plan performance period, with the following state accounting adjustments for net "import" and net "export" of CO_2 allowances:

- <u>Net "imports" of CO_2 allowances</u>: Reported CO_2 emissions from affected EGUs in a state may exceed the state CO_2 mass goal (or mass-based CO_2 goal plus new source CO_2 emission complement) during an identified plan performance period in the amount of an adjustment for the net "imported" CO_2 allowances during the plan performance period. The adjustment represents the CO_2 emissions (in tons) equal to the number of net "imported" CO_2 allowances.[934] Under this adjustment, such allowances must be issued by a state with

[934] Net "imports" and "exports" of CO_2 allowances are defined and explained below.

an emission budget trading program that only applies to affected EGUs (or affected EGUs plus applicable new fossil fuel-fired EGUs). Net "imports" of allowances are determined through review of tracking system compliance accounts.

- <u>Net "exports" of CO_2 allowances</u>: Reported CO_2 emissions from affected EGUs in a state during an identified plan performance period must be equal to or less than the CO_2 mass goal (or mass-based CO_2 goal plus new source CO_2 emission complement) minus an adjustment for the "exported" CO_2 allowances during the plan performance period. The adjustment represents CO_2 emissions (in tons) equal to the number of net "exported" CO_2 allowances. Net "exports" of allowances are determined through review of tracking system compliance accounts.

Where CO_2 emissions from affected EGUs exceed these levels (based on reported CO_2 emissions with applied plus or minus adjustments for net CO_2 allowance "imports" or "exports") over the 8-year interim period or during any final plan reporting period, or by 10 percent or more during the interim step 1 or step 2 periods, a state would be considered to, in the case of the interim and final periods, not have met its CO_2 mass goal during an identified plan performance period, and in the case of the interim step periods, to not be on course to meet the final goal. As a result, under a state measures state plan, implementation of the backstop federally enforceable emission standards for affected EGUs in the state plan would be triggered.

A net transfer of CO_2 allowances during a plan performance period represents the net number of CO_2 allowances (issued by a respective state) that are transferred from the compliance accounts of affected EGUs in that state to the compliance accounts of affected EGUs in another state.[935] This net transfer is determined based on compliance account holdings at the end of the plan performance period.[936] For example, assume two states, State A and State B, with emission budgets of 1,000 tons of CO_2.

---

[935] A net transfer metric is applied as of the end of the plan performance period. This net accounting as of a specified date is necessary because multiple individual allowance transfers may occur among accounts during a plan performance period, representing normal trading activity. In addition, net transfers are based on compliance account holdings, because these represent the CO_2 allowances directly available at that point in time for use by an affected EGU for complying with its emission limit. Emission budget trading programs typically allow non-affected entities to hold allowances in general accounts. These parties are free to hold and trade CO_2 allowances, providing market liquidity. General account holdings are not assessed as part of a periodic state net transfer accounting, as these allowances may subsequently be transferred to other accounts in multiple states and do not represent allowances currently held by an affected EGU that can be used for complying with its emission limit.

[936] Compliance account holdings, as used here, refer to the number of CO_2 allowances surrendered for compliance during a plan performance period, as well as any remaining CO_2 allowances held in a compliance account as of the end of a plan performance period.

Each state issues 1,000 CO_2 allowances. At the end of a plan performance period, affected EGUs in State A collectively hold 500 CO_2 allowances in their compliance accounts that were issued by State A. Affected EGUs in State B collectively hold in their compliance accounts 500 CO_2 allowances issued by State A and 1,000 CO_2 allowances issued by State B. In this simplified example, a net transfer of 500 CO_2 allowances has occurred between State A and State B. State A has "exported" 500 CO_2 allowances to State B, while State B has "imported" 500 CO_2 allowances from state A.

K. Additional Considerations and Requirements for Rate-Based State Plans

This section discusses considerations and requirements for rate-based state plans. This section discusses eligibility, accounting, and quantification and verification requirements (EM&V) for the use of CO_2 emission reduction measures that provide substitute generation for affected EGUs or avoid the need for generation from affected EGUs in rate-based state plans. These measures may be used to adjust the CO_2 emission rate of an affected EGU under a rate-based state plan. This adjustment may occur when an affected EGU is demonstrating compliance with a rate-based emission standard, or when a state is demonstrating achievement of the CO_2 emission performance rates or applicable rate-based state CO_2 emission goal in the emission guidelines. This section also discusses requirements for state plans that include rate-based emission trading programs, including approaches and requirements for coordination among such programs where states retain individual state rate-based CO_2 emission goals.

1. Adjustments to CO_2 emission rates in rate-based state plans

Section VIII.K.1.a below describes the basic accounting method for adjusting a CO_2 emission rate, as well as eligibility requirements for measures that may be used for adjusting a CO_2 emission rate. Section VIII.K.1.b addresses measures that may not be used to adjust the CO_2 emission rate of an affected EGU in a state plan, and explains the basis for this exclusion. Section VIII.K.1.c addresses measures that reduce CO_2 emissions outside the electric power sector. Such measures may not be counted under either a rate-based or mass-based state plan.

a. <u>Measures taken to adjust the CO_2 emission rate of an affected EGU</u>. This section describes how measures that substitute for generation from affected EGUs or avoid the need for generation from affected EGUs may be used in a state plan to adjust the CO_2 emission rate of an affected EGU. This section discusses the required accounting method for adjusting a CO_2 emission rate, as well as general eligibility requirements that apply to different categories of measures that may be used to adjust a CO_2 emission rate. Where relevant, this section also discusses additional specific accounting methods and other relevant requirements that apply to different categories of measures.

A CO_2 emission rate adjustment may be applied in different rate-based state plan contexts. For example, in a rate-based emission trading program, adjustments may be applied through the use of ERCs.[937] Regardless of the type of plan in which an adjustment is applied, the same basic accounting and general eligibility requirements described in this section will apply.

As discussed in this section, a wide range of actions may be taken to adjust the reported CO_2 emission rate of an affected EGU in order to meet a rate-based emission standard and/or demonstrate achievement of a state CO_2 rate-based emissions goal. All of the measures described in this section will substitute for generation from affected EGUs or avoid the need for generation from affected EGUs, thereby reducing CO_2 emissions. This includes RE measures included in the EPA's determination of the BSER, as well as other measures that were not included in the determination of the BSER, such as other RE resources, demand-side EE, CHP, WHP, electricity transmission and

[937] ERCs may be issued for the measures presented in this section, as well as to affected EGUs that emit at a CO_2 emission rate below their assigned emission rate limit. ERC issuance and trading is discussed in detail in section VIII.K.2. That section addresses the accounting method for ERC issuance to affected EGUs that perform below their assigned CO_2 emission rate.

distribution improvements, nuclear energy, and international RE imports connected to the grid in the contiguous U.S., as discussed elsewhere in this preamble.

The EPA believes that the broad categories of measures listed in this section address the wide range of actions that are available to reduce CO_2 emissions from affected EGUs under a rate-based state plan. However, the actions that a state could include in a rate-based state plan are not necessarily limited to those described in this section. Other specific actions not listed here may be incorporated in a state plan, provided they meet the general eligibility requirements listed in this section, as well as the other relevant requirements in the emission guidelines.[938] Nor are states required to include in their plans all of the actions that are described in this section.

This section discusses the basic accounting method for adjusting the reported CO_2 emission rate of an affected EGU, through the use of measures that substitute for or avoid generation from affected EGUs. That method is based on adding MWh from such measures to the denominator of an affected EGU's reported CO_2 emission rate (lb CO_2/MWh). Those additional MWh are based on quantified and verified electricity generation or

[938] These requirements are discussed in section VIII.D.

electricity savings from eligible measures, and in the case of an affected EGU's compliance with its emission standard, are reflected in ERCs. This section also addresses eligibility requirements for resources that are used to adjust an affected EGU's CO_2 emission rate.

(1) General accounting approach for adjusting a CO_2 emission rate.

In this final rule, the reported CO_2 emission rate of an affected EGU may be adjusted based on quantified and verified MWh from qualifying zero-emitting and low-emitting resources, as described in sections VIII.K.1.a.(2)-(10) below. These MWh are added to the denominator of an affected EGU's reported CO_2 emission rate, resulting in a lower adjusted CO_2 emission rate.

The measures described in these sections reduce mass CO_2 emissions from affected EGUs by substituting zero- or low-emitting generation for generation from affected EGUs, or by avoiding the need for generation altogether (in the case of resources that lower electricity demand through improved demand-side EE and DSM). In both of these cases, generation from an affected EGU is replaced, through substitute generation or a reduction in electricity demand. To the extent that qualifying zero-emitting and low-emitting resources result in reduced generation and CO_2 emissions from an individual affected EGU, those emission impacts are reflected in lower reported CO_2

emissions and a reduction in MWh generation from the affected EGU. However, while there will be a reduction in CO_2 emissions at the affected EGU, the fact that both CO_2 emissions and MWh generation are reduced means that such impacts do not alter the reported CO_2 emission rate of the affected EGU. As a result, the MWh of replacement generation must be added to the denominator of the reported CO_2 emission rate in order to represent those impacts in the form of an adjusted CO_2 emission rate. In this manner, adding MWh from these resources to the denominator of an affected EGU's CO_2 emission rate allows mass CO_2 emission reductions from these measures to be fully reflected in an adjusted CO_2 emission rate.

The following provides a simple calculation example of how MWh of replacement generation added to the denominator of an affected EGU's reported CO_2 emission rate results in a lower adjusted CO_2 emission rate. Assume an affected EGU with CO_2 emissions of 200,000 lb and electric generation of 100 MWh during a reporting period. The affected EGU's reported CO_2 emission rate is 2,000 lb/MWh (200,000 lb CO_2/100 MWh = 2,000 lb/MWh). When complying with its rate-based emission limit, the affected EGU submits 10 ERCs, representing 10 MWh of replacement generation.[939] Adding 10 MWh of replacement generation to the reported MWh generation of the affected EGU results in an adjusted CO_2 emission rate of 1,818 lb CO_2/MWh (200,000 lb CO_2/110 MWh = 1,818 lb CO_2/MWh).

In the case of rate-based CO_2 emission standards, an affected EGU demonstrates compliance with the emission standards if the affected EGU's adjusted CO_2 emission rate calculated in the aforementioned manner is less than or equal to the applicable CO_2 emission standard rate.[940] The CO_2 emission performance rates or rate-based CO_2 goal in the emission guidelines are met if the adjusted CO_2 emission rate of affected EGUs in a state is at or below the specified CO_2 emission rate in a state plan that applies for an identified plan performance period.

Numerous commenters requested that the EPA ensure consistency between goal-setting calculations and the methodology used to demonstrate achievement of a CO_2 emission rate under a state plan. This approach for adjusting a CO_2 emission rate corresponds with how RE, the one component of the BSER that involves adjustment of a CO_2 emission rate, is

[939] Requirements for the issuance of ERCs and a further discussion of how ERCs are used in compliance with rate-based emission limits are addressed in section VIII.K.2.

[940] Any ERCs used to adjust a CO_2 emission rate must meet requirements in the emission guidelines.

represented in the CO_2 emission performance rates in the emission guidelines. Specifically, in the calculation of final CO_2 emission performance rates, the MWhs of RE are reflected in two adjustments of the rate: a reduction of CO_2 emissions from affected EGUs in the numerator and a one-to-one replacement of affected EGU generation in the denominator, where it is assumed that replaced generation from an affected EGU is subtracted from the denominator and the same number of zero-emitting MWh are added.[941]

When demonstrating achievement of a CO_2 emission performance rate, the reported CO_2 emissions already reflect the actual emission reductions from the deployment of qualifying zero-emitting and low-emitting resources across the regional grid; a further adjustment of CO_2 emissions would double count CO_2 emissions impacts across the grid. Consistent with the EPA's calculation of the CO_2 emission performance rates and state rate-based CO_2 goals in the emission guidelines, the zero-emitting MWhs (from substitute generation or a reduction in electricity demand) must still be added to the denominator of a reported CO_2 emission rate to calculate an adjusted CO_2 emission rate that appropriately reflects the replaced generation. Thus, the resultant rate, where the numerator reflects CO_2 emission

[941] For a detailed discussion of this method, see Section VI.C.3. Form of the Performance Rates, in the Equation section.

reductions from qualifying measures, and the denominator reflects replaced generation, is consistent with the goal-setting calculation.

Several commenters suggested that the EPA consider the regional nature of the electricity grid and how RE and demand-side EE impacts generation and CO_2 emissions across the grid when accounting for the impacts of RE and demand-side EE measures in a rate-based plan approach. This MWh accounting structure corresponds with the regional treatment of RE resources in the BSER that provide substitute generation in the EPA-calculated CO_2 emission performance rates in the emission guidelines. Consistent with assumptions used in calculating the CO_2 emission performance rates in the emission guidelines, affected EGUs and states can take full credit for the MWh resulting from eligible measures they are responsible for deploying, no matter where those measures are implemented. CO_2 emission reductions from the eligible measures may occur across the region; however, an affected EGU or a state may only take credit for avoided CO_2 emissions at that affected EGU or set of EGUs in question, as reflected in the reported stack CO_2 emissions of affected EGUs.

Because of the separate accounting of MWhs and CO_2 emissions, with emission impacts inherent in reported stack CO_2 emissions and zero-emitting MWh impacts requiring explicit adjustments, the accounting method corresponds with the use of

MWh-denominated ERCs in the rate-based emission trading framework specified in this rule. The accounting method only requires a quantification of the MWh generated or avoided by an eligible measure, and thus credits or adjustments can be denominated in MWh and do not need to represent an approximation of the CO_2 emission reductions that result from those MWhs. This creates a crediting system or rate adjustment process that is simpler to implement than one that requires an approximation of avoided CO_2 emissions.

The MWh accounting method also creates a crediting system or rate adjustment process that is indifferent to the rate-based CO_2 emission goals of individual states, or the specific CO_2 emission rate standards that states may apply, and the relative stringency of those goals or standards. Use of ERCs in rate-based emission trading programs is addressed in detail in section VIII.K.2. As a result, the MWh accounting method addresses interstate effects, because it inherently accounts for how generation replacement and CO_2 emission reduction impacts may cross state borders. For example, if the accounting method was informed by avoided CO_2 emission rates, it could create perverse incentives for development of zero- or low-emitting resources in states that result in the greatest calculated estimate of CO_2 emission reductions for each replacement MWh. Instead, this accounting method is indifferent to avoided CO_2 emission rates and creates the same number of zero-emitting credits or adjustment for each MWh of energy generation or savings, wherever they occur. For a detailed discussion on how the accounting method addresses interstate effects, see section VIII.L.

(2) General eligibility requirements for resources used to adjust a CO_2 emission rate.

The EPA is finalizing certain general eligibility requirements for resources used to adjust a CO_2 emission rate. These requirements align eligibility with certain factors and assumptions used in establishing the BSER, and by extension, application of the BSER to the performance levels established for affected EGUs in the emission guidelines, as well as state rate and mass CO_2 goals. As a result, the requirements ensure that measures that may be used in a state plan are treated consistently (to the extent possible) with the EPA's assessment of the BSER.[942] These general requirements also address potential interactions among rate and mass plans, as discussed more fully in section VIII.L.

As discussed in the sections that follow, the general

[942] For example, eligibility requirements include installation dates for eligible RE measures that may be used in a state plan. These dates generally align with the dates used for broadly defining incremental RE resources that were considered in establishing the BSER.

eligibility criteria address:

- the date from which eligible measures may be installed (e.g., installation of RE generating capacity and installation of EE measures);
- the date from which MWh from eligible measures may be counted, and applied toward adjusting a CO_2 rate; and
- the need to demonstrate that eligible measures replace or avoid generation from affected EGUs.

(a) <u>Eligibility date for installation of RE/EE and other measures and MWh generation and savings</u>.

Incremental emission reduction measures, such as RE and demand-side EE, can be recognized as part of state plans, but only for the emission reductions they provide during a plan performance period. Specifically, this means that measures installed in any year after 2012 are considered eligible measures under this final rule, but only the quantified and verified MWh of electricity generation or electricity savings that they produce in 2022 and future years, may be applied toward adjusting a CO_2 emission rate. For example, MWh generation in 2022 from a wind turbine installed in 2013 may be applied toward adjusting a CO_2 emission rate. This 2012 date applies to all eligible measures that are used to adjust a CO_2 emission rate under a state plan. For example, eligible measures, such as CHP, nuclear power and DSM, also must be installed after 2012, but only their generation or savings produced in 2022 and after can be used to adjust a CO_2 emission rate.

As discussed in section VIII.C.2.a, a MWh of generation or savings that occurs in 2022 or a subsequent year may be carried forward (or "banked") and applied in a future year. For example, a MWh of RE generation that occurs in 2022 may be applied to adjust a CO_2 emission rate in 2023 or future years, without limitation.[943] These MWh may be banked from the interim to final periods.

This eligibility date criterion is consistent with the date of installation for "incremental" RE capacity that is included in the BSER building block 3, which is the basis for RE MWh incorporated in the CO_2 emission performance rates for affected EGUs in the emission guidelines. For more information on RE in the BSER, see section V.E.

Many commenters asserted that proposed state goals did not sufficiently account for actions states take that reduce CO_2 emissions prior to the first plan performance period, and therefore requested that MWhs of electricity generation or electricity savings that occur prior to the first plan performance period be eligible to apply toward adjusting the CO_2

[943] Similarly, as discussed in section VIII.C.2.b.(2).(a), allowances may be banked in a mass-based trading program.

emission rates of affected EGUs. The EPA recognizes the importance of early state action as the basis for significant CO_2 emission reductions and as a key part of enabling state plans to achieve the CO_2 emission performance levels or state CO_2 goals. The ability to count eligible measures installed in 2013 and subsequent years for the MWhs they generate during a plan performance period provides significant recognition for early action, corresponding with the BSER framework that is based on cost-effective actions that many sources are already doing, while still conforming to CO_2 performance rates and state goals that are forward-looking. In order to provide additional incentives for early investment in RE and demand-side EE, the EPA is also establishing the CEIP, as discussed in section VIII.B.2. ERCs distributed by states and the EPA through this program may also be used by affected EGUs to demonstrate compliance with an emission standard, and may be banked from the interim to final periods.

Commenters concerns about treatment of early actions are further addressed by changes from proposal to the BSER assumptions and the methodology used by the EPA to establish the CO_2 emission performance levels and rate-based state CO_2 goals in the emission guidelines. The specifics of these changes are addressed in section V.A.3. Three examples of those changes are provided below.

First, affected EGUs that have maximized their CO_2 emission reduction opportunities available through early action will be better positioned to meet the BSER CO_2 emission performance rates or state goal applied to affected EGUs in their state. For example, a steam generating unit that has already reduced its CO_2 emission rate through a heat rate improvement may have a CO_2 emission rate of 2,000 lb/MWh whereas its rate was 2,100 lb/MWh prior to the improvement. Therefore, it has less distance to cover to meet its CO_2 emission performance rate.

Second, generation from existing RE capacity installed prior to 2013 has been excluded from the EPA's calculation of the CO_2 emission performances rates in the emission guidelines. That RE generating capacity will still provide zero-emitting generation to the grid meeting demand that will not need to be addressed by existing affected EGUs and will better position states and affected EGUs to meet the CO_2 performances rates or state rate- or mass-based CO_2 goals.

Third, commenters expressed concern that demand-side EE targets as part of proposed state goals reflected an assumption of installation of increased EE measures starting in 2017, which seemed to be an implicit requirement to take action prior to the performance period. Because demand-side EE is not used in calculating the CO_2 emission performance rates in the final emission guidelines, this is no longer a concern. Furthermore, eligible demand-side EE actions that occur after 2012 can be applied toward adjusting the CO_2 emission rates of affected EGUs, providing a significant compliance option that is not assumed in emission performance rates or state goals.

(b) Demonstration that measures substitute for grid generation.

Eligible measures must be grid-connected. This eligibility criterion aligns with RE generation in building block 3 of the BSER, which substitutes for the need for generation from affected EGUs.

All EE measures must result in electricity savings at a building, facility, or other end-use location that is connected to the electricity grid. EE measures only avoid electric generation from grid-connected EGUs if the electrical loads where the efficiency improvements are made are interconnected to the grid.

Commenters sought clarity on this issue, so the EPA is providing this requirement as part of the final rule. Some commenters advocated for the inclusion of measures that were not grid connected as eligible resources, arguing that some of these measures substituted for non-affected EGUs and resulted in reductions in CO_2 emissions. However, eligible measures must be able to substitute for generation from affected EGUs as defined under this rule, and thus must be tied to the electrical grid.

(c) Geographic eligibility.

All eligible emission reduction measures, including RE generation and demand-side EE, may occur in any state, with certain limitations, as described below. To the extent these measures are tied to a state plan,[944] these measures may be used to adjust a CO_2 emission rate, regardless of whether the associated generation or electricity savings occur inside or outside the state.[945] This approach is generally consistent with the approach used in building block 3 of the BSER, which reflects regionally available RE. It also recognizes that emission reduction measures have impacts on electricity generation across the electricity system, both within and beyond a state's borders. A more in-depth discussion of the basis for treatment of in-state and out-of-state measures is provided in section VIII.L.

State plans must demonstrate that emission standards and

[944] As used here, a measure is "tied to a state plan" if it is issued an ERC under approved procedures in a rate-based emission standards plan or represents quantified and verified MWh energy generation or energy savings achieved by an approved state measure in a state measures plan.

[945] For example, under a rate-based emission standard with credit trading, ERCs may be issued for qualifying actions that occur both inside and outside the state, provided the measures meet requirements of EPA-approved state regulations and the provider applies to the state for the issuance of ERCs. Similarly, under a state measures plan, a state might include state requirements such as an RPS, where compliance with the RPS can be met through out-of-state RE generation.

state measures (if applicable) are non-duplicative. Given the geographic eligibility approach described here, this includes a demonstration that a state plan does not allow recognition of a MWh, for use in adjusting the CO_2 emission rate of an affected EGU, if the MWh is being or has been used for such a purpose under another state plan. Discussion of how such a demonstration can be made in the context of a rate-based emission trading program is in section VIII.D.2.b.

The EPA received many comments on the treatment of in-state and out-of-state RE and demand-side EE. Most commenters recommended crediting of both in-state and out-of-state RE and demand-side EE measures, similar to the final rule approach for eligible emission reductions measures. Commenters argued that this approach makes sense based on the nature of the interconnected electricity grid and allows states and utilities to fully account for their RE and demand-side EE efforts, whether that RE or EE, and its related impacts, occurs inside or outside of their state. Some commenters expressed concerns that, at proposal, states with significant RE resources had large amounts of existing RE capacity included in their state CO_2 goals, but that RE was functionally credited to other states for use in meeting their goals because it was associated with measures (such as an RPS) likely to be included in another state's plan. This concern has been addressed through changes in the BSER RE assumptions in the final rule. This includes regionalization of the RE building block, and removal of existing RE capacity constructed prior to 2012 from the building block. The result of these changes is that the RE incorporated in the BSER is more equally shared across states.

(i) Measures that occur in states with mass-based plans.

As discussed above, eligible measures for adjusting the CO_2 emission rate of an affected EGU may occur in any state, with certain conditions. This includes a condition that applies to eligible measures that occur in a state with an EPA-approved plan that is meeting a state mass-based CO_2 goal. Eligible measures that could be used to adjust a CO_2 emission rate under a rate-based state plan which are located in a state with a mass-based plan are restricted from being counted under another state's rate-based plan. An exception is made for RE measures that occur in such mass-based states, because of its unique role in BSER. RE measures must meet additional eligibility criteria in order to be used to adjust the CO_2 emission rate of an affected EGU in a state with a rate-based plan. This exception only applies to RE; other emission reduction measures that were not included in the determination of the BSER located in mass-based states, including demand-side EE, are restricted from ERC issuance in rate-based states.

These criteria are intended to address the fact that eligible measures should lead to substitution of generation from affected EGUs, with related impacts on CO_2 emissions from affected EGUs. Where states with mass-based plans implement mass-based CO_2 emission standards, CO_2 emissions reductions from affected EGUs must occur in order to comply with these emission standards and, unlike the rate-based approach, zero- and low-emitting MWhs do not play a specified role in demonstrating that the mass-based standards have been met.[946] Since they are not counted in the mass-based demonstration, eligible measures located in mass-based states could be used in a state with a rate-based plan to adjust the CO_2 emission rate of affected EGUs. Such adjustments would obviate the need for comparable CO_2 emission reductions at affected EGUs in the rate-based state or the use of other measures to make a rate adjustment. In this scenario, to the extent that eligible measures substitute solely for generation from affected EGUs in a state with mass-based emission limits, and are also used to adjust the reported CO_2 emission rate of affected EGUs in a rate-based state, no incremental CO_2 emissions reductions would occur in the rate-based state as a result of the eligible measures.[947] The result

---

[946] Where such measures substitute for generation from affected EGUs subject to a mass CO_2 emission limit, such measures reduce the cost of meeting those mass emission limits, but do not result in incremental CO_2 emission reductions.
[947] As used here, incremental emission reductions refers to

would be forgone CO_2 emission reductions that would otherwise occur across the two states. These dynamics are further addressed in section VIII.L.

For RE measures located in a mass-based state to have some or all of its generation counted under a rate-based plan in another state, it must be demonstrated that the generation was delivered to the grid to meet electricity load in a state with a rate-based plan.[948] Some examples of documentation that can serve as a demonstration include a power delivery contract or power purchase agreement. The EPA is giving states flexibility regarding the nature of this demonstration, but a state plan must describe the nature of the required demonstration and have it be approved by the EPA.

Under an emission standards plan, this demonstration must be made by the provider of the RE measure seeking ERC issuance under the rate-based emission standards in a rate-based state, as part of the eligibility application for the measure.[949] The rate-based state must include in its state plan provisions that describe a sufficient demonstration of geographic eligibility

emission reductions that are above and beyond what would be achieved solely through compliance with the emission standards in the mass-based state.

[948] This does not need to necessarily be the state where the MWh of energy generation from the measure is used to adjust the CO_2 emission rate of an affected EGU.

[949] Requirements for ERC issuance are addressed in section VIII.K.2.

for the RE generation under rate-based emission standards.

Further examples of eligible demonstrations and how they should be outlined in state plans are provided in section VIII.L.

(ii) Measures that occur in states, including areas of Indian country, that do not have affected EGUs.

States, including areas of Indian country, that do not have any affected EGUs within their borders may be providers of credits for generation from zero- or low-emitting resources to adjust CO_2 emission rates. In its supplemental proposal for the proposed rulemaking, the EPA sought comment on whether or not jurisdictions without affected fossil fuel generation units subject to the proposed emission guidelines should be authorized to participate in state plans. Commenters were supportive of allowing those jurisdictions without affected EGUs the opportunity to participate in state plans. CO_2 reduction measures in areas without affected EGUs have the potential to provide cost-effective opportunities to reduce emissions and should be available on a voluntary basis to affected EGUs. Commenters noted that some tribes, for example, have many untapped RE resources that could be developed, and they should be able to realize the benefits of contributing to a state plan. Commenters stated that because of the integrated nature of the U.S. electricity grid, it is appropriate to allow all jurisdictions with the ability to contribute to and benefit from CO_2 emission reductions or CO_2 emission rate adjustments.

For participating states, they must adhere to EM&V standards, installation dates, and any other criteria that apply to all states. Section VIII.K.3 below identifies and discusses the EM&V requirements used to quantify MWh savings from generation from zero- or low-emitting sources.

States, including areas of Indian country, that do not have any affected EGUs may provide ERCs to adjust CO_2 emissions provided they are connected to the contiguous U.S. grid and meet the other requirements for eligibility. To qualify for ERCs from zero or low-emitting resources, it must be demonstrated that the generation was delivered to the grid to meet electricity load in a state with a rate-based plan.[950] Some examples of documentation that can serve as a demonstration include a power delivery contract or power purchase agreement. The EPA is giving states flexibility regarding the nature of this demonstration, but a state plan must describe the nature of the required demonstration and have it be approved by the EPA.

In addition to generation from zero- or low-emitting resources, demand-side EE resources in areas of Indian country

[950] This does not need to necessarily be the state where the MWh of energy generation from the measure is used to adjust the CO_2 emission rate of an affected EGU.

located within the borders of states with rate-based emission standards for affected EGUs may also be issued ERCs. In these instances, the area of Indian country is located within the rate-based service area subject to a rate-based state plan. The ERCs from demand-side EE resources must meet the eligibility requirements to adjust a CO_2 emission rate, including installation date and EM&V requirements described below in section VIII.K.3. If the area of Indian country is located within the borders of a state that is meeting a mass-based CO_2 goal, then the demand-side EE resources are not eligible to be issued ERCs. Similarly, demand-side EE resources in any state with a mass-based CO_2 goal are not eligible to provide ERCs.

Non-contiguous states and territories may not be providers of ERCs to the contiguous U.S. states. As discussed previously in section VII.F, we have not set CO_2 emission performance goals for Alaska, Hawaii, Guam, or Puerto Rico in this final rule at this time.

(iii) Measures that occur outside the U.S.

The EPA will work with states using the rate-based approach that are interested in allowing the use of RE from outside the U.S. to adjust CO_2 emission rates. In these cases, all conditions for creditable domestic RE must be met, including that RE resources must be incremental and installed after 2012, and all EM&V standards must be met. In addition, the country generating the ERCs must be connected to the U.S. grid, and there must be a power purchase agreement or other contract for delivery of the power with an entity in the U.S. RE generation capacity outside the U.S. that existed prior to 2012 but was not exported to the U.S. is not considered new or incremental generation and, therefore, not eligible for adjusting CO_2 emission rates under this rule. For example, a new transmission interconnection to existing RE in Canada would not be considered incremental, but a new interconnection to RE where the RE was built after 2012 would be considered incremental. See below in section VIII.K.1.a.(3) for more specifics regarding the use of incremental hydroelectric power in a rate-based approach.

The EPA received comments encouraging the use of international zero-emitting electricity imports in state plans, particularly hydroelectric power from Canada. Canada currently provides states such as Minnesota and Wisconsin with RE through existing grid connections. New projects are in various stages of development to increase generating capacity, which could be called upon as a base load resource to supplement variable forms of RE generation. Commenters said that the EPA should permit the use of all incremental hydropower—both domestic and international—towards EGU CO_2 emission rate adjustments providing that double-counting can be prevented; and the EPA acknowledges this may be allowable, as long as the specified criteria have been met.

(3) RE.

RE measures may be used to adjust a CO_2 emission rate, provided they meet the general eligibility requirements outlined above and the MWh electricity generation is properly quantified and verified.[951] As used in this section, RE includes electric generating technologies using RE resources, such as wind, solar, geothermal, hydropower, biomass and wave and tidal power. A capacity uprate at an existing RE facility (i.e., an uprate to generating capacity originally installed as of 2012 or earlier) is eligible to adjust a CO_2 emission rate. The capacity uprate must occur after 2012. Such uprates to capacity represent incremental capacity added after 2012.

Quantification and accounting criteria for incremental RE (and nuclear generation) are as follows. The incremental generating capacity (in nameplate MW) is divided by the total uprated generating capacity (in nameplate MW) and then multiplied by generation output (in MWh) from the uprated generator. For example, if a hydroelectric power plant expands generating nameplate capacity from 100 MW to 125 MW and generation output

[951] All state plans must demonstrate that measures included in the plan are quantifiable and verifiable. See section VIII.K.2 for discussion of requirements for the issuance of ERCs, and section VIII.K.3 for discussion of EM&V requirements for use of RE relied on in a state plan.

increased to 1,000 MWh, then 200 MWh ((25 MW/125 MW) * 1,000 MWh) is eligible for use in adjusting a CO_2 emission rate, regardless of the overall level of generation for the period.[952]

Many commenters supported using RE deployment as measures to adjust the CO_2 emission rate of affected EGUs. Some commenters specifically agreed with the EPA’s determination that only new and incremental RE (including hydropower) should be used to adjust CO_2 emission rates. Those commenters objected to counting existing RE that are already embedded in the baseline emissions and generation mix. A significant number of commenters supported the integration of RE into a rate-based credit trading system.

Certain additional requirements apply for hydropower and biomass (including waste-to-energy) RE, as described below.

(a) Hydroelectric power.

Consistent with other types of RE, new hydroelectric power generating capacity installed after 2012 is eligible for use in adjusting a CO_2 emission rate.

Relicensed facilities are considered existing capacity and, therefore, are not eligible for use in adjusting a CO_2 emission rate, unless there is a capacity uprate as part of the relicensed permit. In such a case, only the incremental capacity

---

[952] For example, the overall generation from the uprated hydroelectric power plant may be higher or lower than generation levels that occurred at the plant prior to the capacity uprate.

is eligible for use in adjusting a CO_2 emission rate.

The EPA noted that many commenters preferred that generation from hydropower displace generation from fossil sources. One commenter suggested that existing zero-emitting sources, including hydropower, do not reduce emissions from existing fossil generation, but that new or uprated zero-emitting sources would, because of their low variable rate, reduce fossil emissions. Several commenters recommended allowing incremental generation from new or uprated zero-emitting sources, including hydropower, be available for compliance.

(b) Biomass.

RE generating capacity installed after 2012 that uses qualified biomass as a fuel source is eligible for use in adjusting a CO_2 emission rate.[953] As discussed in section VIII.I.2.c., if a state intends to allow for the use of biomass as a compliance option for an affected EGU to meet a CO_2 emission standard, a state must propose qualified biomass feedstocks and treatment of biogenic CO_2 emissions in its plan, along with supporting analysis and quality control measures, and the EPA will review the appropriateness and basis for such determinations in the course of its review of a state plan. Where an RE generating unit uses qualified biomass, as

[953] As with other RE, only generating capacity installed after 2012 would be eligible for use in adjusting a CO_2 emission rate.

designated in an approved state plan, MWh generation from the unit could be used to adjust the reported CO_2 emission rate of an affected EGU. Total MWh generation from an RE generating unit that uses qualified biomass must be prorated based on either the heat input supplied from qualified biomass as a proportion of total heat input or on the proportion of biogenic CO_2 emissions compared to total stack CO_2 emissions from the RE generating unit. Either approach must incorporate the approved valuation of biogenic CO_2 emissions from qualified biomass in the plan (i.e., the proportion of biogenic CO_2 emissions from use of qualified biomass feedstock that would not be counted)

Section VIII.K describes the requirements and procedures for EM&V, and discusses how all eligible resources must demonstrate how they will quantify and verify MWh savings using best-practice EM&V approaches. One way to make this demonstration for eligible resources could be to use the presumptively approvable EM&V approaches that are included in the final model trading rule.

(c) Waste-to-energy.

Qualified biomass may include the biogenic portion of MSW combusted in a waste-to-energy facility.[954] With regard to assessing qualified biomass proposed in state plans, the EPA

[954] As with other RE, only generating capacity installed after 2012 would be eligible for use in adjusting a CO_2 emission rate.

generally acknowledges the CO_2 emissions and climate policy benefits of waste-derived biomass, which includes biogenic MSW inputs to waste-to-energy facilities. The process and considerations for the use of biomass in state plans are discussed in section VIII.I.2.c.

MSW can be directly combusted in waste-to-energy facilities to generate electricity as an alternative to landfill disposal. In the U.S., almost all incineration of MSW occurs at waste-to-energy facilities or industrial facilities where the waste is combusted and energy is recovered.[955] Total MSW generation in 2012 was 251 million tons, but of that total volume generated, almost 87 million tons were recycled and composted.[956] Increasing demand for electricity generated from waste-to-energy facilities could increase competition for and generation of waste stream materials - including discarded organic waste materials – which could work against programs promoting waste reduction or cause diversion of these materials from existing or future efforts promoting composting and recycling. The EPA and many states have recognized the importance of integrated waste materials management strategies that emphasize a hierarchy of waste

---

[955] Inventory of U.S. Greenhouse Gas Emissions and Sinks: 1990-2012. http://www.epa.gov/climatechange/ghgemissions/usinventoryreport.html.

[956] http://www.epa.gov/osw/nonhaz/municipal/pubs/2012_msw_fs.pdf.

prevention, starting with waste reduction programs as the highest priority and then focusing on all other productive uses of waste materials to reduce the volume of disposed waste materials.[957] For example, Oregon and Vermont have strategies that emphasize waste prevention, followed by reuse, then recycling and composting materials prior to treatment and disposal.[958]

Information in the revised *Framework for Assessing Biogenic CO_2 Emissions from Stationary Sources* and other technical studies and tools (e.g., EPA Waste Reduction Model, EPA Decision Support Tool) should assist both states and the EPA in assessing the role of biogenic feedstocks used in waste-to-energy processes, where use of such feedstocks is included in a state plan.[959]

When developing their plans, states planning to use waste-to-energy as an option for the adjustment of a CO_2 emission rate should assess both their capacity to strengthen existing or implement new waste reduction, reuse, recycling and composting programs, and measures to minimize any potential negative impacts of waste-to-energy operations on such programs. States must include that information in their plan submissions. The EPA

---

[957] http://www.epa.gov/wastes/nonhaz/municipal/hierarchy.htm.

[958] http://www.anr.state.vt.us/dec/wastediv/WastePrevention/main.htm.

[959] http://epa.gov/epawaste/conserve/tools/warm/Warm_Form.html, https://mswdst.rti.org/.

will reject as qualified biomass any proposed waste-to-energy component of state plans if states do not include information on their efforts to strengthen existing or implement new waste reduction as well as reuse, recycling and composting programs, and measures to minimize any potential negative impacts of waste-to-energy operations on such programs. Only electric generation at a waste-to-energy facility that is related to the biogenic fraction of MSW and that is added after 2012 is eligible for use in adjusting a CO_2 emission rate.

A state plan must include a method for determining the proportion of total MWh generation from a waste-to-energy facility that is eligible for use in adjusting a CO_2 emission rate. The EPA will evaluate the method as part of its evaluation of the approvability of the state plan. Measuring the proportion of biogenic to fossil CO_2 emissions can be performed through sampling and testing of the biogenic fraction of the MSW used as fuel at a waste-to-energy facility (e.g., via ASTM D-6866-06 testing or other methods - ASTM, 2006; Bohar, et al. 2010), or based on the proportion of biogenic CO_2 emissions to total CO_2 emissions from the facility. For an example of the former method, if the biogenic fraction of MSW is 50 percent by input weight, only the proportion of MWh output attributable to the biogenic portion of MSW at the waste-to-energy facility may be used to adjust an affected EGU CO_2 emission rate. Alternatively, as an example of the latter method, if biogenic CO_2 emissions represent 50 percent of total reported CO_2 emissions, a facility would need to estimate the fraction of biogenic to fossil MSW utilized and the net energy output of each component (based on relative higher heating values) to determine the percent of the MWh output from the waste-to-energy facility that may be used to adjust an affected EGU's CO_2 emission rate. Section VIII.K describes the requirements and procedures for EM&V, and discusses how all eligible resources must demonstrate how they will quantify and verify MWh savings using best-practice EM&V approaches. One way to make this demonstration for eligible resources could be to use the presumptively approvable EM&V approaches that are included in the final model trading rule.

The EPA received multiple comments supporting the use of waste-to-energy as part of state plans. Some commenters expressed concern that non-biogenic materials, such as plastics and metal, would be incinerated along with biogenic materials. As discussed above, only electric generation related to the biogenic fraction of MSW at a waste-to-energy facility added after 2012 is eligible for use in adjusting a CO_2 emission rate. The EPA also received comments that expressed concern about the potential negative impacts on recycling and waste reduction efforts, while other commenters asserted that waste-to-energy practices encourage recycling programs. Some commenters also expressed concern about what treatment would be approvable for emissions from waste-to-energy practices. As discussed above, potential negative impacts from waste-to-energy production on recycling, waste reduction, and composting programs should be evaluated and efforts to mitigate negative impacts must be discussed in the supporting documentation of state plans.

(4) DSM.

Avoided MWh that result from DSM may be used to adjust a CO_2 emission rate. Eligible DSM actions are those that are zero-emitting and avoid, rather than shift, the use of electricity by an electricity end-user.[960] The MWh that may be used for such an adjustment are determined based on the MW of demand reduction multiplied by the hours during which such a demand reduction is achieved (MW of demand reduction x hours = MWh avoided). DSM measures must be appropriately quantified and verified, in accordance with requirements in the emission guidelines, as discussed in section VIII.K.3.

(5) Energy storage.

Energy storage may not be directly recognized as an

---

[960] An example is a utility direct load control program, such as those where customer air conditioning units are cycled during periods of peak electricity demand. Actions that shift electricity demand from one time of day to another, without reducing net electricity use, are not eligible, as these measures do not avoid electricity use from the grid. Use of emitting generators as a DSM measure is also not eligible.

eligible measure that can be used to adjust a CO_2 emission rate, because storage does not directly substitute for electric generation from the grid or avoid electricity use from the grid.[961] The electric generation that is input to an energy storage unit may be used to adjust a CO_2 emission rate, but the output from the energy storage unit may not.[962] However, energy storage can be used as an enabling measure that facilitates greater use of RE, which can be used to adjust a CO_2 emission rate. For example, utility scale energy storage may be used to facilitate greater grid penetration of RE generating capacity and can also be used to store RE generation that may have otherwise been shed in times of excess generating capacity. Likewise, on-site energy storage at an electricity end-user can enable greater use of RE to meet on-site electricity demand.[963]

The EPA received multiple comments regarding the overall merits of energy storage. Consistent with the discussion above,

---

[961] Energy storage depends on a generation source, either from a utility-scale EGU (e.g., a fossil EGU, a wind turbine, etc.) or a distributed generation source at an electricity end-user (e.g., a PV system installed at a building).

[962] This approach focuses on counting the qualifying electric generation, which may be an input to an energy storage unit. Counting both the generation input to energy storage and the output from the energy storage unit would be a form of double counting. The electric generation that is stored may be counted; the subsequent output from the storage unit may not.

[963] For example, battery storage at a building with solar PV can enable the PV system to meet the building's entire electrical load, by storing energy during times of peak PV system output for later use when the sun is not shining.

the majority of commenters observed that storage technology enables greater grid penetration of RE and supports more efficient and effective operations of both RE and fossil-fuel plants. Commenters further noted that energy storage can provide RE to the grid when it is most needed, while simultaneously taking pressure off fossil-fuel plants to respond to sudden shifts in demand. Despite broad acknowledgment of the benefits of storage, public comments underscore its indirect and supporting role in providing zero-emission MWh to the grid (consistent with the EPA's decision to exclude energy storage as an eligible measure that can be used to adjust a CO_2 emission rate).

(6) Transmission and distribution (T&D) measures.

Electricity T&D measures that improve the efficiency of the T&D system and/or reduce electricity use may be used to adjust a CO_2 emission rate. This includes T&D measures that reduce losses of electricity during delivery from a generator to an end-user (sometimes referred to as "line losses"[964]) and T&D measures that

[964] T&D system losses (or "line losses") are typically defined as the difference between electricity generation to the grid and electricity sales. These losses are the fraction of electricity lost to resistance along the T&D lines, which varies depending on the specific conductors, the current, and the length of the lines. The Energy Information Administration (EIA) estimates that national electricity T&D losses average about 6 percent of the electricity that is transmitted and distributed in the U.S. each year.

reduce electricity use at the end-user, such as conservation voltage reduction (CVR).[965] The EPA received many comments in support of advanced energy technologies, including energy storage and transmission and distribution upgrades, and including these technologies in the suite of potential measures that states could consider for emission rate adjustments in their state plans. Comments pointed out that in addition to helping achieve emission standards, T&D efficiency improvements make the grid more robust and flexible, as well as delivering environmental benefits. In many parts of the country, grid operators, transmission planners, transmission owners and regulators are already taking steps to expand and modernize T&D networks. Commenters suggested that the EPA clarify the eligibility and criteria under which such measures would be permitted in a state plan.

---

[965] Volt/VAR optimization (VVO) refers to coordinated efforts by utilities to manage and improve the delivery of power in order to increase the efficiency of electricity distribution. VVO is accomplished primarily through the implementation of smart grid technologies that improve the real-time response to the demand for power. Technologies for VVO include load tap changers and voltage regulators, which can help manage voltage levels, as well as capacitor banks that achieve reductions in transmission line loss. VVO efforts are often closely related to CVR, which are actions taken to reduce initial delivered voltage levels in feeder transmission lines while remaining within the 114 volt to 126 volt range (for normal 120-volt service) required at the customer meter, per the ANSI C84.1 standards.

To be eligible, T&D measures must be installed after 2012. This general eligibility requirement is discussed above in section VIII.K.1.a. The MWh of avoided losses or reduction in end-use that result from T&D measures must be appropriately quantified and verified, as discussed in section VIII.K.3.

(7) Demand-side EE, including water system efficiency.

Demand-side EE measures may be used to adjust a CO_2 emission rate, provided they meet the general eligibility requirements outlined above and the MWh electricity savings are properly quantified and verified.[966] As used in this section, demand-side EE may include a range of eligible measures, provided that the measures can be quantified and verified in accordance with the EM&V requirements in the emission guidelines, which are addressed in section VIII.K.3. Examples of demand-side EE measures include, but are not limited to, EE measures that reduce electricity use in residential and commercial buildings, industrial facilities, and other grid-connected equipment. Water efficiency programs that improve EE at water and wastewater treatment facilities also provide demand-side EE savings opportunities. EE measures, for the purposes of this section,

[966] All state plans must demonstrate that measures included in the plan are quantifiable and verifiable. See section VIII.K.2 for discussion of requirements for the issuance of ERCs, and section VIII.K.3 for discussion of EM&V requirements for use of demand-side EE relied on in a state plan.

may consist of EE measures installed as the result of individual EE projects, such as those implemented by energy service companies, as well as multiple EE measures installed through an EE deployment program (e.g. appliance replacement and recycling programs, and behavioral programs) administered by electric utilities, state entities, and other private and non-profit entities.[967] EE measures, for the purposes of this section, may also consist of state or local requirements that result in electricity savings, such as building energy codes and state appliance and equipment standards. Other interventions that result in electricity savings may also be considered an EE measure for the purposes of this section, provided the intervention can be specified and quantified and verified in accordance with EM&V requirements in the emission guidelines.

Numerous commenters expressed support for including demand-side EE as an eligible measure states and affected EGUs can use to meet the emission guidelines. Commenters touted the value of demand-side EE as a resource that delivers energy savings, lowers bills, creates jobs and reduces CO_2 emissions. Commenters called for the EPA to allow for the use of a broad range of demand-side EE measures to meet the emission guidelines,

[967] EE programs may also be implemented by other entities. Eligible EE measures that are deployed through EE programs are not limited to those EE measures deployed through EE programs administered by the types of entities listed here.

including, but not limited to, utility and non-utility EE deployment programs; energy savings performance contracts; measures that reduce electricity use in residential and commercial buildings, industrial facilities and other grid-connected equipment; state and local requirements that result in electricity savings, such as building energy codes and state appliance and equipment standards; appliance replacement and recycling programs; and behavioral programs. The EPA also received comments supporting the use of water sector EE programs and projects. Commenters identified water and wastewater utilities as particularly well-suited for participating in EE programs and providing a source of electricity savings. Investments such as replacing pumps and other aging equipment and repairing leaks can result in greater EE. The EPA agrees that these electricity savings should be eligible for adjustments to CO_2 emission rates at affected EGUs.

(8) Nuclear power.

As is discussed in section V.A.3, upon consideration of comments received, the EPA has not included nuclear generation from either existing or under construction units in the determination of the BSER. In addition to comments received on the provisions for determining the BSER, the EPA also received comments requesting that the EPA allow all generation from nuclear generating units to be recognized as an eligible measure that can be used to adjust a CO_2 emission rate. Commenters also recommended that the EPA consider nuclear generating units and RE generating units in a consistent manner for CO_2 emission rate adjustments in state plans. We agree with comments that nuclear generation and RE should be treated consistently when it comes to CO_2 emission rate adjustments.

The EPA has determined that generation from new nuclear units and capacity uprates at existing nuclear units will be eligible for use in adjusting a CO_2 emission rate, just like new and uprated capacity RE. However, consistent with the reasons discussed for not including the preservation of existing nuclear capacity in the BSER – namely, that such preservation does not actually reduce existing levels of CO_2 emissions from affected EGUs – preserving generation from existing nuclear capacity is not eligible for use in adjusting a CO_2 emission rate.

In contrast, any incremental zero-emitting generation from new nuclear capacity would be expected to replace generation from affected EGUs and, thereby, reduce CO_2 emissions; and the continued commitment of the owner/operators to completion of the new units and improving the efficiency of existing units through uprates can play a key role in state plans. Therefore, consistent with treatment of other low- and zero-emitting generation, new nuclear power generating capacity installed after 2012 and incremental generation resulting from nuclear uprates after 2012 are measures eligible for adjusting a CO_2 emission rate. However, existing nuclear units (i.e., those that originally commenced operation in 2012 or earlier years) that receive operating license extensions are not eligible for use in adjusting a CO_2 emission rate, except where such units receive a capacity uprate as a result of the relicensing process. Only the incremental capacity from the uprate is eligible for use to adjust a CO_2 emission rate.

Applicable generation (in MWh) from incremental nuclear power is determined in the same manner as that described for incremental RE above.

(9) Combined heat and power (CHP) units.

Electric generation from non-affected CHP units[968] may be used to adjust the CO_2 emission rate of an affected EGU, as CHP units are low-emitting electric generating resources that can replace generation from affected EGUs. Electrical generation from non-affected CHP units that meet the eligibility criteria

[968] The accounting considerations described in this section are for a "topping cycle" CHP unit. A topping cycle CHP unit refers to a configuration where fuel is first used to generate electricity and then heat is recovered from the electric generation process to provide additional useful thermal and/or mechanical energy. A CHP unit can also be configured as a "bottoming cycle" unit. In a bottoming cycle CHP unit, fuel is first used to provide thermal energy for an industrial process and the waste heat from that process is then used to generate electricity. Some waste heat power (WHP) units are also bottoming cycle units and the accounting treatment for bottoming cycle CHP units is provided with the WHP description below.

under section VIII.K.1.a can be used to adjust the reported CO_2 emission rate of an affected EGU.

Where a state plan provides for the use of electrical generation from eligible non-affected CHP units to adjust the reported CO_2 emission rate of an affected EGU, the state plan must provide a required calculation method for determining the MWh that may be used to adjust the CO_2 emission rate. This proposed accounting method must adequately address the considerations discussed below. The EPA will review whether a state's proposed accounting method for electric generation from eligible non-affected CHP units is approvable per the requirements of the final emission guidelines, as part of its overall plan review of the rate-based emission standards and implementing and enforcing measures in the state plan. The EPA notes that the proposed model rule for a rate-based emission trading program includes a proposed accounting method for non-affected CHP units. The accounting method provided in a final model rule could be a presumptively approvable accounting approach.

The proposed accounting method in a state plan must address the following considerations. The accounting approach proposed in a state plan must take into account the fact that a non-affected CHP unit is a fossil fuel-fired emission source, as well as the fact that the incremental CO_2 emissions related to electrical generation from a non-affected CHP unit are typically very low. In accordance with these considerations, a non-affected CHP unit's electrical MWh output that can be used to adjust the reported CO_2 emission rate of an affected EGU should be prorated based on the CO_2 emission rate of the electrical output associated with the CHP unit (a CHP unit's "incremental CO_2 emission rate") compared to a reference CO_2 emission rate. This "incremental CO_2 emission rate" related to the electric generation from the CHP unit would be relative to the applicable CO_2 emission rate for affected EGUs in the state and would be limited to a value between 0 and 1.

This low CO_2 emission rate for electrical generation from a non-affected CHP unit is a product of both the fact that CHP units are typically very thermally efficient and the fact that a portion of the CO_2 emissions from a non-affected CHP unit would have occurred anyway from an industrial boiler used to meet the thermal load in the absence of the CHP unit. In contrast, the CHP unit also provides the benefit of electricity generation while resulting in very low incremental CO_2 emissions beyond what would have been emitted by an industrial boiler. As a result, the accounting method proposed in a state plan should not presume that CO_2 emission reductions occur outside the electric power sector, but instead only would account for the CO_2 emissions related to the electrical production from a CHP unit that is used to substitute for electrical generation from affected EGUs.

Non-affected CHP units can use qualified biomass fuels. As described in section VIII.I.2.c, states must submit state plan requirements regarding qualified biomass feedstocks and treatment of biogenic CO_2 emissions in state plans, along with supporting analysis and quality control measures, and the EPA would review the appropriateness and basis for such determinations in the course of its review of the approvability of a state plan. Considerations for qualified biomass included in state plans are discussed in section VIII.I.2.c, while accounting requirements for RE using biomass are provided in section VIII.K.1.a.(3)(b).

Most comments received on CHP recommended that the EPA explicitly describe how CHP can be accounted for in a state plan. Commenters described the CO_2 emission reductions achieved through CHP's thermal efficiency and the precedent set in other federal and state rules that have included CHP as a compliance option. Some commenters pointed out that without such a description, states would not be able to readily take advantage of the CO_2 emission reductions that result from the use of CHP.

(10) WHP.

WHP units that meet the eligibility criteria under section VIII.K.1 may be used to adjust the CO_2 emission rate of an affected EGU. There are several types of WHP units. There are units, also referred to as bottoming cycle CHP units, where the fuel is first used to provide thermal energy for an industrial process and the waste heat from that process is then used to generate electricity.[969] There are also WHP facilities where the waste heat from the initial combustion process is used to generate additional power. Under both configurations, unless the WHP unit supplements waste heat with fossil fuel use, there is no additional fossil fuel used to generate this additional power. As a result, there are no incremental CO_2 emissions associated with that additional power generation. As a result, the incremental electric generation output from the WHP facilities could be considered zero-emitting, for the purposes of meeting the emission guidelines, and the MWh of electrical output could be used to adjust the CO_2 emission rate of an affected EGU.[970] The MWh of electrical output from a WHP unit that can be recognized may not exceed the MWh of industrial or

[969] In such a configuration, the waste heat stream could also be generated from a mechanical process, such as at natural gas pipeline compressors.
[970] This only applies where no additional fossil fuel is used to supplement the use of waste heat in a WHP facility. Where fossil fuel is used to supplement waste heat in a WHP application, MWh of electrical generation that can be used to adjust the CO_2 emission rate of an affected EGU must be prorated based on the proportion of fossil fuel heat input to total heat input that is used by the WHP unit to generate electricity.

other thermal load that is being met by the WHP unit, prior to the generation of electricity.[971] Most commenters that addressed WHP noted the benefits of WHP at the same time that they discussed the benefits of CHP. The commenters reflected that WHP is another potential compliance option and requested it be discussed explicitly as a compliance option that can be used to meet the emission guidelines. The comments discussed WHP benefits but did not elaborate on a preferred accounting method for MWh of electrical generation from WHP that could be used to adjust the CO_2 emission rate of an affected EGU.

b. Measures that may not be used to adjust a CO_2 emission rate. This section addresses measures that may not be used to adjust a CO_2 emission rate. New, modified, and reconstructed EGUs covered under the CAA section 111(b) final Standards of Performance for Greenhouse Gas Emissions from New Stationary Sources: Electric Utility Generating Units rule are not approvable sources of electric generation for adjusting the CO_2 emission rate of an affected EGU under a rate-based state plan. As discussed earlier in section VII.D of this preamble, a key concern under this rule is leakage to new units that are not covered by the emission guidelines. Emissions leakage, or increased CO_2 emissions due to

[971] This limitation prevents oversizing the thermal output of a WHP unit to exceed the useful industrial or other thermal load it is meeting, prior to generation of electricity.

increased utilization of unaffected sources, is contradictory to objectives of this rule and should, therefore, be minimized. Allowing affected EGUs to adjust their emission rates as a result of lower-emitting new NGCC units not covered under this section 111(d) rule would not mitigate leakage concerns, and could even exacerbate the situation. Consequently, new EGUs covered under the CAA section 111(b) rule are not allowable measures in state plans because the EPA believes it would result in increased emission leakage.

The EPA received comments both supporting and opposing the use of new NGCC units in state plans. In addition to leakage concerns, commenters expressed concern with the potential incentives created by including new NGCC capacity in the BSER or as a compliance mechanism in state plans. Some commenters suggested that including new NGCC capacity in the BSER or for compliance would distort market incentives to build new NGCC units, particularly if new units were allowed to generate ERCs that could be sold to affected EGUs. These commenters suggested that the additional incentive for new NGCC units could make existing NGCC units less competitive. Other commenters suggested that including new NGCC capacity in state plans would promote generation from new CO_2-emitting units at the expense of new zero-emitting units, increasing overall emissions within a state. This effect would be exacerbated if state plans allowed new NGCC units to be treated as "zero-emitting" for purposes of compliance -- as suggested by other commenters. In addition, commenters expressed concern that the EPA's inclusion of new NGCC capacity in setting the BSER or in compliance could negatively impact ratepayers over the long-term by sending the wrong signal to industry and resulting in stranded assets if, in the future, carbon emissions become more expensive or the EPA proposes to incorporate sources built under the forthcoming section 111(b) standard into the section 111(d) program. Commenters also expressed concern that including generation from new NGCC units could create unreasonable uncertainty, given limitations on the ability to accurately project new NGCC builds, could create undue pressure on natural gas prices, and could create unfair disparities in the compliance opportunities afforded different states. In light of the emissions leakage concerns, and in consideration of these comments, the EPA is not allowing shifting generation to new NGCC units to be used as a measure for adjusting CO_2 emission rates for affected EGUs in rate-based state plans.

In addition, other new and existing non-affected fossil fuel-fired EGUs that are not subject to CAA section 111(b) or 111(d), such as simple cycle combustion turbines, may not be used to adjust the CO_2 emission rate of an affected EGU. While generation from such units could substitute for generation from affected EGUs, the EPA has determined that additional incentives for such generation, in the form of an explicit adjustment to the CO_2 rate of an affected EGU, are not necessary or warranted. Providing for such an adjustment could create perverse incentives for the construction of new simple cycle combustion turbines that are not subject to the applicability criteria of the final Standards of Performance for Greenhouse Gas Emissions from New Stationary Sources: Electric Utility Generating Units rule. These units could provide only limited adjustment credit, as operation beyond a certain capacity factor threshold would trigger applicability under CAA section 111(b). Further, providing for the ability to generate adjustment credits would provide incentives for construction of less efficient fossil generating capacity than would likely otherwise be constructed (e.g., addition of a simple cycle combustion turbine rather than a NGCC unit). In addition, providing for the ability to generate adjustment credits could create perverse incentives for the continued operation of less efficient existing fossil generating capacity. Such outcomes run counter to the objectives of this final rule.

c. Measures that reduce CO_2 emissions outside the electric power sector. Measures that reduce CO_2 emissions outside the electric power sector may not be counted toward meeting a CO_2 emission performance level for affected EGUs or a state CO_2 goal, under either a rate-based or mass-based approach, because all of the emission reduction measures included in the EPA's determination of the BSER reduce CO_2 emissions from affected EGUs. Examples of measures that may not be counted toward meeting a CO_2 emission performance level for affected EGUs or a state CO_2 goal include GHG offset projects representing emission reductions that occur in the forestry and agriculture sectors,[972] direct air capture, and crediting of CO_2 emission reductions that occur in the transportation sector as a result of vehicle electrification.

2. Requirements for rate-based emission trading approaches

As made clear in the proposal,[973] all emission standards in a state plan must be quantifiable, verifiable, enforceable, non-duplicative and permanent.[974] This requirement is applicable to emission standards that include a rate-based emission trading program. The State Plan Considerations TSD for the proposal also explained that in order to ensure a plan is enforceable, a state plan must: identify in its plan the entity or entities

[972] We note, however, that the final emission guidelines allow state measures like emission budget trading programs to include out-of-sector GHG offsets. For example, both the California and RGGI programs allow for the use of allowances awarded to GHG offset projects to be used to meet a specified portion of an affected emission source's compliance obligation. The RGGI program contains a cost containment allowance reserve that makes available additional allowances up to a certain amount, at specified allowance price triggers.
[973] 79 FR 34830, 34913.
[974] These requirements are described in detail in section VIII.D.2.

responsible for meeting compliance and other enforceable obligations under the plan; include mechanisms for demonstrating compliance with plan requirements or demonstrating that other binding obligations are met; and provide a mechanism(s) for legal action if affected EGUs are not in compliance with plan requirements or if other entities fail to meet enforceable plan obligations. A state plan using a rate-based emission trading approach must therefore include rate-based emission standards for affected EGUs along with related implementation and compliance requirements and mechanisms.[975] These related requirements include those applicable to rate-based emission standards more broadly: CO_2 emission monitoring, reporting, and recordkeeping requirements for affected EGUs, including requirements for monitoring and reporting of useful energy output. By satisfactorily addressing these requirements, state plans including a rate-based emission trading program will be able to meet the statutory requirements of CAA section 111(d) regarding the need for state plans to provide for the implementation and enforcement of emission standards, as well as meet the requirement that each emission standard be quantifiable, verifiable, non-duplicative, permanent, and

[975] As described below, these requirements would likely be provided in a state plan in the form of state regulations, but could potentially be provided in another form.

enforceable with respect to each affected EGU.

The EPA also specifically proposed that for state plans that rely on measures that avoid EGU CO_2 emissions, such as RE and demand-side EE measures, the state will also need to include quantification, monitoring, and verification provisions in its plan for these measures. The EPA is finalizing requirements specific to rate-based emission trading programs as requirements the EPA has determined are necessary to assure the integrity of a rate-based approach that includes an emission trading program, and therefore assures a state plan using such an approach appropriately provides for the implementation and enforcement of rate-based emission standards in accordance with CAA section 111(d).[976] These specific requirements for a rate-based emission trading program include provisions for issuance of ERCs by the state and/or its designated agent; provisions for tracking ERCs, from issuance through submission for compliance; and the administrative process for submission of ERCs by the owner or operator of an affected EGU to the state, in order to adjust its reported CO_2 emission rate when demonstrating compliance with a

[976] By "integrity of a rate-based emission trading program", the EPA is referring to elements in the design and administration of a program necessary to assure that emission standards implemented using a rate-based emission trading approach are quantifiable, verifiable, enforceable, non-duplicative, and permanent.

rate-based emission standard.[977] These requirements must be submitted for inclusion in the federally enforceable plan, per the statutory requirement that states provide for the implementation and enforcement of emission standards. A rate-based trading program would provide for the implementation and enforcement of rate-based emission standards for a state plan that allows its affected EGUs to adjust a rate by the use of an ERC.

The EPA will review a state plan submittal including a rate-based emission trading program to assure that the plan contains the requirements necessary to assure the integrity of a rate-based approach, and therefore provide for the implementation and enforcement of rate-based emission standards. These requirements are discussed in more detail in this section.

The EPA also notes it is proposing model rules for both mass-based and rate-based emission trading programs. State plans that include the finalized model rule for a rate-based emission trading program could be presumptively approvable as meeting the requirements of CAA section 111(d) and these emission guidelines. The EPA would evaluate the approvability of such plans through independent notice and comment rulemaking.

A state may issue ERCs to an affected EGU that performs at

[977] See section VIII.K.1 for a discussion of the accounting method used to adjust a CO_2 emission rate.

a CO_2 emission rate below a specified CO_2 emission rate, as well as to providers of qualifying measures that provide substitute generation for affected EGUs or avoid the need for generation from affected EGUs. This latter category includes providers of qualifying RE and demand-side EE measures, as well as other types of measures, as discussed in section VIII.K.1.a.[978]

ERCs may be used by an affected EGU to adjust its reported CO_2 emission rate when demonstrating compliance with a rate-based emission standard. This adjustment is made by adding MWh to the denominator of an affected EGU's reported CO_2 emission rate, in the amount of submitted ERCs, resulting in a lower adjusted rate. To demonstrate compliance with a rate-based emission standard, an affected EGU would report its CO_2 lb/MWh emission rate to the state regulatory body, and would also surrender to the state any ERCs it wishes to use to adjust its reported emission rate. The state regulator would then cancel the submitted ERCs. The affected EGU would add the MWh the ERCs represent to the denominator of its reported CO_2 lb/MWh emission

[978] As used in this section, the term "EE program" refers to an EE deployment program. An EE program involves deployment of multiple EE measures or EE projects, such as utility- or state-administered EE incentive programs that accelerate the deployment of EE technologies and practices. As used in this section, the term "EE/RE project" refers to a discrete EE project (e.g., an EE upgrade to a commercial building or set of buildings) or a RE generator (e.g., a single wind turbine or group of turbines).

rate to demonstrate compliance with its emission standard. The state regulator could facilitate its evaluation of the affected EGU's compliance (as well as evaluation by the affected EGU, the EPA, and others) by providing functionality in its tracking system to run such compliance calculations. If the affected EGU's adjusted CO_2 emission rate is equal to or lower than its applicable emission rate standard, the affected EGU would be in compliance.

a. Issuance of ERCs to affected EGUs. ERCs may be issued to affected EGUs that emit below a specified CO_2 emission rate, as discussed below. For issuance of ERCs to affected EGUs, the state plan must specify the accounting method and administrative process for ERC issuance. This includes the calculation method for determining the number of ERCs to be issued to an affected EGU, based on reported CO_2 emissions and MWh energy output, in comparison to a reference CO_2 emission rate. The reference rate is a specified CO_2 lb/MWh emission rate that an affected EGU's reported CO_2 emission rate is compared to, when determining the amount of ERCs that may be issued to an affected EGU.

Following determination of the number of ERCs an affected EGU is eligible to receive, based on an affected EGU's reported CO_2 emission rate compared to a specified reference rate, the state regulatory body would issue those ERCs into a tracking system account held by the owner or operator of the affected

EGU. Tracking system requirements are addressed below at section VIII.K.2.c.

The accounting method that may be applied in a state plan differs depending on whether a state plan includes a single rate-based emission standard that applies to all affected EGUs (e.g., if a plan is designed to meet a state rate-based CO_2 goal) or separate rate-based emission standards that apply to subcategories of affected EGUs, namely fossil fuel-fired electric utility steam generating units and stationary combustion turbines. In both cases, ERCs are issued in MWh, based on the difference between an affected EGU's reported CO_2 emission rate (in CO_2 lb/MWh) and a specified CO_2 lb/MWh emission rate that the reported rate is compared to (referred to as a "reference rate"). The reference rate may be an affected EGU's assigned CO_2 emission limit rate or another CO_2 emission rate, as described below. Where an affected EGU's reported CO_2 emission rate is lower than the specified reference CO_2 emission rate, ERCs may be issued.

Where a state plan includes emission standards in the form of a single rate-based emission standard that applies to all affected EGUs, the reference rate is the CO_2 emission rate limit for affected EGUs. In this instance, ERCs may be issued based on an affected EGU's reported CO_2 emission rate as a proportion of the emission limit rate. For example, if the emission rate limit is 2,000 lb CO_2/MWh and the affected EGU emits at a rate of 1,000 lb CO_2/MWh, 0.5 MWh would be awarded for every MWh generated by the affected EGU. ERCs would be issued to affected EGUs in whole MWh increments. The calculation method is as follows:

ERCs[979] = reported MWh by affected EGU[980] x ((CO_2 emission rate limit for affected EGUs[981] – affected EGU reported CO_2 emission rate[982])/ CO_2 emission rate limit for affected EGUs)

For the example above, the calculation is as follows:

ERCs = MWh reported x (2,000 – 1,000)/2,000 = MWh reported x 0.5

If the affected EGU in this example generated 1,000,000 MWh, 500,000 ERCs would be issued.

Where a state plan includes separate emission standards for subcategories of affected EGUs, specifically affected fossil fuel-fired electric utility steam generating units and stationary combustion turbines, the reference rate differs for affected fossil fuel-fired electric utility steam generating units and stationary combustion turbines. Additionally, if the state plan applies emission standards for its affected EGUs that

---

[979] For all calculations in this section, where the result is a negative value, no ERCs would be issued.

[980] This term represents the reported MWh by the affected EGU on an annual basis.

[981] This term represents the "reference rate."

[982] This term represents the annual reported CO_2 emission rate of the affected EGU.

are equal to the subcategorized CO_2 emission performance rates there is a unique opportunity for the adjustment of an affected EGU's emission rate using ERCs that are generated as a result of building block 2 incremental NGCC unit operation. The EPA is requiring state plans to account for incremental NGCC generation in ERC generation if a state plan applies the subcategorized CO_2 emission performance rates to its affected EGUs as emission standards. Additionally, the EPA is requiring that a NGCC unit is not able to use ERCs generated by it or any other NGCC unit's building block 2 incremental generation.

For affected steam generating units, the reference CO_2 emission rate is the assigned CO_2 emission rate limit for steam generating units, and the following accounting method for generating ERCs applies:

ERCs[983] = reported MWh x ((steam generating unit CO_2 emission rate limit[984] – steam generating unit reported CO_2 emission rate)/ steam generating unit CO_2 emission rate limit).

For an affected NGCC stationary combustion turbine in a subcategorized rate-based emission trading program, the following equation provides a required accounting method for

[983] For all calculations in this section, where the result is a negative value, no ERCs would be issued.
[984] The "reference rate."

generating ERCs based on operation with respect to the NGCC unit's emission standard:

ERCs = NGCC unit's reported MWh x ((NGCC unit's CO_2 emission standard[985] – NGCC unit's reported CO_2 emission rate)/ NGCC unit's CO_2 emission standard)

According to this equation, ERC issuance is assessed based on the difference between the CO_2 emission rate standard for the NGCC unit[986] and the reported CO_2 emission rate of the affected NGCC unit. In other words, affected NGCC stationary combustion turbines earn ERCs for generation when they perform at an emission rate better than the reference rate for stationary combustion turbines, similarly to how affected steam units can earn ERCs.

To account for incremental generation for a NGCC stationary combustion turbine to generate ERCs in a subcategorized rate-based emission trading program, a state must use the incremental operation of an affected NGCC unit quantified for building block 2 to allow a NGCC unit to generate ERCs based on its expected incremental generation.

A state plan that provides for the use of ERCs issued based on incremental affected NGCC generation must provide a required

---

[985] The "reference rate."
[986] This is the CO_2 emission performance rate for affected stationary combustion turbines in the emission guidelines.

calculation method that allows for issuance of ERCs based on the ability of incremental generation from affected stationary combustion turbines to substitute for generation from affected steam generating units (as represented in building block 2), while also respecting the fact that affected stationary combustion turbines must also meet an assigned CO_2 emission rate limit for the entirety of its MWh energy output. This accounting method must reflect the application of the BSER, as described in section V, and the accounting method must not create incentives to rearrange dispatch between existing NGCC units to generate additional ERCs without changing the overall level of NGCC generation.

The EPA will review whether a state's accounting method is approvable per the requirements of the statute and this final rule as part of its overall plan review of the rate-based emission standards and implementing and enforcing measures in the state plan. The EPA notes that the proposed model rule for a rate-based emission trading program includes a proposed accounting method and takes comments on alternatives. The accounting method provided in a final model rule could be a presumptively approvable approach for issuance of ERCs based on the ability of incremental generation from affected stationary combustion turbines to substitute for generation from affected steam generating units. A state's accounting requirements for generation of ERCs based on incremental affected NGCC generation must maintain consistency with the EPA’s application of the BSER when calculating CO_2 emission performance rates for affected stationary combustion turbine and steam generating units. In particular, a state’s accounting method must maintain consistency of accounting in a state rate-based CO_2 emission standard with the EPA’s application of building block 2 in calculating CO_2 emission performance rates for affected fossil fuel-fired electric utility steam generating units and stationary combustion turbines, which is based on use of incremental generation from affected stationary combustion turbine to replace generation from affected steam generating units.

b. Issuance of ERCs for RE, demand-side EE, and other measures. ERCs may be issued for qualifying measures.[987] For issuance of ERCs for qualifying measures, state plan requirements for ERC issuance must include a two-step process. In the first step of the process, a potential ERC provider submits an eligibility application for a qualifying program or project[988] to the

[987] Qualifying measures that can be used to adjust the CO_2 emission rate of an affected EGU are discussed at section VIII.K.1, and include RE, demand-side EE, and other measures, such as DSM, CHP and incremental nuclear generation.
[988] For example, for an EE/RE program or project, as described in this section for illustrative purposes. The requirements described in this section for EE/RE programs and projects also

administering state regulator (or its agent[989]). The state regulator reviews the application to determine whether, in this example, an EE/RE program or project meets eligibility requirements for the issuance of ERCs.[990] An eligibility application must include a description of the program or project, a projection of the MWh generation or energy savings anticipated over the life of the program or project, and an EM&V plan that meets state plan requirements. The EM&V plan must describe how MWh of RE generation or energy savings resulting from the program or project will be quantified and verified.[991] A

---

apply for all other eligible qualifying measures discussed in section VIII.K.1.

[989] As used here, an agent is a party acting on behalf of the state, based on authority vested in it by the state, pursuant to the legal authority of the state. A state could designate an agent to provide certain limited administrative services, or could choose to vest an agent with greater authority. Where an agent issues an ERC on behalf of the state, such issuance would have the same legal effect as issuance of an ERC by the state.

[990] The entity implementing the EE/RE program or project (referred to in the preamble as a "provider") would submit the application. This is the identified entity to which ERCs would ultimately be issued, to a tracking system account held by the entity. Such entities could include a wide variety of parties that implement EE/RE programs and projects, including owners or operators of affected EGUs, electric distribution companies, independent power producers, energy service companies, administrators of state EE programs, and administrators of industrial EE programs, among others.

[991] The verification process includes confirmation that quantified MWh are non-duplicative and permanent (i.e., are not being used in any other state plan to demonstrate compliance with an emission standard or achievement of an emission performance rate or state CO_2 emission goal).

state, in its emission standard regulations, must include requirements for EM&V plans that are consistent with the requirements in the emission guidelines for EE/RE measures and other eligible measures, as discussed in sections VIII.K.1 and VIII.K.3.

The EPA has determined that state requirements for an eligibility application must include review of the application by an independent verifier, approved by the state as eligible per the requirements of the final emission guidelines to provide such verification, prior to submittal. This requirement builds on the approach used for assessing GHG offset projects, both in international emission trading programs and the GHG emission budget trading programs implemented by California and the RGGI participating states.[992] An assessment by an independent verifier would be included as a component of an eligibility application.

The EPA has determined that independent verification requirements are necessary to ensure the integrity of state rate-based emission trading programs included in a state plan, given the wide range of eligible measures that may generate ERCs

[992] Information about the verification process for GHG offsets under the RGGI program, including verifier accreditation requirements and access to relevant documents, is available at http://www.rggi.org/market/offsets/verification. Similar information about the verification process for GHG offsets under the California program is available at http://www.arb.ca.gov/cc/capandtrade/offsets/verification/verification.htm.

and the broad geographic locations in which those measures may occur. Inclusion of an independent verification component provides technical support for state regulatory bodies to ensure that eligibility applications and M&V reports are thoroughly reviewed prior to issuance of ERCs. Inclusion of an independent verification component is also consistent with similar approaches required by state PUCs for the review of demand-side EE program results and GHG offset provisions included in state GHG emission budget trading programs.

State plans with rate-based emission trading programs must include requirements regarding the qualification status of an independent verifier. An independent verifier is a person (including any company, any corporate parent or subsidiary, any contractors or subcontractors, and the actual person) who has the appropriate technical and other qualifications to provide verification reports. The independent verifier must not have, or have had, any direct or indirect financial or other interest in the subject of its verification report or ERCs that could impact its impartiality in performing verification services. State plans must require that a person be approved by the state as an independent verifier, as defined by this final rule, as eligible to perform the verifications required under the approved state plan. State plans must also include a mechanism to temporarily or permanently revoke the qualification status of an independent verifier, such that it can no longer provide verification services related to an eligibility application or M&V report for at least the duration of the period it does not meet the qualification requirements for independent verifiers in an approved state plan. The EPA's proposed model rate-based emission trading rule contains provisions addressing accreditation and conflicts of interest for independent verifiers. State plans that adopt the finalized model rule could be presumptively approvable with respect to these requirements regarding independent verifiers.

The state's eligibility requirements and application procedures must ensure that only eligible actions may generate ERCs and that documentation is submitted only once for each program or project, and to only one state program.[993] These provisions will ensure that actions that are eligible for the issuance of ERCs are "non-duplicative."[994] The tracking system used to administer a state's rate-based emission trading system must provide transparent, electronic, public access to information about program and project eligibility applications, including EM&V plans, and regulatory approval status.

[993] This includes ensuring that multiple parties do not submit an eligibility application for the same EE program or project, or for the same RE generator.

[994] Emission standards must be "non-duplicative" as described in section VIII.D.2.

In the second step of the process, following implementation of the RE/EE program or project (as described in this example) that was approved in step one, the RE/EE provider periodically submits a M&V report to the state regulatory body documenting the results of the program or project in MWh of electric generation or energy savings.[995] These results are quantified according to the EM&V plan that was approved as part of step one. These results are verified by an accredited independent verifier, and its verification assessment must be included as part of the M&V report submitted to the state regulatory body. The administering state regulator (or its agent) then reviews the M&V report, and determines the number of ERCs (if any) that should be issued, based on the report. Finally, the state regulatory body (or its agent) issues ERCs to the provider of the approved program or project. These ERCs are issued to the tracking system account held by the program or project provider.

State plan requirements must ensure that only one ERC is issued for each verified MWh. This is addressed through registration in the tracking system of programs and projects

[995] State rate-based emission trading program regulations must specify the frequency for submission of M&V reports for approved qualified measures that have been deemed eligible to generate ERCs. These reporting periods should be annual, but a state could consider shorter or longer periods, depending on the type of ERC resource.

that have been qualified for the issuance of ERCs, to ensure that documentation is submitted only once for each RE/EE action, and to only one state program.[996] The tracking system must provide transparent electronic public access to submitted M&V reports and regulatory approvals related to such reports.[997] Such reports are the basis for issuance of ERCs.

c. Tracking system requirements. State requirements must include provisions to ensure that ERCs issued to any eligible entity are properly tracked from issuance to submission by affected EGUs for compliance (where ERCs are "surrendered" by the owner or operator of an affected EGU and "retired" or "cancelled" by the administering state regulatory body), to ensure they are only used once to meet a regulatory obligation. This is addressed through specified requirements for tracking system account holders, ERC issuance, ERC transfers among accounts, compliance true-up for affected EGUs,[998] and an accompanying tracking system that meets requirements specified in the emission trading

[996] EE/RE programs and projects, and other eligible measures, with an approved eligibility application would be designated in a tracking system as qualified programs or projects. Qualified programs and projects may be issued ERCs, based on approved M&V reports.

[997] This must include electronic Internet access to such information in the tracking system.

[998] "Compliance true-up" refers to ERC submission by an owner or operator of an affected EGU to adjust a reported CO_2 emission rate, and determination of whether the adjusted rate is equal to or lower than the applicable rate-based emission standard.

program regulations. Each issued ERC must have a unique identifier (e.g., serial number) and the tracking system must provide for traceability of issued ERCs back to the program or project for which they were issued.

The EPA received a number of comments from states and stakeholders about the value of the EPA's support in developing and/or administering tracking systems to support state administration of rate-based emission trading systems. This could include regional systems and/or a national system. The EPA is exploring options for providing such support and is conducting an initial scoping assessment of tracking system support needs and functionality.

d. Effect of improperly issued ERCs. Because the goal of this rulemaking is the actual reduction of CO_2 emissions, it is fundamental that ERCs represent the MWh of energy generation or savings they purport to represent. To this end, only valid ERCs that actually meet the standards articulated in this rule may be used to satisfy any aspect of compliance by an affected EGU with emission standards. Despite safeguards included in the structure of ERC issuance and tracking systems, such as the review of eligibility applications and M&V reports, and state issuance of ERCs, ERCs may be issued that do not, in fact, represent eligible zero-emission MWh as required in the emission guidelines. A variety of situations may result in such improper

ERC issuance, ranging from simple paperwork errors to outright fraud.

An approvable state plan that allows affected EGUs to comply with their emission standards in part through reliance on ERCs must include provisions making clear that an affected EGU may only demonstrate compliance with an ERC that actually represents the one MWh of energy generation or savings that it purports to represent and otherwise meets the emission guidelines.

e. Banking of ERCs. ERCs issued in 2022 or a subsequent year may be carried forward (or "banked") and used for demonstrating compliance in a future year.[999] For example, an ERC issued for a MWh of RE generation that occurs in 2022 may be applied to adjust a CO_2 emission rate in 2023 or future years without limitation. ERCs may be banked from the interim plan performance period to the final plan performance period. Banking provides a number of advantages while ensuring that the same output-weighted average CO_2 emission rates of the interim and final state CO_2 goals are achieved over the course of a state plan.

[999] States also have the option to participate in the CEIP, under which they can issue ERCs for MWh generation or savings that occur in 2020-2021 for measures implemented following submission of a final state plan, and receive matching ERCs from a federal pool. See section VIII.B.2 for a detailed discussion. The ERCs issued under this program can also be banked during and between the interim and final compliance period.

Banking provisions have been used extensively in rate-based environmental programs and mass-based emission budget trading programs.[1000] This is because banking reduces the cost of attaining the requirements of the regulation. The EPA has determined that the same rationale and outcomes apply under a CO_2 emission rate approach, in that allowing banking will reduce compliance costs. Banking encourages additional emission reductions in the near-term if economic to meet a long-term emission rate constraint, which is beneficial due to social preferences for environmental improvements sooner rather than later.[1001] State plans must specify whether the state is allowing or restricting the banking of ERCs between compliance periods for affected EGUs. State plans must also prohibit borrowing of any ERCs from future compliance periods by affected EGUs or eligible resources.

[1000] Banking under mass-based emission budget trading programs, and the rationale for banking provisions, is addressed below in section VIII.J.2.c.

[1001] The absence of banking creates an incentive to defer both relatively low-cost and higher-cost CO_2 emission reduction actions until a later period when emission rate limits become more stringent, rather than incentives to undertake the low-cost activities sooner in order to further delay the high cost actions. Under a rate-based emission trading program, banking will encourage ERC providers to generate larger numbers of ERCs in early years of a plan performance period, in anticipation of rising ERC prices over time, when demand for ERCs is expected to increase as rate-based CO_2 emission standards become more stringent.

f. Considerations for ERC issuance. The EPA notes that state-administered and state-overseen EE programs, such as those administered by state-regulated electric distribution utilities, could play a key role in supplying energy savings to a rate-based emission trading system in the form of ERCs. These programs have been the primary means for delivering EE programs and energy savings at scale, and also allow for a state to conduct a portfolio planning process to guide EE program design and focus in a manner that best provides multiple benefits to electricity ratepayers in a state. Such portfolio planning processes typically treat EE as an energy resource comparable to electricity generation.

The EPA also notes that non-ERC certificates may be issued by states and other bodies for MWh of energy generation and energy savings that are used to meet other state regulatory requirements, such as state RPS and EERS, or by individuals to make environmental or other claims in voluntary markets.

The EPA defines an ERC in the emission guidelines as a tradable compliance instrument that represents a zero-emission MWh (for the purposes of meeting the emission guidelines) from a qualifying measure that may be used to adjust the reported CO_2 emission rate of an affected EGU subject to a rate-based emission standard in an approved state plan under CAA section 111(d). The sole purpose of an ERC is for use by an affected EGU in demonstrating compliance with a rate-based emission standard in such an approved state plan.

An ERC is issued separately from any other instruments that may be issued for a MWh of energy generation or energy savings from a qualifying measure. Such other instruments may be issued for use in meeting other regulatory requirements (e.g., such as state RPS and EERS requirements) or for use in voluntary markets. An ERC may be issued based on the same data and verification requirements used by existing REC and EEC tracking systems for issuance of RECs and EECs.

The EPA notes that the definitions of other instruments, such as RECs, differ (as established under state statute, regulations, and PUC orders) and that requirements under state regulatory programs that use such instruments, such as state RPS, also differ. As a result, states may want to assess, when developing their state plan, how such existing instruments may interact with ERCs. For example, a state may want to assess how issuance of ERCs pursuant to a state plan may interact with compliance with a state RPS by entities affected under relevant state RPS regulations or PUC orders. The interaction of other instruments and ERCs may also impact existing or future arrangements in the private marketplace. Actions taken by states, separate from the design of their state plan, could address a number of these potential interactions. For example, state RPS regulations that specify a REC for a MWh of RE generation, and the attributes related to that MWh, may or may not explicitly or implicitly recognize that the holder of the REC is also entitled to the issuance of an ERC for a MWh of electricity generation from the eligible RE resource. This could impact existing and future RE power purchase agreements or REC purchase agreements. Such interactions among existing instruments and ERCs could also impact how marketing claims are made in the voluntary RE market. How a state might choose to address these potential interactions will depend on a number of factors, including the utility regulatory structure in the state, existing statutory and regulatory requirements for state RPS, and existing RE power purchase agreements and REC contracts.

g. Program review. The EPA is requiring that states periodically review the administration of their rate-based emission trading programs. The results of these program reviews must be submitted by states to the EPA as part of their required reports on the implementation of their state plans, as described in sections VIII.D.a.(5) and VIII.D.2.b.(4), and must be made publicly available. Such a review submitted as part of a required state report provides for the implementation of rate-based emission standards per the requirements of CAA section 111(d)(2). For a rate-based emission trading program, the review must cover the reporting period addressed in the state's periodic reports to the EPA on plan implementation.

The program review must address all aspects of the administration of a state's rate-based emission trading program, including the state's evaluations and regulatory decisions regarding eligibility applications for ERC resources and M&V reports (and associated EM&V activities), and the state's issuance of ERCs. The program review must assess whether the program is being administered properly in accordance with the state's approved plan; whether ERC eligibility applications and M&V reports are being properly evaluated and acted upon (i.e., approved or disapproved); whether reported annual MWh of generation and savings from qualified ERC resources are being properly quantified, verified, and reported in accordance with approved EM&V plans, and whether appropriate records are being maintained. The program review must also address determination of the eligibility of verifiers by the state and the conduct of verifiers, including the quality of verifier reviews. Where significant deficiencies are identified by the state's program review, those deficiencies must be rectified by the state in a timely manner.

States must collect, compile, and maintain sufficient data in an appropriate format to support the periodic program review. The EPA will review the results of each program review. The EPA may also audit a state's administration of its rate-based emission trading program and pursue appropriate remedies where significant deficiencies are identified.

3. EM&V requirements for RE, demand-side EE, and other measures used to adjust a CO_2 rate

This section discusses EM&V for RE, demand-side EE, and other measures that are used to generate ERCs or otherwise adjust an emission rate.[1002] EM&V is applied for purposes of quantifying and verifying MWh in rate-based state plans, as described below. Rate-based state plans must require that eligible resources document in EM&V plans and M&V reports how all MWh saved and generated from eligible measures will be quantified and verified. Additionally, with respect to EM&V, the EPA's proposed model rule identifies certain industry best practices that, upon finalization, could be adopted as presumptively approvable components of a state plan.[1003]

[1002] EM&V is defined to mean the set of procedures, methods, and analytic approaches used to quantify the MWh from demand-side EE and RE and other measures, and thereby ensure that the resulting savings and generation are quantifiable and verifiable.

[1003] The EPA recognizes that EM&V best practices are routinely evolving to reflect changes in markets, technologies and data availability. Therefore the agency is providing draft EM&V guidance with the proposed model rule, which can be updated over time to address any such changes to best practices. The guidance can also identify and describe alternative quantification approaches that may be approved for use, provided that such approaches meet the requirements of the finalized EM&V requirements.

As discussed in section VIII.K.1, quantified and verified MWh of RE generation, EE savings,[1004] and other eligible measures may be used to adjust a CO_2 emission rate when demonstrating compliance with the emission guidelines. In states implementing emission standard type plans with rate-based trading, affected EGUs adjust their reported emission rate using ERCs, which represent MWh that are quantified and verified according to the EM&V requirements described in this section. The EPA will evaluate the overall approvability of the state plan taking into consideration whether the state's submitted EM&V requirements satisfy these final emission guidelines.

a. Discussion of proposed EM&V approach and public comment. The EPA proposed that a state plan that incorporates RE and demand-side EE measures must include an EM&V plan that explains how the effect of these measures will be determined in the course of plan implementation. The proposal sought comment on the suitability of current state and utility EM&V approaches for RE and demand-side EE programs in the context of an approvable state plan, and on whether harmonization of state approaches, or

[1004] In the context of demand-side EE, "measure" refers to an installed piece of equipment or system at an end-use energy consumer facility, a strategy intended to affect consumer energy use behaviors, or a modification of equipment, systems or operations that reduces the amount of electricity that would have delivered an equivalent or improved level of end-use service in the absence of EE.

supplemental actions and procedures, should be required in an approvable state plan, provided that supporting EM&V documentation meets applicable minimum requirements. In the proposal, the EPA also indicated that it would issue guidance to help states, sources, and project providers quantify and verify MWh savings and generation resulting from zero-emitting RE and demand-side EE efforts.

The proposal and associated "State Plans Considerations" TSD[1005] suggested that the EPA's EM&V requirements could leverage existing industry practices, protocols, and tracking mechanisms currently utilized by the majority of states implementing RE and demand-side EE. The EPA further noted that many state regulatory bodies and other entities already have significant EM&V infrastructure in place and have been applying, refining, and enhancing their evaluation and quality assurance approaches for over 30 years, particularly with regard to the quantification and verification of energy savings resulting from utility-administered EE programs. The proposal also observed that the majority of RE generation is typically quantified and verified using readily available, reliable, and transparent methods such as direct metering of MWh.

[1005] See discussion beginning on p. 34 of the State Plan Considerations TSD for the Clean Power Plan Proposed Rule: http://www2.epa.gov/carbon-pollution-standards/clean-power-plan-proposed-rule-state-plan-considerations.

As a result, the agency took comment on whether this infrastructure is appropriate in the context of approvable state plans for use in rate-based state plans that include RE, demand-side EE, and other measures. The majority of commenters addressing this question responded affirmatively, indicating that existing EM&V infrastructure is appropriate to assure quality, credibility, and integrity. However, commenters also noted that EM&V methods are routinely improving and changing over time, and that the EPA's requirements and guidance should be responsive to such changes, should avoid locking in outdated methods, and should be updated to maintain relevance.

Another point made by commenters is that, despite the observed improvements in EM&V over time, quantification knowledge is more robust for some EE program and policy types than for others. Additionally, there is relatively limited experience applying EM&V protocols and procedures to emission trading programs, where each MWh of replaced generation that can be bought and sold by a regulated source. As a result, the EPA's final emission guidelines and proposed model rule include a number of safeguards and quality-control features that are intended to ensure the accuracy and reliability of quantified EE savings.

b. <u>Requirements for EM&V and M&V submittals</u>. As discussed in section VIII.K.2, these final guidelines require that state plans include a requirement that EM&V plans and M&V reports be submitted to the state for rate-based emission trading programs. States must require that at the initiation of an eligible measure, project providers must develop and submit to the state an EM&V plan that documents how requirements for quantification and verification will be carried out over the period that MWh generation or savings are produced. States must also require that after a project or program is implemented, the provider must submit periodic M&V reports to confirm and describe how each of the requirements was applied. These reports must also specify the actual MWh savings or generation results, as quantified by applying EM&V methods on a retrospective (ex-post) basis. States may not allow MWh values that are quantified using ex-ante (pre-implementation) estimates of savings. As previously described, the EPA took comment on the suitability of current state and utility EM&V approaches for RE and demand-side EE programs in the context of an approvable state plan. These final requirements regarding EM&V plans and M&V reports are intended to leverage and closely resemble those already in routine use.

For energy generating resources, including RE resources, states may leverage the programs and infrastructure they have in place for achievement of their RPS and take advantage of registries in place for the issuance and tracking of RECs. Many existing REC tracking systems already include well-established safeguards, documentation requirements, and procedures for registry operations that could be adapted to serve similar functions in relation to the final emission guidelines. For example, a key element of RPS compliance in many states that parallels the final rule's requirements is that each generating unit must be uniquely identified and recorded in a specified registry to avoid the double counting of credits at the time of issuance and retirement. In addition, the existing reports and documentation from tracking systems may, together with eligible independent third party verification reports, serve as the substantive basis for eligibility applications, EM&V plans and M&V reports for the issuance of ERCs to energy generating resources for affected EGUs to meet their obligations under the final rule. With respect to actual monitoring requirements, many existing REC registries include provisions for the monitoring of MWh of generation that would be appropriate to meet state plan requirements pursuant to the final rule, such as requirements to use a revenue quality meter.

For demand-side EE, states must require that EM&V plans that are developed for purposes of adjusting an emission rate under this final rule include several specific components. The EPA notes these components reflect existing provisions in a wide range of publicly or rate-payer funded EE programs and energy service company projects. One of these components state plans must require is a demonstration of how savings will be quantified and verified by applying industry best-practice protocols and guidelines, as well as an explanation of the key assumptions and data sources used. State plans must require EM&V plans to include and address the following:

- A baseline that represents what would have happened in the absence of the EE intervention, such as the equipment that would most likely have been installed – or that a typical consumer or building owner would have continued using – in a given circumstance at the time of EE implementation
- The effects of changes in independent factors affecting energy consumption and savings; that is, factors not directly related to the EE action, such as weather, occupancy, or production levels
- The length of time the EE action is anticipated to continue to remain in place and operable, effectively providing savings (in years)

Examples and discussion of industry best-practices for executing each of the above-listed components is provided in the EPA's draft EM&V guidance for demand-side EE, which is being released in conjunction with the proposed model rule. The model trading rule defines certain EM&V provisions for demand-side EE, as well as specific provisions for non-affected CHP and RE resources, including incremental hydroelectric power, biomass RE facilities, and waste-to-energy facilities, that may be presumptively approvable upon finalization.

The EPA notes that state plans incorporating the finalized model rule for rate-based emission trading programs could be presumptively approvable as meeting the requirements of CAA section 111(d) and the EM&V provisions in these emission guidelines. The EPA will evaluate the approvability of such state plans through independent notice and comment rulemaking.

c. Skill certification standards. Using a skilled workforce to implement demand-side EE and RE projects and other measures intended to reduce CO_2 emissions, and to evaluate, measure, quantify and verify the savings associated with EE projects or the additional generation from performance improvements at existing RE projects are both important in existing best industry practices. Several commenters pointed out that skill certification standards can help to assure quality and credibility of demand-side EE, RE, and other CO_2 emission reduction projects. The EPA also recognizes that a skilled workforce performing the EM&V is important to substantiate the authenticity of emissions reductions.

The EPA is therefore recommending in conjunction with the EM&V requirements discussed in this section, that states are encouraged to include in their plans a description of how states will ensure that the skills of workers installing demand-side EE and RE projects or other measures intended to reduce CO_2 emissions as well as the skills of workers who perform the EM&V of demand-side EE and RE performance will be certified by a third party entity that:

1) Develops a competency based program aligned with a job task analysis and certification scheme;
2) Engages with subject matter experts in the development of the job task analysis and certification schemes that represent appropriate qualifications, categories of the jobs, and levels of experience;
3) Has clearly documented the process used to develop the job task analysis and certification schemes, covering such elements as the job description, knowledge, skills, and abilities;
4) Has pursued third-party accreditation aligned with consensus-based standards, for example ISO/IEC 17024.

Examples of such entities include: parties aligned with the Department of Energy's (DOE) Better Building Workforce Guidelines and validated by a third party accrediting body recognized by DOE; or by an apprenticeship program that is registered with the federal Department of Labor (DOL), Office of Apprenticeship; or with a state apprenticeship program approved by the DOL, or by another skill certification validated by a third party accrediting body. This can help to substantiate the authenticity of emission reductions due to demand-side EE and RE and other CO_2 emission reduction measures.

4. Multi-state coordination: rate-based emission trading programs

Individual rate-based state plans may provide for the interstate transfer of ERCs, which would enable an ERC issued by one state to be used for compliance by an affected EGU with a rate-based emission standard in another state. Such plans would include regulatory provisions in each state's emission standard requirements that indicate that ERCs issued in other partner states may be used by affected EGUs for compliance. Such plans must indicate how ERCs will be tracked from issuance through use for compliance, through either a joint tracking system, interoperable tracking systems, or an EPA-administered tracking system.[1006]

The approaches described in this section are only allowed for states that impose rate-based emission limits for affected

[1006] The emission standards in each individual state plan must include regulatory provisions that address the issuance of ERCs and tracking of ERCs from issuance through use for compliance, as described in section VIII.K.2. The description here addresses how those regulatory provisions will be implemented through the use of a joint tracking system, interoperable tracking systems, or an EPA-administered tracking system.

EGUs that are equal to the CO_2 emission performance levels in the emission guidelines. This approach is necessary to ensure that each state that is allowing for the interstate transfer of ERCs is implementing rate-based emission standards for affected EGUs at the same lb CO_2/MWh level.[1007] This assures that all the participating states are issuing ERCs to affected fossil steam and NGCC units that emit below their assigned emission standards on the same basis.

This approach avoids providing different incentives, in the form of issued ERCs, to affected steam generating units and NGCC units in different states that have comparable CO_2 emission rates. Providing different incentives to similar affected EGUs across states could create distortionary effects that lead to shifts in generation among states based on the different CO_2 emission rate standards applied by states to similar types of affected EGUs. Providing for the interstate trading of ERCs in this instance would exacerbate these distortionary effects by providing arbitrage opportunities.

[1007] As noted above in section VIII.C.6, states also have the option of implementing a multi-state plan with a single rate-based emission standard that applies to all affected EGUs in the participating states. This approach would also allow for interstate transfers of ERCs. Under this approach, a rate-based multi-state plan would include emission standards for affected EGUs based on a weighted average rate-based emission goal, derived by calculating a weighted average CO_2 emission rate based on the individual rate-based goals for each of the participating states and 2012 generation from affected EGUs.

When demonstrating that a state's CO_2 emission goal is achieved as a result of plan implementation, a state with linkages to other states would be required to demonstrate that any ERCs issued by another state that are used by affected EGUs in the state for compliance with its rate-based CO_2 emission standards were issued by states with an EPA-approved state plan.[1008]

States could implement these linkages among state plans with rate-based emission trading systems through three different implementation approaches: (1) plans that are "ready-for-interstate-trading;" (2) plans that include specified bilateral or multilateral linkages; and (3) plans that provide for joint ERC issuance among states with materially consistent regulations. These approaches are summarized below:

- Ready-for-interstate-trading plans: A state plan recognizes ERCs issued by any state with an EPA-approved plan that also uses a specified EPA-approved[1009] or EPA-administered

[1008] This could be done by reference to data in the tracking system used to implement a state's rate-based emission trading program that identifies the origin of each ERC (e.g., by serial identifier).
[1009] The EPA would designate tracking systems that it has determined adequately address the integrity elements necessary for the issuance and tracking of ERCs, as described in section VIII.K.2. Under this approach, a state could include in its plan such a designated tracking system, which has already been reviewed by the EPA.

tracking system. Plans are approved individually. A state plan need not designate the individual states by name from which it would accept issued ERCs. States can join such a coordinated approach over time, without the need for plan revisions.[1010]

- Specified bilateral linkage: States recognize ERCs issued by named partner states. Partner states must demonstrate that they use a shared tracking system, interoperable tracking systems, or an EPA-administered tracking system. Plans are approved individually, including review of the shared tracking system or interoperable tracking systems.
- Joint ERC issuance: States implement materially consistent rate-based emission trading program regulations and share a tracking system. States coordinate their review of submissions for ERC issuance[1011] and their issuance of ERCs

[1010] The EPA notes that it is proposing a model rule for a rate-based emission trading program that could be used by states interested in implementing a ready-for-interstate-trading plan approach. A state plan that included the finalized rate-based model rule could be presumptively approvable as meeting the requirements of CAA section 111(d) and the emission guidelines. If a state plan also met the requirements described in this section for ready-for-interstate-trading plans, it could be approved as ready-for-interstate trading.
[1011] This refers to eligibility applications and M&V reports, which are required submittals for non-affected EGU entities seeking the issuance of ERCs. Where affected EGUs are issued ERCs for emission performance below a specified CO_2 emission rate, these ERCs are issued by the individual state in which

to the shared tracking system. Issued ERCs are recognized as usable for compliance in all states using the shared tracking system. Plans are approved individually, including review of the shared tracking system.

These implementation approaches are designed to streamline the process for linking emission trading programs, avoid or limit the need for plan revisions as new states join a collaborative emission trading approach, and facilitate the development of regional or broader multi-state markets for ERCs.[1012]

L. Treatment of Interstate Effects

This section discusses how differing characteristics across states and sources could create risks of increased emissions under this rule through double counting of emission reduction measures or through foregone emission reductions due to movement

---

they are subject to a rate-based emission standard. Requirements for ERC issuance are discussed in section VIII.K.2.

[1012] The EPA also notes that individual state plans may utilize RE and demand-side EE (and other eligible measures), that occur in other states, as described in section VIII.L addressing interstate effects. Under an individual state plan, ERCs could be issued for RE and demand-side EE measures that occur in other states, provided the EE/RE provider submits the measures to the state and the measures meet requirements in the state's rate-based emission trading program requirements. The multi-state approaches described above provide additional flexibility for states to informally and formally coordinate their implementation of rate-based plans across states while retaining individual rate-based state goals.

of generation from source to source. The section also discusses how the final rule addresses these concerns: first, through the characteristics of goal-setting and the framework of state plans, and second, through specific requirements intended to minimize the risk of double counting and increased emissions.[1013]

The section is structured as follows. First, this section discusses the dynamics that cause these risks to potentially arise. Second, it provides a discussion of how the risks of double counting and foregone reductions are minimized through the following provisions: the nature of the final emission performance rates, multi-state plan options that limit distortionary effects, the structure of mass-based plan and rate-based plan accounting for emission reductions measures, and specified restrictions on the counting in a rate-based plan of emission reduction measures located in a mass-based state. Finally, the section discusses how the rate-based accounting framework minimizes incentives to develop emission reduction measures in particular states due to differences in rates.

In the June 2014 proposal, the EPA acknowledged that emission reduction measures implemented under a state plan will

---

[1013] This section does not discuss emission leakage and how it is addressed by this final rule. See section VII.D for a discussion of emission leakage and its impact on state goal equivalence. See section VIII.J for a discussion of requirements for mass-based plans to address leakage.

likely have impacts across many affected sources both within and across state boundaries due to the dynamic and interstate nature of the electric grid. These interactions may be driven in part due to differences in power sector dynamics across states, including the types of affected EGUs in a state, the availability of eligible zero-emitting resources, and the costs of different compliance options and existing policies in states. These state-level characteristics play out across dynamic regional grids that provide electricity across states. EGUs are dispatched both within and across state borders and are constantly adjusting behavior in response to available generation and electricity demand on the regional grid. Whenever CO_2 emission reduction measures, such as RE or demand-side EE, are implemented, the measure can affect EGU generation and CO_2 emissions across the regional grid. These impacts can change across multiple affected EGUs on a minute-to-minute, hour-to-hour, and day-to-day basis as electricity demand changes and different generating resources are dispatched. These impacts will also change in the long-term, as the generating fleet and load behavior change over a period of years. Interactions among EGUs across states may be further driven by the plan types (i.e., rate-based or mass-based) and the individual characteristics of the plans that states choose to adopt.

In the context of this complex environment of federal and state policies and interstate grids, commenters expressed concern about the risk of double-counting of measure impacts, particularly across state plans. Commenters stated that there is potential for distortionary incentives that could undermine overall CO_2 emission reductions (often termed emissions "leakage"). Commenters requested that the EPA ensure that states avoid double-counting and minimize leakage effects when demonstrating achievement of state goals.

The EPA acknowledges that some amount of shifts in generation between sources within and across state borders will inevitably be present and unavoidable in the context of this rule and may affect how affected EGUs achieve the applicable CO_2 performance rates or state goals under a state plan. In fact, the definition of the BSER is premised upon shifts in generation across sources, particularly shifts from higher- to lower-emitting units that result in overall emission reductions. However, in the context of these shifts, the extent to which the movement of generation may be driven not by the potential to capture lower-cost emission reduction but by arbitrage across different emission rates, causing inefficiencies in the power markets and possibly eroding overall emission reductions, should be minimized.

In particular, the EPA has determined final emission performance rates that serve to reduce relative differences between state goals, and thus also focus the potential for generation shifting between affected EGUs on achieving the emission reductions quantified in the BSER. In the proposal, goals differed more substantially between states based upon an assessment of what emission reduction potential units could access located within their state. Commenters observed that due to the interconnected nature of the power sector, units are not limited to such emission reduction measures within their state, and indeed any operational decisions that units take necessarily influence operational decisions at other units throughout the interconnected grid. As a result, in the final rule, we are finalizing CO_2 emission performance rates, informed by regional emission reduction potential, for fossil fuel-fired electric utility steam generating units and stationary combustion turbines that are applied consistently across all affected EGUs. As the same source category-specific performance rates are applied to all units in the contiguous U.S. regardless of the state in which they are located, any differences between state goals in this final rule stem only from the relative prevalence in each state of fossil fuel-fired electric utility steam generating units and stationary combustion turbines. Consequently, there is substantially less incentive in this final rule for units to shift generation across state lines based solely on differences in state goals, since there is substantially less difference between the final rule's state goals, and since those state goals are themselves premised on nationally consistent source category-specific performance rates.

The EPA has also incorporated elements into the rule that seek to minimize double-counting and the distortionary effects that could potentially increase emissions. First, states have the option to adopt multi-state plans that reflect regional interactions while eliminating chances for double counting and providing a level playing field for trading of rate-based ERCs or mass-based allowances. Second, in the method for rate-based plan compliance, the rule provides a general accounting approach for adjusting an affected EGU's or state's CO_2 rate that inherently acts to minimize state differences. These points are further discussed below.

For both rate-based and mass-based approaches, the rule provides states with the option of creating either "ready-for-interstate-trading" plans or multi-state plans. These options for states working together provide opportunities to enable protections against double counting and minimize the presence of distortionary effects.

"Ready-for-interstate-trading" and multi-state plans engage multiple states in the same system for the purpose of trading mass-based allowances or issuing and trading rate-based ERCs.

This allows for efficient implementation of protections against double counting provided in state plan requirements, as multiple state are participating in the same tracking systems. This is particularly useful in the context of rate-based ERC issuance and tracking, where it must be ensured that the ERCs being generated are unique across rate-based plans.

This final rule also reduces distortionary effects within the context of multi-state plans. It does so by restricting states to interstate trading with equivalently denominated mass-based allowances or rate-based ERCs. In a mass-based context, all affected EGUs will trade uniform mass-based allowances, whether in a "ready-for-interstate-trading" plan or multi-state plan. In a rate-based plan context, "ready-for-interstate-trading" states must all adopt as their goal the CO_2 emission performance rates as their joint goal. This assures that all the participating states are issuing ERCs using the same subcategorized performance rates, and that the sources in each state have equivalent incentives for trading ERCs. Similarly, under multi-state plans, the relevant states must choose to adopt identical rates, either the CO_2 emission performance rates or a weighted average goal rate based on the rate-based goals of all the states involved. These requirements along with a method for calculating a weighted average goal rate are specified in section VIII.C.5.

Under all types of state plans, states must ensure that the emission reduction measures counted as part of meeting their plan requirements are not duplicative of any measures that are counted by another state, in order to avoid double counting of the MWhs of generation or energy savings that these measure produce. Depending on the accounting method used to reflect these measures in state goals, interstate effects could still allow for the double counting of the emission reductions resulting from these measures, particularly if mathematical adjustments were made to stack emissions to reflect these reductions. Depending on how these measures are accounted for, the reductions could be counted by both the state that deployed the measure, and the state that reports a reduction in fossil generation or reported emissions. In this final rule, the MWh-based general accounting approaches for both mass-based and rate-based plans have been specifically designed to eliminate the risk of double counting of reductions, because emission reduction measures are accounted for only through their inherent impact on stack emissions for affected EGUs.

Mass-based plans rely exclusively on reported stack emissions for determining whether a mass-based CO_2 emission goal is achieved. This means that under a mass-based plan any emission reduction measures that are implemented are automatically accounted for in reduced stack emissions of CO_2

from affected EGUs, which avoids concerns about counting the same mass reductions in two different mass-based states.

In a rate-based plan, there needs to be an explicit adjustment of reported CO_2 emission rates from affected EGUs, to reflect the measures that substitute low- or zero-emitting generation or energy savings for affected EGU generation. States with rate-based plans must demonstrate that measures used to adjust their CO_2 emission rate, such as RE and demand-side EE, are non-duplicative. The proposal attempted to address this issue in part by limiting demand-side EE that states could claim to in-state measures. In fact, those in-state measures still have an impact outside of the state and under the proposal's approach, states would have been restricted from taking credit for all the measures they have put in place that reduce CO_2 emissions. Therefore, the EPA is finalizing a treatment that allows states to count all in-state and out-of-state measures, while addressing interstate effects through the structure of the rule's accounting approach for adjusting the CO_2 emission rate of an affected EGU, detailed in section VIII.K.1 above, used to show that the state has met its obligation under its state plan.

The general accounting approach for adjusting the CO_2 emission rate of an affected EGU inherently accounts for the regional nature of how substitute generation and energy savings will impact affected EGU generation and CO_2 emissions. The following discussions refer to the substituting generation and energy savings in question as RE and demand-side EE, but this method can apply to other measures that were not included in the determination of the BSER that substitute for affected EGU generation. The adjusted CO_2 emission rate gives credit to the affected EGU or state for the MWhs of RE and demand-side EE it is responsible for deploying, by allowing those MWhs to be added to the denominator of the CO_2 rate, but makes no adjustment to the numerator. Instead, the numerator reflects reported stack emissions, which will reflect the extent to which RE and demand-side EE reduced the affected EGU's generation and emissions, without needing to account for the state in which the RE or demand-side EE originated, or approximating exactly how it impacted the regional grid. Double-counting of CO_2 emission reductions is prevented because the reported emissions from each unit are represented in the numerator of each of those units' emission rates, and those real emissions capture whatever emission reduction impact occurred with regard to any particular MWh of RE or demand-side EE. Because the general accounting approach disallows any adjustment to any EGU's reported emissions, it is not possible for the real emission reductions prompted by any particular measure to be double-counted.

Double-counting of MWhs in the denominator can be avoided because it is relatively straightforward to quantify the MWhs that the affected EGU is responsible for deploying and add them to the denominator, and this method aligns well with the MWh-denominated trading system described in this final rule. As long as it is assured that the MWhs of RE and demand-side EE are only being claimed by one affected EGU or state, as is outlined in section VIII.K, then there is no double-counting of MWh. Therefore, the accounting method avoids double counting of both CO_2 emission reductions and MWhs, the two characteristics of RE and demand-side EE measures that affect CO_2 emission rates. For further discussion of the MWh-based accounting method, including a calculation example, see section VIII.K.1.

There may also be interactions between mass-based and rate-based plans regarding counting measures, specifically where measures that provide substitute or avoided generation, such as RE and demand-side EE, are located in a mass-based state and can also be used by a rate-based state in meeting the CO_2 performance rates or state goals. The EPA received comments on this particular issue, and many expressed concerns that this use of mass-based resources in a rate-based state would result in double-counting of emission reductions.

Commenters provided analyses specifying how two states can benefit from the same RE and demand-side EE measures as a result of rate- and mass-based plan interactions. Some commenters considered this double-counting of emission reductions, and requested specific mathematical adjustments of reported generation or CO_2 emissions from affected EGUs under either rate-based or mass-based state plans in order to eliminate double-counting.

The EPA has determined that, in the context of interactions among rate-based and mass-based plans, there is not explicit double-counting of the CO_2 emission reductions associated with counting measures located in mass-based states, considering the accounting methods outlined in this final rule. First, as discussed above, the accounting method for adjusting the CO_2 emission rate only counts the MWhs generated by a measure to adjust the MWh in the denominator of its reported CO_2 emission rate. The CO_2 emissions impacts of the measures will be reflected in the rate-based state only to the extent that the MWhs resulted in lower reported CO_2 emissions from an affected EGU in the rate-based state. To the extent that measures that provide substitute or avoided generation reduce generation from affected EGUs in a mass-based state, the effect of those measures is reflected in lower reported CO_2 emissions of the mass-based EGUs. The CO_2 emission reductions reflected in the rate and the mass state will necessarily be mutually exclusive, because both are based on reported stack emissions. Additionally, the mechanism in the mass-based state that is assuring CO_2 emission reductions is the mass budget, which is met by affected EGUs adjusting their generation. Low- or zero-emitting MWhs from resources like RE and demand-side EE can serve load in the mass-based state and play a role in lowering compliance costs, but they play no direct role in mass-based compliance. As a result, no double-counting of emission reductions can take place.

Though there is no risk of double-counting emissions, some commenters expressed the concern that overall CO_2 emissions reductions would be foregone in situations where a source in a rate-based state counts the MWh from measures in a mass-based state, but the generation from that measure acts solely to serve load in the mass-based state. In that scenario, expected CO_2 emission reduction actions in the rate-based state are foregone as a result of counting MWh that resulted in CO_2 emission reductions in a mass-based state. Therefore the EPA is restricting the ability of rate-based states to claim emission reduction measures, such as RE and demand-side EE, located in mass-based states.

While the EPA understands this concern regarding foregone reductions, we do not believe it is appropriate to restrict RE crediting unilaterally between rate-based and mass-based states. Such a restriction could cut some states off from regional RE supplies that are assumed in the BSER building block 3 and incorporated in the CO_2 emission performance rates and state CO_2 goals. Allowing crediting between rate- and mass-based states, as long as the risk of foregone CO_2 emission reduction actions in rate-based states are minimized, will assure a supply of eligible RE MWhs that will further enable affected EGUs and states to meet obligations under the final rule. Therefore, the EPA has determined that it is appropriate for rate-based states to count MWhs from RE located in mass-based states, subject to the condition that the generation in question was intended to meet electricity load in a state with a rate-based plan.[1014] This may apply to some or all of the generation from an individual RE installation. To assure that the RE generation in question meets this condition, the EPA is requiring that RE generation from RE installations located in a mass-based state can only be counted in a rate-based state if the electricity generated is delivered with the intention to meet load in a state with a rate-based plan, and was treated as a generation resource used to serve regional load that included the rate-based state. This can be demonstrated through, for example, the provision of a power delivery contract or power purchase agreement in which an entity in the rate-based state contracts for the supply of the MWhs in question. The EPA is providing flexibility to states regarding the nature of the required demonstration, though the state must

[1014] This does not need to necessarily be the state where the MWh of energy generation from the RE measure is used to adjust the CO_2 emission rate of an affected EGU.

specify eligible demonstrations for approval in state plans. Under an emission standards plan, this demonstration would be made by the provider of the measure seeking ERC issuance to the rate-based state.

The following are examples of how requirements for a demonstration could be established in state plans and used to allow RE in a mass-based state to be counted in a rate-based state. For an emission standards state plan, a state could specify in the regulations for the rate-based emission standards included in its state plan that it will require an RE provider that seeks the issuance of ERCs to show that load-serving entities in the rate-based state have contracted for the delivery of the RE generation that occurs in a mass-based state to meet load in a rate-based state. Under this approach, an RE provider in a mass-based state could submit as part of an eligibility application a delivery contract or power purchase agreement showing that the generation was procured by the utility, and was treated as a generation resource used to serve regional load that included the rate-based state. This documentation would be sufficient demonstration to allow the RE generating resource to meet this additional geographic eligibility requirement for the amount of generation in question. All quantified and verified RE MWhs submitted for ERC issuance would need to be associated with that power purchase contract or agreement, and this fact would need to be demonstrated in the M&V reports submitted for issuance of ERCs.

The ability for a rate-based state to count MWhs located in a mass-based state under the above conditions is limited to RE. Rate-based states are not allowed to claim demand-side EE or any other emission reduction measures that were not included in the determination of the BSER located in mass-based states for ERC issuance. While this limits rate-based sources' access to additional resources, providing that access would result in a risk of foregone reductions. Further, unlike RE, there is no obligation related to demand-side EE and other measures that were not included in the determination of the BSER incorporated in the CO_2 emission performance rates or state rate-based goals which would necessitate facilitating access to those resources. This treatment also does not apply to fossil-fuel fired EGUs, such as NGCC units. If a mass-based emission standard has been applied to an affected EGU, there is no valid way to calculate whether it has MWh that are eligible for crediting, as is possible under a rate-based plan.

Finally, as stated earlier, commenters also expressed concern about the potential for relative increases in emissions to occur given relative differences between sources and states. These differences could include states' goals under either the rate- or mass-based approaches, or states' accounting of new sources. These differences could induce increased generation in one state over another because the costs of compliance and relative costs of generation would vary between states. There was particular concern regarding how these differences would provide incentives for increasing generation at new fossil sources and expanding utilization of existing affected EGU generation in states that have less stringent goals, and that this movement of generation would result in increased emissions overall. This could potentially result in the achievement of performance rates but with fewer overall CO_2 emissions reductions than projected nationally under the proposal.

Commenters suggested that the issuance and trading of emission credits across states under a rate-based approach would result in incentives to create credits, through the development of RE for example, in certain states with higher state goals, and this could also be a source of increased overall emissions. They noted that RE siting would thus not occur in the most optimal locations. The commenters assumed that zero-emitting credits are denominated in mass units by multiplying the number of MWh by some emission rate: either the state goal rate, the current state emission rate, a regional emission rate, or a calculated marginal rate. If those rates were higher in any states, zero-emitting MWhs would create more mass-denominated credits in those states, and thus RE and demand-side EE would be more valuable.

The incentive to target the location of zero-emitting generation or energy savings between states based on variation in its emission reduction value has been minimized by the fact that states participating in rate-based interstate trading must adopt the same emission performance rates or rate-based state goals. It is further minimized, even outside of an interstate trading framework, by the nature of the accounting method finalized in this rule. As explained above regarding the general accounting approach and the trading framework, we are adjusting rates using calculated MWhs, not based upon an emission reduction approximation as commenters outlined above. Not only does the method allow emission reductions to be accounted for as they occur across the grid, but it means the ERCs being traded across states represent one MWh of zero-emitting generation in whatever state it originated, and its value is unaffected by any emission rate associated with its state of origin. Thus, the finalized accounting and trading methods minimize the relative incentives for generating zero-emitting ERCs in a particular state based upon the rates that apply to that state.

IX. Community and Environmental Justice Considerations

In this section we provide an overview of the actions that the agency is taking to help ensure that vulnerable communities are not disproportionately impacted by this rulemaking.[1015]As described in the Executive Summary, climate change is an environmental justice issue. Low-income communities and communities of color already overburdened with pollution are likely to be disproportionately affected by, and less resilient to, the impacts of climate change. This rulemaking will provide broad benefit to communities across the nation, as its purpose is to reduce GHGs, the most significant driver of climate change. While addressing climate change will provide broad benefits, it is particularly beneficial to low-income populations and some communities of color (in particular, populations defined jointly by ethnic/racial characteristics and geographic location) where people are most vulnerable to the impacts of climate change (a more robust discussion of the impacts of climate change on vulnerable communities is provided in the Executive Order 12898 section XII.J of this preamble).

[1015] In this preamble, the EPA discusses environmental justice in two sections. Section XI.J specifically addresses how the agency has met the directives under Executive Order 12898. The EPA defines environmental justice as the fair treatment and meaningful involvement of all people regardless of race, color, national origin or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. This section of the preamble addresses actions that the agency is taking related to environmental justice and other issues (e.g., increased electricity costs) that may affect communities covered by Executive Order 12898 as well as other communities.

While climate change is a global phenomenon, the adverse effects of climate change can be very localized, as impacts such as storms, flooding, droughts, and the like are experienced in individual communities.

Vulnerable communities also often receive more than their fair share of conventional air pollution, with the attendant adverse health impacts. The changes in electricity generation that will result from this rule will further benefit communities by reducing existing air pollution that directly contributes to adverse localized health effects. These air quality improvements will be achieved through this rule because the electric generating units that emit the most GHGs also have the highest emissions of conventional pollutants, such as SO_2, NOx, fine particles, and HAP. These pollutants are known to contribute to adverse health outcomes, including the development of heart or lung diseases, such as asthma and bronchitis, increased susceptibility to respiratory and cardiac symptoms, greater numbers of emergency room visits and hospital admissions, and premature deaths.[1016] The EPA expects that the reductions in utilization of higher-emitting units likely to occur during the implementation of state plans will produce significant reductions in emissions of conventional pollutants, particularly

[1016] Six Common Air Pollutants. http://www.epa.gov/oaqps001/urbanair/

in those communities already overburdened by pollution, which are often low-income communities, communities of color, and indigenous communities. These reductions will have beneficial effects on air quality and public health both locally and regionally. Further, this rulemaking complements other actions already taken by the EPA to reduce conventional pollutant emissions and improve health outcomes for overburdened communities.

By reducing millions of tons of CO_2 emissions that are contributing to global GHG levels and providing strong leadership to encourage meaningful reductions by countries across the globe, this rule is a significant step to address health and economic impacts of climate change that will fall disproportionately on vulnerable communities. By reducing millions of tons of conventional air pollutants, the rule will lead to better air quality and improved health in those communities. We heard from many commenters who recognize and welcome those benefits.

There are other ways in which the actions that result from this rulemaking may affect communities in positive or potentially adverse ways and we also heard about these from commenters.

While the agency expects overall emission decreases as a result of this rulemaking, we recognize that some EGUs may operate more frequently, as a result of this rulemaking. To the extent that we project increases in utilization as a result of this rulemaking, we expect these increases to occur generally in lower-emitting NGCC units, which have minimal or no emissions of SO_2 and HAP, lower emissions of particulate matter, and much lower emissions of NOx compared to higher-emitting steam units. We acknowledge the concerns that have been raised on this point but also the difficulty in anticipating prior to plan implementation where those impacts might occur. In addition to providing for a robust state planning process with opportunity for meaningful input, the EPA is encouraging states to evaluate the actual impacts of their plans once implemented and, as described below, the EPA intends to conduct an assessment of whether and where emission increases may that may result from plan implementation and to work with states to mitigate adverse impacts, if any, in overburdened communities.

In addition to the many positive anticipated health benefits of this rulemaking, it also will increase the use of clean energy and will encourage EE. These changes in the electricity generation system, which are already occurring but may be accelerated by this program, are expected to have other positive benefits for communities. The electricity sector is, and will continue to be, investing more in RE and EE. The construction of renewable generation and the implementation of EE programs such as residential weatherization will bring investment and employment opportunities to the communities where they take place. We recognize that certain communities whose economies may be affected by changes in the utility and related sectors may be particularly impacted by the final rule. The EPA encourages states to make an effort to engage with these communities, including workers and their representatives in these sectors, including EE. It is important to ensure that all communities share in the benefits of this program. And while we estimate that its benefits will greatly exceed its costs (as noted in the RIA for this rulemaking), it is also important to ensure that to the extent there are increases in electricity costs, that those do not fall disproportionately on those least able to afford them.

The EPA has engaged with community groups throughout this rulemaking, and we received many comments on the issues outlined above from community groups, environmental justice organizations, faith-based organizations, public health organizations, and others.[1017] This input has informed this final rulemaking and prompted the EPA to consider other steps that the agency can take in the short and long term to assist states and

[1017] Detailed information on the outreach conducted as part of this rulemaking is provided in section I of this preamble.

stakeholders to consider environmental justice and impacts to communities in plan development and implementation.

It has also prompted us to work with our federal partners to make sure that states and communities have information on federal resources available to assist communities. We describe these resources below, as well as resources that the EPA will be providing to assist communities in accessing EE/RE and financial assistance programs. In our discussion below we also provide models of programs that other states are currently using to assist communities in accessing available resources that states could use when developing their plans.

Finally, and importantly, we recognize that communities must be able to participate meaningfully in state plan development. In this section, we discuss the requirements in the final rule for states, as they develop their plans, to provide opportunities for public involvement, and resources available to states and communities to enhance the success of the public process.

A. Proximity Analysis

The EPA is committed to assisting states and communities to develop plans that ensure there are no disproportionate, adverse impacts on overburdened communities. To provide information fundamental to beginning that process, the EPA has conducted a proximity analysis for this final rulemaking that summarizes demographic data on the communities located near power plants.[1018] The EPA understands that, in order to prevent disproportionately, high and adverse human health or environmental effects on these communities, both states and communities must have information on the communities living near facilities, including demographic data, and that accessing and using census data files requires expertise that some community groups may lack. Therefore, the EPA used census data from the American Community Survey (ACS) 2008-2012 to conduct a proximity analysis that can be used by states and communities as they develop state plans and as they later assess the final plans' impacts. The analysis and its results are presented in the EJ Screening Report for the Clean Power Plan, which is located in the docket for this rulemaking at EPA-HQ-OAR-2013-0602.

The proximity analysis provides detailed demographic information on the communities located within a 3-mile radius of each affected power plant in the U.S. Included in the analysis is the breakdown by percentage of community characteristics such as income and minority status. The analysis shows a higher percentage of communities of color and low-income communities living near power plants than national averages. It is important to note that the impacts of power plant emissions are not

[1018] The proximity analysis was conducted using the EPA's environmental justice mapping and screening tool, EJSCREEN.

limited to a 3-mile radius and the impacts of both potential increases and decreases in power plant emissions can be felt many miles away. Still, being aware of the characteristics of communities closest to power plants is a starting point in understanding how changes in the plant's air emissions may affect the air quality experienced by some of those already experiencing environmental burdens.

Although overall there is a higher fraction of communities of color and low-income populations living near power plants than national averages, there are differences between rural and urban power plants. There are many rural power plants that are located near small communities with high percentages of low-income populations and lower percentages of communities of color. In urban areas, nearby communities tend to be both low-income communities and communities of color. In light of this difference between rural and urban communities proximate to power plants and in order to adequately capture both the low-income and minority aspects central to environmental justice considerations, we use the terms "vulnerable" or "overburdened" when referring to these communities. Our intent is for these terms to be understood in an expansive sense, in order to capture the full scope of communities, including indigenous communities most often located in rural areas, thatare central to our environmental justice and community considerations.

As stated in the Executive Order 12898 discussion located in section XII.J of this preamble, the EPA believes that all communities will benefit from this final rulemaking because this action directly addresses the impacts of climate change by limiting GHG emissions through the establishment of CO_2 emission guidelines for existing affected fossil fuel-fired power plants. The EPA also believes that the information provided in the proximity analysis will promote engagement between vulnerable communities and their states and will be useful for states as they begin developing their plans. In addition to providing the proximity analysis in the docket of this rulemaking, the EPA will disseminate the proximity analysis to states and will make it publicly available on its Clean Power Plan (CPP) Community Portal. Furthermore, the EPA has also created an interactive mapping tool that illustrates where power plants are located and provides information on a state level. This tool is available at: http://cleanpowerplanmaps.epa.gov/CleanPowerPlan/.

Additionally, the EPA encourages states to conduct their own analyses of community considerations when developing their plans. Each state is uniquely knowledgeable about its own communities and well-positioned to consider the possible impacts of plans on vulnerable communities within its state. Conducting state-specific analyses would not only help states assess possible impacts of plan options, but it would also enhance a state's understanding of the means to engage these communities that would most effectively reach them and lead to valuable exchanges of information and concerns. A state analysis, together with the proximity analysis conducted by the EPA, would provide a solid foundation for engagement between a state and its communities.

Such state-specific analyses need not be exhaustive. An examination of the options a state is considering for its plan, and any projections of likely resulting increases in power plant emissions affecting low-income populations, communities of color populations, or indigenous communities, would be informative for communities. The analyses could include available air quality monitoring data and information from air quality models, and, if available, take into account information about local health vulnerabilities such as asthma rates or access to healthcare. Alternatively, a simple analysis may consider expected EGU utilization in geographic proximity to overburdened communities. The EPA will provide states with information on its publicly available environmental justice screening and mapping tool, EJ SCREEN, which they may use in conducting a state-specific analysis. The EPA will also provide states with resources containing examples of analyses that other states have conducted to examine the impacts of their programs on overburdened communities. Additionally, the EPA encourages states to submit a copy of their analysis if they choose to conduct one, with their initial and final plan submittals.

B. Community Engagement in State Plan Development

In sections VIII.D-E of this preamble, the EPA explains that states need to engage meaningfully with communities and other stakeholders during the initial and final plan submittal processes. Meaningful engagement includes outreach to vulnerable communities, sharing information and soliciting input on state plan development and on any accompanying assessments such as those described above, and selecting methods for engagement to support communities' involvement at critical junctures in plan formulation and implementation. This engagement also includes providing the public the opportunity to comment on the state's initial submittal and responding to significant comments received, including comments from vulnerable communities, as well as conducting a public hearing and responding to comments before a final state plan is submitted. Additionally, the EPA expects that states will conduct outreach meetings, which could include public hearings or listening sessions, before the initial submittal is made. The EPA also encourages states to provide background information about their proposed final state plan or their initial state plan in the appropriate languages in advance of their public hearing and at their public hearing. The EPA recommends that states provide translators and other resources at their public hearings, to ensure that members of the public can provide oral feedback.

In the initial submittal, the final rule requires that states provide information to the agency about the community engagement they have undertaken and the means by which they intend to involve vulnerable communities and other stakeholders as they develop their final plan. Furthermore, as noted in section VIII.E of this preamble, in determining if states are eligible for a 2-year extension for submission of final plans, the rule requires that states demonstrate how they are meaningfully engaging vulnerable communities and other interested stakeholders as part of their public participation process. The EPA consulted its May 2015, *Guidance on Considering Environmental Justice During the Development of Regulatory Actions*, when crafting this rulemaking and recommends that states consult it to assist them in engaging meaningfully with vulnerable communities.[1019] Additionally, states in their initial submittal and 2017 update must show how they identified the communities with whom they are engaging as they develop their plans. Some suggested actions that states could take to engage actively with the public, including conducting meaningful

[1019] Guidance on Considering Environmental Justice During the Development of Regulatory Actions. http://epa.gov/environmentaljustice/resources/policy/considering-ej-in-rulemaking-guide-final.pdf. May 2015.

engagement with vulnerable communities, are outlined in section VIII.E of this preamble. Additionally, as outlined in section VIII.D, the final plan submitted by states must include an overview of the public hearing(s) conducted and information on how the state ensured that the hearing(s) were accessible to stakeholders including vulnerable communities.

The EPA is committed to supporting states in effectively engaging with communities as they develop and implement their plans. The EPA will provide training and other resources throughout the implementation process that will assist states and communities in understanding plan requirements and options for plan development. These trainings will be a continuation of those that the EPA has already conducted with communities and states both pre- and post-proposal. The EPA will reach out to a wide variety of community stakeholders, including groups representing environmental justice communities, faith-based organizations, academic organizations working with vulnerable and overburdened communities, affordable housing advocates, public health professionals, public health organizations, and other community stakeholders.

C. Providing Communities with Access to Additional Resources

In addition to providing resources to states, the EPA encourages states to be aware of existing efforts undertaken by other states aimed at providing low-income communities access to financial and technical assistance programs for EE and RE, and to consider similar approaches that may make sense for their own states. The EPA encourages states to consider targeting economic development resources to communities that are likely to be negatively affected by ongoing changes in the utility and related sectors in support of efforts to diversify their economies, attract new sources of investment, and create new jobs.

One example of a program targeted at low-income communities is the Maryland EmPOWER Low Income Energy Efficiency Program (LIEEP).[1020] The LIEEP program administered by the Maryland Department of Housing and Community Development (DHCD) helps low-income households through free installation of energy conservation materials (i.e., installation, hot water system improvements, lighting retrofits, furnace cleaning, tuning and safety repairs, refrigerator retrofits, etc.).[1021] Funding for this program is provided by EmPOWER Maryland partners: Baltimore Gas and Electric, Southern Maryland Electric Cooperative, Delmarva Power, Allegheny Energy and Pepco.[1022] This program is available to both homeowners and renters.[1023] Additionally, the

[1020] EmPOWER Maryland Low Income Energy Efficiency Programs (LIEEP). http://www.mdhousing.org/website/Programs/lieep/Default.aspx.
[1021] Ibid.
[1022] Ibid.
[1023] Ibid.

Maryland Department of Housing provides low-income families with home heating bill assistance and furnace repairs and replacements through the Maryland Energy Assistance Program (MEAP).[1024] Maryland's Electric Universal Service Program (EUSP) helps low-income electric customers with their electric bills.[1025]

Another example of a program is EmPower New York, which provides no-cost energy solutions to low-income populations.[1026] Currently there are about 100,000 people who are receiving assistance. Both homeowners and renters are eligible to receive assistance under this program. The types of assistance available include EE upgrades (plugging leaks, adding insulation, replacing inefficient refrigerators and freezers and new energy-efficient lighting). Other states, like the State of Colorado's Energy Outreach Colorado program, offer similar resources for low-income populations.[1027]

In 2013, the New York State Energy and Research Development Authority (NYSERDA) was able to secure a triple-A rated financial guarantee from the state's Clean Water State Revolving Fund (SRF) for a $24 million bond issue. Proceeds funded residential EE loans that were available to all utility

customers, including low-income households. SRF eligibility was based on the beneficial impact of EE investment in reducing atmospheric deposition on impaired water bodies consistent with Section 319 of the Clean Water Act.

As discussed below, there are also many federal programs that can help low-income populations access the benefits of RE, EE, and the economic benefits of a cleaner energy economy.

In the coming months, the EPA will continue to provide information and resources for communities and states on existing federal, state, local, and other financial assistance programs to encourage EE/RE opportunities that are already available to communities. For example the EPA will provide a catalog of current or recent state and local programs that have successfully helped communities adopt EE/RE measures. The goal of these resources is to help vulnerable communities gain the benefits of this rulemaking by encouraging that states use these types of tools in their state plans. The use of these RE/EE tools can also help low-income households reduce their electricity consumption and bills.

The EPA recognizes the potential impacts that this rulemaking could have on jobs in communities. Therefore, in section VIII.G of this preamble, the EPA has outlined that states, in designing their state plans, should consider the effects of their plans on employment and overall economic development to realize the opportunities for economic growth and jobs that the plans offer. To the extent possible, states should try to assure that communities that may be expected to experience job losses can also take advantage of the opportunities for job growth or otherwise transition to healthy, sustainable economic growth (e.g., with regard to delivering EE measures and installing rooftop solar panels). Additionally, as part of the resources that we will be providing to states and low-income communities, the EPA will provide information on the Administration's Partnerships for Opportunity and Workforce and Economic Revitalization (POWER) Initiative and other programs that specifically target economic development assistance to communities affected by changes in the coal industry and the utility power sector.[1028]

D. Federal Programs and Resources Available to Communities

Federal agencies have a history of bringing EE and RE to low-income communities. Earlier this summer, the Administration announced a new initiative to scale up access to solar energy and cut energy bills for all Americans, in particular low- and moderate-income communities, and to create a more inclusive solar workforce. As part of this new initiative, the U.S. Department of Energy (DOE), the U.S. Department of Housing and

[1028] http://www.eda.gov/power

Urban Development (HUD), U.S. Department of Agriculture (USDA), and the EPA launched a National Community Solar Partnership to unlock access to solar energy for the nearly 50 percent of households and businesses that are renters or do not have adequate roof space to install solar systems, with a focus on low- and moderate- income communities. The Administration also set a goal to install 300 megawatts (MW) of RE in federally subsidized housing by 2020 and plants to provide technical assistance to make it easier to install solar energy on affordable housing, including clarifying how to use federal funding for EE and RE. To continue enhancing employment opportunities in the solar industry for all Americans, AmeriCorps is providing funding to deploy solar energy and create jobs in underserved communities, and DOE is working to expand solar energy education and opportunities for job training.

These recent announcements build on the many existing federal programs and resources available to improve EE and accelerate the deployment of RE in vulnerable communities. Some examples of these resources include: the Department of Energy's Weatherization Assistance Program, Health and Human Service's Low Income Home Energy Assistance Program, the Department of Agriculture's Energy Efficiency and Conservation Loan Program, High Cost Energy Grant Program, and the Rural Housing Service's Multi-Family Housing Program.

HUD supports EE improvements and the deployment of RE on affordable housing through its Energy Efficient Mortgage Program, Multifamily Property Assessed Clean Energy Pilot with the State of California, PowerSaver Program, and the use of Section 108 Community Development Block Grants. The Department of Treasury provides several tax credits to support RE development and EE in low-income communities, including the New Markets Tax Credit Program and the Low-Income Housing Tax Credit. The EPA's RE-Powering America's Land Initiative promotes the reuse of potentially contaminated lands, landfills and mine sites – many of which are in low-income communities – for RE through a combination of tailored redevelopment tools for communities and developers, as well as site-specific technical support. The EPA's Green Power Partnership is increasing community use of renewable electricity across the country and in low-income communities. The EPA partners with EE programs throughout the country that leverage ENERGY STAR to deliver broad consumer energy-saving benefits, of particular value to low-income households who can least afford high energy bills. ENERGY STAR also works with houses of worship to reduce energy costs – savings that can then be repurposed to their community mission, including programs and assistance to residents in low-income communities. The EPA will be working with these federal partners and others to ensure that states and vulnerable communities have access to information on these programs and their resources.

The federal government also has a number of programs to expand employment opportunities in the energy sector, including for underserved populations. Examples of these include HUD, DOE, and the Department of Education's "STEM, Energy, and Economic Development" program; DOE's Diversity in Science and Technology Advances National Clean Energy in Solar (DISTANCE-Solar) Program; Grid Engineering for Accelerated Renewable Energy Deployment (GEARED); the Department of Labor's Trade Adjustment Assistance Community College and Career Training (TAACCCT), Apprenticeship USA Advancing Apprenticeships in the Energy Field, Job Corps Green Training and Greening of Centers, and YouthBuild; and the EPA's Environmental Workforce Development and Job Training (EWDJT) program.

E. Multi-pollutant planning and Co-Pollutants

As outlined in the final Clean Power Plan, states and sources have continued obligations to meet all other CAA requirements addressing conventional pollutants. Because the CAA envisions control of these other pollutants as a continuous process (through provisions such as periodic review of the NAAQS and residual risk requirements under the MACT program), the EPA believes that the Clean Power Plan provides an opportunity for states to consider strategies for meeting future CAA planning obligations as they develop their plans under this rulemaking. Multi-pollutant strategies that incorporate criteria pollutant reductions over the planning horizons specific to particular states, jointly with strategies for reducing CO_2 emissions from affected EGUs needed to meet Clean Power Plan requirements over the time horizon of this rule, may accomplish greater environmental results with lower long-term costs. Such strategies may also provide opportunities for states, communities, and affected facilities to consider the most effective means of meeting these obligations while limiting or eliminating localized emission increases that would otherwise affect overburdened communities. Furthermore, this type of multi-pollutant approach has been suggested by states and regulated sources in past rulemakings as a tool to determine the best system of emission reductions. The EPA recommends that states consider such strategies in consultation with their communities, affected facilities, and other stakeholders.

Air quality in a given area is affected by emissions from nearby sources and may be influenced by emissions that travel hundreds of miles and mix with emissions from other sources.[1029] In the Cross-State Air Pollution Rule the EPA used its authority to reduce emissions that significantly contribute to downwind exposures. The RIA for the final Cross-State Air Pollution Rule anticipates substantial health benefits for the population across a wide region. Similarly, the EPA believes that, like the Cross-State Air Pollution Rule, this rulemaking will result in significant health benefits because it will reduce co-pollutant emissions of SO2 and NOx on a regional and national basis.[1030] Thus, localized increases in NOx emissions may well be more than offset by NOx decreases elsewhere in the region that produce a net improvement in ozone and particulate concentrations across the area.

Another effect of the final CO_2 emission guidelines for affected existing fossil fuel-fired EGUs may be increased utilization of other, unmodified EGUs - in particular, high efficiency gas-fired EGUs - with relatively low GHG emissions per unit of electrical output. These plants may operate more hours during the year and could emit pollutants, including pollutants whose environmental effects would be localized and regional rather than global as is the case with GHG emissions. Changes in utilization already occur in response to energy

---

[1029] 76 FR 48348.
[1030] 76 FR 48347.

demands and evolving energy sources, but the final CO_2 emission guidelines for affected existing fossil fuel-fired EGUs can be expected to cause more such changes. Increased utilization of solid fossil fuel-fired units generally would not increase peak concentrations of $PM_{2.5}$, NOx, or ozone around such EGUs to levels higher than those that are already occurring because peak hourly or daily emissions generally would not change; however, increased utilization may make periods of relatively high concentrations more frequent. It should be noted that the gas-fired sources likely to be dispatched more frequently have very low emissions of primary PM, SO_2, and HAP per unit of electrical output and that they must continue to comply with other CAA requirements that directly address the conventional pollutants, including federal emission standards, rules included in SIPs, and conditions in Title V operating permits, in addition to the guidelines in this final rulemaking. Therefore, local (or regional) air quality for these pollutants is not likely to be significantly affected.

For natural gas-fired EGUs, the EPA found that regulation of HAP emissions "is not appropriate or necessary because the impacts due to HAP emissions from such units are negligible based on the results of the study documented in the utility

RTC."[1031] Because gas-fired EGUs emit essentially no mercury, increased utilization will not increase methyl mercury concentrations in water bodies near these affected EGUs. In studies done by DOE/NETL comparing cost and performance of coal- and NGCC-fired generation, they assumed SO_2, NOx, PM (and Hg) emissions to be "negligible." Their studies predict NOx emissions from a NGCC unit to be approximately 10 times lower than a subcritical or supercritical coal-fired boiler.[1032] Many, although not all, NGCC units are also very well controlled for emissions of NOx through the application of after combustion controls such as selective catalytic reduction.

F. Assessing Impacts of State Plan Implementation

It is important to the EPA that the implementation of state plans be assessed in order to identify whether they cause any adverse impacts on communities already overburdened by disproportionate environmental harms and risks. The EPA will conduct its own assessment during the implementation phase of this rulemaking to determine whether the implementation of state plans developed pursuant to this rulemaking and other air quality rules are, in fact, reducing emissions and improving air

---

[1032] "Cost and Performance Baseline for Fossil Energy Plants Volume 1: Bituminous Coal and Natural Gas to Electricity" Rev 2a, September 2013 Revision 2, November 2010 DOE/NETL-2010/1397.

quality in all areas or whether there are localized air quality impacts that need to be addressed under other CAA authorities. Furthermore, the EPA recommends that states conduct evaluations of their own to determine the impacts of their plans on overburdened communities. An example of one such approach to assessing a state plan for reducing GHGs is the California Air Resources Board's (CARB), *First Update on the Climate Change Scoping Plan: Building on the Framework Pursuant to AB32: The California Global Warming Solutions Act of 2006,* which outlines ongoing evaluations that it will conduct to determine the impacts of its programs (throughout the implementation stages) on overburdened communities.[1033] CARB's Adaptive Management Plan for the Cap-and-Trade Program is one particular evaluation, which is intended to assess any localized emissions increases resulting from the program so that the state can appropriately respond.[1034] The EPA recommends that states consider CARB's approaches and other programs as models for conducting ongoing assessments of the impacts of their state plans on overburdened communities. The EPA will provide training for states and

[1033] *First Update on the Climate Change Scoping Plan: Building on the Framework Pursuant to AB32: The California Global Warming Solutions Act of 2006*. http://www.arb.ca.gov/cc/scopingplan/2013_update/first_update_climate_change_scoping_plan.pdf. May 2014.

[1034] *Adaptive Management Plan for the Cap-and-Trade Regulation*. http://www.arb.ca.gov/cc/capandtrade/adaptive_management/plan.pdf. October 2011.

communities on resources that they can use to assess options for plan development and implementation that appropriately consider localized impacts, especially effects of co-pollutants, as well as training on how to develop and carry out these evaluations.

This training will include guidance in accessing the publicly available information that sources and states currently report that can help with ongoing assessments of state plan impacts. For example, unit-specific emissions data and air quality monitoring data are readily available. This information, together with the assessment that the EPA will conduct in the implementation phase of this rulemaking and other analyses that states may develop, will enable states and communities to monitor any disproportionate emissions that may result in adverse impacts and to address them.

G. EPA Continued Engagement

The EPA is committed to helping ensure that this action will not have disproportionate adverse human health or environmental effects on vulnerable communities. Throughout the implementation phase of this rulemaking, the agency will continue to provide trainings and resources to assist communities and states as they engage with one another. Additionally, we will provide states with recommendations on best practices for engaging with vulnerable communities. The EPA, through its outreach efforts during implementation, will continue to solicit feedback from communities and states on topics for which they would like additional trainings and resources.

The EPA will also provide states with resources containing examples of analyses that other states have conducted to examine the impacts of their programs on vulnerable communities, as well as information on its publicly available environmental justice screening and mapping tool, EJ SCREEN. States are encouraged to use this preliminary information as well as other available information to conduct their own analyses. As described above, the EPA will assess the impacts of this rulemaking during its implementation. The EPA will house this assessment, along with the proximity analysis and other information generated throughout the implementation process, on its Clean Power Plan (CPP) Community Portal that will be linked to this rulemaking's website (www.epa.gov/cleanpowerplan). In addition, the EPA has expanded its set of resources that are being developed to help states and communities understand the breadth of policy options and programs that have successfully brought EE/RE to overburdened communities. The EPA is committed to continuing its engagement with states and communities from the beginning of plan development through plan implementation.

A more detailed discussion concerning the application of Executive Order 12898 in this rulemaking can be found in section

XI.J of this preamble. A summary of the EPA's interactions with communities is in the EJ Screening Report for the Clean Power Plan, available in the docket of this rulemaking. Furthermore, the EPA's responses to public comments, including comments received from communities, are provided in the response to comments documents located in the docket for this rulemaking.

In summary, the EPA in this final rulemaking has designed an integrative approach that helps to ensure that vulnerable communities are not disproportionately impacted by this rulemaking. The proximity analysis that the agency has conducted for this rulemaking is a central component of this approach. Not only is the proximity analysis a useful tool to help identify overburdened communities that may be impacted by this rulemaking, states can use this tool as they engage with communities in the development of their plans, consider a multi-pollutant approach, help low-income communities access EE/RE and financial assistance programs and assess the impacts of their state plans. Additionally, in order to continue to ensure that vulnerable communities are not disproportionately impacted by this rulemaking, the EPA will also be conducting its own assessment during the implementation phase. Furthermore, the EPA will continue to engage with communities and states throughout the implementation phase of this rulemaking to help ensure that vulnerable communities are not disproportionately impacted.

X. Interactions with Other EPA Programs and Rules

A. Implications for the New Source Review Program

The new source review (NSR) program is a preconstruction permitting program that requires major stationary sources of air pollution to obtain permits prior to beginning construction. The requirements of the NSR program apply both to new construction and to modifications of existing major sources. Generally, a source triggers these permitting requirements as a result of a modification when it undertakes a physical or operational change that results in a significant emission increase and a net emissions increase. NSR regulations define what constitutes a significant net emissions increase, and the concept is pollutant-specific. As a result of the decision in *Utility Air Regulatory Group (UARG) v. Environmental Protection Agency (EPA)*, 134 S. Ct. 2427 (2014), a modification that increases only GHG emissions above the applicable level will not trigger the requirement to obtain a PSD permit. Under existing EPA regulations, a modifying major stationary source would trigger PSD permitting requirements for GHGs if it undergoes a change or change in the method of operation (modification) that results in a significant increase in the emissions of a pollutant other than GHGs and results in a GHG emissions increase of 75,000 tons per year CO_2e as well as a GHG emissions increase on a mass basis. Once it has been determined that a change triggers the requirements of the NSR program, the source must obtain a permit prior to making the change. The pollutant(s) at issue and the air quality designation of the area where the facility is located or proposed to be built determine the specific permitting requirements.

As part of its CAA section 111(d) plan, a state may impose requirements that require an affected EGU to undertake a physical or operational change to improve the unit's efficiency that results in an increase in the unit's dispatch and an increase in the unit's annual emissions. If the emissions increase associated with the unit's changes exceeds the thresholds in the NSR regulations for one or more regulated NSR pollutants, including the netting analysis, the changes would trigger NSR.

While there may be instances in which an NSR permit would be required, we expect those situations to be few. As previously discussed in this preamble, states have considerable flexibility in selecting varied measures as they develop their plans to meet the goals of the emission guidelines. One of these flexibilities is the ability of the state to establish emission standards in their CAA section 111(d) plans in such a way so that their affected sources, in complying with those standards, in fact would not have emissions increases that trigger NSR. To achieve this, the state would need to conduct an analysis consistent with the NSR regulatory requirements that supports its determination that as long as affected sources comply with the emission standards in their CAA section 111(d) plan, the source's emissions would not increase in a way that trigger NSR requirements.

For example, a state could decide to use demand-side measures or increase reliance on RE as a way of reducing the future emissions of an affected source initially predicted (without such alterations) to increase its emissions as a result of a CAA section 111(d) plan requirement. In other words, a state plan's incorporation of expanded use of cleaner generation or demand-side measures could yield the result that units that would otherwise be projected to trigger NSR through a physical change that might result in increased dispatch would not, in fact, increase their emissions, due to reduced demand for their operation. The state could also, as part of its CAA section 111(d) plan, develop conditions for a source expected to trigger NSR that would limit the unit's ability to move up in the dispatch enough to result in a significant net emissions increase that would trigger NSR (effectively establishing a synthetic minor limit).[1035]

In addition, in this final rule, we have also adjusted the date of the period for mandatory reductions to 2022, instead of 2020, and provided states with flexibility with respect to the glide path. This obviates concerns that there is insufficient time for sources that may need permits to obtain them and allows additional planning time for these changes to be undertaken in a manner that does not trigger PSD. As a result of such flexibility and anticipated state involvement, we expect that a limited number of affected sources would trigger NSR when states implement their plans.

B. Implications for the Title V Program

In the preamble to the June 18, 2014 proposal, the EPA discussed the issue of excessive title V fees resulting inadvertently as a consequence of the promulgation of the first section 111 standard to regulate GHGs. Specifically, the EPA

[1035] Certain stationary sources that emit or have the potential to emit a pollutant at a level that is equal to or greater than specified thresholds are subject to major source requirements. *See, e.g.,* CAA sections 165(a)(1), 169(1), 501(2), 502(a). A synthetic minor limitation is a legally and practicably enforceable restriction that has the effect of limiting emissions below the relevant level and that a source voluntarily obtains to avoid major stationary source requirements, such as the PSD or Title V permitting programs. *See, e.g.,* 40 CFR 52.21(b)(4), 51.166(b)(4), 70.2 (definition of “potential to emit”).

explained that when the first section 111 standard is promulgated for GHGs, if we do not revise 40 CFR parts 70 and 71 (the operating permit rule), then certain permitting authorities would be required to charge emissions-based fees for GHGs, resulting in fees that would be far in excess of what is required to cover the reasonable costs of the permitting programs. To avoid this situation, the EPA proposed as part of the re-proposed carbon pollution standards for newly constructed fossil fuel-fired power plants (70 FR 1429-1519; January 8, 2014) to exempt GHGs from the list of air pollutants that are subject to fee calculation requirements under the operating permit rules. Also, we proposed several options to impose a smaller fee adjustment for GHGs that would be reasonable and designed to recover the costs of addressing GHGs in permitting without being excessive.

In a separate action in today's *Federal Registe*r **[INSERT THE FEDERAL REGISTER REFERENCE FOR THE FINAL GHG NEW SOURCE RULE]**, the EPA is finalizing changes to the operating permits rules to address the title V fee issue. In particular, we are taking final action to exempt GHGs from emissions-based fee calculation requirements under the operating permit rules. In addition, we are also finalizing a modest GHG fee adjustment to recover the costs of addressing GHGs in permitting. The GHG adjustments we are finalizing are based on accounting for the number of permit actions that require a GHG assessment in a given period, rather than accounting for emissions levels of GHGs. Finally, the EPA is also finalizing the addition of text within 40 CFR part 60, subpart TTTT, to clarify that the fee pollutant for operating permit purposes is GHG (as defined in 40 CFR 70.2 and 71.2) to add clarity to our regulations and to avoid the potential need for possible future rulemakings to adjust the title V fee regulations if any constituent of GHG, other than CO_2, becomes subject to regulation under CAA section 111 for the first time.

This title V fee issue is a one-time occurrence resulting from the promulgation of the first CAA section 111 standard to regulate GHGs (the standards of performance for new, modified, and reconstructed EGUs, also promulgated in today's *Federal Register*). The title V fee issue is not an issue for any other subsequent CAA section 111 regulations, such as this section 111(d) standard; thus, there is no need to address any title V fee issues in this final rule as part of this action.

In the proposal, the EPA discussed that the section 111 rules would have no effect on the applicability thresholds for GHG under the operating permit rules. After the proposal for this rulemaking was published, the U.S. Supreme Court issued its opinion in *UARG v EPA*, 134 S.Ct. 2427 (June 23, 2014), and in accordance with that decision, the D.C. Circuit subsequently issued an amended judgment in *Coalition for Responsible Regulation, Inc. v. Environmental Protection Agency*, Nos. 09-1322, 10-073, 10-1092 and 10-1167 (D.C. Cir., April 10, 2015). Those decisions support the same overall conclusion, as the EPA discussed in the proposal, with respect to the effect of this final section 111 rule on the applicability thresholds for GHGs under the operating permits rules, though for different reasons.

With respect to title V, the Supreme Court said that EPA may not treat GHGs as an air pollutant for purposes of determining whether a source is a major source required to obtain a title V operating permit. In accordance with that decision, the D.C. Circuit's amended judgment vacated the title V regulations under review in that case to the extent that they require a stationary source to obtain a title V permit solely because the source emits or has the potential to emit GHGs above the applicable major source thresholds. The D.C. Circuit also directed the EPA to consider whether any further revisions to its regulations are appropriate in light of *UARG v. EPA*, and, if so, to undertake to make such revisions. These court decisions make clear that promulgation of CAA section 111 requirements for GHGs will not result in EPA imposing a requirement that stationary sources obtain a title V permit solely because such sources emit or have the potential to emit GHGs above the applicable major source thresholds.

C. Interactions with Other EPA Rules

Fossil fuel-fired EGUs are, or potentially will be, impacted by several other recently finalized or proposed EPA rules.[1036] The EPA recognizes the importance of assuring that each of the rules described below can achieve its intended environmental objectives in a commonsense, cost-effective manner, consistent with underlying statutory requirements, and while assuring a reliable power system. Executive Order 13563, "Improving Regulation and Regulatory Review," issued on January 18, 2011, states that "[i]n developing regulatory actions and identifying appropriate approaches, each agency shall attempt to promote... coordination, simplification, and harmonization. Each agency shall also seek to identify, as appropriate, means to achieve regulatory goals that are designed to promote innovation." Within the EPA, we are paying careful attention to the interrelatedness and potential impacts on the industry, reliability and cost that these various rulemakings can have.

1. Mercury and Air Toxics Standards (MATS)

On February 16, 2012, the EPA issued the MATS rule (77 FR 9304) to reduce emissions of toxic air pollutants from new and existing coal- and oil-fired EGUs. The MATS rule will reduce

---

[1036] We discuss other rulemakings solely for background purposes. The effort to coordinate rulemakings is not a defense to a violation of the CAA. Sources cannot defer compliance with existing requirements because of other upcoming regulations.

emissions of heavy metals, including mercury, arsenic, chromium, and nickel; and acid gases, including hydrochloric acid and hydrofluoric acid. These toxic air pollutants, also known as hazardous air pollutants or air toxics, are known to cause, or suspected of causing, damage nervous system damage, cancer, and other serious health effects. The MATS rule will also reduce SO_2 and fine particle pollution, which will reduce particle concentrations in the air and prevent thousands of premature deaths and tens of thousands of heart attacks, bronchitis cases and asthma episodes.

New or reconstructed EGUs (i.e., sources that commence construction or reconstruction after May 3, 2011) subject to the MATS rule are required to comply by April 16, 2012 or upon startup, whichever is later.

Existing sources subject to the MATS rule were required to begin meeting the rule’s requirements on April 16, 2015. Controls that will achieve the MATS performance standards are being installed on many units. Certain units, especially those that operate infrequently, may be considered not worth investing in given today’s electricity market, and are closing. The final MATS rule provided a foundation on which states and other permitting authorities could rely in granting an additional, fourth year for compliance provided for by the CAA. States report that these fourth year extensions are being granted. In addition, the EPA issued an enforcement policy that provides a clear pathway for reliability-critical units to receive an administrative order that includes a compliance schedule of up to an additional year, if it is needed to ensure electricity reliability.

2. Cross-State Air Pollution Rule (CSAPR)

The CSAPR requires states to take action to improve air quality by reducing SO_2 and NO_X emissions that cross state lines. These pollutants react in the atmosphere to form fine particles and ground-level ozone and are transported long distances, making it difficult for other states to attain and maintain the NAAQS. The first phase of CSAPR became effective on January 1, 2015, for SO_2 and annual NO_X, and May 1, 2015, for ozone season NO_X. The second phase will become effective on January 1, 2017, for SO_2 and annual NO_x, and May 1, 2017, for ozone season NO_x. Many of the power plants participating in CSAPR have taken actions to reduce hazardous air pollutants for MATS compliance that will also reduce SO_2 and/or NO_x. In this way these two rules are complementary. Compliance with one helps facilities comply with the other.

3. Requirements for Cooling Water Intake Structures at Power Plants (316(b) Rule)

On May 19, 2014, the EPA issued a final rule under section 316(b) of the Clean Water Act (CWA) (33 U.S.C. section 1326(b)) (referred to hereinafter as the 316(b) rule.) The rule was published on August 15, 2014 (79 FR 48300; August 15, 2014), and became effective October 14, 2014. The 316(b) rule establishes new standards to reduce injury and death of fish and other aquatic life caused by cooling water intake structures at existing power plants and manufacturing facilities.[1037] The 316(b) rule subjects existing power plants and manufacturing facilities that withdraw in excess of 2 million gallons per day) of cooling water, and use at least 25 percent of that water for cooling purposes, to a national standard designed to reduce the number of fish destroyed through impingement and a national standard for establishing entrainment reduction requirements. All facilities subject to the rule must submit information on their operations for use by the permit authority in determining 316(b) permit conditions. Certain plants that withdraw very large volumes of water will also be required to conduct additional studies for use by the permit authority in determining the site-specific entrainment reduction measures for such facilities. The rule provides significant flexibility for compliance with the impingement standards and, as a result, is not projected to

[1037] CWA section 316(b) provides that standards applicable to point sources under sections 301 and 306 of the Act must require that the location, design, construction and capacity of cooling water intake structures reflect the best technology available for minimizing adverse environmental impacts.

impose a substantial cost burden on affected facilities. With respect to entrainment, the rule calls upon the permitting authority to establish appropriate entrainment reduction measures, taking into account, among other factors, remaining useful plant life and quantified and qualitative social benefits and cost. The permit writer may also consider impacts on the reliability of energy delivery within the facility’s immediate area. Existing sources subject to the 316(b) rule are required to comply with the impingement requirements as soon as practicable after the entrainment requirements are determined. They must comply with applicable site-specific entrainment reduction controls based on the schedule of requirements established by the permitting authority.

4. Disposal of Coal Combustion Residuals from Electric Utilities (CCR Rule)

On December 19, 2014, the EPA issued the final rule for the disposal of coal combustion residuals from electric utilities. The rule provides a comprehensive set of requirements for the safe disposal of coal combustion residuals (CCRs), commonly known as coal ash, from coal-fired power plants. The CCR rule is the culmination of extensive study on the effects of coal ash on the environment and public health. The CCR rule establishes technical requirements for existing and new CCR landfills and surface impoundments under Subtitle D of the Resource

Conservation and Recovery Act, the nation's primary law for regulating solid waste.

These regulations address the risks from coal ash disposal -- leaking of contaminants into ground water, blowing of contaminants into the air as dust, and the catastrophic failure of coal ash surface impoundments by establishing requirements for where CCR landfills and surface impoundments may be located, how they must be designed, operated and monitored, when they must be inspected, and how they must be closed and cared for after closure. Additionally, the CCR rule sets out recordkeeping and reporting requirements, as well as the requirement for each facility to establish and post specific information to a publicly-accessible website. The final rule also supports the responsible recycling of CCRs by distinguishing safe, beneficial use from disposal.

5. Steam Electric Effluent Limitation Guidelines and Standards (SE ELG Rule)

The EPA is reviewing public comments and working to finalize the proposed SE ELG rule which will impact existing fossil fuel-fired EGUs. In 2013, the EPA proposed the SE ELG rule (78 FR 34432; June 7, 2013) to strengthen the controls on discharges from certain steam electric power plants by revising technology-based effluent limitations guidelines and standards for the steam electric power generating point source category.

The current regulations, which were last updated in 1982, do not adequately address the toxic pollutants discharged from the electric power industry, nor have they kept pace with process changes that have occurred over the last three decades. Existing steam electric power plants currently contribute 50-60 percent of all toxic pollutants discharged to surface waters by all industrial categories regulated in the U.S. under the CWA. Furthermore, power plant discharges to surface waters are expected to increase as pollutants are increasingly captured by air pollution controls and transferred to wastewater discharges. The proposed regulation, which includes new requirements for both existing and new generating units, would reduce impacts to human health and the environment by reducing the amount of toxic metals and other pollutants currently discharged to surface waters from power plants. The EPA intends to take final action on the proposed rule by September 30, 2015.

The EPA is endeavoring to enable EGUs to comply with applicable obligations under other power sector rules as efficiently as possible (e.g., by facilitating their ability to coordinate planning and investment decisions with respect to those rules) and, where possible, implement integrated compliance strategies. For example, in the proposed SE ELG rule, the EPA describes its thinking on how it might effectively harmonize the potential requirements of that rule with the requirements of the final CCR rule. Because these two rules affect similar units and may be met with similar compliance strategies, common-sense implementation timeframes were established in the CCR final rule so that utilities would not be required to make major decisions about CCR units without first understanding the implications that such decisions would have for meeting the surface water protection requirements of the final ELG rule. The EPA is taking into account these new CCR requirements for coal ash as it develops the final SE ELG rule. The EPA's goal in harmonizing the SE ELG and CCR rules is to minimize the overall complexity of the two regulatory structures and avoid creating unnecessary burden.

6. Other EPA Rules

In addition to the power sector rules discussed above, the development of SIPs for criteria pollutants (ozone, $PM_{2.5}$, and SO_2) and regional haze may also have implications for existing fossil-fired EGUs.

Regarding ozone, the proposal included a discussion of the June 6, 2013, proposed implementation rule for the 2008 ozone National Ambient Air Quality Standards (NAAQS), addressing the statutory requirements for areas EPA has designated as nonattainment for the 2008 ozone NAAQS. The final implementation rule for the 2008 ozone NAAQS was signed on February 13, 2015, and published on March 6, 2015, with an effective date of April

6, 2015. In general, the 2008 ozone NAAQS implementation rule interprets applicable statutory requirements and provides flexibility to states to minimize administrative burdens associated with developing and implementing plans to meet and maintain the NAAQS. The rule establishes due dates for attainment plans and clarifies attainment dates for each ozone nonattainment area according to its classification based on air quality thresholds, with attainment dates starting in July 2015 through July 2032 depending on an area's classification.

On November 25, 2014, the EPA Administrator signed the proposed rulemaking for the 2015 revisions to the ozone NAAQS. The proposal was published in the Federal Register on December 17, 2014 (79 FR 75234). The Administrator proposed to revise the primary ozone standard to a level in the range of 0.065 to 0.070 ppm and took comment on lower levels including 0.060 ppm and on retaining the current standard of 0.075 ppm. Among other things, the ozone NAAQS proposal also proposed to retain the current indicator, averaging time, and form of the standard and included a proposed secondary ozone NAAQS in the 0.065 to 0.070 ppm range.

The proposal also outlined the key implementation milestones requiring revised SIPs, with due dates starting in October 2018 for infrastructure and interstate transport SIPs, attainment plans due 2020-21, and attainment dates of 2020-37.

The EPA is under a court order to finalize its review of the ozone NAAQS by October 1, 2015.

Some commenters expressed concern with the potential impact proposed revisions to the ozone NAAQS could have on state planning efforts and affected entities' ability to comply with any potentially new requirements associated with a revised ozone NAAQS and those related to the 111(d) emission guidelines. In particular, commenters raised issues with a potentially more stringent ozone standard and the permitting and state planning implications this may create. While there was no discussion of the proposed revisions to the ozone NAAQS in the 111(d) emission guidelines proposal, commenters expressed a desire for the EPA to coordinate promulgation of the final 111(d) emission guidelines (and any other climate regulations) with the potential revision to the ozone standard to provide certainty and flexibility for states and affected sources.

While it is premature to speculate about the outcome of the ozone NAAQS review and how a more stringent ozone NAAQS may impact sources of ozone precursor emissions, including EGUs, we believe the planning and compliance timeframes that would follow from a revised ozone NAAQS and the timeframes we are finalizing today for submittal of the CAA section 111(d) state plans will allow considerable time for coordination by states in the development of their respective plans, as needed. As stated in the proposal, the EPA is prepared to work with states to assist them in coordinating their efforts across these planning processes.

Regarding $PM_{2.5}$ NAAQS implementation, the proposal stated that the EPA was developing a proposed implementation rule to provide guidance to states on the development of SIPs for the 2012 $PM_{2.5}$ NAAQS. The proposed $PM_{2.5}$ SIP requirements rule was signed on March 10, 2015, and published on March 23, 2015 (80 FR 15340). The proposal addresses a number of requirements including attainment plan due dates, attainment dates and attainment date extension criteria for Moderate and Serious nonattainment areas; determination criteria for Reasonably Available Control Measures (RACM) for Moderate areas and Best Available Control Measures (BACM) for Serious areas; plans for demonstrating reasonable further progress and for meeting periodic quantitative milestones; and criteria for reclassifying a Moderate nonattainment area to Serious. The EPA is planning to finalize the $PM_{2.5}$ implementation rule in early 2016.

There are currently only 9 areas designated nonattainment for the 2012 $PM_{2.5}$ NAAQS, with an effective date of April 15, 2015. Since the attainment plans for these areas must be completed and submitted to the EPA in September 2016, we expect that the four states with such areas should have already decided on their approach to implementing the 2012 $PM_{2.5}$ NAAQS when they begin to develop their plans for implementing the 111(d) guidelines, and will be able to coordinate the two.

Related to the SO_2 NAAQS, and as stated in the proposal, the SO_2 NAAQS was revised in June 2010 to protect public health from the short-term effects of SO_2 exposure. In July 2013, the EPA designated 29 areas in 16 states as nonattainment for the SO_2 NAAQS. The EPA based these nonattainment designations on the most recent set of certified air quality monitoring data as well as an assessment of nearby emission sources and weather patterns that contribute to the monitored levels. The date for attainment plans for these areas to be completed and submitted to the EPA was April 2015. As such, we expect states with such areas to have already decided on their approach to implementing the SO_2 NAAQS as they start planning for implementation of the 111(d) guidelines, which should allow for coordination and consideration of SO_2 related air quality measures into their 111(d) planning. The EPA intends to address the designations for all other areas in three separate actions in the future.[1038] These

[1038] The EPA has developed a comprehensive implementation strategy for these future actions that focuses resources on identifying and addressing unhealthy levels of SO_2 in areas where people are most likely to be exposed to violations of the standard. The strategy is available at http://www.epa.gov/airquality/sulfurdioxide/implement.html, and the associated area designations schedule is at http://www.epa.gov/airquality/sulfurdioxide/designations/pdfs/201503Schedule.pdf.

designations must be completed by no later than July 2, 2016, December 31, 2017, and December 31, 2020 with attainment plans due between 2018 and 2022.

Regarding requirements under the regional haze program, several affected EGUs have deadlines in the 2016-2021 timeframe to install controls to comply with the Best Available Retrofit Technology (BART) and reasonable progress requirements of the Regional Haze Rule. Soon after these deadlines, some of the same affected EGUs may be required to reduce their utilization, convert into natural gas-fired facilities, or shut down entirely as a result of state 111(d) plans. Some commenters have expressed concern that for these affected EGUs, specifically those that choose to retire, the capital equipment installed to comply with the Regional Haze Rule would likely become stranded assets.

While the EPA is providing considerable flexibility for states and sources under the final 111(d) emission guidelines, the EPA acknowledges the possibility that some sources could ultimately be faced with the potential for stranded assets as a result of state 111(d) plans. For these sources, however, states have the option of developing BART alternatives that replace control requirements that would otherwise result in stranded assets at a particular EGU with the aggregate emission reductions that will result from retirements, fuel switching, reduced utilization, or lesser controls at multiple EGUs.

In fact, the EPA already has experience working with states to account for these very types of changed circumstances.[1039] The EPA will continue to work with states to explore options for integrating compliance requirements across multiple regulatory programs, as warranted.

The EPA believes that CAA section 111(d) efforts and actions will tend to contribute to overall air quality improvements and thus should be complementary to criteria pollutant and regional haze SIP efforts.

7. Final Rule Flexibilities

As discussed in Section VIII of this preamble, the EPA is providing states flexibility in developing approvable plans under CAA section 111(d), including the ability to impose

[1039] For example, Oregon replaced its BART determination for the Boardman Coal Plant with a new requirement that accounted for a planned shutdown before the EPA took action on the state's SIP submission (76 FR 12661). Washington similarly replaced its BART determination for the TransAlta Centralia Power Plant before the EPA took action on the state's SIP submission (77 FR 72742). Oklahoma submitted a SIP revision with a new BART determination for the AEP/PSO Northeastern Power Station, which included enforceable requirements for reduced utilization and early unit retirements, to replace a FIP that had been promulgated by the EPA (79 FR 12944). Finally, the EPA finalized a BART determination for Unit 3 at the Dave Johnston Power Plant in Wyoming that included two compliance options, one of which included a federally enforceable retirement date and less costly controls.

source-by-source limitations reflecting the BSER performance rates to each affected EGU or to adopt rate-based or mass-based emission performance goals, and to rely on a wide range of CO_2 emission reduction measures, including measures that are not part of the BSER. The EPA is also providing states considerable flexibility with respect to the timeframes for plan development and implementation, with up to 3 years permitted for final plans to be submitted after the GHG emission guidelines are finalized, and up to 15 years for all emission reduction measures to be fully implemented. The EPA is establishing an 8-year interim period over which to achieve the full required reductions to meet the CO_2 performance rates, and this begins in 2022, more than seven years from the June 18, 2014 date of proposal of the rulemaking. The 8-year interim period from 2022 through 2029, is separated into three steps, 2022-2024, 2025-2027, and 2028-2029, each associated with its own interim CO_2 emission performance rates.

In light of these broad flexibilities, we believe that states will have ample opportunity, when developing and implementing their CAA section 111(d) plans, to coordinate their response to this requirement with source and state responses to any obligations that may be applicable to affected EGUs as a result of the MATS, CSAPR, 316(b), SE ELG and CCR rules, all of which are or soon will be final rules. In addition, we believe that states will be able to design CAA section 111(d) plans that use innovative, cost-effective regulatory strategies, that spark investment and innovation across a wide variety of clean energy technologies, and that will help reduce cost and ensure reliability, while also ensuring that all applicable environmental requirements are met.[1040] We also believe that the broad flexibilities in this action will enable states and affected EGUs to build on their longstanding, successful records of complying with multiple CAA, CWA, and other environmental requirements, while assuring an adequate, affordable, and reliable supply of electricity.

XI. Impacts of the Final Action[1041]

A. What are the air impacts?

The EPA anticipates significant emission reductions under the final guidelines for the utility power sector. In the final

[1040] It should be noted that regulatory obligations imposed upon states and sources operate independently under different statutes and sections of statutes; the EPA expects that states and sources will take advantage of available flexibilities as appropriate, but will comply with all relevant legal requirements.

[1041] The impacts presented in this section of the preamble represent an illustrative implementation of the guidelines. As states implement the final guidelines, they have sufficient flexibility to adopt different state-level or regional approaches that may yield different costs, benefits, and environmental impacts. For example, states may use the flexibilities described in these guidelines to find approaches that are more cost-effective for their particular state or choose approaches that shift the balance of co-benefits and impacts to match broader state priorities.

emission guidelines, the EPA has translated the source category-specific CO_2 emission performance rates into equivalent state-level rate-based and mass-based CO_2 goals in order to maximize the range of choices that states will have in developing their plans. Because of the range of choices available to states and the lack of *a priori* knowledge about the specific choices states will make in response to the final goals, the Regulatory Impact Analysis (RIA) for this final action presents two scenarios designed to achieve these goals, which we term the "rate-based" illustrative plan approach and the "mass-based" illustrative plan approach.[1042]

Under the rate-based approach, when compared to 2005, CO_2 emissions are projected to be reduced by approximately 22 percent in 2020, 28 percent in 2025, and 32 percent in 2030. Under the mass-based approach, when compared to 2005, CO_2 emissions are projected to be reduced by approximately 23 percent in 2020, 29 percent in 2025, and 32 percent in 2030. The final guidelines are projected to result in substantial co-

[1042] It is important to note that the differences between the analytical results for the rate-based and mass-based illustrative plan approaches presented in the RIA may not be indicative of likely differences between the approaches if implemented by states and affected EGUs in response to the final guidelines. If one approach performs differently than the other on a given metric during a given time period, this does not imply this will apply in all instances.

benefits through reductions of SO_2, NO_X and $PM_{2.5}$ that will have direct public health benefits by lowering ambient levels of these pollutants and ozone. Tables 15 and 16 show expected CO_2 and other air pollutant emissions in the base case and reductions under the final guidelines for 2020, 2025, and 2030 for the rate-based and mass-based approaches, respectively.

Table 15. Summary of CO_2 and Other Air Pollutant Emission Reductions from the Base Case under Rate-based Illustrative Plan Approach

	CO_2 (millions short tons)	SO_2 (thousand short tons)	NO_X (thousand short tons)
2020 Final Guidelines			
Base Case	2,155	1,311	1,333
Final Guidelines	2,085	1,297	1,282
Emissions Reductions	69	14	50

Note: Emissions may not sum due to rounding.

The reductions in Tables 15 and 16 do not account for reductions in hazardous air pollutants (HAPs) that may occur as a result of this rule. For instance, the fine particulate reductions presented above do not reflect all of the reductions in many heavy metal particulates.

B. Endangered Species Act

As explained in the preamble to the proposed rule (79 FR at 34933-934), the EPA has carefully considered the requirements of section 7(a)(2) of the Endangered Species Act (ESA) and applicable ESA regulations, and reviewed relevant ESA case law and guidance, to determine whether consultation with the U.S. Fish and Wildlife Service (FWS) and/or National Marine Fisheries Service (together, the Services) is required by the ESA. The EPA proposed to conclude that the requirements of ESA section 7(a)(2) would not be triggered by promulgation of the rule, and we now finalize that determination.

Section 7(a)(2) of the ESA requires federal agencies, in consultation with one or both of the Services (depending on the species at issue), to ensure that actions they authorize, fund, or carry out are not likely to jeopardize the continued existence of federally listed endangered or threatened species or result in the destruction or adverse modification of designated critical habitat of such species. 16 U.S.C. 1536(a)(2). Under relevant implementing regulations, section 7(a)(2) applies only to actions where there is discretionary federal involvement or control. 50 CFR 402.03. Further, under the regulations consultation is required only for actions that "may affect" listed species or designated critical habitat. 50 CFR section 402.14. Consultation is not required where the action has no effect on such species or habitat. Under this standard, it is the federal agency taking the action that evaluates the action and determines whether consultation is required. *See* 51 FR 19926, 19949 (June 3, 1986). Effects of an action include both the direct and indirect effects that will be added to the environmental baseline. 50 CFR 402.02. Direct effects are the direct or immediate effects of an action on a listed species or its habitat.[1043] Indirect effects are those that

[1043] *See* Endangered Species Consultation Handbook, U.S. Fish & Wildlife Service and National Marine Fisheries Service at 4-25 (March 1998) (providing examples of direct effects: *e.g.*, are "caused by the proposed action and are later in time, but still are reasonably certain to occur." *Id.* To trigger the consultation requirement, there must thus be a causal connection between the federal action, the effect in question, and the listed species, and if the effect is indirect, it must be reasonably certain to occur.

The EPA notes that the projected environmental effects of this rule are positive: reductions in overall GHG emissions, and reductions in PM and ozone-precursor emissions (SO_2 and NO_X). The EPA recognizes that beneficial effects to listed species can, as a general matter, result in a "may affect" determination under the ESA. However, the EPA's assessment that the rule will have an overall net positive environmental effect by virtue of reducing emissions of certain air pollutants does not address whether the rule may affect any listed species or designated critical habitat for ESA section 7(a)(2) purposes and does not constitute any finding of effects for that purpose. The fact that the rule will have overall positive effects on the national and global environment does not mean that the rule may affect any listed species in its habitat or the designated critical habitat of such species within the meaning of ESA section

driving an off road vehicle through the nesting habitat of a listed species of bird and destroying a ground nest; building a housing unit and destroying the habitat of a listed species).

7(a)(2) or the implementing regulations or require ESA consultation. The EPA has considered various types of potential effects in reaching the conclusion that ESA consultation is not required for this rule.

With respect to the projected GHG emission reductions, the EPA considered in detail in the proposal why such reductions do not trigger ESA consultation requirements under section 7(a)(2). As explained in the proposal, in reaching this conclusion the EPA was mindful of significant legal and technical analysis undertaken by FWS and the U.S. Department of the Interior (DOI) in the context of listing the polar bear as a threatened species under the ESA. In that context, in 2008, FWS and DOI expressed the view that the best scientific data available were insufficient to draw a causal connection between GHG emissions and effects on the species in its habitat.[1044] The DOI Solicitor concluded that where the effect at issue is climate change, proposed actions involving GHG emissions cannot pass the "may affect" test of the section 7 regulations and thus are not subject to ESA consultation.

[1044] *See, e.g.*, 73 FR 28212, 28300 (May 15, 2008); Memorandum from David Longly Bernhardt, Solicitor, U.S. Department of the Interior re: ''Guidance on the Applicability of the Endangered Species Act's Consultation Requirements to Proposed Actions Involving the Emission of Greenhouse Gases'' (Oct. 3, 2008).

As described in the proposal, the EPA has also previously considered issues relating to GHG emissions in connection with the requirements of ESA section 7(a)(2) and has supplemented DOI's analysis with additional consideration of GHG modeling tools and data regarding listed species. Although the GHG emission reductions projected for this final rule are large (estimated reductions of about 415 million short tons of CO_2 in 2030 relative to the base case under the rate-based illustrative plan approach– see Table 14 above), the EPA evaluated larger reductions in assessing this same issue in the context of the light duty vehicle GHG emission standards for model years 2012-2016 and 2017-2025. There the agency projected emission reductions over the lifetimes of the model years in question[1045] which are roughly five to six times those projected above and, based on air quality modeling of potential environmental effects, concluded that "EPA knows of no modeling tool which can link these small, time-attenuated changes in global metrics to particular effects on listed species in particular areas. Extrapolating from global metric to local effect with such small numbers, and accounting for further links in a causative chain, remain beyond current modeling capabilities." EPA, *Light Duty Vehicle Greenhouse Gas Standards and Corporate Average Fuel*

[1045] *See* 75 FR at 25438 Table I.C 2-4 (May 7, 2010); 77 FR at 62894 Table III-68 (Oct. 15, 2012).

Economy Standards, Response to Comment Document for Joint Rulemaking at 4-102 (Docket EPA-OAR-HQ-2009-4782). The EPA reached this conclusion after evaluating issues relating to potential improvements relevant to both temperature and oceanographic pH outputs. The EPA's ultimate finding was that "any potential for a specific impact on listed species in their habitats associated with these very small changes in average global temperature and ocean pH is too remote to trigger the threshold for ESA section 7(a)(2)."*Id.* The EPA believes that the same conclusion applies to the present rule. *See, e.g., Ground Zero Center for Non-Violent Action* v. *U.S. Dept. of Navy,* 383 F. 3d 1082, 1091-92 (9th Cir. 2004) (where the likelihood of jeopardy to a species from a federal action is extremely remote, ESA does not require consultation). The EPA's conclusion is entirely consistent with DOI's analysis regarding ESA requirements in the context of federal actions involving GHG emissions.[1046]

[1046] The EPA has received correspondence from a U.S. Senator and a Member of the U.S. House of Representatives noting that the Services have identified several listed species affected by global climate change. *See* Letter from Rob Bishop, Chairman, House Committee on Natural Resources, to Gina McCarthy, Administrator, U.S. Environmental Protection Agency, dated June 11, 2015; Letter from Rob Bishop, Chairman, House Committee on Natural Resources, and James M. Inhofe, Chairman, Senate Committee on Environment and Public Works, to Gina McCarthy, Administrator, U.S. Environmental Protection Agency, dated June 15, 2015. EPA's assessment of ESA requirements in connection

With regard to non-GHG air emissions, the EPA also projects substantial reductions of SO_2 and NO_X as a collateral consequence of this final action. However, CAA section 111(d)(1) standards cannot directly control emissions of criteria pollutants. See CAA section 111(d)(1)(i). Consequently, CAA section 111(d) provides no discretion to adjust the standard based on potential impacts to endangered species of reduced criteria pollutant emissions. Section 7(a)(2) consultation thus is not required with respect to the projected reductions of criteria pollutant emissions. *See* 50 CFR 402.03; *see also, WildEarth Guardians v. U.S. Envt'l Protection Agency,* 759 F.3d 1196, 1207-10 (10th Cir. 2014) (EPA has no duty to consult under section 7(a)(2) of the ESA regarding hazardous air pollutant controls that it did not require – and likely lacked authority to require – in a federal implementation plan for regional haze controls under section 169A of the CAA).

Finally, the EPA has also considered other potential effects of the rule (beyond reductions in air pollutants) and

---

with the present rule does not address whether global climate change may, as a general matter, be a relevant consideration in the status of certain listed species. Rather, the requirements of ESA section 7(a)(2) must be considered and applied to the specific action at issue. As explained above, EPA's conclusion that ESA section 7(a)(2) consultation is not required here is premised on the specific facts and circumstances of the present rule and is fully consistent with prior relevant analyses conducted by DOI, FWS, and EPA.

whether any such effects are "caused by" the rule and "reasonably certain to occur" within the meaning of the ESA regulatory definition of the effects of an action. 50 CFR 402.02. As the EPA noted in the proposal, there are substantial questions as to whether any potential for relevant effects results from any element of the rule or would result instead from separate decisions and actions made in connection with the development, implementation, and enforcement of a plan to implement the standards established in the rule. *Cf. American Trucking Assn's* v. *EPA,* 175 F. 3d 1027, 1043-45 (D.C. Cir. 1999), *rev'd on different grounds sub nom., Whitman* v. *American Trucking Assn's,* 531 U.S. 457 (2000) (National Ambient Air Quality Standards have no economic impact, for purposes of Regulatory Flexibility Act, because impacts result from the actions of states through their development, implementation and enforcement of SIPs).[1047] The EPA recognized, for instance, that

[1047] One commenter questioned the EPA's citation to *American Trucking Assn's.* As stated by the commenter, the statute at issue in that case – the Regulatory Flexibility Act (RFA) – is distinguishable from the ESA in that it addresses only direct effects and does not consider indirect effects. The commenter misreads the EPA's citation to this case. The EPA cites this case simply to reference a decision considering the impacts of an EPA action – the revision of a NAAQS under the CAA– that in certain respects provides a useful analogy to the present rule. A NAAQS is implemented through a series of subsequent planning decisions generally taken by states by means of adoption of SIPs. States can choose to impose or avoid the types of impacts at issue in the D.C. Circuit case through their planning questions may exist whether decisions such as increased utilization of solar or wind power could have effects on listed species. The EPA received comments on the proposal asserting that because potential increased reliance on wind or solar power may be an element of building block 3, and because wind and solar facilities may in some cases have effects on listed species, the EPA must consult under the ESA on this aspect of the rule. The EPA is also aware of certain questions regarding potential effects of the rule on the Big Bend Power Station located in Florida, which discharges effluent that provides a warm water refuge for manatees. The Big Bend Power Station and another coal-fired facility located in Florida – the Crystal

---

decisions; thus such impacts were not viewed as having been caused – for purposes of the RFA – by the EPA's promulgation of the revised NAAQS in the first instance. The standard setting and implementation mechanisms under section 111(d) are very similar. Under section 111(d), the EPA is required to establish "a procedure similar to that provided by section 7410" – the provision establishing the SIP mechanism for implementing NAAQS. Thus, the D.C. Circuit's discussion provides a useful analogy to the present rule and the various types of potential effects that may be attributable to future implementation planning decisions by states and other entities as they exercise their discretion in determining how to implement the federal guidelines, but not to promulgation of the rule itself. The EPA's citation to this case was not intended to address any comparison of the scope of effects covered by the RFA and the effects cognizable under section 7(a)(2) of the ESA. The EPA is aware that the ESA addresses both direct and indirect effects as defined by the applicable ESA regulations. The discussion supporting the EPA's ESA conclusion expressly acknowledges the relevance of indirect effects to the ESA analysis and explains why such effects are not present here.

River Plant – are, for example, referenced in the June 11, 2015, and June 15, 2015, congressional letters to EPA cited above.

The EPA has carefully considered the comments and the correspondence from Congress as well as the case law and other materials cited in those documents. The EPA does not believe that the effects of potential future changes in the energy sector – including increased reliance on wind or solar power as a result of future potential actions by states or other implementing entities – or any potential alterations in the operations of any particular facility are caused by the current rule or sufficiently certain to occur so as to require ESA consultation on the rule. The EPA appreciates that the ESA regulations call for consultation where actions authorized, funded, or carried out by federal agencies may have indirect effects on listed species or designated critical habitat. However, as noted above, indirect effects must be caused by the action at issue and must be reasonably certain to occur. At this point, there is no reasonable certainty regarding implementation of any planning measures in any location, let alone in any location occupied by a listed species or its designated critical habitat. The EPA cannot predict with reasonable certainty where such measures may take effect or which measures may be adopted. It is not clear, for instance, whether a particular implementation plan will call, if at all, for increased reliance on wind power, as opposed to solar power, or on some other form of low or zero carbon emitting generation. It is also entirely uncertain how a future implementation plan for a particular state might affect, if at all, operations at a specific facility.[1048] The precise steps included in an implementation plan cannot be determined or ordered by this federal action, and they are not sufficiently certain to be attributable to this final rule for ESA purposes. These steps will flow from a series of later in time decisions generally made by other entities – usually states – in their distinct planning processes. These later decisions cannot now be required by the rule, are not caused by the rule, and are not reasonably certain to occur. The EPA also notes that the plans adopted for particular states may themselves provide wide degrees of implementation flexibility, thus further increasing the uncertainty that any species-

[1048] A congressional letter of June 11, 2015, referenced above asserts that EPA's modeling suggests that the Big Bend Power Station and Crystal River Energy Complex in Florida will be prematurely retired as a result of the rule. EPA notes that any such facility-level projections associated with the rule cannot be stated with sufficient certainty to qualify as potential indirect effects under the ESA. These projections are based on numerous assumptions regarding a variety of planning and business decisions yet to be made by the implementing governments (usually states) and facility owners. Given the wide degrees of discretion and flexibility and the numerous options available for such decision making, the potential for such outcomes to be realized as currently projected is at this point too uncertain to qualify as an effect under the ESA.

impacting activity will occur in any particular location, if at all. The Services have explained that section 7(a)(2) was not intended to preclude federal actions based on potential future speculative effects.[1049] These are precisely the types of speculative future activities and effects at issue here.[1050] For this additional reason, the EPA concludes that the rule does not

---

[1049] *See* 51 FR at 19933 (describing effects that are "reasonably certain to occur" in the context of consideration of cumulative effects and distinguishing broader consideration that may be appropriate in applying a procedural statute such as the National Environmental Policy Act, as opposed to a substantive provision such as ESA section 7(a)(2) that may prohibit certain federal actions); Endangered Species Consultation Handbook, U.S. Fish & Wildlife Service and National Marine Fisheries Service at 4-30 (March 1998) (in the same context, describing indicators that an activity is reasonably certain to occur as including governmental approvals of the action or indications that such approval is imminent, project sponsors' assurance that the action will proceed, obligation of venture capital, or initiation of contracts; and noting that the more governmental administrative discretion remains to be exercised, the less there is reasonable certainty the action will proceed).

[1050] EPA also notes that some of the future implementing activities may involve federal actions that are subject to ESA consultation, thus providing consideration of any impacts on listed species at the appropriate point when particular activities have become reasonably certain. Several commenters on the proposal specifically noted that such future activities – *e.g.*, development of additional RE facilities such as wind farms – may call for ESA consultation. Further, EPA notes that section 9 of the ESA, which prohibits the take of individuals of most listed species, provides an additional protection for listed species as future implementing activities become reasonably certain.

have effects on listed species that trigger the section 7(a)(2) consultation requirement.[1051]

C. What are the energy impacts?

The final guidelines have important energy market implications. Table 17 presents a variety of important energy

---

[1051] The commenters cite certain cases that they assert support consulting under ESA section 7(a)(2). The EPA has considered these cases, each of which is distinguishable from the present rule. By way of example, a commenter cites two cases involving EPA actions: *Defenders of Wildlife v. EPA*, 420 F.3d 946 (9th Cir. 2005), *rev'd*, *National Association of Homebuilders v. Defenders of Wildlife*, 551 U.S. 644 (2007); and *Washington Toxics Coalition v. EPA*, 413 F.3d 1024 (9th Cir. 2005). In *Defenders of Wildlife* (a decision that was reversed by the U.S. Supreme Court), a principal relevant impact of the federal action at issue – the EPA's approval of a state's permitting program under the Clean Water Act – was that following the action, the relevant permitted activities would no longer be subject to consultation under the ESA. By contrast, promulgation of the present rule will result in no change to any ESA requirements applicable to any future activities directed by plans (either state or federal) implementing the rule. The action at issue in *Washington Toxics Coalition* involved the EPA's registration of certain pesticide active ingredients under the Federal Insecticide, Fungicide, and Rodenticide Act. Such actions provide authorization for the sale and distribution of those products, consistent with applicable labelling requirements. The EPA also notes that under the EPA's regulations, registered pesticide labels must, among other things, specify the product ingredients and the methods and sites of product application. 40 CFR 156.10. By contrast, the present rule only sets goals and describes potential pathways to meeting those goals, all of which are subject to future considerations and decisions involved in the implementation of plans (generally by states). The rule neither authorizes, nor directs, any of the future measures to meet the rule's goals. Those activities remain subject to the full range of future decision making addressing which types of measures to implement, what emitting entities will be affected, how much, and when.

market impacts for 2020, 2025, and 2030 under both the rate-based and mass-based illustrative plan approaches.

Table 17. Summary Table of Important Energy Market Impacts for Rate-based and Mass-based Illustrative Plan Approaches (Percent Change from Base Case)

	Rate-Based			Mass-Based		
	2020	**2025**	**2030**	**2020**	**2025**	**2030**
Retail electricity prices	3%	1%	1%	3%	2%	0%
Price of coal at minemouth	-1%	-5%	-4%	-1%	-5%	-3%
Coal production for power sector use	-5%	-14%	-25%	-7%	-17%	-24%
Price of natural gas delivered to power sector	5%	-8%	2%	4%	-3%	-2%
Natural gas use for electricity generation	3%	-1%	-1%	5%	0%	-4%

These figures reflect the EPA's illustrative modeling that presumes policies that lead to generation shifts and growing use of demand-side EE and renewable electricity generation out to 2029. If states make different policy choices, impacts could be different. For instance, if states implement renewable and/or demand-side EE policies on a more aggressive time-frame, impacts on natural gas and electricity prices would likely be less. Implementation of other measures not included in the BSER calculation or compliance modeling, such as nuclear uprates, transmission system improvements, use of energy storage technologies or retrofit CCS, could also mitigate gas price and/or electricity price impacts.

Energy market impacts from the guidelines are discussed more extensively in the RIA found in the docket for this rulemaking.

D. What are the compliance costs?

The compliance costs of this final action are represented in this analysis as the change in electric power generation costs between the base case and the final rule in which states pursue a distinct set of strategies beyond the strategies taken in the base case to meet the terms of the final guidelines. The compliance costs estimates include cost estimates for demand-side EE. The compliance assumptions – and, therefore, the projected compliance costs - set forth in this analysis are illustrative in nature and do not represent the full suite of compliance flexibilities states may ultimately pursue. The illustrative analysis is designed to reflect, to the extent possible, the scope and the nature of the final guidelines. However, there is considerable uncertainty with regards to the precise measures that states will adopt to meet the final requirements, because there are considerable flexibilities afforded to the states in developing their state plans.

The incremental cost is the projected additional cost of complying with the guidelines in the year analyzed and includes the amortized cost of capital investment, needed new capacity, shifts between or amongst various fuels, deployment of demand-side EE programs, and other actions associated with compliance. These important dynamics are discussed in more detail in the RIA in the rulemaking docket.

The EPA estimates the annual incremental compliance cost for the rate-based approach for final emission guidelines to be $2.5 billion in 2020, $1.0 billion in 2025 and $8.4 billion in 2030, including the costs associated with monitoring, reporting, and recordkeeping (MR&R).[1052] The EPA estimates the annual incremental compliance cost for the mass-based approach for final emission guidelines to be $1.4 billion in 2020, $3.0 billion in 2025 and $5.1 billion in 2030, including the costs associated with MR&R.

More detailed cost estimates are available in the RIA included in the rulemaking docket.

E. What are the economic and employment impacts?

The final standards are projected to result in certain changes to power system operation as a compliance with the

[1052] The MR&R costs estimates are $65 million in 2020, $15 million in 2025 and $15 million in 2030 and are assumed to be the same for both rate-based and mass-based illustrative plan approaches.

standards. See Table 16 above for a variety of important energy market impacts for 2020, 2025, and 2030 under both the rate-based and mass-based illustrative plan approaches.

It is important to note that the EPA's modeling does not necessarily account for all of the factors that may influence business decisions regarding future coal-fired capacity. Many power companies already factor a potential financial liability associated with carbon emissions into their long term capacity planning that would further influence business decisions to replace these aging assets with modern, and significantly cleaner, generation.

The compliance modeling done to support the final rule assumes that overall electric demand will decrease as states ramp up programs that result in lower overall demand. Demand-side EE levels are expected to increase such that they achieve about a 7.8 percent reduction on overall electricity demand levels in 2030 under the final guidelines.

Changes in price or demand for electricity, natural gas, and coal can impact markets for goods and services produced by sectors that use these energy inputs in the production process or supply those sectors. Changes in the cost of production may result in changes in prices, quantities produced, and profitability of affected firms. The EPA recognizes that these guidelines provide significant flexibilities and states implementing the guidelines may choose to mitigate impacts to some markets outside the utility power sector. Similarly, demand for new generation or demand-side EE as a result of states implementing the guidelines can result in shifts in production and profitability for firms that supply those goods and services.

Executive Order 13563 directs federal agencies to consider the effect of regulations on job creation and employment. According to the Executive Order, "our regulatory system must protect public health, welfare, safety, and our environment while promoting economic growth, innovation, competitiveness, and job creation. It must be based on the best available science." (Executive Order 13563, 2011) Although standard benefit-cost analyses have not typically included a separate analysis of regulation-induced employment impacts, we typically conduct employment analyses. While the economy continues moving toward full-employment, employment impacts are of particular concern and questions may arise about their existence and magnitude.

States have the responsibility and flexibility to implement policies and practices for compliance with the final guidelines. Quantifying the associated employment impacts is complicated by the wide range of approaches that states may use. As such, the EPA's employment analysis includes projected employment impacts associated with illustrative plan approaches for these guidelines for the electric power industry, coal and natural gas production, and demand-side EE activities. These projections are derived, in part, from a detailed model of the utility power sector used for this regulatory analysis, and U.S government data on employment and labor productivity. In the electricity, coal, and natural gas sectors, the EPA estimates that these guidelines could result in a net decrease of approximately 25,000 job-years in 2025 for the final guidelines under the rate-based illustrative plan approach and approximately 26,000 job-years in 2025 under the mass-based approach. For 2030, the estimates of the net decrease in job-years are 31,000 under the rate-based approach and 34,000 under the mass-based approach. The agency is also offering an illustrative calculation of potential employment effects due to demand-side EE programs. Employment impacts from demand-side energy EE programs in 2030 could range from approximately 52,000 to 83,000 jobs under the final guidelines.

By its nature, demand-side EE reduces overall demand for electric power. The EPA recognizes as more efficiency is built into the U.S. power system over time, lower fuel requirements may lead to fewer jobs in the coal and natural gas extraction sectors, as well as in fossil-fuel fired EGU construction and operation than would otherwise have been expected. The EPA also recognizes the fact that, in many cases, employment gains and losses that might be attributable to this rule would be expected to affect different sets of people. Moreover, workers who lose jobs in these sectors may find employment elsewhere just as workers employed in new jobs in these sectors may have been previously employed elsewhere. Therefore, the employment estimates reported in these sectors may include workers previously employed elsewhere. This analysis also does not capture potential economy-wide impacts due to changes in prices (of fuel, electricity, labor, for example) or other factors such as improved labor productivity and reduced health care expenditures resulting from cleaner air. For these reasons, the numbers reported here should not be interpreted as a net national employment impact.

F. What are the benefits of the final goals?

Implementing the final standards will generate benefits by reducing emissions of CO_2 and criteria pollutant precursors, including SO_2, NO_X, and directly-emitted particles. SO_2 and NO_X are precursors to $PM_{2.5}$ (particles smaller than 2.5 microns), and NO_X is a precursor to ozone. The estimated benefits associated with these emission reductions are beyond those achieved by previous EPA rulemakings including the Mercury and Air Toxics Standards rule. The health and welfare benefits from reducing air pollution are considered co-benefits for these standards.

For this rulemaking, we were only able to quantify the climate benefits from reduced emissions of CO_2 and the health co-benefits associated with reduced exposure to $PM_{2.5}$ and ozone. There are many additional benefits which we are not able to quantify, leading to an underestimate of monetized benefits. In summary, we estimate the total combined climate benefits and health co-benefits for the rate-based approach to be $3.5 to $4.6 billion in 2020, $18 to $28 billion in 2025, and $34 to $54 billion in 2030 (3 percent discount rate, 2011$). Total combined climate benefits and health co-benefits for the mass-based approach are estimated to be $5.3 to $8.1 billion in 2020, $19 to $29 billion in 2025, and $32 to $48 billion in 2030 (3 percent discount rate, 2011$). A summary of the emission reductions and monetized benefits estimated for this rule at all discount rates is provided in Tables 15 through 22 of this preamble.

Table 18. Summary of the Monetized Global Climate Benefits for the Final Guidelines (billions of 2011$)[a]

	Discount Rate (Statistic)	**Monetized Climate Benefits**		
YEAR		**2020**	**2025**	**2030**
		Rate-based Approach		
CO_2 Reductions (million short tons)		69	232	415
	5 percent (average SC-CO_2)	$0.80	$3.1	$6.4

	3 percent (average $SC\text{-}CO_2$)	$2.8	$10	$20
	2.5 percent (average $SC\text{-}CO_2$)	$4.1	$15	$29
	3 percent (95th percentile $SC\text{-}CO_2$)	$8.2	$31	$61
Mass-based Approach				
CO_2 Reductions (million short tons)		81	265	413
	5 percent (average $SC\text{-}CO_2$)	$0.94	$3.6	$6.4
	3 percent (average $SC\text{-}CO_2$)	$3.3	$12	$20
	2.5 percent (average $SC\text{-}CO_2$)	$4.9	$17	$29
	3 percent (95th percentile $SC\text{-}CO_2$)	$9.7	$35	$60

[a] Climate benefit estimates reflect impacts from CO_2 emission changes in the analysis years presented in the table and do not account for changes in non-CO_2 GHG emissions. These estimates are based on the global social cost of carbon ($SC\text{-}CO_2$) estimates for the analysis years and are rounded to two significant figures.

Table 19. Summary of the Monetized Health Co-Benefits in the U.S. for the Final Guidelines, Rate-based Approach (billions of 2011$)[a]

Pollutant	National Emission Reductions (thousands of short tons)	Monetized Health Co-benefits (3 percent discount)	Monetized Health Co-benefits (7 percent discount)
Final Guidelines, Rate-based Approach, 2020			
$PM_{2.5}$ precursors [b]			

SO_2	14	\$0.44 to \$0.99	\$0.39 to \$0.89
NO_X	50	\$0.14 to \$0.33	\$0.13 to \$0.30
Ozone precursor [c]			
NO_X (ozone season only)	19	\$0.12 to \$0.52	\$0.12 to \$0.52
Total Monetized Health Co-benefits		\$0.70 to \$1.8	\$0.64 to \$1.7
Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]		\$3.5 to \$4.6	\$3.5 to \$4.5
Final Guidelines, Rate-based Approach, 2025			
$PM_{2.5}$ precursors [b]			
SO_2	178	\$6.4 to \$14	\$5.7 to \$13
NO_X	165	\$0.56 to \$1.3	\$0.50 to \$1.1
Ozone precursor [c]			
NO_X (ozone season only)	70	\$0.49 to \$2.1	\$0.49 to \$2.1
Total Monetized Health Co-benefits		\$7.4 to \$18	\$6.7 to \$16
Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]		\$18 to \$28	\$17 to \$26
Final Guidelines, Rate-based Approach, 2030			
$PM_{2.5}$ precursors [b]			
SO_2	318	\$12 to \$28	\$11 to \$25
NO_X	282	\$1.0 to \$2.3	\$0.93 to \$2.1
Ozone precursor [c]			
NO_X (ozone season only)	118	\$0.86 to \$3.7	\$0.86 to \$3.7
Total Monetized Health Co-benefits		\$14 to \$34	\$13 to \$31
Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]		\$34 to \$54	\$33 to \$51

[a] All estimates are rounded to two significant figures, so estimates may not sum. It is important to note that the

monetized co-benefits do not include reduced health effects from direct exposure to SO_2, direct exposure to NO_2, exposure to mercury, ecosystem effects or visibility impairment. Air pollution health co-benefits are estimated using regional benefit-per-ton estimates for the contiguous U.S.

[b] The monetized $PM_{2.5}$ co-benefits reflect the human health benefits associated with reducing exposure to $PM_{2.5}$ through reductions of $PM_{2.5}$ precursors, such as SO_2 and NO_X. The co-benefits do not include the benefits of reductions in directly emitted $PM_{2.5}$. These additional benefits would increase overall benefits by a few percent based on the analyses conducted for the proposed rule. PM co-benefits are shown as a range reflecting the use of two concentration-response functions, with the lower end of the range based on a function from Krewski et al. (2009) and the upper end based on a function from Lepeule et al. (2012). These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type.

[c] The monetized ozone co-benefits reflect the human health benefits associated with reducing exposure to ozone through reductions of NO_X during the ozone season. Ozone co-benefits are shown as a range reflecting the use of several different concentration-response functions, with the lower end of the range based on a function from Bell, et al. (2004) and the upper end based on a function from Levy, et al. (2005). Ozone co-benefits occur in the analysis year, so they are the same for all discount rates.

[d] We estimate climate benefits associated with four different values of a one ton CO_2 reduction (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent). Referred to as the social cost of carbon, each value increases over time. For the purposes of this table, we show the benefits associated with the model average at 3 percent discount rate, however we emphasize the importance and value of considering the full range of social cost of carbon values. We provide combined climate and health estimates based on additional discount rates in the RIA.

Table 20. Summary of the Monetized Health Co-Benefits in the U.S. for the Final Guidelines, Mass-based Approach (billions of 2011$)[a]

Pollutant	National Emission Reductions	Monetized Health Co-benefits	Monetized Health Co-benefits

	(thousands of short tons)	(3 percent discount)	(7 percent discount)
Final Guidelines, Mass-based Approach, 2020			
$PM_{2.5}$ precursors [b]			
SO_2	54	\$1.7 to \$3.8	\$1.5 to \$3.4
NO_X	60	\$0.17 to \$0.39	\$0.16 to \$0.36
Ozone precursor [c]			
NO_X (ozone season only)	23	\$0.14 to \$0.61	\$0.14 to \$0.61
Total Monetized Health Co-benefits		\$2.0 to \$4.8	\$1.8 to \$4.4
Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]		\$5.3 to \$8.1	\$5.1 to \$7.7
Final Guidelines, Mass-based Approach, 2025			
$PM_{2.5}$ precursors [b]			
SO_2	185	\$6.0 to \$13	\$5.4 to \$12
NO_X	203	\$0.58 to \$1.3	\$0.52 to \$1.2
Ozone precursor [c]			
NO_X (ozone season only)	88	\$0.56 to \$2.4	\$0.56 to \$2.4
Total Monetized Health Co-benefits		\$7.1 to \$17	\$6.5 to \$16
Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]		\$19 to \$29	\$18 to \$27
Final Guidelines, Mass-based Approach, 2030			
$PM_{2.5}$ precursors [b]			
SO_2	280	\$10 to \$23	\$9.0 to \$20
NO_X	278	\$0.87 to \$2.0	\$0.79 to \$1.8
Ozone precursor [c]			
NO_X (ozone season only)	121	\$0.82 to \$3.5	\$0.82 to \$3.5
Total Monetized Health Co-benefits		\$12 to \$28	\$11 to \$26

Total Monetized Health Co-benefits combined with Monetized Climate Benefits [d]	$32 to $48	$31 to $46

[a] All estimates are rounded to two significant figures, so estimates may not sum. It is important to note that the monetized co-benefits do not include reduced health effects from direct exposure to SO_2, direct exposure to NO_2, exposure to mercury, ecosystem effects or visibility impairment. Air pollution health co-benefits are estimated using regional benefit-per-ton estimates for the contiguous U.S.
[b] The monetized $PM_{2.5}$ co-benefits reflect the human health benefits associated with reducing exposure to $PM_{2.5}$ through reductions of $PM_{2.5}$ precursors, such as SO_2 and NO_X. The co-benefits do not include the benefits of reductions in directly emitted $PM_{2.5}$. These additional benefits would increase overall benefits by a few percent based on the analyses conducted for the proposed rule. PM co-benefits are shown as a range reflecting the use of two concentration-response functions, with the lower end of the range based on a function from Krewski et al. (2009) and the upper end based on a function from Lepeule et al. (2012). These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type.
[c] The monetized ozone co-benefits reflect the human health benefits associated with reducing exposure to ozone through reductions of NO_X during the ozone season. Ozone co-benefits are shown as a range reflecting the use of several different concentration-response functions, with the lower end of the range based on a function from Bell, et al. (2004) and the upper end based on a function from Levy, et al. (2005). Ozone co-benefits occur in the analysis year, so they are the same for all discount rates.
[d] We estimate climate benefits associated with four different values of a one ton CO_2 reduction (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent). Referred to as the social cost of carbon, each value increases over time. For the purposes of this table, we show the benefits associated with the model average at 3 percent discount rate, however we emphasize the importance and value of considering the full range of social cost of carbon values. We provide combined climate and health estimates based on additional discount rates in the RIA.

The EPA has used the social cost of carbon (SC-CO_2) estimates presented in the *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866 (May 2013, Revised June 2015)* ("current TSD") to analyze CO_2 climate impacts of this rulemaking.[1053] We refer to these estimates, which were developed by the U.S. government, as "SC-CO_2 estimates." The SC-CO_2 is a metric that estimates the monetary value of impacts associated with marginal changes in CO_2 emissions in a given year. It includes a wide range of anticipated climate impacts, such as net changes in agricultural productivity and human health, property damage from increased flood risk, and changes in energy system costs, such as reduced costs for heating and increased costs for air conditioning. It is typically used to assess the avoided damages as a result of regulatory actions (i.e.,

[1053] Docket ID EPA-HQ-OAR-2013-0495, Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866, Interagency Working Group on Social Cost of Carbon, with participation by Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Domestic Policy Council, Environmental Protection Agency, National Economic Council, Office of Management and Budget, Office of Science and Technology Policy, and Department of Treasury (May 2013, Revised July 2015). Available at: http://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-tsd-final-july-2015.pdf.

benefits of rulemakings that lead to an incremental reduction in cumulative global CO_2 emissions).

The SC-CO_2 estimates used in this analysis were developed over many years, using the best science available, and with input from the public. Specifically, an interagency working group (IWG) that included the EPA and other executive branch agencies and offices used three integrated assessment models (IAMs) to develop the SC-CO_2 estimates and recommended four global values for use in regulatory analyses. The SC-CO_2 estimates were first released in February 2010 and updated in 2013 using new versions of each IAM. The 2010 SC-CO_2 Technical Support Document (2010 TSD)[1054] provides a complete discussion of the methods used to develop these estimates and the current TSD presents and discusses the 2013 update (including two recent minor corrections to the estimates).[1055]

[1054] Docket ID EPA-HQ-OAR-2009-0472-114577, *Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866, Interagency Working Group on Social Cost of Carbon*, with participation by the Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Environmental Protection Agency, National Economic Council, Office of Energy and Climate Change, Office of Management and Budget, Office of Science and Technology Policy, and Department of Treasury (February 2010). Also available at: http://www.whitehouse.gov/sites/default/files/omb/inforeg/for-agencies/Social-Cost-of-Carbon-for-RIA.pdf.

[1055] The current version of the TSD is available at: https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-

The EPA received numerous comments on the SC-CO_2 estimates as part of this rulemaking. The comments covered a wide range of topics including the technical details of the modeling conducted to develop the SC-CO_2 estimates, the aggregation and presentation of the SC-CO_2 estimates, and the process by which the SC-CO_2 estimates were derived. Many but not all commenters were supportive of the SC-CO_2 and its application to this rulemaking. Commenters also provided constructive recommendations for potential opportunities to improve the SC-CO_2 estimates in future updates. Many of these comments were similar to those that OMB's Office of Information and Regulatory Affairs received in response to a separate request for public comment on the approach used to develop the estimates. After careful evaluation of the full range of comments submitted to OMB, the IWG continues to recommend the use of the SC-CO_2 estimates in regulatory impact analysis.[1056] With the release of the response

response-to-comments-final-july-2015.pdf, Docket ID EPA-HQ-OAR-2013-0495, *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866*, Interagency Working Group on Social Cost of Carbon, with participation by Council of Economic Advisers, Council on Environmental Quality, Department of Agriculture, Department of Commerce, Department of Energy, Department of Transportation, Domestic Policy Council, Environmental Protection Agency, National Economic Council, Office of Management and Budget, Office of Science and Technology Policy, and Department of Treasury (May 2013, Revised July 2015).

[1056] See https://www.whitehouse.gov/omb/oira/social-cost-of-carbon for additional details, including the OMB Response to Comments and the SC-CO_2 TSDs.

to comments, the IWG announced plans to obtain expert independent advice from the National Academies of Sciences, Engineering, and Medicine (Academies) to ensure that the SC-CO_2 estimates continue to reflect the best available scientific and economic information on climate change. The Academies review will be informed by the public comments received and focus on the technical merits and challenges of potential approaches to improving the SC-CO_2 estimates in future updates. See the EPA Response to Comments document for the complete response to comments received on SC-CO_2 as part of this rulemaking.

Concurrent with OMB's publication of the response to comments on SC-CO_2 and announcement of the Academies process, OMB posted a revised TSD that includes two minor technical corrections to the current estimates. One technical correction addressed an inadvertent omission of climate change damages in the last year of analysis (2300) in one model and the second addressed a minor indexing error in another model. On average the revised SC-CO_2 estimates are one dollar less than the mean SC-CO_2 estimates reported in the November 2013 revision to the May 2013 TSD. The change in the estimates associated with the 95th percentile estimates when using a 3 percent discount rate is slightly larger, as those estimates are heavily influenced by the results from the model that was affected by the indexing error.

The EPA, as a member of the IWG on the SC-CO_2, has carefully examined and evaluated the minor technical corrections in the revised TSD and the public comments submitted to OMB's separate SC-CO_2 comment process. Additionally, the EPA has carefully examined and evaluated all comments received regarding the SC-CO_2 through this rulemaking process. The EPA concurs with the IWG's conclusion that it is reasonable, and scientifically appropriate, to use the current SC-CO_2 estimates for purposes of regulatory impact analysis, including for this proceeding.

The four SC-CO_2 estimates are as follows: $12, $40, $60, and $120 per short ton of CO_2 emissions in the year 2020 (2011$).[1057] The first three values are based on the average SC-CO_2 from the three IAMs, at discount rates of 5, 3, and 2.5 percent, respectively. The SC-CO_2 value at several discount rates are included because the literature shows that the SC-CO_2 is quite sensitive to assumptions about the discount rate, and because no consensus exists on the appropriate rate to use in an intergenerational context (where costs and benefits are incurred by different generations). The fourth value is the 95th

---

[1057] The current version of the TSD is available at: https://www.whitehouse.gov/sites/default/files/omb/inforeg/scc-tsd-final-july-2015.pdf. The 2010 and 2013 TSDs present SC-CO_2 in 2007$ per metric ton. The estimates were adjusted to (1) short tons for using conversion factor 0.90718474 and (2) 2011$ using GDP Implicit Price Deflator, http://www.gpo.gov/fdsys/pkg/ECONI-2013-02/pdf/ECONI-2013-02-Pg3.pdf.

percentile of the SC-CO_2 from all three models at a 3 percent discount rate. It is included to represent higher-than-expected impacts from temperature change further out in the tails of the SC-CO_2 distribution (representing less likely, but potentially catastrophic, outcomes).

There are limitations in the estimates of the benefits from the final emission guidelines, including the omission of climate and other CO_2 related benefits that could not be monetized. The 2010 TSD discusses a number of limitations to the SC-CO_2 analysis, including the incomplete way in which the IAMs capture catastrophic and non-catastrophic impacts, their incomplete treatment of adaptation and technological change, uncertainty in the extrapolation of damages to high temperatures, and assumptions regarding risk aversion. Currently, IAMs do not assign value to all of the important impacts of CO_2 recognized in the literature, such as ocean acidification or potential tipping points, for various reasons, including the inherent difficulties in valuing non-market impacts and the fact that the science incorporated into these models understandably lags behind the most recent research. Nonetheless, these estimates and the discussion of their limitations represent the best available information about the social benefits of CO_2 emission reductions to inform the benefit-cost analysis. As previously noted, the IWG plans to seek independent expert advice on technical opportunities to improve the SC-CO_2 estimates from the Academies. The Academies process will help to ensure that the SC-CO_2 estimates used by the federal government continue to reflect the best available science and methodologies. Additional details are provided in the TSDs.

The health co-benefits estimates represent the total monetized human health benefits for populations exposed to reduced $PM_{2.5}$ and ozone resulting from emission reductions from the illustrative compliance strategy for the final standards. Unlike the global SC-CO_2 estimates, the air pollution health co-benefits are estimated for the contiguous U.S. only. We used a "benefit-per-ton" approach to estimate the benefits of this rulemaking. To create the $PM_{2.5}$ benefit-per-ton estimates, we conducted air quality modeling for an illustrative scenario reflecting the proposed standards to convert precursor emissions into changes in ambient $PM_{2.5}$ and ozone concentrations. We then used these air quality modeling results in BenMAP[1058] to calculate average regional benefit-per-ton estimates using the health impact assumptions used in the PM NAAQS RIA[1059] and Ozone NAAQS

regarding the derivation of the benefit-per-ton estimates is available in the RIA.

PM benefit-per-ton values are generated using two concentration-response functions, Krewski et al. (2009) [1063] and Lepeule et al. (2012) [1064]. These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type. Even though we assume that all fine particles have equivalent health effects, the benefit-per-ton estimates vary between $PM_{2.5}$ precursors depending on the location and magnitude of their impact on $PM_{2.5}$ concentrations, which drive population exposure.

It is important to note that the magnitude of the $PM_{2.5}$ and ozone co-benefits is largely driven by the concentration response functions for premature mortality and the value of a statistical life used to value reductions in premature mortality. For $PM_{2.5}$, we use two key empirical studies, one based

[1063] Krewski D.; M. Jerrett; R. T. Burnett; R. Ma; E. Hughes; Y. Shi, et al. 2009. *Extended Follow-up and Spatial Analysis of the American Cancer Society Study Linking Particulate Air Pollution and Mortality.* Health Effects Institute. (HEI Research Report number 140). Boston, MA: Health Effects Institute.
[1064] Lepeule, J.; F. Laden; D. Dockery; J. Schwartz. 2012. "Chronic Exposure to Fine Particles and Mortality: An Extended Follow-Up of the Harvard Six Cities Study from 1974 to 2009." *Environmental Health Perspective*, 120(7), July, pp. 965-970.

on the American Cancer Society cohort study (Krewski et al, 2009) and one based on the extended Six Cities cohort study (Lepuele et al, 2012). We present the $PM_{2.5}$ co-benefits results as a range based on benefit-per-ton estimates calculated using the concentration-response functions from these two epidemiology studies, but this range does not capture the full range of uncertainty inherent in the co-benefits estimates. In the RIA for this rule, which is available in the docket, we also include $PM_{2.5}$ co-benefits estimates using benefit-per-ton estimates based on expert judgments of the effect of $PM_{2.5}$ on premature mortality (Roman et al., 2008)[1065] as a characterization of uncertainty regarding the $PM_{2.5}$-mortality relationship.

For the ozone co-benefits, we present the results as a range reflecting benefit-per-ton estimates which use several different concentration-response functions for mortality, with the lower end of the range based on a benefit-per-ton estimate using the function from Bell et al. (2004)[1066] and the upper end based on a benefit-per-ton estimate using the function from Levy et al.

(2005).[1067] Similar to $PM_{2.5}$, the range of ozone co-benefits does not capture the full range of inherent uncertainty.

In this analysis, in estimating the benefits-per-ton for $PM_{2.5}$ precursors, the EPA assumes that the health impact function for fine particles is without a threshold. This is based on the conclusions of EPA's *Integrated Science Assessment for Particulate Matter*,[1068] which evaluated the substantial body of published scientific literature, reflecting thousands of epidemiology, toxicology, and clinical studies that documents the association between elevated $PM_{2.5}$ concentrations and adverse health effects, including increased premature mortality. This assessment, which was twice reviewed by the EPA's independent Science Advisory Board, concluded that the scientific literature consistently finds that a no-threshold model most adequately portrays the PM-mortality concentration-response relationship.

In general, we are more confident in the magnitude of the risks we estimate from simulated $PM_{2.5}$ concentrations that coincide with the bulk of the observed PM concentrations in the

[1068] U.S. Environmental Protection Agency. 2009. *Integrated Science Assessment for Particulate Matter (Final Report)*. Research Triangle Park, NC: National Center for Environmental Assessment, RTP Division. (EPA document number EPA-600-R-08-139F, December). Available at: http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=216546.

epidemiological studies that are used to estimate the benefits. Likewise, we are less confident in the risk we estimate from simulated $PM_{2.5}$ concentrations that fall below the bulk of the observed data in these studies.

For this analysis, policy-specific air quality data are not available,[1069] and thus, we are unable to estimate the percentage of premature mortality associated with this specific rule that is above the lowest measured $PM_{2.5}$ levels (LML) for the two $PM_{2.5}$ mortality epidemiology studies that form the basis for our analysis. As a surrogate measure of mortality impacts above the LML, we provide the percentage of the population exposed above the lowest measured $PM_{2.5}$ level (LML) in each of the two studies, using the estimates of baseline projected $PM_{2.5}$ from the air quality modeling for the proposed guidelines used to calculate the benefit-per-ton estimates for the EGU sector. Using the Krewski et al. (2009) study, 88 percent of the population is exposed to annual mean $PM_{2.5}$ levels at or above the LML of 5.8 micrograms per cubic meter (μg/m^3). Using the Lepeule et al. (2012) study, 46 percent of the population is exposed above the LML of 8 μg/m^3. It is important to note that baseline exposure is only one parameter in the health impact function, along with baseline incidence rates, population, and change in air quality.

[1069] In addition, site-specific emission reductions will depend upon how states implement the guidelines.

Every benefit analysis examining the potential effects of a change in environmental protection requirements is limited, to some extent, by data gaps, model capabilities (such as geographic coverage) and uncertainties in the underlying scientific and economic studies used to configure the benefit and cost models. Despite these uncertainties, we believe the air quality co-benefit analysis for this rule provides a reasonable indication of the expected health benefits of the air pollution emission reductions for the illustrative analysis of the final standards under a set of reasonable assumptions. This analysis does not include the type of detailed uncertainty assessment found in the 2012 $PM_{2.5}$ National Ambient Air Quality Standard (NAAQS) RIA (U.S. EPA, 2012) because we lack the necessary air quality input and monitoring data to conduct a complete benefits assessment. In addition, using a benefit-per-ton approach adds another important source of uncertainty to the benefits estimates. The 2012 $PM_{2.5}$ NAAQS benefits analysis provides an indication of the sensitivity of our results to various assumptions.

We note that the monetized co-benefits estimates shown here do not include several important benefit categories, including exposure to SO_2, NO_X, and hazardous air pollutants (e.g., mercury and hydrogen chloride), as well as ecosystem effects and visibility impairment. Although we do not have sufficient information or modeling available to provide monetized estimates for this rule, we include a qualitative assessment of these unquantified benefits in the RIA for the final guidelines. In addition, in the RIA for the final standards, we did not estimate changes in emissions of directly emitted particles. As a result, quantified $PM_{2.5}$ related benefits are underestimated by a relatively small amount. In the RIA for the proposed guidelines, the benefits from reductions in directly emitted $PM_{2.5}$ were less than 10 percent of total monetized health co-benefits across all scenarios and years.

For more information on the benefits analysis, please refer to the RIA for this rule, which is available in the rulemaking docket.

XII. Statutory and Executive Order Reviews

Additional information about these Statutory and Executive Orders can be found at http://www2.epa.gov/laws-regulations/laws-and-executive-orders.

A. Executive Order 12866: Regulatory Planning and Review, and Executive Order 13563: Improving Regulation and Regulatory Review

This final action is an economically significant regulatory action that was submitted to the OMB for review. Any changes made in response to OMB recommendations have been documented in the docket. The EPA prepared an analysis of the potential costs and benefits associated with this action. This analysis, which is contained in the "Regulatory Impact Analysis for Clean Power Plan Final Rule" (EPA-452/R-15-003, July 2015), is available in the docket and is briefly summarized in section XI of this preamble.

Consistent with Executive Order 12866 and Executive Order 13563, the EPA estimated the costs and benefits for illustrative compliance approaches of implementing the guidelines. The final rule establishes: 1) carbon dioxide (CO_2) emission performance rates for two source categories of existing fossil fuel-fired EGUs, fossil fuel-fired electric utility steam generating units and stationary combustion turbines, and 2) guidelines for the development, submittal and implementation of state plans that implement the CO_2 emission performance rates. Actions taken to comply with the guidelines will also reduce the emissions of directly-emitted $PM_{2.5}$, SO_2 and NO_X. The benefits associated with these $PM_{2.5}$, SO_2 and NO_X reductions are referred to as co-benefits, as these reductions are not the primary objective of this rule.

The EPA has used the social cost of carbon estimates presented in the *Technical Support Document: Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866 (May 2013, Revised July 2015)* ("current TSD") to analyze CO_2 climate impacts of this rulemaking. We refer to these estimates, which were developed by the U.S. government, as "SC-CO_2 estimates." The SC-CO_2 is an estimate of the monetary value of impacts associated with a marginal change in CO_2 emissions in a given year. The four SC-CO_2 estimates are associated with different discount rates (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent), and each increases over time. In this summary, the EPA provides the estimate of climate benefits associated with the SC-CO_2 value deemed to be central in the current TSD: the model average at 3 percent discount rate.

In the final emission guidelines, the EPA has translated the source category-specific CO_2 emission performance rates into equivalent state-level rate-based and mass-based CO_2 goals in order to maximize the range of choices that states will have in developing their plans. Because of the range of choices available to states and the lack of *a priori* knowledge about the specific choices states will make in response to the final goals, the Regulatory Impact Analysis (RIA) for this rule analyzed two implementation scenarios designed to achieve these goals, which we term the "rate-based" illustrative plan approach and the "mass-based" illustrative plan approach.

It is very important to note that the differences between the analytical results for the rate-based and mass-based illustrative plan approaches presented in the RIA may not be indicative of likely differences between the approaches if implemented by states and affected EGUs in response to the final guidelines. Rather, the two sets of analyses are intended to illustrate two different approaches to accomplish the emission performance rates finalized in the Clean Power Plan Final Rule. In other words, if one approach performs differently than the other on a given metric during a given time period, this does not imply this will apply in all instances in all time periods in all places.

The EPA estimates that, in 2020, the final guidelines will yield monetized climate benefits (in 2011$) of approximately $2.8 billion for the rate-based approach and $3.3 billion for the mass-based approach (3 percent model average). For the rate-based approach, the air pollution health co-benefits in 2020 are estimated to be $0.7 billion to $1.8 billion (2011$) for a 3 percent discount rate and $0.64 billion to $1.7 billion (2011$) for a 7 percent discount rate. For the mass-based approach, the air pollution health co-benefits in 2020 are estimated to be $2.0 billion to $4.8 billion (2011$) for a 3 percent discount rate and $1.8 billion to $4.4 billion (2011$) for a 7 percent discount rate. The annual, illustrative compliance costs estimated by IPM and inclusive of demand-side EE program and participant costs and MRR costs in 2020, are approximately \$2.5 billion for the rate-based approach and \$1.4 billion for the mass-based approach (2011\$). The quantified net benefits (the difference between monetized benefits and compliance costs) in 2020 are estimated to range from \$1.0 billion to \$2.1 billion (2011\$) for the rate-based approach and from \$3.9 billion to 6.7 billion (2011\$) for the mass-based approach, using a 3 percent discount rate (model average).

The EPA estimates that, in 2025, the final guidelines will yield monetized climate benefits (in 2011\$) of approximately \$10 billion for the rate-based approach and \$12 billion for the mass-based approach (3 percent model average). For the rate-based approach, the air pollution health co-benefits in 2025 are estimated to be \$7.4 billion to \$18 billion (2011\$) for a 3 percent discount rate and \$6.7 billion to \$16 billion (2011\$) for a 7 percent discount rate. For the mass-based approach, the air pollution health co-benefits in 2025 are estimated to be \$7.1 billion to \$17 billion (2011\$) for a 3 percent discount rate and \$6.5 billion to \$16 billion (2011\$) for a 7 percent discount rate. The annual, illustrative compliance costs estimated by IPM and inclusive of demand-side EE program and participant costs and MRR costs in 2025, are approximately \$1.0 billion for the rate-based approach and \$3.0 billion for the mass-based approach (2011$). The quantified net benefits (the difference between monetized benefits and compliance costs) in 2025 are estimated to range from $17 billion to $27 billion (2011$) for the rate-based approach and $16 billion to $26 billion (2011$) for the mass-based approach, using a 3 percent discount rate (model average).

The EPA estimates that, in 2030, the final guidelines will yield monetized climate benefits (in 2011$) of approximately $20 billion for the rate-based approach and $20 billion for the mass-based approach (3 percent model average). For the rate-based approach, the air pollution health co-benefits in 2030 are estimated to be $14 billion to $34 billion (2011$) for a 3 percent discount rate and $13 billion to $31 billion (2011$) for a 7 percent discount rate. For the mass-based approach, the air pollution health co-benefits in 2030 are estimated to be $12 billion to $28 billion (2011$) for a 3 percent discount rate and $11 billion to $26 billion (2011$) for a 7 percent discount rate. The annual, illustrative compliance costs estimated by IPM and inclusive of demand-side EE program and participant costs and MRR costs in 2030, are approximately $8.4 billion for the rate-based approach and $5.1 billion for the mass-based approach (2011$). The quantified net benefits (the difference between monetized benefits and compliance costs) in 2030 are estimated to range from $26 billion to $45 billion (2011$) for the rate-based approach and from $26 billion to $43 billion (2011$) for the mass-based approach, using a 3 percent discount rate (model average).

Tables 20 and 21 provide the estimates of the climate benefits, health co-benefits, compliance costs and net benefits of the final emission guidelines for rate-based and mass-based illustrative plan approaches, respectively.

Table 21. Summary of the Monetized Benefits, Compliance Costs, and Net Benefits for the Final Guidelines in 2020, 2025 and 2030 Under the Rate-Based Illustrative Plan Approach [Billions of 2011$][a]

	Rate-Based Approach		
	2020	**2025**	**2030**
Climate Benefits[b]			
5% discount rate	$0.80	$3.1	$6.4
3% discount rate	$2.8	$10	$20
2.5% discount rate	$4.1	$15	$29
95th percentile at 3% discount rate	$8.2	$31	$61
	Air Quality Co-benefits Discount Rate		

	3%	7%	3%	7%	3%	7%
Air Quality Health Co-benefits[c]	\$0.70 to \$1.8	\$0.64 to \$1.7	\$7.4 to \$18	\$6.7 to \$16	\$14 to \$34	\$13 to \$31
Compliance Costs[d]	\$2.5		\$1.0		\$8.4	
Net Benefits[e]	\$1.0 to \$2.1	\$1.0 to \$2.0	\$17 to \$27	\$16 to \$25	\$26 to \$45	\$25 to \$43
Non-Monetized Benefits	Non-monetized climate benefits Reductions in exposure to ambient NO_2 and SO_2 Reductions in mercury deposition Ecosystem benefits associated with reductions in emissions of NO_X, SO_2, PM, and mercury Visibility impairment					

[a] All are rounded to two significant figures, so figures may not sum.

[b] The climate benefit estimate in this summary table reflects global impacts from CO_2 emission changes and does not account for changes in non-CO_2 GHG emissions. Also, different discount rates are applied to SC-CO_2 than to the other estimates because CO_2 emissions are long-lived and subsequent damages occur over many years. The benefit estimates in this table are based on the average SC-CO_2 estimated for a 3 percent discount rate. However, we emphasize the importance and value of considering the full range of SC-CO_2 values. As shown in the RIA, climate benefits are also estimated using the other three SC-CO_2 estimates (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95[th] percentile at 3 percent). The SC-CO_2 estimates are year-specific and increase over time.

[c] The air pollution health co-benefits reflect reduced exposure to $PM_{2.5}$ and ozone associated with emission reductions of SO_2 and NO_X. The range reflects the use of concentration-response functions from different epidemiology studies. The co-benefits do not include the benefits of reductions in directly emitted $PM_{2.5}$. These additional benefits would increase overall benefits by a few percent based on the analyses conducted for the proposed rule. The reduction in premature fatalities each year

accounts for over 98 percent of total monetized co-benefits from $PM_{2.5}$ and ozone. These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type.

[d] Total costs are approximated by the illustrative compliance costs estimated using the Integrated Planning Model for the final guidelines and a discount rate of approximately 5 percent. This estimate includes monitoring, recordkeeping, and reporting costs and demand-side EE program and participant costs.

[e] The estimates of net benefits in this summary table are calculated using the global SC-CO_2 at a 3 percent discount rate (model average). The RIA includes combined climate and health estimates based on additional discount rates.

Table 22. Summary of the Monetized Benefits, Compliance Costs, and Net Benefits for the Final Guidelines in 2020, 2025 and 2030 Under the Mass-Based Illustrative Plan Approach [Billions of 2011$][a]

	Mass-Based Approach		
	2020	**2025**	**2030**
Climate Benefits[b]			
5% discount rate	$0.9	$3.6	$6.4
3% discount rate	$3.3	$12	$20
2.5% discount rate	$4.9	$17	$29
95th percentile at 3%	$9.7	$35	$60

discount rate

	Air Quality Co-benefits Discount Rate					
	3%	7%	3%	7%	3%	7%
Air Quality Health Co-benefits[c]	$2.0 to $4.8	$1.8 to $4.4	$7.1 to $17	$6.5 to $16	$12 to $28	$11 to $26
Compliance Costs[d]	$1.4		$3.0		$5.1	
Net Benefits[e]	$3.9 to $6.7	$3.7 to $6.3	$16 to $26	$15 to $24	$26 to $43	$25 to $40
Non-Monetized Benefits	Non-monetized climate benefits Reductions in exposure to ambient NO_2 and SO_2 Reductions in mercury deposition Ecosystem benefits associated with reductions in emissions of NO_X, SO_2, PM, and mercury Visibility improvement					

[a] All are rounded to two significant figures, so figures may not sum.

[b] The climate benefit estimate in this summary table reflects global impacts from CO_2 emission changes and does not account for changes in non-CO_2 GHG emissions. Also, different discount rates are applied to SC-CO_2 than to the other estimates because CO_2 emissions are long-lived and subsequent damages occur over many years. The benefit estimates in this table are based on the average SC-CO_2 estimated for a 3 percent discount rate. However, we emphasize the importance and value of considering the full range of SC-CO_2 values. As shown in the RIA, climate benefits are also estimated using the other three SC-CO_2 estimates (model average at 2.5 percent discount rate, 3 percent, and 5 percent; 95th percentile at 3 percent). The SC-CO_2 estimates are year-specific and increase over time.

[c] The air pollution health co-benefits reflect reduced exposure to $PM_{2.5}$ and ozone associated with emission reductions of SO_2 and

NO_X. The co-benefits do not include the benefits of reductions in directly emitted $PM_{2.5}$. These additional benefits would increase overall benefits by a few percent based on the analyses conducted for the proposed rule. The range reflects the use of concentration-response functions from different epidemiology studies. The reduction in premature fatalities each year accounts for over 98 percent of total monetized co-benefits from $PM_{2.5}$ and ozone. These models assume that all fine particles, regardless of their chemical composition, are equally potent in causing premature mortality because the scientific evidence is not yet sufficient to allow differentiation of effect estimates by particle type.

[d] Total costs are approximated by the illustrative compliance costs estimated using the Integrated Planning Model for the final guidelines and a discount rate of approximately 5 percent. This estimate includes monitoring, recordkeeping, and reporting costs and demand-side EE program and participant costs.

[e] The estimates of net benefits in this summary table are calculated using the global SC-CO_2 at a 3 percent discount rate (model average). The RIA includes combined climate and health estimates based on additional discount rates.

There are additional important benefits that the EPA could not monetize. Due to current data and modeling limitations, our estimates of the benefits from reducing CO_2 emissions do not include important impacts like ocean acidification or potential tipping points in natural or managed ecosystems. Unquantified benefits also include climate benefits from reducing emissions of non-CO_2 GHGs (e.g., nitrous oxide and methane) and co-benefits from reducing direct exposure to SO_2, NO_X and hazardous air pollutants (e.g., mercury), as well as from reducing ecosystem effects and visibility impairment. Based upon the foregoing discussion, it remains clear that the benefits of this final action are substantial, and far exceed the costs. Additional details on benefits, costs, and net benefits estimates are provided in this RIA.

B. Paperwork Reduction Act (PRA)

The information collection requirements in this rule have been submitted for approval to OMB under the PRA. The Information Collection Request (ICR) document prepared by the EPA has been assigned the EPA ICR number 2503.02. You can find a copy of the ICR in the docket for this rule, and it is briefly summarized here. The information collection requirements are not enforceable until OMB approves them.

This rule does not directly impose specific requirements on EGUs located in states or areas of Indian country. The rule also does not impose specific requirements on tribal governments that have affected EGUs located in their area of Indian country. For areas of Indian country, the rule establishes CO_2 emission performance goals that could be addressed through either tribal or federal plans. A tribe would have the opportunity under the Tribal Authority Rule (TAR), but not the obligation, to apply to the EPA for Treatment as State (TAS) for purposes of a CAA section 111(d) plan and, if approved by the EPA, to establish a CAA section 111(d) plan for its area of Indian country. To date, no tribe has requested or obtained TAS eligibility for purposes of a CAA section 111(d) plan. For areas of Indian country with affected EGUs where a tribe has not applied for TAS and submitted any needed plan, if the EPA determines that a CAA section 111(d) plan is necessary or appropriate, the EPA would have the responsibility to establish the plans. Because tribes are not required to implement section 111(d) plans and because no tribe has yet sought TAS eligibility for this purpose, this action is not anticipated to impose any information collection burden on tribal governments over the 3-year period covered by this ICR.

This rule does impose specific requirements on state governments with affected EGUs. The information collection requirements are based on the recordkeeping and reporting burden associated with developing, implementing, and enforcing a plan to limit CO_2 emissions from existing sources in the utility power sector. These recordkeeping and reporting requirements are specifically authorized by CAA section 114 (42 U.S.C. 7414). All information submitted to the EPA pursuant to the recordkeeping and reporting requirements for which a claim of confidentiality is made is safeguarded according to agency policies set forth in 40 CFR part 2, subpart B.

The annual burden for this collection of information for the states (averaged over the first 3 years following promulgation) is estimated to be a range of 505,000 to 821,000 hours at a total annual labor cost of $35.8 to $58.1 million. The lower bound estimate reflects the assumption that some states already have EE and RE programs in place. The higher bound estimate reflects the overly-conservative assumption that no states have EE and RE programs in place.

The total annual burden for the federal government associated with the state collection of information (averaged over the first 3 years following promulgation) is estimated to be 54,000 hours at a total annual labor cost of $3.00 million. Burden is defined at 5 CFR 1320.3(b).

An agency may not conduct or sponsor, and a person is not required to respond to, a collection of information unless it displays a currently valid OMB control number. The OMB control numbers for the EPA's regulations in 40 CFR are listed in 40 CFR part 9. When OMB approves this ICR, the agency will announce that approval in the *Federal Register* and publish a technical amendment to 40 CFR part 9 to display the OMB control number for the approved information collection activities contained in this final rule.

C. Regulatory Flexibility Act (RFA)

I certify that this action will not have a significant economic impact on a substantial number of small entities under the RFA. This action will not impose any requirements on small entities. Specifically, emission guidelines established under

CAA section 111(d) do not impose any requirements on regulated entities and, thus, will not have a significant economic impact upon a substantial number of small entities. After emission guidelines are promulgated, states establish emission standards on existing sources, and it is those requirements that could potentially impact small entities.

Our analysis here is consistent with the analysis of the analogous situation arising when the EPA establishes NAAQS, which do not impose any requirements on regulated entities. As here, any impact of a NAAQS on small entities would only arise when states take subsequent action to maintain and/or achieve the NAAQS through their SIPs. See American Trucking Assoc. v. EPA, 175 F.3d 1029, 1043-45 (D.C. Cir. 1999) (NAAQS do not have significant impacts upon small entities because NAAQS themselves impose no regulations upon small entities).

Nevertheless, the EPA is aware that there is substantial interest in the rule among small entities and, as detailed in section III.A of the preamble to the proposed carbon pollution emission guidelines for existing EGUs (79 FR 34845-34847; June 18, 2014) and in section II.D of the preamble to the proposed carbon pollution emission guidelines for existing EGUs in Indian Country and U.S. Territories (79 FR 65489; November 4, 2014), has conducted an unprecedented amount of stakeholder outreach. As part of that outreach, agency officials participated in many meetings with individual utilities and electric utility associations, as well as industry leaders and trade association representatives from various industries. While formulating the provisions of the rule, the EPA considered the input provided over the course of the stakeholder outreach as well as the input provided in the many public comments.

D. Unfunded Mandates Reform Act (UMRA)

This action does not contain an unfunded mandate of $100 million or more as described in UMRA, 2 U.S.C. 1531–1538, and does not significantly or uniquely affect small governments. The emission guidelines do not impose any direct compliance requirements on EGUs located in states or areas of Indian country. As explained in section XII.B above, the rule also does not impose specific requirements on tribal governments that have affected EGUs located in their area of Indian country. The rule does impose specific requirements on state governments that have affected EGUs. Specifically, states are required to develop plans to implement the guidelines under CAA section 111(d) for affected EGUs. The burden for states to develop CAA section 111(d) plans in the 3-year period following promulgation of the rule was estimated and is listed in section XII.B above, but this burden is estimated to be below $100 million in any one year. Thus, this rule is not subject to the requirements of section 202 or section 205 of the UMRA.

This rule is also not subject to the requirements of section 203 of UMRA because it contains no regulatory requirements that might significantly or uniquely affect small governments. Specifically, the state governments to which rule requirements apply are not considered small governments.

In light of the interest among governmental entities, the EPA conducted outreach with national organizations representing state and local elected officials and tribal governmental entities while formulating the provisions of this rule. Sections III.A and XI.F of the preamble to the proposed carbon pollution emission guidelines for existing EGUs (79 FR 34845-34847; June 18, 2014) and sections II.D and VI.F of the preamble to the proposed carbon pollution emission guidelines for existing EGUs in areas of Indian Country and U.S. Territories (79 FR 65489; November 4, 2014) describes the extensive stakeholder outreach the EPA has conducted on setting emission guidelines for existing EGUs. The EPA considered the input provided over the course of the stakeholder outreach as well as the input provided in the many public comments when developing the provisions of these emission guidelines.

E. Executive Order 13132: Federalism

The EPA has concluded that this action may have federalism implications, pursuant to agency policy for implementing the Order, because it imposes substantial direct compliance costs on state or local governments, and the federal government will not provide the funds necessary to pay those costs. As discussed in the Supporting Statement found in the docket for this rulemaking, the development of state plans will entail many hours of staff time to develop and coordinate programs for compliance with the rule, as well as time to work with state legislatures as appropriate, to develop a plan submittal. Consistent with this determination, the EPA provides the following federalism summary impact statement.

The EPA consulted with state and local officials early in the process of developing the proposed action to permit them to have meaningful and timely input into its development. As described in the Federalism discussion in the preamble to the proposed standards of performance for GHG emissions from new EGUs (79 FR 1501; January 8, 2014), the EPA consulted with state and local officials in the process of developing the proposed standards for newly constructed EGUs. This outreach addressed planned actions for new, reconstructed, modified and existing sources. The EPA invited the following 10 national organizations representing state and local elected officials to a meeting on April 12, 2011, in Washington DC: (1) National Governors Association; (2) National Conference of State Legislatures, (3) Council of State Governments, (4) National League of Cities, (5) U.S. Conference of Mayors, (6) National Association of Counties,

(7) International City/County Management Association, (8) National Association of Towns and Townships, (9) County Executives of America, and (10) Environmental Council of States. The National Association of Clean Air Agencies also participated. On February 26, 2014, the EPA re-engaged with those governmental entities to provide a pre-proposal update on the emission guidelines for existing EGUs and emission standards for modified and reconstructed EGUs. In addition, as described in section III.A of the preamble to the proposed carbon pollution emission guidelines for existing EGUs (79 FR 34845-34847; June 18, 2014), extensive stakeholder outreach conducted by the EPA allowed state leaders, including governors, state attorneys general, environmental commissioners, energy officers, public utility commissioners, and air directors, opportunities to engage with EPA officials and provide input regarding reducing carbon pollution from power plants.

In the spirit of Executive Order 13132, and consistent with the EPA’s policy to promote communications between the EPA and state and local governments, the EPA specifically solicited comment on the proposed action from state and local officials. The EPA received comments from over 400 entities representing state and local governments.

Several themes emerged from state and local government comments. Commenters raised concerns with the building blocks that comprise the best system of emission reduction (BSER), including the stringency of the building blocks, and the timing of achieving interim CO_2 levels. They also identified the potential for electric system reliability issues and stranded assets due to the proposed timeframe for plan submittals and CO_2 emission reductions. In addition, states commented on state plan development and implementation topics, including state plan approaches, early actions, trading programs, interstate crediting for RE, and EPA guidance and outreach.

Commenters identified overarching concerns regarding the stringency of the CO_2 goals and the timeframe for achieving reductions that encompassed the building blocks, the BSER, and associated timing for achievement of interim CO_2 levels. State commenters, in particular, identified changes to the stringency of the building blocks, concerns with the timeframe over which reductions must be achieved, and concerns with the approaches and measures used for the BSER. For the final rule, in response to stakeholder comments, the EPA has made refinements to the building blocks, the period of time over which measures are deployed, and the stringency of emission limitations that those measures can achieve in a practical and reasonable cost way. The final BSER reflects those refinements.

To many commenters, the proposal’s 2020 compliance date, together with the stringency of the interim CO_2 goal, bore significant reliability implications. In this final rule, the agency is addressing those concerns via adjustments to the compliance timeframe (an 8-year interim period that begins in 2022) and to the approach for meeting interim CO_2 emission performance rates (a glide path separated into three steps, 2022-2024, 2025-2027, and 2028-2029), as well as a more gradual phase in of the emission reduction expectations. These adjustments provide more time for planning, consultation and decision making in the formulation of state plans and in EGUs' choices of compliance strategies. The final rule also retains flexibilities presented in the proposal and offers additional opportunities, including opportunities for trading within and between states, and other multi-state compliance approaches that will further support electric system reliability. The EPA is also requiring each state to demonstrate in its final state that it has considered electric system reliability issues in developing its plan - and is providing the time to do so. Even with this foundation of flexibility in place, these final guidelines further provide states with the option of proposing amendments to approved plans in the event that unanticipated and significant reliability challenges arise.

Commenters provided compelling information indicating that it will take longer than the agency initially anticipated to for states to complete the tasks necessary to finalize a state plan, including administrative and potential legislative processes. Recognizing this, as well as the urgent need for actions to reduce GHG emissions, the EPA is requiring states to make an initial submittal by September 6, 2016, and is allowing states two additional years to submit a final plan, if justified (to be submitted by September 6, 2018).

States commented on state plan development and implementation topics that included state plan approaches, early actions being taken into account, trading programs being allowed, interstate crediting for RE being allowed, and guidance and outreach being provided by the EPA. For the state plan approaches, commenters expressed concerns with the proposed "portfolio approach" for state plans, including concerns with enforceability of requirements, and identified a "state commitment approach" with backstop measures as an option for state plans. In this final rule, in response to stakeholder comments on the portfolio approach and alternative approaches, the EPA is finalizing a "state measures" approach that includes a requirement for the inclusion of backstop measures.

State commenters supported providing incentives for states and utilities to deploy CO_2-reducing investments, such as RE and demand-side EE measures, as early as possible. The EPA recognizes the value of such early actions, and in this final rule is establishing the CEIP to provide opportunities for investment in RE and demand-side EE projects that deliver results in 2020 and/or 2021.

Many state commenters supported the use of mass-based and rate-based emission trading programs in state plans, including interstate emission trading programs. The EPA also received a number of comments from states and stakeholders about the value of EPA support in developing and/or administering tracking systems to support state administration of rate-based and mass-based emission trading programs. In this final rule, states may use trading or averaging approaches and technologies or strategies that are not explicitly mentioned in any of the three building blocks as part of their overall plans, as long as they achieve the required emission reductions from affected fossil-fuel-fired EGUs. In addition, in response to concerns from states and power companies that the need for up-front interstate cooperation in developing multi-state plans could inhibit the development of interstate programs that could lower cost, the final rule provides additional options to allow individual EGUs to use creditable out-of-state reductions to achieve required CO_2 reductions, without the need for up-front interstate agreements. The EPA is committed to working with states to provide support for tracking of emissions and allowances or credits, to help implement multi-state trading or averaging approaches.

In their comments, many states identified the need for the

EPA to provide guidance, including guidance on RE and EE emission measurement and verification (EM&V), and to maintain regular contact/forums with states throughout the implementation process. To provide state and local governments and other stakeholders with an understanding of the rule requirements, and to provide efficiencies where possible and reduce the cost and administrative burden, the EPA will continue outreach throughout the plan development and submittal process. Outreach will include opportunities for states to participate in briefings, teleconferences, and meetings about the final rule. The EPA's 10 regional offices will continue to be the entry point for states and tribes to ask technical and policy questions. The agency will host (or partner with appropriate groups to co-host) a number of webinars about various components of the final rule during the first two months after the final rule is issued. The EPA will use information from this outreach process to inform the training and other tools that will be of most use to the states and tribes that are implementing the final rule. The EPA expects to issue guidance on specific topics, including evaluation, measurement and verification (EM&V) for RE and demand-side EE, state-community engagement, and resources and financial assistance for RE and demand-side EE. As guidance documents, tools, templates and other resources become available, the EPA, in consultation with the U.S. Department of

Energy and other federal agencies, will continue to make these resources available via a dedicated website.

A list of the state and local government commenters has been provided to OMB and has been placed in the docket for this rulemaking. In addition, the detailed response to comments from these entities is contained in the EPA's response to comments document on this final rulemaking, which has also been placed in the docket for this rulemaking.

As required by section 8(a) of Executive Order 13132, the EPA included a certification from its Federalism Official stating that the EPA had met the Executive Order's requirements in a meaningful and timely manner when it sent the draft of this final action to OMB for review pursuant to Executive Order 12866. A copy of the certification is included in the public version of the official record for this final action.

F. Executive Order 13175: Consultation and Coordination with Indian Tribal Governments

This action has tribal implications. However, it will neither impose substantial direct compliance costs on federally recognized tribal governments, nor preempt tribal law. Tribes are not required to develop or adopt CAA programs, but they may apply to the EPA for treatment in a manner similar to states (TAS) and, if approved, do so. As a result, tribes are not required to develop plans to implement the guidelines under CAA section 111(d) for affected EGUs in their areas of Indian country. To the extent that a tribal government seeks and attains TAS status for that purpose, these emission guidelines would require that planning requirements be met and emission management implementation plans be executed by the tribes. The EPA notes that this rule does not directly impose specific requirements on affected EGUs, including those located in areas of Indian country, but provides guidance to any tribe approved by the EPA to address CO_2 emissions from EGUs subject to section 111(d) of the CAA. The EPA also notes that none of the affected EGUs are owned or operated by tribal governments.

As described in sections III.A and XI.F of the preamble to the proposed carbon pollution emission guidelines for existing EGUs (79 FR 34845-34847; June 18, 2014) and sections II.D and VI.F of the preamble to the proposed carbon pollution emission guidelines for existing EGUs in Indian Country and U.S. Territories (79 FR 65489; November 4, 2014), the rule was developed after extensive and vigorous outreach to tribal governments. These tribes expressed varied points of view. Some tribes raised concerns about the impacts of the regulations on EGUs located in their areas of Indian country and the subsequent impact on jobs and revenue for their tribes. Other tribes expressed concern about the impact the regulations would have on the cost of water covered under treaty to their communities as a result of increased costs to the EGU that provide energy to transport the water to the tribes. Other tribes raised concerns about the impacts of climate change on their communities, resources, ways of life and hunting and treaty rights. The tribes were also interested in the scope of the guidelines being considered by the agency (e.g., over what time period, relationship to state and multi-state plans) and how tribes will participate in these planning activities.

The EPA consulted with tribal officials under the EPA Policy on Consultation and Coordination with Indian Tribes early in the process of developing this action to permit them to have meaningful and timely input into its development. A summary of that consultation follows.

Prior to issuing the supplemental proposal on November 4, 2014, the EPA consulted with tribes as follows. The EPA held a consultation with the Ute Tribe, the Crow Nation, and the Mandan, Hidatsa, Arikara (MHA) Nation on July 18, 2014. On August 22, 2014, the EPA held a consultation with the Fort Mojave Tribe. On September 15, 2014, the EPA held a consultation with the Navajo Nation. The Navajo Nation sent a letter to the EPA on September 18, 2014, summarizing the information presented at the consultation and the Navajo Nation’s position on the supplemental proposal. One issue raised by tribal officials was the potential impacts of the June 18, 2014 proposal and the supplemental proposal on tribes with budgets that are dependent on revenue from coal mines and power plants, as well as employment at the mines and power plants. The tribes noted the high unemployment rates and lack of access to basic services on their lands. Tribal officials also asked whether the rules will have any impact on a tribe's ability to seek TAS. Tribal officials also expressed interest in agency actions with regard to facilitating power plant compliance with regulatory requirements. The Navajo Nation made the following recommendations in their letter of September 18, 2014: the Navajo Nation supports a mass-based CO_2 emission standard based on the highest historical CO_2 emissions since 1996; the Navajo Nation requests that the EPA grant the Navajo Nation carbon credits and that the Navajo Nation retains ownership and control of such credits; building block 2 is not appropriate for the Navajo Nation because there are no NGCC plants located on the Navajo Nation; building block 3 is not appropriate for the Navajo Nation because the Navajo people already receive virtually all of their electricity from carbon-free sources (mostly hydroelectric power) and their use of electricity is negligible compared to the generation at the power plants; building block 4 is not appropriate for the Navajo Nation because of the inadequate access to electricity, and the goal should allow for an increase in energy consumption on the Navajo

Nation; the supplemental proposal should consider the useful life of the power plants located on the Navajo Nation; and the supplemental proposal should clarify that RE projects located within the Navajo Nation that provide electricity outside the Navajo Nation should be counted toward meeting the relevant state's RE goals under the Clean Power Plan.

After issuing the supplemental proposal, the EPA held additional consultation with tribes. On November 18, 2014, the EPA held consultations with the following tribes: Fort McDowell Yavapai Nation, Fort Mojave Tribe, Hopi Tribe, Navajo Nation, and Ak-Chin Indian Community. A consultation with the Ute Indian Tribe of the Uintah and Ouray Reservation was held on December 16, 2014 and with the Gila River Indian Community on January 15, 2015. The Navajo Nation reiterated the concerns raised during the previous consultation. Several tribes also again indicated that they wanted to ensure they would be included in the development of any tribal or federal plans for areas of Indian country. The Fort Mojave Tribe and the Navajo Nation expressed concern with using data from 2012 as the basis for the goal for their areas of Indian country; in their view, that year was not representative for the affected EGU. On April 28, 2015, the EPA held an additional consultation with the Navajo Nation. The issues raised by the Navajo Nation during the consultation included whether the EPA has the authority to set less stringent standards on a case-by-case basis, and a suggested "parity glide path" that would account and adjust for the very low electricity usage by the Navajo Nation and promote Navajo Nation economic growth and demand. Furthermore, on July 7, 2015 the EPA conducted an additional consultation with the Navajo Nation. One of the goals of the consultation was for the new government of the Navajo Nation to deepen their understanding of the rulemaking. The questions raised by the nation had to do with goal setting and carbon credits, the timing of the rulemaking, and the proposed federal plan. Additionally, on July 14, 2015 the EPA conducted an additional consultation with the Fort Mojave Tribe. The Fort Mojave tribes expressed concerns that 2012 is not a representative year, that natural gas-fired combined cycle power plants should be treated differently from coal-fired power plants, and that the proposed goal for Fort Mojave was not appropriate. Additionally, they also expressed interest in being engaged in the federal plan process. Responses to these comments and others received are available in the Response to Comment Document that is in the docket for this rulemaking. As required by section 7(a), the EPA's Tribal Consultation Official has certified that the requirements of the executive order have been met in a meaningful and timely manner. A copy of the certification is included in the docket for this action.

G. Executive Order 13045: Protection of Children from Environmental Health Risks and Safety Risks

This action is subject to Executive Order 13045 (62 FR 19885, April 23, 1997) because it is an economically significant regulatory action as defined by Executive Order 12866, and the EPA believes that the environmental health or safety risk addressed by this action has a disproportionate effect on children. Accordingly, the agency has evaluated the environmental health and welfare effects of climate change on children.

CO_2 is a potent GHG that contributes to climate change and is emitted in significant quantities by fossil fuel-fired power plants. The EPA believes that the CO_2 emission reductions resulting from implementation of these final guidelines, as well as substantial ozone and $PM_{2.5}$ emission reductions as a co-benefit, will further improve children's health.

The assessment literature cited in the EPA's 2009 Endangerment Finding concluded that certain populations and lifestages, including children, the elderly, and the poor, are most vulnerable to climate-related health effects. The assessment literature since 2009 strengthens these conclusions by providing more detailed findings regarding these groups' vulnerabilities and the projected impacts they may experience.

These assessments describe how children's unique physiological and developmental factors contribute to making them particularly vulnerable to climate change. Impacts to children are expected from heat waves, air pollution, infectious and waterborne illnesses, and mental health effects resulting from extreme weather events. In addition, children are among those especially susceptible to most allergic diseases, as well as health effects associated with heat waves, storms, and floods. Additional health concerns may arise in low income households, especially those with children, if climate change reduces food availability and increases prices, leading to food insecurity within households.

More detailed information on the impacts of climate change to human health and welfare is provided in section II.A of this preamble.

H. Executive Order 13211: Actions Concerning Regulations That Significantly Affect Energy Supply, Distribution, or Use

This action, which is a significant regulatory action under EO 12866, is likely to have a significant effect on the supply, distribution, or use of energy. The EPA has prepared a Statement of Energy Effects for this action as follows. We estimate a 1 to 2 percent change in retail electricity prices on average across the contiguous U.S. in 2025, and a 22 to 23 percent reduction in coal-fired electricity generation as a result of this rule. The

EPA projects that utility power sector delivered natural gas prices will increase by up to 2.5 percent in 2030. For more information on the estimated energy effects, please refer to the economic impact analysis for this proposal. The analysis is available in the RIA, which is in the public docket.

I. National Technology Transfer and Advancement Act (NTTAA)

This rulemaking does not involve technical standards.

J. Executive Order 12898: Federal Actions to Address Environmental Justice in Minority Populations and Low-Income Populations

Executive Order 12898 (59 FR 7629; February 16, 1994) establishes federal executive policy on environmental justice. Its main provision directs federal agencies, to the greatest extent practicable and permitted by law, to make environmental justice part of their mission by identifying and addressing, as appropriate, disproportionately high and adverse human health or environmental effects of their programs, policies, and activities on minority populations and low-income populations in the U.S. The EPA defines environmental justice as the fair treatment and meaningful involvement of all people regardless of race, color, national origin, or income with respect to the development, implementation, and enforcement of environmental laws, regulations, and policies. The EPA has this goal for all communities and persons across this Nation. It will be achieved when everyone enjoys the same degree of protection from environmental and health hazards and equal access to the decision-making process to have a healthy environment in which to live, learn, and work.

Leading up to this rulemaking the EPA summarized the public health and welfare effects of GHG emissions in its 2009 Endangerment Finding. See, section VIII.A of this preamble where the EPA summarizes the public health and welfare impacts from GHG emissions that were detailed in the 2009 Endangerment Finding under CAA section 202(a)(1).[1070] As part of the Endangerment Finding, the Administrator considered climate change risks to minority populations and low-income populations, finding that certain parts of the population may be especially vulnerable based on their characteristics or circumstances. Populations that were found to be particularly vulnerable to climate change risks include the poor, the elderly, the very young, those already in poor health, the disabled, those living alone, and/or indigenous populations dependent on one or a few resources. See sections XII.F and XII.G, above, where the EPA discusses Consultation and Coordination with Tribal Governments and Protection of Children. The Administrator placed weight on

[1070] "Endangerment and Cause or Contribute Findings for Greenhouse Gases Under Section 202(a) of the Clean Air Act," 74 FR 66496 (Dec. 15, 2009) ("Endangerment Finding").

the fact that certain groups, including children, the elderly, and the poor, are most vulnerable to climate-related health effects.

The record for the 2009 Endangerment Finding summarizes the strong scientific evidence in the major assessment reports by the U.S. Global Change Research Program (USGCRP), the Intergovernmental Panel on Climate Change (IPCC), and the National Research Council (NRC) of the National Academies that the potential impacts of climate change raise environmental justice issues. These reports concluded that poor communities can be especially vulnerable to climate change impacts because they tend to have more limited adaptive capacities and are more dependent on climate-sensitive resources such as local water and food supplies. In addition, Native American tribal communities possess unique vulnerabilities to climate change, particularly those impacted by degradation of natural and cultural resources within established reservation boundaries and threats to traditional subsistence lifestyles. Tribal communities whose health, economic well-being, and cultural traditions that depend upon the natural environment will likely be affected by the degradation of ecosystem goods and services associated with climate change. The 2009 Endangerment Finding record also specifically noted that Southwest native cultures are especially vulnerable to water quality and availability impacts. Native

Alaskan communities are already experiencing disruptive impacts, including coastal erosion and shifts in the range or abundance of wild species crucial to their livelihoods and well-being.

The most recent assessments continue to strengthen scientific understanding of climate change risks to minority populations and low-income populations in the U.S.[1071] The new assessment literature provides more detailed findings regarding these populations' vulnerabilities and projected impacts they may experience. In addition, the most recent assessment reports provide new information on how some communities of color (more specifically, populations defined jointly by ethnic/racial characteristics and geographic location) may be uniquely

---

IPCC, 2014: *Climate Change 2014: Impacts, Adaptation, and Vulnerability. Part A: Global and Sectoral Aspects.* Contribution of Working Group II to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change [Field, C.B., V.R. Barros, D.J. Dokken, K.J. Mach, M.D. Mastrandrea, T.E. Bilir, M. Chatterjee, K.L. Ebi, Y.O. Estrada, R.C. Genova, B. Girma, E.S. Kissel, A.N. Levy, S. MacCracken, P.R. Mastrandrea, and L.L. White (eds.)]. Cambridge University Press, 1132 pp.

IPCC, 2014: *Climate Change 2014: Impacts, Adaptation, and Vulnerability. Part B: Regional Aspects*. Contribution of Working Group II to the Fifth Assessment Report of the Intergovernmental Panel on Climate Change [Barros, V.R., C.B. Field, D.J. Dokken, M.D. Mastrandrea, K.J. Mach, T.E. Bilir, M. Chatterjee, K.L. Ebi, Y.O. Estrada, R.C. Genova, B. Girma, E.S. Kissel, A.N. Levy, S. MacCracken, P.R. Mastrandrea, and L.L. White (eds.)]. Cambridge University Press, 688 pp.

vulnerable to climate change health impacts in the U.S. These reports find that certain climate change related impacts—including heat waves, degraded air quality, and extreme weather events—have disproportionate effects on low-income populations and some communities of color, raising environmental justice concerns. Existing health disparities and other inequities in these communities increase their vulnerability to the health effects of climate change. In addition, assessment reports also find that climate change poses particular threats to health, well-being, and ways of life of indigenous peoples in the U.S.

As the scientific literature presented above and as the 2009 Endangerment Finding illustrates, low income populations and some communities of color are especially vulnerable to the health and other adverse impacts of climate change. The EPA believes that communities will benefit from this final rulemaking because this action directly addresses the impacts of climate change by limiting GHG emissions through the establishment of CO_2 emission guidelines for existing affected fossil fuel-fired EGUs.

In addition to reducing CO_2 emissions, the guidelines finalized in this rulemaking would reduce other emissions from affected EGUs that reduce generation due to higher adoption of EE and RE. These emission reductions will include SO_2 and NOx, which form ambient $PM_{2.5}$ and ozone in the atmosphere, and hazardous air pollutants (HAP), such as mercury and hydrochloric acid. In the final rule revising the annual $PM_{2.5}$ NAAQS,[1072] the EPA identified low-income populations as being a vulnerable population for experiencing adverse health effects related to PM exposures. Low-income populations have been generally found to have a higher prevalence of pre-existing diseases, limited access to medical treatment, and increased nutritional deficiencies, which can increase this population's susceptibility to PM-related effects.[1073] In areas where this rulemaking reduces exposure to $PM_{2.5}$, ozone, and methylmercury, low-income populations will also benefit from such emissions reductions. The RIA for this rulemaking, included in the docket for this rulemaking, provides additional information regarding the health and ecosystem effects associated with these emission reductions.

Additionally, as outlined in the community and environmental justice considerations section IX of this preamble, the EPA has taken a number of actions to help ensure that this action will not have potential disproportionately high

[1072] "National Ambient Air Quality Standards for Particulate Matter, Final Rule," 78 FR 3086 (Jan. 15, 2013).
[1073] U.S. Environmental Protection Agency (U.S. EPA). 2009. *Integrated Science Assessment for Particulate Matter (Final Report)*. EPA-600-R-08-139F. National Center for Environmental Assessment – RTP Division. December. Available on the Internet at <http://cfpub.epa.gov/ncea/cfm/recordisplay.cfm?deid=216546>.

and adverse human health or environmental effects on overburdened communities. The EPA consulted its May 2015, *Guidance on Considering Environmental Justice During the Development of Regulatory Actions*, when determining what actions to take.[1074] As described in the community and environmental justice considerations section of this preamble the EPA also conducted a proximity analysis, which is available in the docket of this rulemaking and is discussed in section IX. Additionally, as outlined in sections I and IX of this preamble, the EPA has engaged with communities throughout this rulemaking and has devised a robust outreach strategy for continual engagement throughout the implementation phase of this rulemaking.

K. Congressional Review Act (CRA)

This final action is subject to the CRA, and the EPA will submit a rule report to each House of the Congress and to the Comptroller General of the United States. This action is a "major rule" as defined by 5 U.S.C. 804(2).

XIII. Statutory Authority

The statutory authority for this action is provided by sections 111, 301, 302, and 307(d)(1)(C) of the CAA as amended

[1074] Guidance on Considering Environmental Justice During the Development of Regulatory Actions. http://epa.gov/environmentaljustice/resources/policy/considering-ej-in-rulemaking-guide-final.pdf. May 2015.

(42 U.S.C. 7411, 7601, 7602, 7607(d)(1)(C)). This action is also subject to section 307(d) of the CAA (42 U.S.C. 7607(d)).

List of Subjects in 40 CFR Part 60

Environmental protection, Administrative practice and procedure, Air pollution control, Intergovernmental relations, Reporting and recordkeeping requirements.

Dated: ___________________.

____
Gina McCarthy,
Administrator.

For the reasons stated in the preamble, title 40, chapter I, part 60 of the Code of the Federal Regulations is amended as follows:

PART 60--STANDARDS OF PERFORMANCE FOR NEW STATIONARY SOURCES

1. The authority citation for Part 60 continues to read as follows:

Authority: 42 U.S.C. 7401 et seq.

2. Add subpart UUUU to read as follows:

Subpart--UUUU Emission Guidelines for Greenhouse Gas Emissions and Compliance Times for Electric Utility Generating Units

Sec.

Introduction

State and Multi-State Plan Requirements

guidelines to the EPA?

Definitions

Introduction

§60.5700 What is the purpose of this subpart?

This subpart establishes emission guidelines and approval criteria for State or multi-State plans that establish emission standards limiting greenhouse gas (GHG) emissions from an affected steam generating unit, integrated gasification combined cycle (IGCC), or stationary combustion turbine. An affected steam generating unit, IGCC, or stationary combustion turbine shall, for the purposes of this subpart, be referred to as an affected EGU. These emission guidelines are developed in accordance with sections 111(d) of the Clean Air Act and subpart B of this part. To the extent any requirement of this subpart is inconsistent with the requirements of subparts A or B of this part, the requirements of this subpart will apply.

§60.5705 Which pollutants are regulated by this subpart?

(a) The pollutants regulated by this subpart are greenhouse gases. The emission guidelines for greenhouse gases established in this subpart are expressed as carbon dioxide (CO_2) emission performance rates and equivalent statewide CO_2 emission goals.

(b) PSD and Title V Thresholds for Greenhouse Gases.

(1) For the purposes of §51.166(b)(49)(ii), with respect to GHG emissions from facilities, the "pollutant that is subject to the standard promulgated under section 111 of the Act" shall be considered to be the pollutant that otherwise is subject to regulation under the Act as defined in §51.166(b)(48) and in any State Implementation Plan (SIP) approved by the EPA that is interpreted to incorporate, or specifically incorporates, §51.166(b)(48) of this chapter.

(2) For the purposes of §52.21(b)(50)(ii), with respect to GHG emissions from facilities regulated in the plan, the "pollutant that is subject to the standard promulgated under section 111 of the Act" shall be considered to be the pollutant that otherwise is subject to regulation under the Act as defined in §52.21(b)(49) of this chapter.

(3) For the purposes of §70.2 of this chapter, with respect to greenhouse gas emissions from facilities regulated in the

plan, the “pollutant that is subject to any standard promulgated under section 111 of the Act” shall be considered to be the pollutant that otherwise is "subject to regulation" as defined in §70.2 of this chapter.

(4) For the purposes of §71.2, with respect to greenhouse gas emissions from facilities regulated in the plan, the “pollutant that is subject to any standard promulgated under section 111 of the Act” shall be considered to be the pollutant that otherwise is "subject to regulation" as defined in §71.2 of this chapter.

§60.5710 Am I affected by this subpart?

If you are the Governor of a State in the contiguous United States with one or more affected EGUs that commenced construction on or before January 8, 2014, you must submit a State or multi-State plan to the U.S. Environmental Protection Agency (EPA) that implements the emission guidelines contained in this subpart. If you are the Governor of a State in the contiguous United States with no affected EGUs for which construction commenced on or before January 8, 2014, in your State, you must submit a negative declaration letter in place of the State plan.

§60.5715 What is the review and approval process for my plan?

The EPA will review your plan according to §60.27 except that under §60.27(b) the Administrator will have 12 months after the date the final plan or plan revision (as allowed under §60.5795) is submitted, to approve or disapprove such plan or revision or each portion thereof. If you submit an initial submittal under §60.5765(a) in lieu of a final plan submittal the EPA will follow the procedure in §60.5765(b).

§60.5720 What if I do not submit a plan or my plan is not approvable?

(a) If you do not submit an approvable plan the EPA will develop a Federal plan for your State according to §60.27 except that under §60.27(d) the EPA will have one year to promulgate a Federal plan for your State from the date EPA finds you failed to submit a plan or EPA disapproves your plan. The Federal plan will implement the emission guidelines contained in this subpart. Owners and operators of affected EGUs not covered by an approved plan must comply with a Federal plan implemented by the EPA for the State.

(b) After a Federal plan has been implemented in your State, it will be withdrawn when your State submits, and the EPA approves, a final plan.

§60.5725 In lieu of a State plan submittal, are there other acceptable option(s) for a State to meet its CAA section 111(d) obligations?

A State may meet its CAA section 111(d) obligations only by submitting a final State or multi-State plan submittal or a negative declaration letter (if applicable).

§60.5730 Is there an approval process for a negative declaration letter?

No. The EPA has no formal review process for negative declaration letters. Once your negative declaration letter has been received, the EPA will place a copy in the public docket and publish a notice in the FEDERAL REGISTER. If, at a later date, an affected EGU for which construction commenced on or before January 8, 2014 is found in your State, you will have been found to have failed to submit a final plan as required, and a Federal plan implementing the emission guidelines contained in this subpart will apply to that affected EGU until you submit, and the EPA approves, a final State plan.

§60.5735 What authorities will not be delegated to State, local, or tribal agencies?

The authorities that will not be delegated to State, local, or tribal agencies are specified in paragraphs (a) and (b) of this section.

(a) Approval of alternatives, not already approved by this subpart, to the CO_2 emission performance rates in Table 1 to this subpart established under §60.5855.

(b) Approval of alternatives, not already approved by this subpart, to the CO_2 emissions goals in Tables 2, 3 and 4 to this subpart established under §60.5855.

§60.5736 Will the EPA impose any sanctions?

The EPA will not withhold any existing federal funds from a State on account of a State's failure to submit, implement, or enforce an approvable plan or plan revision, or to meet any other requirements under this subpart or subpart B of this part.

§60.5737 What is the Clean Energy Incentive Program and how do I participate?

(a) This subpart establishes the Clean Energy Incentive Program (CEIP). Participation in this program is optional. The program enables States to award early action emission rate credits (ERCs) and allowances to eligible renewable energy (RE) or demand-side energy efficiency (EE) projects that generate megawatt hours (MWh) or reduce end-use energy demand during 2020 and 2021. Eligible projects are those that:

(1) Are located in or benefit a state that has submitted a final state plan that includes requirements establishing its participation in the CEIP; and

(2) Commence construction in the case of RE, or commence operation in the case of demand-side EE, following the submission of a final state plan to the EPA, or after September

6, 2018 for a state that chooses not to submit a final state plan by that date; and

(3) Generate metered MWh from any type of wind or solar resources; or

(4) Result in quantified and verified electricity savings (MWh) through demand-side EE implemented in low-income communities.

(b) The EPA will award matching ERCs or allowances to States that award early action ERCs or allowances, up to a limit equivalent to 300 million tons of CO_2 emissions. The awards will be executed as follows:

(1) For RE projects that generate metered MWh from wind or solar resources: for every two MWh generated, the project will receive one early action ERC (or the equivalent number of allowances) from the state, and the EPA will provide one matching ERC (or the equivalent number of allowances) to the state to award to the project.

(2) For EE projects implemented in low-income communities: for every two MWh in end-use demand savings achieved, the project will receive two early action ERCs (or the equivalent number of allowances), and the EPA will provide two matching ERCs (or the equivalent number of allowances) to the state to award to the project.

(c) You may participate in this program by including in your State plan a mechanism that enables issuance of early action ERCs or allowances by the State to parties effectuating reductions in the calendar years 2020 and 2021 in a manner that would have no impact on the emission performance of affected EGUs required to meet rate-based or mass-based emission standards during the performance periods. This mechanism is not required to account for matching ERCs or allowances that may be issued to the State by the EPA.

(d) If you are submitting an initial submittal by September 6, 2016, you must include a non-binding statement of intent to participate in the program. If you are submitting a final plan by September 6, 2016, your State plan must either include requirements establishing the necessary infrastructure to implement such a program and authorizing its affected EGUs to use early action allowances or ERCs as appropriate, or you must include a non-binding statement of intent as part of its supporting documentation and revise your plan to include the appropriate requirements at a later date.

(e) Your final State plan, or plan revision if applicable, must require that projects eligible to be awarded under this program be evaluated, monitored, verified, and issued per applicable requirements of the State plan approved by the EPA as meeting §60.5805 through §60.5835.

State and Multi-State Plan Requirements

§60.5740 What must I include in my federally enforceable State or multi State plan?

(a) You must include the components described in paragraphs (a)(1) through (5) of this section in your plan submittal. The final plan must meet the requirements and include the information required under §60.5745.

(1) Identification of affected EGUs. Consistent with §60.25(a), you must identify the affected EGUs covered by your plan and all affected EGUs in your State that meet the applicability criteria in §60.5845. In addition, you must include an inventory of CO_2 emissions from the affected EGUs during the most recent calendar year for which data is available prior to the submission of the plan.

(2) Emission standards. You must include an identification of all emission standards for each affected EGU according to §60.5775, compliance periods for each emission standard according to §60.5770, and a demonstration that the emission standards, when taken together, achieve the applicable CO_2 emission performance rates or CO_2 emission goals described in §60.5855. Allowance systems are an acceptable form of emission standards under this subpart.

(i) Your plan does not need to include corrective measures specified in paragraph (a)(2)(ii) of this section if your plan:

(A) Imposes emission standards on all affected EGUs that, assuming full compliance by all affected EGUs, mathematically assure achievement of the CO_2 emission performance rates in the plan for each plan period;

(B) Imposes emission standards on all affected EGUS that, assuming full compliance by all affected EGUs, mathematically assure achievement of the CO_2 emission goals; or

(C) Imposes emission standards on all affected EGUs that, assuming full compliance by all affected EGUs, in conjunction with applicable requirements under state law for EGUs subject to subpart TTTT of this subpart, assuming the applicable requirements under state law are met by all EGUs subject to subpart TTTT of this subpart, achieve the applicable mass-based CO_2 emission goals plus new source CO_2 emission complement allowed for in §60.5790(b)(5).

(ii) If your plan does not meet the requirements of (a)(2)(i) of this section, your plan must include the requirement for corrective measures to be implemented if triggered. Upon triggering corrective measures, if you do not already have them included in your approved State plan, you must submit corrective measures to EPA for approval as a plan revision per the requirements of §60.5785(c). These corrective measures must ensure that the interim period and final period CO_2 emission performance rates or CO_2 emission goals are achieved by your affected EGUs, as applicable, and must achieve additional emission reductions to offset any emission performance shortfall. Your plan must include the requirement that corrective measures be triggered and implemented according to paragraphs (a)(2)(ii)(A) through (H) of this section.

(A) Your plan must include a trigger for an exceedance of an interim step 1 or interim step 2 CO_2 emission performance rate or CO_2 emission goal by 10 percent or greater, either on average or cumulatively (if applicable).

(B) Your plan must include a trigger for an exceedance of an interim step 1 goal or interim step 2 goal of 10 percent or greater based on either reported CO_2 emissions with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable), or based on the adjusted CO_2 emission rate (if applicable).

(C) Your plan must include a trigger for a failure to meet an interim period goal based on reported CO_2 emissions with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable), or based on the adjusted CO_2 emission rate (if applicable).

(D) Your plan must include a trigger for a failure to meet the interim period or any final reporting period CO_2 emission performance rate or CO_2 emission goal, either on average or cumulatively (if applicable).

(E) Your plan must include a trigger for a failure to meet any final reporting period goal based on reported CO_2 emissions with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable).

(F) Your plan must include a trigger for a failure to meet the interim period CO_2 emission performance rate or CO_2 emission goal based on the adjusted CO_2 emission rate (if applicable).

(G) Your plan must include a trigger for a failure to meet any final reporting period CO_2 emission performance rate or CO_2 emission goal based on the adjusted CO_2 emission rate (if applicable).

(H) A net import adjustment represents the CO_2 emissions (in tons) equal to the number of net imported CO_2 allowances. This adjustment is added to reported CO_2 emissions. Under this adjustment, such allowances must be issued by a state with an emission budget trading program that only applies to affected EGUs (or affected EGUs plus EGUs covered by subpart TTTT of this part as applicable). A net export adjustment represents the CO_2 emissions (in tons) equal to the number of net exported CO_2 allowances. This adjustment is subtracted from reported CO_2 emissions.

(iii) If your plan relies upon State measures, in addition to or in lieu of emission standards on your affected EGUs, then the final State plan must include the information in paragraph (a)(3) of this section and the submittal must include the information listed in §60.5745(a)(6).

(iv) If your plan requires emission standards in addition to relying upon State measures, then you must demonstrate that the emission standards and State measures are, when taken together, results in the achievement of to meet the applicable mass-based CO_2 emission goal described in §60.5855 by your State's affected EGUs.

(3) State measures backstop. If your plan relies upon State measures, you must submit, as part of the plan, a federally enforceable backstop that includes emission standards for affected EGUs that will be put into place, if there is a triggering event listed in paragraph (a)(3)(i) of this section, within 18 months of the due date of the report required in paragraph (b) of §60.5870(c). The emission standards on the affected EGUs as part of the backstop must be able to meet either the CO_2 emission performance rates or mass-based or rate-based CO_2 emission goal for your State during the interim and final periods. You must either submit, along with the backstop emission standards, provisions to adjust the emission standards to make up for the prior emission performance shortfall, such that no modification of the emission standards is necessary in order to address the emission performance shortfall, or you must submit, as part of the final plan, backstop emission standards

that assure affected EGUs would achieve your State's CO_2 emission performance rates or emission goals during the interim and final periods, and then later submit appropriate revisions to the backstop emission standards adjusting for the shortfall through the State plan revision process described in §60.5785. The backstop must also include the requirements in paragraphs (a)(3)(i) through (iii).

(i) A trigger for the backstop to go into effect upon:

(A) A failure to meet a programmatic milestone;

(B) An exceedance of 10 percent or greater of an interim step 1 goal or interim step 2 goal based on reported CO_2 emissions, with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable);

(C) A failure to meet the interim period goal based on reported CO_2 emissions, with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable); or

(D) A failure to meet any final reporting period goal based on reported CO_2 emissions, with applied plus or minus adjustments for net CO_2 allowances "imports" or "exports" (if applicable).

(ii) You may include in your plan any additional triggers so long as they do not reduce the stringency of the triggers required under paragraph (a)(3)(i) of this section.

(iii) A schedule for implementation of the backstop once triggered, and you must identify all necessary State administrative and technical procedures for implementing the backstop.

(4) Identification of applicable monitoring, reporting, and recordkeeping requirements for each affected EGU. You must include in your plan all applicable monitoring, reporting and recordkeeping requirements for each affected EGU and the requirements must be consistent with or no less stringent than the requirements specified in §60.5860.

(5) State reporting. You must include in your plan a description of the process, contents, and schedule for State reporting to the EPA about plan implementation and progress including information required under §60.5870.

(i) You must include in your plan a requirement for a report to be submitted by July 1, 2021, that demonstrates that the State has met, or is on track to meet, the programmatic milestone steps indicated in the timeline required in §60.5770.

(b) You must follow the requirements of subpart B of this part and demonstrate that they were met in your State plan. However, the provisions of §60.24(f) shall not apply.

§60.5745 What must I include in my final plan submittal?

(a) In addition to the components of the plan listed in §60.5740, a final plan submittal to the EPA must include the information in paragraphs (a)(1) through (13) of this section. This information must be submitted to the EPA as part of your final plan submittal but will not be codified as part of the federally enforceable plan upon approval by EPA.

(1) You must include a description of your plan approach and the geographic scope of the plan (i.e., State or multi-State, geographic boundaries related to the plan elements), including, if applicable, identification of multi-State plan participants.

(2) You must identify CO_2 emission performance rates or equivalent statewide CO_2 emission goals that your affected EGUs will achieve. If the geographic scope of your plan is a single State, then you must identify CO_2 emission performance rates or emission goals according to §60.5855. If your plan includes multiple States and you elect to set CO_2 emission performance goals, you must identify CO_2 emission goals calculated according to §60.5750.

(i) You must specify in the plan submittal the CO_2 emission performance rates or emission goals that affected EGUs will meet for the interim period, each interim step, and the final period (including each final reporting period) pursuant to §60.5770.

(3) You must include a demonstration that the affected EGUs covered by the plan are projected to achieve the CO_2 emission performance rates or CO_2 emission goals described in §60.5855.

(4) You must include a demonstration that each affected EGU's emission standard is quantifiable, non-duplicative, permanent, verifiable, and enforceable according to §60.5775.

(5) If your plan includes emission standards on your affected EGUs sufficient to meet either the CO_2 emission performance rates or CO_2 emision goals, you must include in your plan submittal the information in paragraphs (a)(5)(i) through (v) of this section as applicable.

(i) If your plan applies separate rate-based CO_2 emission standards for affected EGUs (in lbs CO_2/MWh) that are equal to or lower than the CO_2 emission performance rates listed in Table 1 of this subpart, then no additional demonstration is required beyond inclusion of the emission standards in the plan.

(ii) If a plan applies rate-based emission standards to individual affected EGUs at a lbs CO_2/MWh rate that differs from the CO_2 emission performance rates in Table 1 of this subpart or the State's rate-based CO_2 emission goal in Table 2 of this subpart, then a further demonstration is required that the application of the CO_2 emission standards will achieve the CO_2 emission performance rates or State rate-based CO_2 goal. You must demonstrate through a projection that the adjusted weighted average CO_2 emission rate of affected EGUs, when weighted by generation (in MWh), will be equal to or less than the CO_2 emission performance rates or the rate-based CO_2 emission goal.

This projection must address the interim period and the final period. The projection in the plan submittal must include the information listed in (a)(5)(v) and in addition the following:

(A) An analysis of the change in generation of affected EGUs given the compliance costs and incentives under the application of different emission rate standards across affected EGUs in a State;

(B) A projection showing how generation is expected to shift between affected EGUs and across affected EGUs and non-affected EGUs over time;

(C) Assumptions regarding the availability and anticipated use of the MWh of electricity generation or electricity savings from eligible resources that can be issued ERCs;

(D) The specific calculation (or assumption) of how eligible resource MWh of electricity generation or savings are being used in the projection to adjust the reported CO_2 emission rate of affected EGUs;

(E) If a state plan provides for the ability of renewable energy resources located in states with mass-based plans to be issued ERCs, consideration in the projection that such resources must meet geographic eligibility requirements, based on power purchase agreements or related documentation; and

(F) Any other applicable assumptions used in the projection.

(iii) If a plan establishes mass-based emission standards for affected EGUs that cumulatively do not exceed the State's EPA-specified mass CO_2 emission goal then no additional demonstration is required beyond inclusion of the emission standards in the plan.

(iv) If a plan applies mass-based emission standards to individual affected EGUs that do not meet the requirements of paragraph (a)(5)(iii) you must include a demonstration that your mass-based emission program will be designed such that compliance by affected EGUs would achieve the State mass-based CO_2 emission goals. This demonstration includes the information listed in paragraph (a)(5)(v) and emission budgets for affected EGUs during the interim period and final periods that are equal to or lower than the applicable State mass-based CO_2 goals specified in Table 3 of this subpart.

(v) Your plan demonstration to be included in your plan submittal, if applicable, must include the information listed in (a)(5)(v)(A) through (M) of this section.

(A) A summary of each affected EGU's anticipated future operation characteristics, including:

(1) Annual generation;

(2) CO_2 emissions;

(3) Fuel use, fuel prices (when applicable), fuel carbon content;

(4) Fixed and variable operations and maintenance costs (when applicable);

(5) Heat rates; and

(6) Electric generation capacity and capacity factors.

(B) An identification of any planned new electric generating capacity.

(C) Analytic treatment of the potential for building unplanned new electric generating capacity.

(D) A timeline for implementation of EGU-specific actions (if applicable).

(E) All wholesale electricity prices.

(F) A geographic representation appropriate for capturing impacts and/or changes in electric system.

(G) A time period of analysis, which must extend through at least 2031.

(H) An anticipated electricity demand forecast (MWh load and MW peak demand) at the State or regional level, including the source and basis for these estimates, and, if appropriate, justification and documentation of underlying assumptions that inform the development of the demand forecast (e.g., annual economic and demand growth rate or population growth rate).

(I) A demonstration that each emission standard included in your plan meets the requirements of §60.5775.

(J) Any ERC or emission allowance prices, when applicable.

(K) An identification of State-enforceable measures with electricity savings and RE generation, in MWh, expected for individual and collective measures and any assumptions related to the quantification of the MWh, as applicable.

(L) An identification of planning reserve margins.

(M) Any other applicable assumptions used in the projection.

(6) If your plan relies upon State measures, in addition to or in lieu of the emission standards required by paragraph §60.5740(a)(2), the final State plan submittal must include the information under paragraphs (a)(5)(iv) and (a)(6)(i) through (v) of this section.

(i) You must include a description of all the State measures the State will rely upon to achieve the applicable CO_2 emission goals required under §60.5855(e), the projected impacts of the State measures over time, the applicable State laws or regulations related to such measures, and identification of parties or entities implementing such State measures.

(ii) You must include the schedule and milestones for the implementation of the State measures. If the State measures in your plan submittal rely upon measures that do not have a direct effect on the emissions measured at an affected EGU's stack, you must also demonstrate how the minimum emission, monitoring and verification (EM&V) requirements listed under §60.5795 that apply to those programs and projects will be met.

(iii) You must demonstrate that federally enforceable emission standards for affected EGUs in conjunction with any State measures relied upon for your plan, are sufficient to achieve the mass-based CO_2 emission goal for the interim period, each interim step in that interim period, the final period, and each final reporting period. In addition, you must demonstrate that each emission standard included in your plan meets the requirements of §60.5775 and each State measure included in your plan submittal meets the requirements of §60.5780.

(iv) You must include a CO_2 performance projection of your State measures that shows how the measures will achieve the future CO_2 performance at affected EGUs. Elements of this projection must include the following for the interim period and the final period:

(A) A baseline demand and supply forecast as well as the underlying assumptions and data sources of each forecast;

(B) The magnitude of energy and emission impacts from all measures included in the plan and applicable assumptions;

(C) An explanation of the tools and emission quantification approaches used in the projection; and

(D) Underlying emission quantification assumptions.

(v) A State must demonstrate that the combined State-enforceable measures, in conjunction with any federally enforceable CO_2 emission standards for affected EGUs, if included, will result in the achievement by the affected EGUs of the State's mass-based CO_2 emission goals for the interim period, interim step, and final reporting periods. In addition, you must demonstrate that each State measure included in your plan submittal meets the requirements of §60.5780.

(7) Your plan submittal must include a demonstration that the reliability of the electrical grid has been considered.

(8) Your plan submittal must include a timeline with all the programmatic milestone steps the State intends to take between the time of the State plan submittal and January 1, 2022 to ensure the plan is effective as of January 1, 2022.

(9) Your plan submittal must adequately demonstrate that your State has the legal authority (e.g., through regulations or legislation) and funding to implement and enforce each component of the State plan submittal, including federally enforceable emission standards for affected EGUs or State measures as applicable.

(10) Your State plan submittal must demonstrate that each interim step goal required under §60.5855(c), will be met and include in its supporting documentation a description of the

analytic process, tools, methods, and assumptions used to make this demonstration.

(11) Your plan submittal must include certification that a hearing required under §60.23(c)(1) on the State plan was held, a list of witnesses and their organizational affiliations, if any, appearing at the hearing, and a brief written summary of each presentation or written submission pursuant to the requirements of §60.23(f).

(12) Your plan submittal must include documentation of any conducted community outreach and community involvement, including engagement with vulnerable communities.

(13) Your plan submittal must include supporting material for your plan including:

(i) Materials demonstrating the State's legal authority to carry out each component of its plan, including emissions standards or State measures;

(ii) Materials supporting that the CO_2 emission performance rates or CO_2 emission goals will be achieved by affected EGUs identified under the plan, according to paragraph (a)(3) of this section;

(iii) Materials supporting any calculations for CO_2 emission goals calculated according to §60.5855, if applicable; and

(iv) Any other materials necessary to support evaluation of the plan by the EPA.

(b) You must submit your final plan to the EPA electronically according to §60.5875.

§60.5750 Can I work with other States to develop a multi-State plan?

A multi-State plan must include all the required elements for a plan specified in §60.5740(a). A multi-State plan must meet the requirements of paragraphs (a) and (b) of this section.

(a) The multi-State plan must demonstrate that all affected EGUs in all participating States will meet the CO_2 emission performance rates listed in Table 1 of this subpart or an equivalent CO_2 emission goal according to paragraphs (a)(1) or (2) of this section. States may only follow the procedures in (a)(1) or (2) if they have functionally equivalent requirements meeting §60.5775 and §60.5790 included in their plans.

(1) For States electing to demonstrate performance with a CO_2 emission rate-based goal, the CO_2 emission goals identified in the plan according to §60.5855 will be an adjusted weighted (by net energy output) average lbs CO_2/MWh emission rate to be achieved by all affected EGUs in the multi-State area during the plan periods; or

(2) For States electing to demonstrate performance with a CO_2 emission mass-based goal, the CO_2 emission goals identified in the multi-State plan according to §60.5855 will be total CO_2 emissions by all affected EGUs in the multi-State area during

the plan periods.

(b) Options for submitting a multi-State plan include the following:

(1) States participating in a multi-State plan may submit one multi-State plan submittal on behalf of all participating States. The joint submittal must be signed electronically, according to §60.5875, by authorized officials for each of the States participating in the multi-State plan. In this instance, the joint submittal will have the same legal effect as an individual submittal for each participating State. The joint submittal must address plan components that apply jointly for all participating States and components that apply for each individual State in the multi-State plan, including necessary State legal authority to implement the plan, such as State regulations and statutes.

(2) States participating in a multi-State plan may submit a single plan submittal, signed by authorized officials from each participating State, which addresses common plan elements. Each participating States must, in addition, provide individual plan submittals that address State-specific elements of the multi-State plan.

(3) States participating in a multi-State plan may separately make individual submittals that address all elements of the multi-State plan. The plan submittals must be materially

consistent for all common plan elements that apply to all participating States, and also must address individual State-specific aspects of the multi-State plan. Each individual State plan submittal must address all required plan components in §60.5740.

(c) A State may elect to participate in more than one multi-State plan. If a State elects to participate in more than one multi-State plan then you must identify in the State plan submittal required under §60.5745, the subset of affected EGUs that are subject to the specific multi-State plan or your State's individual plan. An affected EGU can only be subject to one plan.

(d) A State may elect to allow its affected EGUs to interact with affected EGUs in other States through mass-based trading programs or a rate-based trading program without entering into a formal multi-State plan allowed for under this section, so long as such programs are part of an EPA-approved state plan.

(1) For States that elect to do mass-based trading under this option the State must indicate in its plan that its emission budget trading program will be administered using an EPA-approved (or EPA-administered) emission and allowance tracking system.

(2) For States that elect to use a rate-based trading

program which allows the affected EGUs to use ERCs from other State rate-based trading programs, the plan must require affected EGUs within their State to comply with emission standards equal to the sub-category CO_2 emission performance rates in Table 1 of this subpart.

§60.5760 What are the timing requirements for submitting my plan?

(a) You must submit a final plan with the information required under §60.5745 by September 6, 2016, unless you are submitting an initial submittal, allowed under §60.5765, in lieu of a final State plan submittal, according to paragraphs (b) of this section.

(b) For States seeking a two year extension for a final plan submittal, you must include the information in §60.5765(a) in an initial submittal by September 6, 2016, to receive an extension to submit your final State plan submittal by September 6, 2018.

(c) You must submit all information required under paragraphs (a) and (b) of this section according to the electronic reporting requirements in §60.5875.

§60.5765 What must I include in an initial submittal if requesting an extension for a final plan submittal?

(a) You must sufficiently demonstrate that your State is able to undertake steps and processes necessary to timely submit a final plan by the extended date of September 6, 2018, by addressing the following required components in an initial submittal by September 6, 2016, if requesting an extension for a final plan submittal:

(1) An identification of final plan approach or approaches under consideration and description of progress made to date on the final plan components;

(2) An appropriate explanation of why the State requires additional time to submit a final plan by September 6, 2018; and

(3) Demonstration or description of opportunity for public comment on the initial submittal and meaningful engagement with stakeholders, including vulnerable communities, during the time in preparation of the initial submittal and the plans for engagement during development of the final plan.

(b) You must submit an initial submittal allowed in paragraph (a) of this section, information required under paragraph (c) of this section (only if a State elects to submit an initial submittal to request an extension for a final plan submittal), and a final State plan submittal according to §60.5870. If a State submits an initial submittal, an extension for a final State plan submittal is considered granted and a final State plan submittal is due according to §60.5760(b) unless a State is notified within 90 days of the EPA receiving the initial submittal that the EPA finds the initial submittal does not meet the requirements listed in paragraph (a) of this section and the State has failed to submit the final plan required by September 6, 2016.

(c) If an extension for submission of a final plan has been granted, you must submit a progress report by September 6, 2017. The 2017 report must include the following:

(1) A summary of the status of each component of the final plan, including an update from the 2016 initial submittal and a list of which final plan components are not complete.

(2) A commitment to a plan approach (e.g., single or multi-State, rate-based or mass-based emission performance level, rate-based or mass-based emission standards), including draft or proposed legislation and/or regulations.

(3) An updated comprehensive roadmap with a schedule and milestones for completing the final plan, including any updates to community engagement undertaken and planned.

§60.5770 What schedules, performance periods, and compliance periods must I include in my plan?

(a) The affected EGUs covered by your plan must meet the CO_2 emission requirements required under §60.5855 for the interim period, interim steps, and the final reporting periods according to paragraph (b) of this section. You must also include in your plan compliance periods for each affected EGU regulated under the plan according to paragraphs (c) and (d) of this section.

(b) Your plan must require your affected EGUs to achieve each CO_2 emission performance rate or CO_2 emission goal, as applicable, required under §60.5855 over the periods according to paragraphs (b)(1) through (3) of this section.

(1) The interim period.

(2) Each interim step.

(3) Each final reporting period.

(c) The emission standards for affected EGUs regulated under the plan must include the following compliance periods:

(1) For the interim period, affected EGUs must have emission standards that have compliance periods that are no longer than each interim step and are imposed for the entirety of the interim step either alone or in combination.

(2) For the final period, EGUs must have emission standards that have compliance periods that are no longer than each final reporting period and are imposed for the entirety of the final reporting period either alone or in combination.

(3) Compliance periods for each interim step and each final reporting period may take forms shorter than specified in this regulation, provided the schedules of compliance collectively end on the same schedule as each interim step and final reporting period.

(d) If your plan relies upon State measures in lieu of or in addition to emission standards for affected EGUs regulated under the plan, then the period for achievement of each State measure must be identical to the compliance periods for affected EGUs listed in paragraphs (c)(1) through (3) of this section.

§60.5775 What emission standards must I include in my plan?

(a) Emission standard(s) for affected EGUs under your plan must be quantifiable, verifiable, non-duplicative, permanent, and enforceable with respect to each affected EGU. The plan must include the methods by which each emission standard meets each of the following requirements in paragraphs (b) through (f) of this section.

(b) An affected EGU's emission standard is quantifiable if it can be reliably measured in a manner that can be replicated.

(c) An affected EGU's emission standard is verifiable if adequate monitoring, recordkeeping and reporting requirements are in place to enable the State and the Administrator to independently evaluate, measure, and verify compliance with the emission standard.

(d) An affected EGU's emission standard is non-duplicative with respect to a State plan if it is not already incorporated as an emission standard in another State plan unless incorporated in multi-State plan.

(e) An affected EGU's emission standard is permanent if the emission standard must be met for each compliance period, or unless it is replaced by another emission standard in an approved plan revision, or the State demonstrates in an approvable plan revision that the emission reductions from the emission standard are no longer necessary for the State to meet its State level of performance.

(f) An affected EGU's emission standard is enforceable if:

(1) A technically accurate limitation or requirement and the time period for the limitation or requirement are specified;

(2) Compliance requirements are clearly defined;

(3) The affected EGUs responsible for compliance and liable for violations can be identified;

(4) Each compliance activity or measure is enforceable as a practical matter; and

(5) The Administrator, the State, and third parties maintain the ability to enforce against violations (including if an affected EGU does not meet its emission standard based on its emissions, its allowances if it is subject to a mass-based emission standard, or its ERCs if it is subject to a rate-based emission standard) and secure appropriate corrective actions, in the case of the Administrator pursuant to CAA sections 113(a)-(h), in the case of a State, pursuant to its plan, State law or CAA section 304, as applicable, and in the case of third parties, pursuant to CAA section 304.

§60.5780 What State measures may I rely upon in support of my plan?

You may rely upon State measures in support of your plan that are not emission standard(s) on affected EGUs, provided those State measures meet the requirements in paragraph (a) of this section.

(a) Each State measure is quantifiable, verifiable, non-duplicative, permanent, and enforceable with respect to each affected entity (entities other than affected EGUs with no federally enforceable obligations under a State plan), and your plan supporting materials include the methods by which each State measure meets each of the following requirements in paragraphs (1) through (5) of this subpart.

(1) A State measure is quantifiable with respect to an affected entity if it can be reliably measured in a manner that can be replicated.

(2) A State measure is verifiable with respect to an affected entity if adequate monitoring, recordkeeping and reporting requirements are in place to enable the State to independently evaluate, measure, and verify compliance with the State measure.

(3) A State measure is non-duplicative with respect to an affected entity if it is not already incorporated as a State measure or an emission standard in another State plan or State plan supporting material unless incorporated in multi-State plan.

(4) A State measure is permanent with respect to an affected entity if the State measure must be met for at least each compliance period, or unless it is replaced by another State measure in an approved plan revision, or the State demonstrates in an approved plan revision that the emission reductions from the State measure are no longer necessary for the State's affected EGUs to meet its CO_2 emission performance rates.

(5) A State measure is enforceable against an affected entity if:

(i) A technically accurate limitation or requirement and the time period for the limitation or requirement are specified;

(ii) Compliance requirements are clearly defined;

(iii) The affected entities responsible for compliance and liable for violations can be identified;

(iv) Each compliance activity or measure is enforceable as a practical matter; and

(v) The State maintains the ability to enforce violations and secure appropriate corrective actions.

§60.5785 What is the procedure for revising my plan?

(a) Plans can be revised only with approval by the Administrator. The Administrator will approve a plan revision if it is satisfactory with respect to the applicable requirements of this subpart and any applicable requirements of subpart B of this part, including the requirement in §60.5745(a)(3) to demonstrate achievement of the CO_2 emission performance rates in §60.5855. If one (or more) of the elements of the plan set in §60.5740 require revision with respect to achieving the CO_2 emission performance rates in §60.5855, a request must be submitted to the Administrator indicating the proposed revisions to the plan to ensure the CO_2 emission performance rates are met. In addition, the following provisions in (b) through (d) may apply.

(b) You may submit revisions to a plan to adjust CO_2 emission goals under the following instances:

(1) Addressing the addition of an affected EGU required to be included in a plan under §60.5740(a)(1).

(2) Addressing EGUs that become subject to subpart TTTT of this part and are no longer considered affected EGUs for incorporation in a plan.

(c) If your State is required to submit a notification according to section §60.5870(d) indicating a triggering of corrective measures as described in §60.5740(a)(2)(i) and your plan does not already include corrective measures to be implemented if triggered, you must revise your State plan to include corrective measures to be implemented. The corrective measures must ensure achievement of the CO_2 emission performance rates or State CO_2 emission goal. Additionally, the corrective measures must achieve additional emission reductions to offset any emission performance shortfall relative to the overall interim period or final period CO_2 emission performance rate or State CO_2 emission goal. The State plan revision submission must explain how the corrective measures both make up for the shortfall and address the State plan deficiency that caused the shortfall. The State must submit the revised plan and explanation to the EPA within 24 months after submitting the State report required in section §60.5870(a) indicating the exceedance in lieu of the requirements of §60.28(a). The State must implement corrective measures within 6 months of the EPA's approval of a plan revision adding them. The shortfall must be made up as expeditiously as practicable.

(d) If your plan relies upon State measures, your State triggers the backstop under §60.5740(a)(3)(i), and your State measures plan backstop does not include a mechanism to make up the shortfall, you must revise your backstop emission standards to make up the shortfall. The shortfall must be made up as expeditiously as practicable.

(e) Reliability Safety Valve

(1) In order to trigger a reliability safety valve, you must notify the EPA within 48 hours of an unforeseen, emergency situation that threatens reliability, such that your State will need a short-term modification of emission standards under a

State plan for a specified affected EGU or EGUs. The EPA will consider the notification in §60.5870(g)(1) to be an approved short-term modification to the State plan without needing to go through the full State plan revision process if the State provides a second notification to the EPA within seven days of the first notification. The short-term modification under a reliability safety valve allows modification to emission standards under the State plan for an affected EGU or EGUs for an initial period of up to 90 days. During that period of time, the EGU or EGUs will need to comply with the modified emission standards identified in the initial notification required under §60.5870(g)(1) or amended in the second notification required under §60.5870(g)(2). For the duration of the up to 90-day short-term modification, the emissions of the affected EGU or EGUs that exceed their obligations under the approved State plan will not be counted against the State's CO_2 emission performance rate or goal. The EPA reserves the right to review any such notification required under §60.5870(g), and, in the event that the EPA finds such notification is improper, the EPA may disallow the short-term modification and affected EGUs must continue to operate under the approved State plan emission standards. As described more fully below in §60.5870(g)(3), at least seven days before the end of the initial 90-day reliability safety valve period, the State must notify the appropriate EPA regional office whether the reliability concern has been addressed and the EGU or EGUs can resume meeting the original emission standards established in the State plan prior to the short-term modification or whether a serious, ongoing reliability issue necessitates the EGU or EGUs emitting beyond the amount allowed under the State plan.

(2) Plan revisions submitted pursuant to §60.5870(g)(3) must meet the requirements for State plan revisions under §60.5785(a).

§60.5790 What must I do to meet my plan obligations?

(a) To meet your plan obligations, you must demonstrate that your affected EGUs are complying with their emission standards as specified in §60.5740, and you must demonstrate that the emission standards on affected EGUs in conjunction with any State measures are resulting in achievement of the CO_2 emission performance rates or statewide CO_2 emission goals using the procedures in paragraphs (b) through (d) of this section. If your plan requires the use of allowances for your affected EGUs to comply with their emission standards, you must follow the requirements under paragraph (b) of this section and §60.5830. If your plan requires the use of ERCs for your affected EGUs to comply with their emission standards, you must follow the requirements under paragraphs (c) and (d) of this section and §§60.5795 through 60.5805.

(b) If you submit a plan that sets a mass-based emission trading program for your affected EGUs, the State plan must include emission standards and requirements that specify the allowance system, related compliance requirements and mechanisms, and the emission budget as appropriate. These requirements must include those listed in paragraphs (b)(1) through (5).

(1) CO_2 emission monitoring, reporting, and recordkeeping requirements for affected EGUs.

(2) Requirements for State allocation of allowances consistent with §60.5815.

(3) Requirements for tracking of allowances, from issuance through submission for compliance, consistent with §60.5820.

(4) The process for affected EGUs to demonstrate compliance (allowance "true-up" with reported CO_2 emissions) consistent with §60.5825.

(5) Requirements that address increased emissions from new sources, beyond the emissions expected from new sources if existing EGUs were given standards of performance in the form of the subcategory-specific emission performance rates. You may meet this requirement by requiring one of the options under paragraphs (b)(5)(i) through (iii).

(i) You may include, as part of your plan's supporting documentation, requirements enforceable as a matter of State law regulating emissions from existing affected EGUs and emissions from EGUs covered by subpart TTTT of this part under the mass-based CO_2 goal plus new source CO_2 emission complement applicable to your State in Table 4 of this subpart. If you choose this option, the term "mass-based CO_2 goal plus new source CO_2 emission complement" shall apply rather than "CO_2 mass based goal" and the term "CO_2 emission goal" shall include "mass-based CO_2 goal plus new source CO_2 emission complement" in these emission guidelines.

(ii) You may include requirements in your State plan for emission budget allowance allocation methods that align incentives to generate to existing or new sources;

(iii) You may submit an approvable equivalent method which requires affected EGUs to meet the mass-based CO_2 emission goal. The EPA will evaluate the approvability of such an alternative method on a case by case basis.

(c) If you submit a plan that sets rate-based emission standards on your affected EGUs, to meet the requirements of §60.5775, you must follow the requirements in paragraphs (c)(1) through (4).

(1) You must require the owner or operator of each affected EGU covered by your plan to calculate an adjusted CO_2 emission rate to demonstrate compliance with its emission standard by factoring stack emissions and any ERCs into the following

equation:

$$CO_2 emission\ rate = \frac{\sum M_{CO2}}{\sum MWh_{op} + \sum MWh_{ERC}}$$

Where:

CO_2 emission rate = An affected EGU's calculated CO_2 emission rate that will be used to determine compliance with the applicable CO_2 emission standard.

M_{CO2} = Measured CO_2 mass in units of pounds (lbs) summed over the compliance period for an affected EGU.

MWh_{op} = Total net energy output over the compliance period for an affected EGU in units of MWh.

MWh_{ERC} = ERC replacement generation for an affected EGU in units of MWh (ERCs are denominated in whole integers as specified in paragraph (d) of this section).

(2) Your plan must specify that an ERC qualifies for the compliance demonstration specified in paragraph (c)(1) of this section if the ERC meets the requirements of paragraphs (c)(2)(i) through (iv).

(i) An ERC must have a unique serial number.

(ii) An ERC must represent one MWh of actual energy generated or saved with zero associated CO_2 emissions.

(iii) An ERC must only be issued to an eligible resource that meets the requirements of §60.5795 or to an affected EGU that meets the requirements of §60.5800 and must only be issued by a State or its State agent through an EPA-approved ERC tracking system that meets the requirements of §60.5810, or by the EPA through an EPA-administered tracking system; and

(iv) An ERC must be surrendered and retired only once for purpose of compliance with this regulation through an EPA-approved ERC tracking system that meets the requirements of §60.5810, or by the EPA through an EPA-administered tracking system.

(3) Your plan must specify that an ERC does not qualify for the compliance demonstration specified in paragraph (c)(1) of this section if it does not meet the requirements of paragraph (c)(2) of this section or if any State has used that same ERC for purposes of demonstrating achievement of its State measures. The plan must additionally include provisions that address requirements for revocation or adjustment that apply if an ERC issued by the State is subsequently found to have been improperly issued.

(4) Your plan must include provisions either allowing for or restricting banking of ERCs between compliance periods for affected EGUs, and provisions not allowing any borrowing of any

ERCs from future compliance periods by affected EGUs or eligible resources.

(d) If you want an affected EGU subject to a rate-based emission standard (whether under an emission standards plan or as a part of the federally enforceable backstop in a State measures plan) to be able to use ERCs issued pursuant to your State measures to demonstrate compliance with its emission standard, to meet the requirements of §60.5775, such ERCs must meet the requirements of paragraphs (c) of this section.

Emission Rate Credit Requirements

§60.5795 What affected EGUs qualify for generation of ERCs?

(a) For issuance of ERCs to affected EGUs, the plan must specify the accounting method and process for ERC issuance. For plans that require that affected EGUs meet a rate-based CO_2 emission goal, where all affected EGUs have identical emission standards, you must specify the accounting method listed in paragraph (a)(1) of this section for generating ERCs. For plans that require affected EGUs to meet the CO_2 emission performance rates or CO_2 emission goals where affected EGUs have emission standards that are not equal for all affected EGUs, you must specify the accounting methods listed in paragraphs (a)(1) and (2) of this section for generating ERCs.

(1) You must include the calculation method for determining the number of ERCs, denominated in MWh, that may be issued to an

affected EGU that is in compliance with its emission standard, based on the difference between its emission standard and its CO_2 emission rate for the compliance period; and

(2) You must include the calculation method for determining the number of ERCs, denominated in MWh, that may be issued to affected EGUs that meet the definition of a stationary combustion turbine based on the displaced emissions from affected EGUs not meeting the definition of a stationary combustion turbine, resulting from the difference between its annualized net energy output in MWh for the calendar year(s) in the compliance period and its net energy output in MWh for the 2012 calendar year (January 1, 2012, through December 31, 2012).

(b) Any ERCs generated through the method described as required by paragraph (a)(2) must not be used by any affected EGUs other than steam generating units or IGCCs to demonstrate compliance as prescribed under §60.5790(c)(1).

(c) Any states in a multi-State plan that requires the use of ERCs for affected EGUs to comply with their emission standards must have functionally equivalent requirements pursuant to paragraphs (a)(1) and (2) of this section for generating ERCs.

§60.5800 What other resources qualify for issuance of ERCs?

(a) ERCs may only be issued for generation or savings produced on or after January 1, 2022, to an eligible resource that meets each of the requirements in paragraphs (a)(1) through (4) of this section.

(1) Resources qualifying for eligibility only include resources that increased new installed electrical generation nameplate capacity, or new electrical savings measures installed or implemented on or after January 1, 2013. If a resource had a nameplate capacity uprate, ERCs may be issued only for the difference in generation between the uprated nameplate capacity and its nameplate capacity prior to the uprate. ERCs must not be issued for generation for an uprate that followed a derate that occurred on or after January 1, 2013. A resource that is relicensed or receives a license extension is considered existing capacity and is not an eligible resource, unless it receives a capacity uprate as a result of the relicensing process that is reflected in its relicensed permit. In such a case, only the difference in nameplate capacity between its relicensed permit and its prior permit is eligible to be issued ERCs.

(2) The resource must be connected to, and deliver energy to or save electricity on, the electric grid in the contiguous United States.

(3) The resource is located in either:

(i) A State whose affected EGUs are subject to rate-based emission standards pursuant to this regulation; or

(ii) A State with mass-based emission standards, and the resource can demonstrate (e.g., through a power purchase agreement or contract for delivery) that the electricity generated is delivered with the intention to meet load in a State with affected EGUs which are subject to rate-based emission standards pursuant to this regulation, and was treated as a generation resource used to serve regional load that included the State whose affected EGUs are subject to rate-based emission standards. In this situation the only type of eligible resource in the State with mass-based emission standards is renewable generating technologies listed in (a)(4)(i) of this section.

(4) The resource falls into one of the following categories of resources:

(i) Renewable electric generating technologies using one of the following renewable energy resources: wind, solar, geothermal, hydro, wave, tidal;

(ii) Qualified biomass;

(iii) Waste-to-energy (biogenic portion only);

(iv) Nuclear power;

(v) A non-affected combined heat and power unit, including waste heat power;

(vi) A demand-side EE or demand-side management measure that saves electricity and is calculated on the basis of quantified ex post savings, not "projected" or "claimed" savings; or

(vii) A category identified in a State plan and approved by the EPA to generate ERCs.

(b) Any resource that does not meet the requirements of this subpart or an approved State plan cannot be issued ERCs for use by an affected EGU with its compliance demonstration required under §60.5790(c).

(c) ERCs may not be issued to any of the following:

(1) New, modified, or reconstructed EGUs that are subject to subpart TTTT of this part, except combined heat and power (CHP) units that meet the requirements of a CHP unit under paragraph (a);

(2) EGUs that do not meet the applicability requirements of §§60.5845 and 60.5850, except CHP units that meet the requirements of a CHP unit under paragraph (a);

(3) Measures that reduce CO_2 emissions outside the electric power sector, including GHG offset projects representing emission reductions that occur in the forestry and agriculture sectors, direct air capture, and crediting of CO_2 emission reductions that occur in the transportation sector as a result of vehicle electrification; and

(4) Any measure not approved by the EPA for issuance of ERCs in connection with a specific State plan.

(d) You must include the appropriate requirements in paragraphs (d)(1) through (3) for an applicable eligible resource in your plan.

(1) If qualified biomass is an eligible resource, the plan must include a description of why the proposed feedstocks or feedstock categories should qualify as an approach for controlling increases of CO_2 levels in the atmosphere as well as the proposed valuation of biogenic CO_2 emissions. In addition, for sustainably-derived agricultural and forest biomass feedstocks, the state plan must adequately demonstrate that such feedstocks appropriately control increases of CO_2 levels in the atmosphere and methods for adequately monitoring and verifying these feedstock sources and related sustainability practices. For all qualified biomass feedstocks, plans must specify how biogenic CO_2 emissions will be monitored and reported, and identify specific EM&V, tracking and auditing approaches.

(2) If waste-to-energy is an eligible resource, the plan must assess both their capacity to strengthen existing or implement new waste reduction, reuse, recycling and composting programs, and measures to minimize any potential negative impacts of waste-to-energy operations on such programs. Additionally the plan must include a method for determining the proportion of total MWh generation from a waste-to-energy facility that is eligible for use in adjusting a CO_2 emission

rate (i.e., that which is generated from biogenic materials).

(3) If carbon capture and utilization (CCU) is an eligible resource in a plan, the plan must include analysis supporting how the proposed qualifying CCU technology results in CO_2 emission mitigation from affected EGUs and provide monitoring, reporting, and verification requirements to demonstrate the reductions.

(e) States and areas of Indian country that do not have any affected EGUs, and other countries, may provide ERCs to adjust CO_2 emissions provided they are connected to the contiguous U.S. grid and meet the other requirements for eligibility and eligible resources included in this section.

§60.5805 What is the process for the issuance of ERCs?

If your plan uses ERCs your plan must include the process and requirements for issuance of ERCs to affected EGUs and eligible resources set forth in paragraphs (a) through (f) of this section.

(a) Eligibility application. Your plan must require that, to receive ERCs, the owner or operator must submit an eligibility application to you that demonstrates that the requirements of your State plan as approved by the EPA as meeting §60.5792 (for an affected EGU) or §60.5800 (for an eligible resource) are met, and, in the case of an eligible resource, includes at a minimum:

(1) Documentation that the eligibility application has only been submitted to you, or pursuant to an EPA-approved multi-State collaborative approach;

(2) An EM&V plan that meets the requirements of the State plan as approved by the EPA as meeting §60.5795; and

(3) A verification report from an independent verifier that verifies the eligibility of the eligible resource to be issued an ERC and that the EM&V plan meets the requirements of the State plan as approved by the EPA of meeting §60.5795.

(b) Registration of eligible resources. Your plan must require that any affected EGU or eligible resource register with an ERC tracking system that meets the requirements of §60.5810 prior to the issuance, and your plan must specify that you will only register an affected EGU or eligible resource after you approve its eligibility application and determine that the requirements of paragraph (a) of this section are met.

(c) M&V reports. For an eligible resource registered pursuant to paragraph (b) above, your plan must require that, prior to issuance of ERCs by you, the owner or operator must submit the following:

(1) An M&V report that meets the requirements of your State plan as approved by the EPA as meeting §60.5835; and

(2) A verification report from an independent verifier that verifies that the requirements of the M&V report are met.

(e) Issuance of ERCs. Your plan must specify your procedure for issuance of ERCs based on your review of an M&V report and verification report, and must require that ERCs be issued only on the basis of energy actually generated or saved, and that only one ERC is issued for each verified MWh.

(f) Tracking system. Your plan must require that ERCs may only be issued through an ERC tracking system approved as part of the State plan.

(g) Error Adjustment. Your plan must include a mechanism to adjust the number of ERCs issued if any are issued based on error (clerical, formula input error, etc.).

(h) Qualification status of an eligible resource. Your plan must include a mechanism to temporarily or permanently revoke the qualification status of an eligible resource, such that it can no longer be issued ERCs for at least the duration that it does not meet the requirements for being issued ERCs in your State plan.

(i) Qualification status of an independent verifier.

(1) Eligibility. To be an independent verifier, a person must be approved by the State as:

(A) An independent verifier, as defined by this regulation; and

(B) Eligible to verify EM&V plans and/or M&V reports per the requirements of the approved State plan as meeting §§60.5830 and 60.5835 respectively.

(2) Revocation of qualification. Your plan must include a mechanism to temporarily or permanently revoke the qualification status of an independent verifier, such that it can no longer verify EM&V plans or M&V reports for at least the duration of the period it does not meet the requirements of your State plan.

§60.5810 What applicable requirements are there for an ERC tracking system?

(a) Your plan must include provisions for an ERC tracking system, if applicable, that meets the following requirements:

(1) It electronically records the issuance of ERCs, transfers of ERCs among accounts, surrender of ERCs by affected EGUs as part of a compliance demonstration, and retirement or cancellation of ERCs; and

(2) It documents and provides electronic, internet-based public access to all information that supports the eligibility of eligible resources and issuance of ERCs and functionality to generate reports based on such information, which must include, for each ERC, an eligibility application, EM&V plan, M&V reports, and independent verifier verification reports.

(b) If approved in a State plan, an ERC tracking system may provide for transfers of ERCs to/from another ERC tracking system approved in a State plan, or provide for transfers of ERCs to/from an EPA-administered ERC tracking system used to administer a federal plan.

Mass Allocation Requirements

§60.5815 What are the requirements for State allocation of allowances in a mass-based program?

(a) For a mass-based trading program, a State plan must include requirements for CO_2 allowance allocations according to paragraphs (b) through (f) of this section.

(b) Provisions for allocation of allowances for each compliance period for each affected EGU prior to the beginning of the compliance period.

(c) Provisions for allocation of set-aside allowance, if applicable, must be established to ensure that the eligible resources must meet the same requirements for the ERC eligible resource requirements of §60.5800, and the State must include eligibility application and verification provisions equivalent to those for ERCs in §60.5805 and EM&V plan and M&V report provisions that meet the requirements of §60.5830 and §60.5835.

(d) Provisions for adjusting allocations if the affected EGUs or eligible resources are incorrectly allocated CO_2 allowances.

(e) Provisions allowing for or restricting banking of allowances between compliance periods for affected EGUs.

(f) Provisions not allowing any borrowing of emissions from future compliance periods by affected EGUs.

§60.5820 What are my allowance tracking requirements?

(a) Your plan must include provisions for an allowance tracking system, if applicable, that meets the following requirements:

(1) It electronically records the issuance of allowances, transfers of allowances among accounts, surrender of allowances by affected EGUs as part of a compliance demonstration, and retirement of allowances; and

(2) It documents and provides electronic, internet-based public access to all information that supports the eligibility of eligible resources and issuance of set aside allowances and functionality to generate reports based on such information, which must include, for each set aside allowance, an eligibility application, EM&V plan, M&V reports, and independent verifier verification reports.

(b) If approved in a State plan, an allowance tracking system may provide for transfers of allowances to/from another ERC tracking system approved in a State plan, or provide for transfers of allowances to/from an EPA-administered allowance tracking system used to administer a federal plan.

§60.5825 What is the process for affected EGUs to demonstrate compliance in a mass-based program?

(a) A plan must require affected EGUs owners and operators to demonstrate compliance with emission standards in a mass based program by holding an amount not less than the tons of total CO_2 emissions for such compliance period from all affected EGUs at the facility in the account for the affected EGU's emissions in the allowance tracking system required under 60.5820 during the applicable compliance period.

(b) In a mass-based trading program a plan may allow multiple affected EGUs co-located at the same facility to demonstrate that they are meeting the applicable emission standards on a facility-wide basis by the owner or operator holding enough allowances to cover all the affected EGUs at the facility.

(1) If there are not enough allowances to cover the facility's affected EGUs' emissions then there must be provisions for determining the compliance status of each affected EGU located at that facility.

Evaluation Measurement and Verification Plans and Monitoring and Verification Reports

§60.5830 What are the requirements for EM&V plans for eligible resources?

(a) If your plan requires your affected EGUs to meet their emission standards in accordance with §60.5790, your plan must include requirements that any EM&V plan that is submitted in accordance with the requirements of §60.5805, in support of the issuance of an ERC or set-aside allowance that can be used in accordance with §60.5790, must meet the EM&V criteria approved as part of your State plan.

(b) Your plan must require each EM&V plan to include identification of the eligible resource and its applicable approved eligibility application.

(c) Your plan must require that an EM&V plan must contain specific criteria, as applicable to the specific eligible resource. For example, for RE resources, requirements discussing how the generation data will be physically measured on a continuous basis using a revenue-quality meter.

(1) For demand-side EE, your State plan must require that each EM&V plan quantify and verify electricity savings on a retrospective (ex-post) basis using industry best-practice EM&V protocols and methods that yield accurate and reliable measurements of electricity savings. Your plan must also require each EM&V plan to include an assessment of the independent factors that influence the electricity savings, the expected life of the savings (in years), and a baseline that represents what would have happened in the absence of the demand-side EE activity. Additionally, your plan must require that each EM&V plan include a demonstration of how the industry best-practices protocol and methods were applied to the specific activity, project, measure, or program covered in the EM&V plan, and include an explanation of why these protocols or methods were

selected.

(d) For EM&V plans to be acceptable, eligible resources must clearly demonstrate how all such best-practice approaches will be applied for the purposes of quantifying and verifying MWh results. Subsequent reporting of demand-side EE savings values must demonstrate and explain how the EM&V plan was followed.

§60.5835 What are the requirements for M&V reports for eligible resources?

(a) If your plan requires your affected EGUs to meet their emission standards in accordance with §60.5790, your plan must include requirements that any M&V report that is submitted in accordance with the requirements of §60.5805, in support of the issuance of an ERC or set-aside allocation that can be used in accordance with §60.5790, must meet the requirements of this section.

(b) Your plan must require that each M&V report include the following:

(1) For the first M&V report submitted, documentation that the energy-generating resources, energy-saving measures, or practices were installed or implemented consistent with the description in the approved eligibility application required in §60.5805(a).

(2) Each M&V report submitted must include the following:

(i) Identification of the time period covered by the M&V report;

(ii) A description of how relevant quantification methods, protocols, guidelines, and guidance specified in the EM&V plan were applied during the reporting period to generate the quantified MWh of generation or MWh of energy savings;

(iii) Documentation (including data) of the energy generation and/or energy savings from any activity, project, measure, resource, or program addressed in the EM&V report, quantified and verified in MWh for the period covered by the M&V report, in accordance with its EM&V plan, and based on ex-post energy generation or savings; and

(iv) Documentation of any change in the energy generation or savings capability of the eligible resource from the description of the resource in the approved eligibility application during the period covered by the M&V report and the date on which the change occurred, and/or demonstration that the eligible resource continued to meet the requirements of §60.5800.

Applicability of Plans to Affected EGUs

§60.5840 Does this subpart directly affect EGU owners or operators in my State?

(a) This subpart does not directly affect EGU owners or operators in your State. However, affected EGU owners or operators must comply with the plan that a State or States develop to implement the emission guidelines contained in this subpart.

(b) If a State does not submit, or EPA disapproves, a final plan or initial submittal to implement and enforce the emission guidelines contained in this subpart by September 6, 2016, the EPA will implement and enforce a Federal plan, as provided in §60.5720, to ensure that each affected EGU within the State that commenced construction on or before January 8, 2014 complies with all the provisions of this subpart.

§60.5845 What affected EGUs must I address in my State plan?

(a) The EGUs that must be addressed by your plan are any affected steam generating unit, IGCC, or stationary combustion turbine that commenced construction on or before January 8, 2014.

(b) An affected EGU is a steam generating unit, IGCC, or stationary combustion turbine that meets the relevant applicability conditions specified in paragraph (b)(1) through (3) of this section except as provided in §60.5850.

(1) Serves a generator connected to a utility power distribution system with a nameplate capacity of 25 MW-net or greater (i.e., capable of selling greater than 25 MW of electricity);

(2) Has a base load rating (i.e., design heat input capacity) greater than 260 GJ/hr (250 MMBtu/hr) heat input of fossil fuel (either alone or in combination with any other fuel); and

(3) Stationary combustion turbines that meet the definition of either a combined cycle or combined heat and power combustion turbine.

§60.5850 What EGUs are excluded from being affected EGUs?

(a) EGUs that are excluded from being affected EGUs are:

(1) EGUs that are subject to subpart TTTT of this part as a result of commencing construction after the subpart TTTT applicability date; and those subject to subpart TTTT of this part as a result of commencing modification or reconstruction;

(2) Steam generating units and IGCC units that are currently and always have been subject to a federally enforceable permit limiting annual net-electric sales to one-third or less of its potential electric output, or 219,000 MWh or less;

(3) Non-fossil units (i.e., units that are capable of combusting 50 percent or more non-fossil fuel) that have always historically limited the use of fossil fuels to 10 percent or less of the annual capacity factor or are subject to a federally enforceable permit limiting fossil fuel use to 10 percent or less of the annual capacity factor.

(4) Stationary combustion turbines not capable of combusting natural gas (e.g., not connected to a natural gas pipeline)

(5) EGUs that are combined heat and power units that have always historically limited, or are subject to a federally enforceable permit currently limiting and always historically limiting, annual net-electric sales to a utility distribution system to the design efficiency times the potential electric output or 219,000 MWh (whichever is greater), or less;

(6) EGUs that serve a generator along with other steam generating unit(s), IGCC(s), or stationary combustion turbine(s) where the effective generation capacity (determined based on a prorated output of the base load rating of each steam generating unit, IGCC, or stationary combustion turbine) is 25 MW or less;

(7) EGUs that are a municipal waste combustor unit that is subject to subpart Eb of this part; and

(8) EGUs that are a commercial or industrial solid waste incineration unit that is subject to subpart CCCC of this part.

§60.5855 What are the CO_2 emission performance rates for affected EGUs?

(a) You must require, in your plan, emission standards on affected EGUs to meet the CO_2 emission performance rates listed in Table 1 of this subpart except as provided in paragraph (b) of this section. In addition, you must set CO_2 emission performance rates for the interim steps, according to paragraph (a)(1) of this section.

(1) You must set CO_2 emission performance rates for your affected EGUs to meet during the interim step periods on average and as applicable for the two subcategories of affected EGUs.

(b) You may elect to require your affected EGUs to meet emission standards that differ from the CO_2 emission performance rates listed in Table 1 of this subpart, provided that you demonstrate that the affected EGUs in your State will collectively meet their CO_2 emission performance rate by achieving statewide emission goals that are equivalent and no less stringent than the CO_2 emission performance rates listed in Table 1, and provided that your equivalent statewide CO_2 emission goals take one of the following forms:

(1) Average statewide rate-based CO_2 emission goals listed in Table 2 of this subpart, except as provided in paragraphs (c) and (d); or

(2) Cumulative statewide mass-based CO_2 emission goals listed in Table 3 of this subpart, except as provided in paragraphs (c) and (d).

(c) If your plan incorporates CO_2 emission goals listed in paragraphs (b)(1) or (2) of this section you must develop your own interim step goals and final reporting period goal for your affected EGUs to meet either on average or cumulatively.

Additionally the following applies if you elect to develop your own goals:

(1) The interim period and interim steps CO_2 emission goals must be in the same form, either both rate (in units of pounds per net MWh) or both mass (in tons); and

(2) You must set interim step goals that will either on average or cumulatively meet the State's interim period goal, as applicable to a rate-based or mass-based goal.

(d) Your plan's interim period and final period CO_2 emission goals incorporated pursuant to paragraph (b)(1) or (2) of this section, may be changed in the plan only according to situations listed in paragraphs (d)(1) through (3) of this section. If a situation requires a plan revision, you must follow the procedures in §60.5785 to submit a plan revision.

(1) If your plan implements CO_2 emission goals, you may submit a plan or plan revision, allowed in §60.5785, to make corrections to them, as a result of changes in the inventory of affected EGUs; and

(2) You may address EGUs that become subject to subpart TTTT of this part and are no longer considered affected EGUs for incorporation in a plan.

(3) If you elect to require your affected EGUs to meet emission standards or State measures, in addition to or in lieu of emission standards, to meet mass-based CO_2 emission goals in

your plan, you may elect to incorporate the mass emissions from EGUs that are subject to subpart TTTT of this part that are considered new affected EGUs under subpart TTTT of this part.

(e) If your plan submittal requires your affected EGUs to meet State measures in addition to or in lieu of emission standards, you must only use the mass-based goals allowed for in paragraph (b)(2) of this section to demonstrate that your affected EGUs are meeting the required emissions performance.

(f) Nothing in this subpart precludes an affected EGU from complying with its emission standard or you from meeting your State measures.

§60.5860 What applicable monitoring, recordkeeping, and reporting requirements do I need to include in my plan for affected EGUs?

(a) Your plan must include monitoring for affected EGUs that is no less stringent than what is described in (a)(1) through (8) of this section.

(1) The owner or operator of an affected EGU (or group of affected EGUs that share a monitored common stack) that is required to meet rate-based or mass-based emission standards must prepare a monitoring plan in accordance with the applicable provisions in §75.53(g) and (h) of this chapter, unless such a plan is already in place under another program that requires CO_2

mass emissions to be monitored and reported according to part 75 of this chapter.

(2) For rate-based emission standards, each compliance period shall include only "valid operating hours" in the compliance period, i.e., full or partial unit (or stack) operating hours for which:

(i) "Valid data" (as defined in §60.5880) are obtained for all of the parameters used to determine the hourly CO_2 mass emissions (lbs). For the purposes of this subpart, substitute data recorded under part 75 of this chapter are not considered to be valid data; and

(ii) The corresponding hourly net energy output value is also valid data (Note: for operating hours with no useful output, zero is considered to be a valid value).

(3) For rate-based emission standards, the owner or operator of an affected EGU must measure and report the hourly CO_2 mass emissions (lbs) from each affected unit using the procedures in paragraphs (a)(3)(i) through (vi) of this section, except as otherwise provided in paragraph (a)(4) of this section.

(i) The owner or operator of an affected EGU must install, certify, operate, maintain, and calibrate a CO_2 continuous emissions monitoring system (CEMS) to directly measure and record CO_2 concentrations in the affected EGU exhaust gases emitted to the atmosphere and an exhaust gas flow rate monitoring system according to §75.10(a)(3)(i) of this chapter. However, when an O_2 monitor is used this way, it only quantifies the combustion CO_2; therefore, if the EGU is equipped with emission controls that produce non-combustion CO_2 (e.g., from sorbent injection), this additional CO_2 must be accounted for, in accordance with section 3 of appendix G to part 75 of this chapter. As an alternative to direct measurement of CO_2 concentration, provided that the affected EGU does not use carbon separation (e.g., carbon capture and storage), the owner or operator of an affected EGU may use data from a certified oxygen (O_2) monitor to calculate hourly average CO_2 concentrations, in accordance with §75.10(a)(3)(iii) of this chapter. If CO_2 concentration is measured on a dry basis, the owner or operator of the affected EGU must also install, certify, operate, maintain, and calibrate a continuous moisture monitoring system, according to §75.11(b) of this chapter. Alternatively, the owner or operator of an affected EGU may either use an appropriate fuel-specific default moisture value from §75.11(b) or submit a petition to the Administrator under §75.66 of this chapter for a site-specific default moisture value.

(ii) For each "valid operating hour" (as defined in paragraph (a)(2) of this section), calculate the hourly CO_2 mass emission rate (tons/hr), either from Equation F-11 in Appendix F to part 75 of this chapter (if CO_2 concentration is measured on a wet basis), or by following the procedure in section 4.2 of Appendix F to part 75 of this chapter (if CO_2 concentration is measured on a dry basis).

(iii) Next, multiply each hourly CO_2 mass emission rate by the EGU or stack operating time in hours (as defined in §72.2 of this chapter), to convert it to tons of CO_2. Multiply the result by 2,000 lbs/ton to convert it to lbs.

(iv) The hourly CO_2 tons/hr values and EGU (or stack) operating times used to calculate CO_2 mass emissions are required to be recorded under §75.57(e) of this chapter and must be reported electronically under §75.64(a)(6), if required by a plan. The owner or operator must use these data, or equivalent data, to calculate the hourly CO_2 mass emissions.

(v) Sum all of the hourly CO_2 mass emissions values from paragraph (a)(3)(ii) of this section over the entire compliance period.

(vi) For each continuous monitoring system used to determine the CO_2 mass emissions from an affected EGU, the monitoring system must meet the applicable certification and quality assurance procedures in §75.20 of this chapter and Appendices A and B to part 75 of this chapter.

(4) The owner or operator of an affected EGU that

exclusively combusts liquid fuel and/or gaseous fuel may, as an alternative to complying with paragraph (a)(3) of this section, determine the hourly CO_2 mass emissions according to paragraphs (a)(4)(i) through (a)(4)(vi) of this section.

(i) Implement the applicable procedures in appendix D to part 75 of this chapter to determine hourly EGU heat input rates (MMBtu/hr), based on hourly measurements of fuel flow rate and periodic determinations of the gross calorific value (GCV) of each fuel combusted. The fuel flow meter(s) used to measure the hourly fuel flow rates must meet the applicable certification and quality-assurance requirements in sections 2.1.5 and 2.1.6 of appendix D to part 75 (except for qualifying commercial billing meters). The fuel GCV must be determined in accordance with section 2.2 or 2.3 of appendix D, as applicable.

(ii) For each measured hourly heat input rate, use Equation G-4 in Appendix G to part 75 of this chapter to calculate the hourly CO_2 mass emission rate (tons/hr).

(iii) For each “valid operating hour” (as defined in paragraph (a)(2) of this section), multiply the hourly tons/hr CO_2 mass emission rate from paragraph (a)(4)(ii) of this section by the EGU or stack operating time in hours (as defined in §72.2 of this chapter), to convert it to tons of CO_2. Then, multiply the result by 2,000 lbs/ton to convert it to lbs.

(iv) The hourly CO_2 tons/hr values and EGU (or stack) operating times used to calculate CO_2 mass emissions are required to be recorded under §75.57(e) of this chapter and must be reported electronically under §75.64(a)(6), if required by a plan. You must use these data, or equivalent data, to calculate the hourly CO_2 mass emissions.

(v) Sum all of the hourly CO_2 mass emissions values (lb) from paragraph (a)(4)(iii) of this section over the entire compliance period.

(vi) The owner or operator of an affected EGU may determine site-specific carbon-based F-factors (F_c) using Equation F-7b in section 3.3.6 of appendix F to part 75 of this chapter, and may use these F_c values in the emissions calculations instead of using the default F_c values in the Equation G-4 nomenclature.

(5) For both rate-based and mass-based standards, the owner or operator of an affected EGU (or group of affected units that share a monitored common stack) must install, calibrate, maintain, and operate a sufficient number of watt meters to continuously measure and record on an hourly basis net electric output. Measurements must be performed using 0.2 accuracy class electricity metering instrumentation and calibration procedures as specified under ANSI Standards No. C12.20. Further, the owner or operator of an affected EGU that is a combined heat and power facility must install, calibrate, maintain and operate equipment to continuously measure and record on an hourly basis useful

thermal output and, if applicable, mechanical output, which are used with net electric output to determine net energy output. The owner or operator must use the following procedures to calculate net energy output, as appropriate for the type of affected EGU(s).

(i) Determine P_{net} the hourly net energy output in MWh. For rate-based standards, perform this calculation only for valid operating hours (as defined in paragraph (a)(2) of this section). For mass-based standards, perform this calculation for all unit (or stack) operating hours, i.e., full or partial hours in which any fuel is combusted.

(ii) If there is no net electrical output, but there is mechanical or useful thermal output, either for a particular valid operating hour (for rate-based applications), or for a particular operating hour (for mass-based applications), the owner or operator of the affected EGU must still determine the net energy output for that hour.

(iii) For rate-based applications, if there is no (i.e., zero) gross electrical, mechanical, or useful thermal output for a particular valid operating hour, that hour must be used in the compliance determination. For hours or partial hours where the gross electric output is equal to or less than the auxiliary loads, net electric output shall be counted as zero for this calculation.

(iv) Calculate P_{net} for your affected EGU (or group of affected EGUs that share a monitored common stack) using the following equation. All terms in the equation must be expressed in units of MWh. To convert each hourly net energy output value reported under part 75 of this chapter to MWh, multiply by the corresponding EGU or stack operating time.

$$P_{net} = \frac{(Pe)_{ST} + (Pe)_{CT} + (Pe)_{IE} - (Pe)_{A}}{\text{TDF}} + [(Pt)_{PS} + (Pt)_{HR} + (Pt)_{IE}]$$

Where:

P_{net} = Net energy output of your affected EGU for each valid operating hour (as defined in 60.5860(a)(2)) in MWh.

$(Pe)_{ST}$ = Electric energy output plus mechanical energy output (if any) of steam turbines in MWh.

$(Pe)_{CT}$ = Electric energy output plus mechanical energy output (if any) of stationary combustion turbine(s) in MWh.

$(Pe)_{IE}$ = Electric energy output plus mechanical energy output (if any) of your affected EGU's integrated equipment that provides electricity or mechanical energy to the affected EGU or auxiliary equipment in MWh.

$(Pe)_{A}$ = Electric energy used for any auxiliary loads in MWh.

$(Pt)_{PS}$ = Useful thermal output of steam (measured relative to SATP conditions, as applicable) that is used for applications that do not generate additional electricity, produce mechanical energy output, or enhance the performance of the affected EGU. This is calculated using the equation specified in paragraph (a)(5)(v) of this section in MWh.

$(Pt)_{HR}$ = Non-steam useful thermal output (measured relative to SATP conditions, as applicable) from heat recovery that is used for applications other than steam generation or performance enhancement of the affected EGU in MWh.

$(Pt)_{IE}$ = Useful thermal output (relative to SATP conditions, as applicable) from any integrated equipment is used for applications that do not generate additional steam, electricity, produce mechanical energy output, or enhance the performance of the affected EGU in MWh.

TDF = Electric Transmission and Distribution Factor of 0.95 for a combined heat and power affected EGU where at least on an annual basis 20.0 percent of the total gross or net energy output consists of electric or direct mechanical output and 20.0 percent of the total net energy output consist of useful thermal output on a 12-operating month rolling average basis, or 1.0 for all other affected EGUs.

(v) If applicable to your affected EGU (for example, for combined heat and power), you must calculate $(Pt)_{PS}$ using the following equation:

$$(Pt)_{PS} = \frac{Q_m \times H}{CF}$$

Where:

Q_m = Measured steam flow in kilograms (kg) (or pounds (lbs)) for the operating hour.

H = Enthalpy of the steam at measured temperature and pressure (relative to SATP conditions or the energy in the condensate return line, as applicable) in Joules per kilogram (J/kg) (or Btu/lb).

CF = Conversion factor of 3.6×10^9 J/MWh or 3.413×10^6 Btu/MWh.

(v) For rate-based standards, sum all of the values of P_{net} for the valid operating hours (as defined in paragraph (a)(2) of this section), over the entire compliance period. Then, divide the total CO_2 mass emissions for the valid operating hours from paragraph (a)(3)(v) or (a)(4)(v) of this section, as applicable, by the sum of the P_{net} values for the valid operating hours plus any ERC replacement generation (as shown in §60.5790(c)), to determine the CO_2 emissions rate (lb/net MWh) for the compliance period.

(vi) For mass-based standards, sum all of the values of P_{net} for all operating hours, over the entire compliance period.

(6) In accordance with §60.13(g), if two or more affected EGUs implementing the continuous emissions monitoring provisions in paragraph (a)(2) of this section share a common exhaust gas stack and are subject to the same emissions standard, the owner or operator may monitor the hourly CO_2 mass emissions at the common stack in lieu of monitoring each EGU separately. If an owner or operator of an affected EGU chooses this option, the hourly net electric output for the common stack must be the sum of the hourly net electric output of the individual affected EGUs and the operating time must be expressed as "stack operating hours" (as defined in §72.2 of this chapter).

(7) In accordance with §60.13(g), if the exhaust gases from an affected EGU implementing the continuous emissions monitoring provisions in paragraph (a)(2) of this section are emitted to the atmosphere through multiple stacks (or if the exhaust gases are routed to a common stack through multiple ducts and you elect to monitor in the ducts), the hourly CO_2 mass emissions and the "stack operating time" (as defined in §72.2 of this chapter) at each stack or duct must be monitored separately. In this

case, the owner or operator of an affected EGU must determine compliance with an applicable emissions standard by summing the CO_2 mass emissions measured at the individual stacks or ducts and dividing by the net energy output for the affected EGU.

(8) Consistent with §60.5775 or §60.5780, if two or more affected EGUs serve a common electric generator, you must apportion the combined hourly net energy output to the individual affected EGUs according to the fraction of the total steam load contributed by each EGU. Alternatively, if the EGUs are identical, you may apportion the combined hourly net electrical load to the individual EGUs according to the fraction of the total heat input contributed by each EGU.

(b) For mass-based standards, the owner or operator of an affected EGU must determine the CO_2 mass emissions (tons) for the compliance period as follows:

(1) For each operating hour, calculate the hourly CO_2 mass (tons) according to paragraph (a)(3) or (a)(4) of this section, except that a complete data record is required, i.e., CO_2 mass emissions must be reported for each operating hour. Therefore, substitute data values recorded under part 75 of this chapter for CO_2 concentration, stack gas flow rate, stack gas moisture content, fuel flow rate and/or GCV shall be used in the calculations; and

(2) Sum all of the hourly CO_2 mass emissions values over the entire compliance period.

(3) The owner or operator of an affected EGU must install, calibrate, maintain, and operate a sufficient number of watt meters to continuously measure and record on an hourly basis net electric output. Measurements must be performed using 0.2 accuracy class electricity metering instrumentation and calibration procedures as specified under ANSI Standards No. C12.20. Further, the owner or operator of an affected EGU that is a combined heat and power facility must install, calibrate, maintain and operate equipment to continuously measure and record on an hourly basis useful thermal output and, if applicable, mechanical output, which are used with net electric output to determine net energy output (P_{net}). The owner or operator must calculate net energy output according to paragraphs (a)(5)(i)(A) and (B) of this section.

(c) Your plan must require the owner or operator of each affected EGU covered by your plan to maintain the records, as described in (b)(1) through (2) of this subpart, for at least 5 years following the date of each compliance period, occurrence, measurement, maintenance, corrective action, report, or record.

(1) The owner or operator of an affected EGU must maintain each record on site for at least 2 years after the date of each compliance period, compliance true-up period, occurrence,

measurement, maintenance, corrective action, report, or record, whichever is latest, according to §60.7. The owner or operator of an affected EGU may maintain the records off site and electronically for the remaining year(s).

(2) The owner or operator of an affected EGU must keep all of the following records:

(i) All documents, data files, and calculations and methods used to demonstrate compliance with an affected EGU's emission standard under §60.5775.

(ii) Copies of all reports submitted to the State under paragraph (c) of this section.

(iii) Data that are required to be recorded by 40 CFR Part 75 Subpart F.

(iv) Data with respect to any ERCs generated by the affected EGU or used by the affected EGU in its compliance demonstration including the information in paragraphs (c)(2)(iv)(A) and (B) of this section.

(A) All documents related to any ERCs used in a compliance demonstration, including each eligibility application, EM&V plan, M&V report, and independent verifier verification report associated with the issuance of each specific ERC.

(B) All records and reports relating to the surrender and retirement of ERCs for compliance with this regulation, including the date each individual ERC with a unique serial identification number was surrendered and/or retired.

(d) Your plan must require the owner or operator of an affected EGU covered by your plan to include in a report submitted to you at the end of each compliance period the information in paragraphs (d)(1) through (5) of this section.

(1) Owners or operators of an affected EGU must include in the report all hourly CO_2, for each affected EGU (or group of affected EGUs that share a monitored common stack).

(2) For rate-based standards, each report must include:

(i) The hourly CO_2 mass emission rate values (tons/hr) and unit (or stack) operating times, (as monitored and reported according to part 75 of this chapter), for each valid operating hour in the compliance period;

(ii) The net electric output and the net energy output (P_{net}) values for each valid operating hour in the compliance period;

(iii) The calculated CO_2 mass emissions (lb) for each valid operating hour in the compliance period;

(iv) The sum of the hourly net energy output values and the sum of the hourly CO_2 mass emissions values, for all of the valid operating hours in the compliance period;

(v) ERC replacement generation (if any), properly justified (see paragraph (c)(5) of this section); and

(vi) The calculated CO_2 mass emission rate for the compliance period (lbs/net MWh).

(3) For mass-based standards, each report must include:

(i) The hourly CO_2 mass emission rate value (tons/hr) and unit (or stack) operating time, as monitored and reported according to part 75 of this chapter, for each unit or stack operating hour in the compliance period;

(ii) The calculated CO_2 mass emissions (tons) for each unit or stack operating hour in the compliance period;

(iii) The sum of the CO_2 mass emissions (tons) for all of the unit or stack operating hours in the compliance period;

(iv) The net electric output and the net energy output (P_{net}) values for each unit or stack operating hour in the compliance period; and

(v) The sum of the hourly net energy output values for all of the unit or stack operating hours in the compliance period.

(vi) Notwithstanding the requirements in paragraphs (c)(3)(i) through (c)(3)(iii) of this section, if the compliance period is a discrete number of calendar years (e.g., one year, three years), in lieu of reporting the information specified in those paragraphs, the owner or operator may report:

(A) The cumulative annual CO_2 mass emissions (tons) for each year of the compliance period, derived from the electronic emissions report for the fourth calendar quarter of that year, submitted to EPA under §75.64(a) of this chapter; and

(B) The sum of the cumulative annual CO_2 mass emissions values from paragraph (c)(3)(v)(A) of this section, if the compliance period includes multiple years.

(4) For each affected EGU's compliance period, the report must also include the applicable emission standard and demonstration that it met the emission standard. An owner or operator must also include in the report the affected EGU's calculated emission performance as a CO_2 emission rate or cumulative mass in units of the emission standard required in §§60.5790(b) through (d) and 60.5855, as applicable.

(5) If the owner or operator of an affected EGU is complying with an emission standard by using ERCs, they must include in the report a list of all unique ERC serial numbers that were retired in the compliance period, and, for each ERC, the date an ERC was surrendered and retired and eligible resource identification information sufficient to demonstrates that it meets the requirements of §60.5800 and qualifies to be issued ERCs (including location, type of qualifying generation or savings, date commenced generating or saving, and date of generation or savings for which the ERC was issued).

(6) If the owner or operator of an affected EGU is complying with an emission standard or State measures by using

allowances, they must include in the report a list of all unique allowance serial numbers that were retired in the compliance period, and, for each allowance, the date an allowance was surrendered and retired and if the allowance was a set-aside allowance the eligible resource identification information sufficient to demonstrate that it meets the requirements of §60.5815(c) and qualifies to be issued set-aside allowances (including location, type of qualifying generation or savings, date commenced generating or saving, and date of generation or savings for which the allowance was issued).

(e) The owner or operator of an affected EGU must follow any additional requirements for monitoring, recordkeeping and reporting in a plan that are required under §60.5785, if applicable.

(f) If an affected EGU captures CO_2 to meet the applicable emission limit, owners and operator must report in accordance with the requirements of 40 CFR Part 98 Subpart PP and either:

(1) Report in accordance with the requirements of 40 CFR Part 98 subpart RR, if injection occurs on-site, or

(2) Transfer the captured CO_2 to an EGU or facility that reports in accordance with the requirements of 40 CFR Part 98 subpart RR, if injection occurs off-site.

(3) Transfer the captured CO_2 to a facility that has received an innovative technology waiver from EPA pursuant to paragraph (g) of this section.

(g) Any person may request the Administrator to issue a waiver of the requirement that captured CO_2 from an affected EGU be transferred to a facility reporting under 40 CFR Part 98 subpart RR. To receive a waiver, the applicant must demonstrate to the Administrator that its technology will store captured CO_2 as effectively as geologic sequestration, and that the proposed technology will not cause or contribute to an unreasonable risk to public health, welfare, or safety. In making this determination, the Administrator shall consider (among other factors) operating history of the technology, whether the technology will increase emissions or other releases of any pollutant other than CO_2, and permanence of the CO_2 storage. The Administrator may test the system itself, or require the applicant to perform any tests considered by the Administrator to be necessary to show the technology's effectiveness, safety, and ability to store captured CO_2 without release. The Administrator may grant conditional approval of a technology, the approval conditioned on monitoring and reporting of operations. The Administrator may also withdraw approval of the waiver on evidence of releases of CO_2 or other pollutants. The Administrator will provide notice to the public of any application under this provision, and provide public notice of any proposed action on a petition before the Administrator takes final action.

Recordkeeping and Reporting Requirements

§60.5865 What are my recordkeeping requirements?

(a) You must keep records of all information relied upon in support of any demonstration of plan components, plan requirements, supporting documentation, and the status of meeting the plan requirements defined in the plan for each interim step and the interim period. After 2029, States must keep records of all information relied upon in support of any continued demonstration that the final emissions goals are being achieved.

(b) You must keep records of all data submitted by the owner or operator of each affected EGU that is used to determine compliance with each affected EGU emissions standard or requirements in an approved State plan, consistent with the affected EGU requirements listed in §60.5860.

(c) If your State has a requirement for all hourly CO_2 emissions and net generation information to be used to calculate compliance with an annual emissions standard or State measure for affected EGUs, any information that is submitted by the owners or operators of affected EGUs to the EPA electronically pursuant to requirements in Part 75 meets the recordkeeping requirement of this section and you are not required to keep records of information that would be in duplicate of paragraph (b) of this section.

(d) You must keep records at a minimum for 10 years, for the interim period, and 5 years, for the final period, from the date the record is used to determine compliance with an emissions standard, plan requirement, CO_2 emission performance rate or CO_2 emissions goal. Each record must be in a form suitable and readily available for expeditious review.

§60.5870 What are my reporting and notification requirements?

(a) In lieu of the annual report required under §60.25(e) and (f) of this part, you must report the information in paragraphs (b) through (f) of this section.

(b) You must submit a report covering each interim step within the interim period and each of the final 2-calendar year periods due no later than July 1 of the year following the end of the period. The interim period reporting starts with a reporting covering interim step 1 due no later than July 1, 2025. The final period reports start with a biennual report covering the first final reporting period (which is due by July 1, 2032), a 2-calendar year average of emissions or cumulative sum of emissions used to determine compliance with the final CO_2 emission performance rate or CO_2 emission goal (as applicable).

The report must include the information in paragraphs (b)(1) through (4) of this paragraph.

(1) The report must include the emissions performance achieved by all affected EGUs during the reporting period, consistent with the plan approach according to §60.5745(a), and identification of whether each affected EGU is in compliance with its emission standard and whether the collective of all affected EGUs covered by the State are on schedule to meet the applicable CO_2 emission performance rate or emission goal during the performance periods and compliance periods, as specified in the plan.

(2) The report must include a comparison of the CO_2 emission performance rate or CO_2 emission goal identified in the State plan for the applicable interim step period versus the actual average, cumulative, or adjusted CO_2 emission performance (as applicable) achieved by all affected EGUs.

(i) For interim step 3, you do not need to include a comparison between the applicable interim step 3 CO_2 emission performance rate or emission goal; you must only submit the average, cumulative or adjusted CO_2 emission performance (as applicable) of your affected EGUs during that period in units of your applicable CO_2 emission performance rate or emission goal.

(3) The report must include all other required information, as specified in your State plan according to §60.5740(a)(5).

(4) The report must include a program review that your State has conducted that addresses all aspects of the administration of the state plan and overall program, including State evaluations and regulatory decisions regarding eligibility applications for ERC resources and M&V reports (and associated EM&V activities), and State issuance of ERCs. The program review must assess whether the program is being administered properly in accordance with the approved plan, that reported annual MWh of generation and savings from qualified ERC resources are being properly quantified, verified, and reported in accordance with approved EM&V plans, and that appropriate records are being maintained. The program review must also address determination of the eligibility of verifiers by the State and the conduct of verifiers, including the quality of verifier reviews.

(c) If your plan relies upon State measures, in lieu of or in addition to emission standards, then you must submit an annual report to the EPA in addition to the reports required under paragraph (b) of this section for the interim period. In the final period, you must submit biennual reports consistent with those required under paragraph (b) of this section. The annual reports in the interim period must be submitted no later than July 1 following the end of each calendar year starting with the annual year 2022 (January 1, 2022 to December 31, 2022). The annual and biennual reports must include the information in paragraphs (c)(1) and (2) of this section.

(1) You must include in your report the status of implementation of federally enforceable emission standards (if applicable) and State measures.

(2) You must include information regarding the status of the periodic programmatic milestones to show progress in program implementation. The programmatic milestones with specific dates for achievement must be consistent with the State measures included in the State plan submittal.

(d) If your plan includes the requirement for emission standards on your affected EGUs, then you must submit a notification in the report required under paragraph (b) of this section to the EPA if your affected EGUs trigger corrective measures as described in §60.5740(a)(2)(i). If corrective measures are required you must follow the requirements in 60.5785 for revising your plan to implement the corrective measures.

(e) If your plan relies upon State measures, in lieu of or in addition to emission standards, than you must submit a notification as required under paragraphs (e)(1) and (2) of this section.

(1) You must submit a notification in the report required under paragraph (c) of this section to the EPA if at the end of

the calendar year your State did not meet a programmatic milestone included in your plan submittal. This notification must detail the implementation of the backstop required in your plan to be fully in place within 18 months of the due date of the report required in paragraph (b) of this section. In addition, the notification must describe the steps taken by the State to inform the affected EGUs in its State that the backstop has been triggered.

(2) You must submit a notification in the report required under paragraph (b) of this section to the EPA if you trigger the backstop as described in §60.5740(a)(3)(i). This notification must detail the steps that will be taken by you to implement the backstop so that it is fully in place within 18 months of the due date of the report required in paragraph (b) of this section. In addition, the notification must describe the steps taken by the State to inform the affected EGUs that the backstop has been triggered.

(f) You must include in your 2029 report (which is due by July 1, 2030) the calculation of average emissions, cumulative sum of emissions, or adjusted emissions (as applicable) over the interim period and a comparison of those values to your interim CO_2 emission performance rate or emission goal. The calculated value must be in units consistent with the approach you set in your plan for the interim period.

(g) The notifications listed in paragraphs (g)(1) through (3) of this section are required for the reliability safety valve allowed in §60.5785(e).

(1) As required under §60.5785(e), you must submit an initial notification to the appropriate EPA regional office within 48 hours of an unforeseen, emergency situation. The initial notification must:

(i) Include a full description, to the extent that it is known, of the emergency situation that is being addressed;

(ii) Identify the affected EGU or EGUs that are required to run to assure reliability; and

(iii) Specify the modified emission standards at which the identified EGU or EGUs will operate.

(2) Within 7 days of the initial notification in §60.5870(g)(1), the State must submit a second notification to the appropriate EPA regional office that documents the initial notification. If the State fails to submit this documentation on a timely basis, the EPA will notify the State, which must then notify the affected EGU(s) that they must operate or resume operations under the original approved State plan emissions standards. This notification must include the following:

(i) A full description of the reliability concern and why an unforeseen, emergency situation that threatens reliability requires the affected EGU or EGUs to operate under modified emission standards from those originally required in the State plan including discussion of why the flexibilities provided under the state's plan are insufficient to address the concern;

(ii) A description of how the State is coordinating or will coordinate with relevant reliability coordinators and planning authorities to alleviate the problem in an expedited manner;

(iii) An indication of the maximum time that the State anticipates the affected EGU or EGUs will need to operate in a manner inconsistent with its or their obligations under the State's approved plan;

(iv) A written concurrence from the relevant reliability coordinator and/or planning authority confirming the existence of the imminent reliability threat and supporting the temporary modification request or an explanation of why this kind of concurrence cannot be provided;

(v) The modified emission standards or levels that the affected EGU or EGU will be operating at for the remainder of the 90-day period if it has changed from the initial notification; and

(vi) Information regarding any system-wide or other analysis of the reliability concern conducted by the relevant planning authority, if any.

(3) At least 7 days before the end of the 90-day reliability safety valve period, the State must notify the

appropriate EPA regional office that either:

(i) The reliability concern has been addressed and the affected EGU or EGUs can resume meeting the original emissions standards in the State plan approved prior to the short-term modification; or

(ii) There still is a serious, ongoing reliability issue that necessitates the EGU or EGUs to emit beyond the amount allowed under the State plan. In this case, the State must provide a notification to the EPA that it will be submitting a State plan revision according to paragraph §60.5785(a) of this section to address the reliability issue. The notification must provide the date by which a revised State plan will be submitted to EPA and documentation of the ongoing emergency with a written concurrence from the relevant reliability coordinator and/or planning authority confirming the continuing urgent need for the EGU or EGUs to operate beyond the requirements of the State plan and that there is no other reasonable way of addressing the ongoing reliability emergency but for the EGU or EGUs to operate under an alternative emission standard than originally approved under the State plan. After the initial 90-day period, any excess emissions beyond what is authorized in the original approved State plan will count against the State's overall CO_2 emission goal or emission performance rate for affected EGUs.

§60.5875 How do I submit information required by these Emission

Guidelines to the EPA?

(a) You must submit to the EPA the information required by these emission guidelines following the procedures in paragraphs (b) through (e) of this section.

(b) All negative declarations, State plan submittals, supporting materials that are part of a State plan submittal, any plan revisions, and all State reports required to be submitted to the EPA by the State plan must be reported through EPA's State Plan Electronic Collection System (SPeCS). SPeCS is a web accessible electronic system is accessed at the EPA's Central Data Exchange (CDX) (http://www.epa.gov/cdx/). States who claim that a State plan submittal or supporting documentation includes confidential business information (CBI) must submit that information on a compact disc, flash drive, or other commonly used electronic storage media to the EPA. The electronic media must be clearly marked as CBI and mailed to U.S. EPA/OAQPS/CORE CBI Office, Attention: State and Local Programs Group, MD C539-01, 4930 Old Page Rd., Durham, NC 27703.

(c) Only a submittal by the Governor or the Governor's designee by an electronic submission through SPeCS shall be considered an official submittal to the EPA under this subpart. If the Governor wishes to designate another responsible official the authority to submit a State plan, the EPA must be notified via letter from the Governor prior to the September 6, 2016, deadline for plan submittal so that they have the ability to submit the initial or final plan submittal in the SPeCS. If the Governor has previously delegated authority to make CAA submittals on the Governor's behalf, a State may submit documentation of the delegation in lieu of a letter from the Governor. The letter or documentation must identify the designee to whom authority is being designated and must include the name and contact information for the designee and also identify the State plan preparers who will need access to SPeCS. A State may also submit the names of the State plan preparers via a separate letter prior to the designation letter from the Governor in order to expedite the State plan administrative process. Required contact information for the designee and preparers includes the person's title, organization and email address.

(d) The submission of the information by the authorized official must be in a non-editable format. In addition to the non-editable version all plan components designated as federally enforceable must also be submitted in an editable version. Following initial plan approval, States must provide the EPA with an editable copy of any submitted revision to existing approved federally enforceable plan components, including State plan backstop measures. The editable copy of any such submitted plan revision must indicate the changes made at the State level, if any, to the existing approved federally enforceable plan components, using a mechanism such as redline/strikethrough. These changes are not part of the State plan until formal approval by EPA.

(e) You must provide the EPA with non-editable and editable copies of any submitted revision to existing approved federally enforceable plan components, including State plan backstop measures. The editable copy of any such submitted plan revision must indicate the changes made at the State level, if any, to the existing approved federally enforceable plan components, using a mechanism such as redline/strikethrough. These changes are not part of the State plan until formal approval by EPA.

Definitions

§60.5880 What definitions apply to this subpart?

As used in this subpart, all terms not defined herein will have the meaning given them in the Clean Air Act and in subparts A (General Provisions) and B of this part.

Adjusted CO_2 emission rate means the reported CO_2 emission rate of an affected EGU, adjusted as described in §60.5790(c)(1) to reflect any ERCs used by an affected EGU to demonstrate compliance with its CO_2 emission standards.

Affected electric generating unit or *Affected EGU* means a steam generating unit, integrated gasification combined cycle (IGCC), or stationary combustion turbine that meets the relevant applicability conditions in section §60.5845.

Allowance means an authorization for each specified unit of actual CO_2 emitted from an affected EGU or a facility during a specified period.

Allowance system means a control program under which the owner or operator of each affected EGU is required to hold an authorization for each specified unit of CO_2 emitted from that facility during a specified period and which limits the total amount of such authorizations available to be held for CO_2 for a specified period and allows the transfer of such authorizations not used to meet the authorization-holding requirement.

Annual capacity factor means the ratio between the actual heat input to an EGU during a calendar year and the potential heat input to the EGU had it been operated for 8,760 hours during a calendar year at the base load rating.

Base load rating means the maximum amount of heat input (fuel) that an EGU can combust on a steady-state basis, as determined by the physical design and characteristics of the EGU at ISO conditions. For a stationary combustion turbine, *base load rating* includes the heat input from duct burners.

Biomass means biologically based material that is living or dead (e.g., trees, crops, grasses, tree litter, roots) above and below ground, and available on a renewable or recurring basis. Materials that are biologically based include non-fossilized, biodegradable organic material originating from modern or contemporarily grown plants, animals, or microorganisms (including plants, products, byproducts and residues from agriculture, forestry, and related activities and industries, as well as the non-fossilized and biodegradable organic fractions of industrial and municipal wastes, including gases and liquids recovered from the decomposition of non-fossilized and biodegradable organic material).

CO_2 emission goal means a statewide rate-based CO_2 emission goal or mass-based CO_2 emission goal specified in §60.5855.

Combined cycle unit means an electric generating unit that uses a stationary combustion turbine from which the heat from the turbine exhaust gases is recovered by a heat recovery steam generating unit to generate additional electricity.

Combined heat and power unit or *CHP unit, (*also known as "cogeneration") means an electric generating unit that uses a steam-generating unit or stationary combustion turbine to simultaneously produce both electric (or mechanical) and useful thermal output from the same primary energy source.

Common practice baseline or CPB means a baseline derived based on a default technology or condition that would have been in place at the time of implementation of an EE measure in the absence of the EE measure (for example, the standard or market-average or pre-existing equipment that a typical consumer/building owner would have continued to use or would have installed at the time of project implementation in a given circumstance, such as a given building type, EE program type or delivery mechanism, and geographic region).

Compliance period means a discrete time period for an affected EGU to comply with either an emission standard or State measure. Compliance periods for affected EGUs required in plans must meet the requirements of §60.5770.

Control area operator means an electric system or systems, bounded by interconnection metering and telemetry, capable of controlling generation to maintain its interchange schedule with other control areas and contributing to frequency regulation of the interconnection.

Demand-side energy efficiency means an installed piece of equipment or system, a modification of existing equipment or system, or a strategy intended to affect consumer electricity-use behavior, that results in a reduction in electricity use (in MWh) at an end-use facility, premises, or equipment connected to the electricity grid.

Derate means a decrease in the available capacity of an electric generating unit, due to a system or equipment modification or to discounting a portion of a generating unit's capacity for planning purposes.

Design efficiency means the rated overall net efficiency (e.g., electric plus thermal output) on a higher heating value basis of the EGU at the base load rating and ISO conditions.

Eligible resource means a resource that meets the requirements of §60.5800(a).

Emission Rate Credit or ERC means a tradable compliance instrument that meets the requirements of §60.5790(c).

EM&V plan means a plan that meets the requirements of §60.5830.

ERC tracking system means a system for the issuance, surrender and retirement of ERCs that meets the requirements of §60.5810.

Essential generating characteristics means any characteristic that affects the eligibility of an eligible resource for generating ERCs pursuant to this regulation, including the type of resource.

Existing State program, requirement, or measure means, in the context of a State plan, a regulation, requirement, program, or measure administered by a State, utility, or other entity that is currently established.

Final period means the period that begins on January 1, 2030, and continues thereafter. The final period is comprised of final reporting periods, each of which may be no longer than two calendar years (with a calendar year beginning on January 1 and ending on December 31).

Final reporting period means an increment of plan performance within the final period, with each final reporting period being no longer than two calendar years (with a calendar year beginning on January 1 and ending on December 31), with the first final reporting period in the final period beginning on January 1, 2030, and ending no later than December 31, 2031.

Fossil fuel means natural gas (as defined in subpart TTTT of this part), petroleum (as defined in subpart TTTT of this part), coal (as defined in subpart TTTT of this part), and any form of solid fuel (as defined in subpart TTTT of this part), liquid fuel (as defined in subpart TTTT of this part), or gaseous fuel (as defined in subpart TTTT of this part) derived from such material for the purpose of creating useful heat.

Heat recovery steam generating unit (HRSG) means a unit in which hot exhaust gases from the combustion turbine engine are routed in order to extract heat from the gases and generate useful output. Heat recovery steam generating units can be used with or without duct burners.

Independent verifier means a person (including any company, any corporate parent or subsidiary, any contractors or subcontractors, and the actual person) who has the appropriate technical and other qualifications to provide verification reports. The independent verifier must not have, or have had, any direct or indirect financial or other interest in the subject of its verification report or ERCs that could impact their impartiality in performing verification services.

Integrated gasification combined cycle facility or *IGCC facility* means a combined cycle facility that is designed to burn fuels containing 50 percent (by heat input) or more solid-derived fuel not meeting the definition of natural gas plus any integrated equipment that provides electricity or useful thermal output to either the affected facility or auxiliary equipment. The Administrator may waive the 50 percent solid-derived fuel requirement during periods of the gasification system construction, startup and commissioning, shutdown, or repair. No solid fuel is directly burned in the unit during operation.

Interim period means the period of eight calendar years from January 1, 2022, to December 31, 2029. The interim period is composed of at least three interim steps, interim step 1, interim step 2, and interim step 3, and may be composed of more than three interim steps at your discretion, provided your first and second interim steps and no single interim step is longer than three calendar years each (with a calendar year beginning on January 1 and ending on December 31), and your last interim step is no longer than two calendar years (with a calendar year beginning on January 1 and ending on December 31).

Interim step means an increment of plan performance within the interim period. You must have at least three interim steps within the interim period. You may have more than three interim steps at your discretion, provided your first and second interim steps and no single interim step is longer than three calendar years each (with a calendar year beginning on January 1 and ending on December 31), and your last interim step is no longer than two calendar years (with a calendar year beginning on January 1 and ending on December 31).

Interim step 1 means the period of three calendar years from January 1, 2022, to December 31, 2024.

Interim step 2 means the period of three calendar years from January 1, 2025, to December 31, 2027.

Interim step 3 means the period of two calendar years from January 1, 2028, to December 31, 2029.

ISO conditions means 288 Kelvin (15° C), 60 percent relative humidity and 101.3 kilopascals pressure.

M&V report means a report that meets the requirements of §60.5835].

Mechanical output means the useful mechanical energy that is not used to operate the affected facility, generate electricity and/or thermal output, or to enhance the performance of the affected facility. Mechanical energy measured in horsepower hour must be converted into MWh by multiplying it by 745.7 then dividing by 1,000,000.

Nameplate capacity means, starting from the initial installation, the maximum rated output of a generator, prime mover, or other electric power production equipment under specific conditions designated by the manufacturer is capable of producing on a steady-state basis and during continuous operation (when not restricted by seasonal or other deratings) as of such installation as specified by the manufacturer of the equipment, starting from the completion of any subsequent physical change resulting in an increase in the maximum electrical generating output that the equipment is capable of producing on a steady-state basis and during continuous operation (when not restricted by seasonal or other deratings), such increased maximum amount (in MWe, rounded to the nearest tenth) as of such completion as specified by the person conducting the physical change.

Natural gas means a fluid mixture of hydrocarbons (e.g., methane, ethane, or propane), composed of at least 70 percent methane by volume or that has a gross calorific value between 35 and 41 megajoules (MJ) per dry standard cubic meter (950 and 1,100 Btu per dry standard cubic foot), that maintains a gaseous State under ISO conditions. In addition, natural gas contains 20.0 grains or less of total sulfur per 100 standard cubic feet. Finally, natural gas does not include the following gaseous fuels: landfill gas, digester gas, refinery gas, sour gas, blast furnace gas, coal-derived gas, producer gas, coke oven gas, or any gaseous fuel produced in a process which might result in highly variable sulfur content or heating value.

Net allowance export/import means a net transfer of CO_2 allowances during an interim step, the interim period, or final reporting period which represents the net number of CO_2 allowances (issued by a respective State) that are transferred from the compliance accounts of affected EGUs in that state to the compliance accounts of affected EGUs in another State. This net transfer is determined based on compliance account holdings at the end of the plan performance period. Compliance account holdings, as used here, refer to the number of CO_2 allowances surrendered for compliance during a plan performance period, as well as any remaining CO_2 allowances held in a compliance account as of the end of a plan performance period.

Net-electric output means the amount of gross generation the generator(s) produce (including, but not limited to, output from steam turbine(s), combustion turbine(s), and gas expander(s)), as measured at the generator terminals, less the electricity used to operate the plant (i.e., auxiliary loads); such uses include fuel handling equipment, pumps, fans, pollution control equipment, other electricity needs, and transformer losses as measured at the transmission side of the step up transformer (e.g., the point of sale).

Net energy output means:

(1) The net electric or mechanical output from the affected facility, plus 100 percent of the useful thermal output measured relative to SATP conditions that is not used to generate additional electric or mechanical output or to enhance the performance of the unit (e.g., steam delivered to an industrial process for a heating application).

(2) For combined heat and power facilities where at least 20.0 percent of the total gross or net energy output consists of electric or direct mechanical output and at least 20.0 percent of the total gross or net energy output consists of useful thermal output on a 12-operating month rolling average basis, the net electric or mechanical output from the affected EGU divided by 0.95, plus 100 percent of the useful thermal output; (e.g., steam delivered to an industrial process for a heating application).

Qualified biomass means a biomass feedstock that is demonstrated as a method to control increases of CO_2 levels in the atmosphere.

Standard ambient temperature and pressure (SATP) conditions means 298.15 Kelvin (25° C, 77 °F)) and 100.0 kilopascals (14.504 psi, 0.987 atm) pressure. The enthalpy of water at SATP conditions is 50 Btu/lb.

State agent means an entity acting on behalf of the State, with the legal authority of the State.

State measures means measures that the State adopts and implements as a matter of State law. Such measures are enforceable only per State law, and are not included in and codified as part of the federally enforceable State plan.

Stationary combustion turbine means all equipment, including but not limited to the turbine engine, the fuel, air, lubrication and exhaust gas systems, control systems (except emissions control equipment), heat recovery system, fuel compressor, heater, and/or pump, post-combustion emissions control technology, and any ancillary components and sub-components comprising any simple cycle stationary combustion turbine, any combined cycle combustion turbine, and any combined heat and power combustion turbine based system plus any integrated equipment that provides electricity or useful thermal output to the combustion turbine engine, heat recovery system or auxiliary equipment. Stationary means that the combustion turbine is not self-propelled or intended to be propelled while performing its function. It may, however, be mounted on a vehicle for portability. If a stationary combustion turbine burns any solid fuel directly it is considered a steam generating unit.

Steam generating unit means any furnace, boiler, or other device used for combusting fuel and producing steam (nuclear steam generators are not included) plus any integrated equipment that provides electricity or useful thermal output to the affected facility or auxiliary equipment.

Uprate means an increase in available electric generating unit power capacity due to a system or equipment modification.

Useful thermal output means the thermal energy made available for use in any heating application (e.g., steam delivered to an industrial process for a heating application, including thermal cooling applications) that is not used for electric generation, mechanical output at the affected EGU, to directly enhance the performance of the affected EGU (e.g., economizer output is not useful thermal output, but thermal energy used to reduce fuel moisture is considered useful thermal output), or to supply energy to a pollution control device at the affected EGU. Useful thermal output for affected EGU(s) with no condensate return (or other thermal energy input to the affected EGU(s)) or where measuring the energy in the condensate (or other thermal energy input to the affected EGU(s)) would not meaningfully impact the emission rate calculation is measured against the energy in the thermal output at SATP conditions. Affected EGU(s) with meaningful energy in the condensate return (or other thermal energy input to the affected EGU) must measure the energy in the condensate and subtract that energy relative to SATP conditions from the measured thermal output.

Valid data means quality-assured data generated by continuous monitoring systems that are installed, operated, and maintained according to part 75 of this chapter. For CEMS, the initial certification requirements in §75.20 of this chapter and appendix A to part 75 of this chapter must be met before quality-assured data are reported under this subpart; for on-going quality assurance, the daily, quarterly, and semiannual/annual test requirements in sections 2.1, 2.2, and 2.3 of appendix B to part 75 of this chapter must be met and the data validation criteria in sections 2.1.5, 2.2.3, and 2.3.2 of appendix B to part 75 of this chapter apply. For fuel flow meters, the initial certification requirements in section 2.1.5 of appendix D to part 75 of this chapter must be met before quality-assured data are reported under this subpart (except for qualifying commercial billing meters under section 2.1.4.2 of appendix D), and for on-going quality assurance, the provisions in section 2.1.6 of appendix D to part 75 of this chapter apply (except for qualifying commercial billing meters).

Waste-to-Energy means a process or unit (e.g., solid waste incineration unit) that recovers energy from the conversion or combustion of waste stream materials, such as municipal solid waste, to generate electricity and/or heat.

Table 1 to Subpart UUUU of Part 60—CO_2 Emission Performance Rates

(Pounds of CO_2 per Net MWh)

Affected EGU	Interim Rate	Final Rate
Steam generating unit or integrated gasification combined cycle (IGCC)	1,534	1,305
Stationary combustion turbine	832	771

The White House

Office of the Press Secretary

For Immediate Release March 28, 2017

Presidential Executive Order on Promoting Energy Independence and Economic Growth

EXECUTIVE ORDER

\- - - - - - -

PROMOTING ENERGY INDEPENDENCE AND ECONOMIC GROWTH

By the authority vested in me as President by the Constitution and the laws of the United States of America, it is hereby ordered as follows:

Section 1. Policy. (a) It is in the national interest to promote clean and safe development of our Nation's vast energy resources, while at the same time avoiding regulatory burdens that unnecessarily encumber energy production, constrain economic growth, and prevent job creation. Moreover, the prudent development of these natural resources is essential to ensuring the Nation's geopolitical security.

(b) It is further in the national interest to ensure that the Nation's electricity is affordable, reliable, safe, secure, and clean, and that it can be produced from coal, natural gas, nuclear material, flowing water, and other domestic sources, including renewable sources.

(c) Accordingly, it is the policy of the United States that executive departments and agencies (agencies) immediately review existing regulations that potentially burden the development or use of domestically produced energy resources and appropriately suspend, revise, or rescind those that unduly burden the development of domestic energy resources beyond the degree necessary to protect the public interest or otherwise comply with the law.

(d) It further is the policy of the United States that, to the extent permitted by law, all agencies should take appropriate actions to promote clean air and clean water for the American people, while also respecting the proper roles of the Congress and the States concerning these matters in our constitutional republic.

(e) It is also the policy of the United States that necessary and appropriate environmental regulations comply with the law, are of greater benefit than cost, when permissible, achieve environmental improvements for the American people, and are developed through transparent processes that employ the best available peer-reviewed science and economics.

Sec. 2. Immediate Review of All Agency Actions that Potentially Burden the Safe, Efficient Development of Domestic Energy Resources. (a) The heads of agencies shall review all existing regulations, orders, guidance documents, policies, and any other similar agency actions (collectively, agency actions) that potentially burden the development or use of domestically produced energy resources, with particular attention to oil, natural gas, coal, and nuclear energy resources. Such review shall not include agency actions that are mandated by law, necessary for the public interest, and consistent with the policy set forth in section 1 of this order.

(b) For purposes of this order, "burden" means to unnecessarily obstruct, delay, curtail, or otherwise impose significant costs on the siting, permitting, production, utilization, transmission, or delivery of energy resources.

(c) Within 45 days of the date of this order, the head of each agency with agency actions described in subsection (a) of this section shall develop and submit to the Director of the Office of Management and Budget (OMB Director) a plan to carry out the review required by subsection (a) of this section. The plans shall also be sent to the Vice President, the Assistant to the President for Economic Policy, the Assistant to the President for Domestic Policy, and the Chair of the Council on Environmental Quality. The head of any agency who determines that such agency does not have agency actions described in subsection (a) of this section shall submit to the OMB Director a written statement to that effect and, absent a determination by the OMB Director that such agency does have agency actions described in subsection (a) of this section, shall have no further responsibilities under this section.

(d) Within 120 days of the date of this order, the head of each agency shall submit a draft final report detailing the agency actions described in subsection (a) of this section to the Vice President, the OMB Director, the Assistant to the President for Economic Policy, the Assistant to the President for Domestic Policy, and the Chair of the Council on Environmental Quality. The report shall include specific recommendations that, to the extent permitted by law, could alleviate or eliminate aspects of agency actions that burden domestic energy production.

(e) The report shall be finalized within 180 days of the date of this order, unless the OMB Director, in consultation with the other officials who receive the draft final reports, extends that deadline.

(f) The OMB Director, in consultation with the Assistant to the President for Economic Policy, shall be responsible for coordinating the recommended actions included in the agency final reports within the Executive Office of the President.

(g) With respect to any agency action for which specific recommendations are made in a final report pursuant to subsection (e) of this section, the head of the relevant agency shall, as soon as practicable, suspend, revise, or rescind, or publish for notice and comment proposed rules suspending, revising, or rescinding, those actions, as appropriate and consistent with law. Agencies shall endeavor to coordinate such regulatory reforms with their activities undertaken in compliance with Executive Order 13771 of January 30, 2017 (Reducing Regulation and Controlling Regulatory Costs).

Sec. 3. Rescission of Certain Energy and Climate-Related Presidential and Regulatory Actions. (a) The following Presidential actions are hereby revoked:

(i) Executive Order 13653 of November 1, 2013 (Preparing the United States for the Impacts of Climate Change);

(ii) The Presidential Memorandum of June 25, 2013 (Power Sector Carbon Pollution Standards);

(iii) The Presidential Memorandum of November 3, 2015 (Mitigating Impacts on Natural Resources from Development and Encouraging Related Private Investment); and

(iv) The Presidential Memorandum of September 21, 2016 (Climate Change and National Security).

(b) The following reports shall be rescinded:

(i) The Report of the Executive Office of the President of June 2013 (The President's Climate Action Plan); and

(ii) The Report of the Executive Office of the President of March 2014 (Climate Action Plan Strategy to Reduce Methane Emissions).

(c) The Council on Environmental Quality shall rescind its final guidance entitled "Final Guidance for Federal Departments and Agencies on Consideration of Greenhouse Gas Emissions and the Effects of Climate Change in National Environmental Policy Act Reviews," which is referred to in "Notice of Availability," 81 Fed. Reg. 51866 (August 5, 2016).

(d) The heads of all agencies shall identify existing agency actions related to or arising from the Presidential actions listed in subsection (a) of this section, the reports listed in subsection (b) of this section, or the final guidance listed in subsection (c) of this section. Each agency shall, as soon as practicable, suspend, revise, or rescind, or publish for notice and comment proposed rules suspending, revising, or rescinding any such actions, as appropriate and consistent with law and with the policies set forth in section 1 of this order.

Sec. 4. Review of the Environmental Protection Agency's "Clean Power Plan" and Related Rules and Agency Actions. (a) The Administrator of the Environmental Protection Agency (Administrator) shall immediately take all steps necessary to review the final rules set forth in subsections (b)(i) and (b)(ii) of this section, and any rules and guidance issued pursuant to them, for consistency with the policy set forth in section 1 of this order and, if appropriate, shall, as soon as practicable, suspend, revise, or rescind the guidance, or publish for notice and comment proposed rules suspending, revising, or rescinding those rules. In addition, the Administrator shall immediately take all steps necessary to review the proposed rule set forth in subsection (b)(iii) of this section, and, if appropriate, shall, as soon as practicable, determine whether to revise or withdraw the proposed rule.

(b) This section applies to the following final or proposed rules:

(i) The final rule entitled "Carbon Pollution Emission Guidelines for Existing Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64661 (October 23, 2015) (Clean Power Plan);

(ii) The final rule entitled "Standards of Performance for Greenhouse Gas Emissions from New, Modified, and Reconstructed Stationary Sources: Electric Utility Generating Units," 80 Fed. Reg. 64509 (October 23, 2015); and

(iii) The proposed rule entitled "Federal Plan Requirements for Greenhouse Gas Emissions From Electric Utility Generating Units Constructed on or Before January 8, 2014; Model Trading Rules; Amendments to Framework Regulations; Proposed Rule," 80 Fed. Reg. 64966 (October 23, 2015).

(c) The Administrator shall review and, if appropriate, as soon as practicable, take lawful action to suspend, revise, or rescind, as appropriate and consistent with law, the "Legal Memorandum Accompanying Clean Power Plan for Certain Issues," which was published in conjunction with the Clean Power Plan.

(d) The Administrator shall promptly notify the Attorney General of any actions taken by the Administrator pursuant to this order related to the rules identified in subsection (b) of this section so that the Attorney General may, as appropriate, provide notice of this order and any such action to any court with jurisdiction over pending litigation related to those rules, and may, in his discretion, request that the court stay the litigation or otherwise delay further litigation, or seek other appropriate relief consistent with this order, pending the completion of the administrative actions described in subsection (a) of this section.

Sec. 5. Review of Estimates of the Social Cost of Carbon, Nitrous Oxide, and Methane for Regulatory Impact Analysis. (a) In order to ensure sound regulatory decision making, it is essential that agencies use estimates of costs and benefits in their regulatory analyses that are based on the best available science and economics.

(b) The Interagency Working Group on Social Cost of Greenhouse Gases (IWG), which was convened by the Council of Economic Advisers and the OMB Director, shall be disbanded, and the following documents issued by the IWG shall be withdrawn as no longer representative of governmental policy:

(i) Technical Support Document: Social Cost of Carbon for Regulatory Impact Analysis Under Executive Order 12866 (February 2010);

(ii) Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis (May 2013);

(iii) Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis (November 2013);

(iv) Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis (July 2015);

(v) Addendum to the Technical Support Document for Social Cost of Carbon: Application of the Methodology to Estimate the Social Cost of Methane and the Social Cost of Nitrous Oxide (August 2016); and

(vi) Technical Update of the Social Cost of Carbon for Regulatory Impact Analysis (August 2016).

(c) Effective immediately, when monetizing the value of changes in greenhouse gas emissions resulting from regulations, including with respect to the consideration of domestic versus international impacts and the consideration of appropriate discount rates, agencies shall ensure, to the extent permitted by law, that any such estimates are consistent with the guidance contained in OMB Circular A-4 of September 17, 2003 (Regulatory Analysis), which was issued after peer review and public comment and has been widely accepted for more than a decade as embodying the best practices for conducting regulatory cost-benefit analysis.

Sec. 6. Federal Land Coal Leasing Moratorium. The Secretary of the Interior shall take all steps necessary and appropriate to amend or withdraw Secretary's Order 3338 dated January 15, 2016 (Discretionary Programmatic Environmental Impact Statement (PEIS) to Modernize the Federal Coal Program), and to lift any and all moratoria on Federal land coal leasing activities related to Order 3338. The Secretary shall commence Federal coal leasing activities consistent with all applicable laws and regulations.

Sec. 7. Review of Regulations Related to United States Oil and Gas Development. (a) The Administrator shall review the final rule entitled "Oil and Natural Gas Sector: Emission Standards for New, Reconstructed, and Modified Sources," 81 Fed. Reg. 35824 (June 3, 2016), and any rules and guidance issued pursuant to it, for consistency with the policy set forth in section 1 of this order and, if appropriate, shall, as soon as practicable, suspend, revise, or rescind the guidance, or publish for notice and comment proposed rules suspending, revising, or rescinding those rules.

(b) The Secretary of the Interior shall review the following final rules, and any rules and guidance issued pursuant to them, for consistency with the policy set forth in section 1 of this order and, if appropriate, shall, as soon as practicable, suspend, revise, or rescind the guidance, or publish for notice and comment proposed rules suspending, revising, or rescinding those rules:

(i) The final rule entitled "Oil and Gas; Hydraulic Fracturing on Federal and Indian Lands," 80 Fed. Reg. 16128 (March 26, 2015);

(ii) The final rule entitled "General Provisions and Non-Federal Oil and Gas Rights," 81 Fed. Reg. 77972 (November 4, 2016);

(iii) The final rule entitled "Management of Non Federal Oil and Gas Rights," 81 Fed. Reg. 79948 (November 14, 2016); and

(iv) The final rule entitled "Waste Prevention, Production Subject to Royalties, and Resource Conservation," 81 Fed. Reg. 83008 (November 18, 2016).

(c) The Administrator or the Secretary of the Interior, as applicable, shall promptly notify the Attorney General of any actions taken by them related to the rules identified in subsections (a) and (b) of this section so that the Attorney General may, as appropriate, provide notice of this order and any such action to any court with jurisdiction over pending litigation related to those rules, and may, in his discretion, request that the court stay the litigation or otherwise delay further litigation, or seek other appropriate relief consistent with this order, until the completion of the administrative actions described in subsections (a) and (b) of this section.

Sec. 8. General Provisions. (a) Nothing in this order shall be construed to impair or otherwise affect:

(i) the authority granted by law to an executive department or agency, or the head thereof; or

(ii) the functions of the Director of the Office of Management and Budget relating to budgetary, administrative, or legislative proposals.

(b) This order shall be implemented consistent with applicable law and subject to the availability of appropriations.

(c) This order is not intended to, and does not, create any right or benefit, substantive or procedural, enforceable at law or in equity by any party against the United States, its departments, agencies, or entities, its officers, employees, or agents, or any other person.

DONALD J. TRUMP

THE WHITE HOUSE,
March 28, 2017.

E&E NEWS

The Clean Power Plan faces attacks by the Trump administration and a long and complicated legal fight

President Trump's White House victory significantly dimmed the outlook for U.S. EPA's Clean Power Plan. Trump will try to unravel the rule along with other environmental regulations that he deems burdensome.

He has directed EPA to review or rescind the rule, which will take time and face lawsuits from environmental groups. The Trump administration also could try to rewrite a finding that CO2 is a dangerous air pollutant. That would face substantial legal hurdles.

Implementation of the Clean Power Plan has been on hold since the Supreme Court in February 2016 froze the rule until legal battles were resolved. More than half of states and numerous industry groups are challenging the regulation. Dozens of lawyers faced off in the U.S. Court of Appeals for the District of Columbia Circuit in oral arguments in September 2016. If the court issues a decision, parties on the losing side may appeal to the Supreme Court. The court in late April agreed to put the case on hold for 60 days, until the end of June – partially granting a Trump administration request to freeze proceedings indefinitely. Now the judges are considering arguments from both sides on whether to put a long-term hold on the case or simply close it.

The Clean Power Plan case has seen several plot twists. The D.C. Circuit in May 2016 decided to bypass review by a panel of three judges and hear the case en banc -- with the full court. In February 2016, the Supreme Court blocked EPA from implementing the rule after the D.C. Circuit had declined to issue a stay. For many, that signaled doom. But then Justice Antonin Scalia died, leaving an opening on the bench. Scalia had cast the pivotal vote by which the Supreme Court decided 5-4 to halt the Clean Power Plan, giving critics reason to believe justices would torpedo the rule along those same lines.

Litigation Timeline

The Clean Power Plan has been in and out of federal court since before it was even finalized. Lawsuits challenging the final rule are now consolidated at the D.C. Circuit and may ultimately land at the Supreme Court. In the meantime, the rule remains frozen, and state compliance deadlines are no longer certain.

JUNE 2014

U.S. EPA releases draft Clean Power Plan.

2014 - 2015

Industry and states file suit in D.C. Circuit to block draft rule. Court rejects early challenges as premature.

AUGUST 2015

EPA announces final rule. (States would have been required to submit initial plans in 2016 and final plans in 2018. The compliance period would have begun in 2022 and ramped up through 2030.)

OCTOBER 2015

Clean Power Plan is published in *Federal Register*.

LATE 2015 - EARLY 2016

States and industry sue and ask for stay. D.C. Circuit declines to stay rule.

FEBRUARY 2016

U.S. Supreme Court grants stay, pending D.C. Circuit litigation.

SEPTEMBER 2016

D.C. Circuit hears oral arguments en banc, bypassing planned review by a three-judge panel.

2016 - 2018 (PRE-STAY)

State plans due.

EARLY 2017

D.C. Circuit expected to issue decision. Losing side may appeal to the Supreme Court.

2017

White House begins process to unravel rule.

2017

President Trump directed the Justice Department to ask the court to forego or postpone consideration of the Clean Power Plan.

MAY 2017

Court freezes litigation for 60 days, until the end of June.

2016 Gas Outlook

Natural Gas Supply, Demand, Capacity and Prices in the Pacific Northwest

Projections through October 2026

This report, compiled by the Northwest Gas Association (NWGA) and its members, provides a consensus industry perspective of the Pacific Northwest's current and projected natural gas supply, demand, prices and delivery capabilities through 2026. The Pacific Northwest in this case includes British Columbia (BC) and the U.S. states of Washington, Oregon and Idaho. Additional information, including white papers on specific natural gas topics, can be found at www.nwga.org.

NWGA
NORTHWEST GAS ASSOCIATION

What's New

The golden age of natural gas continues and appears to be gaining longevity. This means consumers could continue to enjoy low prices and ample supply for decades.

Yet, as the good news about natural gas endures, the market is causing many to scratch their heads. Not much has changed…but everything is different. Despite historic low prices and dropping rig counts, North American production actually increased in 2015 and supply has remained plentiful. On the demand side, consumers are enjoying the resulting cost savings, but demand growth from all sectors has been slower than anticipated – a trend we also noted last year. While there are explanations for these incongruities, the general take-away is this: We have lots of affordable natural gas and will for the foreseeable future. Perhaps the biggest difference today is the imperative we have to make the case that natural gas is a foundation fuel, an energy, economic and environmental solution. The question is, are we fully capitalizing on the potential benefits of this abundant, low-cost, clean-burning resource, given readily available technology to do so? For instance, opportunities for the direct use of natural gas in homes and businesses remain and transportation uses have barely been tapped.

Not much has changed . . . but everything is different

Natural gas has historically been and will continue to be a bargain among energy resources. According to the U.S. Energy Information Administration (EIA), natural gas averaged more than $4/Dekatherm (Dth)[1] from 1981-2000 in real dollars ($2015); was well under $3/Dth in 2015 and is projected to reach $5/Dth by 2025 and remain there through 2040.[2] Weather driven price volatility may occur, however, especially if large loads materialize in the region. That is why it remains important for providers to have access to and make use of a variety of tools to prudently manage their natural gas purchases.

In the Pacific Northwest, according to the EIA, natural gas utility customers saw the cost of the commodity portion of their bills drop by almost 50 percent in 2015 over what they would have paid in 2008. Yet demand growth in most sectors is tepid at best, despite a decent uptick in the region's economy.

Also, 2015 saw our region burn more natural gas than ever before to generate electricity, largely due to a very

---

[1] A Dth is a measure of energy content representing one million British Thermal Units (Btu). A Mcf is a volumetric measure representing 1,000 cubic ft. While the energy content of a Mcf varies according to a variety of factors, it is roughly equivalent to a Dth (typically 0.95 to 1.05 Dth per Mcf). We use volumetric measures (thousand, million and billion cubic feet; Mcf, MMcf, Bcf) interchangeably with energy measures (dekatherm, thousand dekatherm, million dekatherm; Dth, MDth, MMDth).

[2] EIA, *Natural Gas Spot and Futures Prices,* July, 2016; EIA, *2016 Annual Energy Outlook,* July, 2016

warm and dry water year. Gas for generation remains the only sector showing material growth. Regional electric utilities continue to add gas-fired generation to their portfolios out of a recognition that gas plants provide an immediate, cost-effective means to reduce greenhouse gas (GHG) emissions;[3] deliver an on-demand supply to support variable renewable resources such as wind and solar; and build reliable, affordable base load assets when they become necessary. For instance, construction of a 440-megawatt (MW) Portland General Electric (PGE) natural gas base load plant is under way in Boardman, OR, joining a flexible dispatch 220-MW plant that went online in 2014. Others may be planned as coal-fired generation is retired in the region.

In the industrial sector, large natural gas users are still considering locating or expanding in the Northwest, including an LNG export facility in Coos Bay, OR and methanol refineries proposed in Clatskanie, OR, and the Port of Kalama, WA. But industrial demand growth in 2015 was nearly nonexistent. Unless and until these plans are finalized, we project almost no additional growth in regional industrial loads.

While there will be ample natural gas to serve whatever demand emerges, one question is whether there will be enough capacity to move the supply from where its produced to where it is needed. The seas are calm right now, but an inflection point could happen if some combination of LNG export, methanol and new gas-fired power generation loads emerge. This Outlook examines the potential affect that new large loads could have on regional infrastructure capacity.

We have updated data in this 2016 Outlook, but most key conclusions are similar to last year. Most of the trends identified in the 2015 Outlook continue to be relevant. Where appropriate, revised analyses and updated tables/graphics provide details of what's new.

[3] Natural gas emits about 50% less carbon dioxide as coal when burned in power plants and 25% less than gasoline or diesel when used for vehicle fuel. http://www.eia.gov/tools/faqs/faq.cfm?id=73&t=11

Regional Economic Outlook

The U.S. and Canada continue to grow despite headwinds created by low energy prices and sputtering growth outside of North America. That being said, growth in both countries is far from booming. An increasing number of forecasters in the public and private sectors see U.S. GDP growth in the low 2% range for 2016 and 2017. In Canada, growth is forecasted to come in under 2% in 2016 and slightly above 2% in 2017.

Overall Inflation in both countries is expected to be below 2% in 2016, and then rising to around 2% by 2017. Beyond 2017, both market-based and professional forecasts see inflation near the 2% targets of the Federal Reserve (the Fed) and the Bank of Canada (BOC). Broadly speaking, the U.S. and Canada are slipping into a prolonged "two-two" growth pattern — that is, annual 2% growth in both output and prices.

Moderate national growth, weak external growth, and subdued inflation pressures will keep the Fed and BOC cautious about the timing of any future interest rate increases. This, along with low oil prices, will help keep the dollar strong relative to the loonie.

However, diverging from the U.S., Canada's new government will embark on an expansionary fiscal policy in 2016. This will provide benefits on both sides of the border. Unfortunately, given America's somewhat eccentric political environment, U.S. fiscal policy will remain sidelined for the current election cycle.

In the U.S. Pacific Northwest (PNW), Idaho, Oregon and Washington continue to outperform the U.S., thanks to continued strong growth in the major metropolitan areas. However, the PNW's smaller metropolitan areas are also showing relatively strong growth. Leading indicators produced by the Federal Reserve Bank of Philadelphia suggest the PNW will continue to outperform the U.S. through the rest of this year. Specifically, PNW employment growth will likely exceed U.S. growth in 2016, with U.S. growth expected to be just under 2%. Excluding manufacturing, employment growth will continue to be broad-based in terms of sector.

Like the U.S. PNW, British Columbia (BC) also continues to outperform Canada's national economy — in 1Q 2016, BC employment growth was 3% compared to 0.7% nationally. Growth is centered in the Vancouver and Victoria metropolitan areas with strength in both the goods and service sectors. In 2016, Canadian forecasters see BC's employment growth to be nearly twice the expected national level of less than 1%.

External risks to the U.S. and Canadian economies are weak growth and political instability outside of North America. Of particular concern is slower growth in China and Brazil, and repercussions of the U.K.'s recent decision to exit from the European Union. In this context, another sharp drop in global energy prices would hit investment spending in both countries. More regionally, BC's housing market continues to defy expectations in terms of price appreciation. Of particular concern is the Vancouver housing market. A sharp housing contraction would be a significant drag on BC growth.

2016 GAS OUTLOOK – Supply

Key Conclusions

- North America's abundant natural gas resource, made available by accessing shale rock formations deep underground, continues to transform the energy landscape. (See Figure S1.)
- Enhanced production technologies continue to safely, responsibly and more cost-effectively deliver results that exceed expectations, despite lower natural gas and oil prices, declining rig counts, reallocation of capital, and stronger regulation.
- Pacific Northwest natural gas consumers benefit from their proximity to the prolific Western Canadian Sedimentary Basin (WCSB) and U.S. Rocky Mountain (Rockies) natural gas-producing regions.

Summary

In 2015, the Potential Gas Committee (PGC) released an updated estimate of Total Potential Natural Gas Resource in the U.S. The estimate of 2,515 trillion cubic feet (Tcf) was the largest in its half-century history of issuing this biennial report. The 2014 estimate exceeded the 2012 assessment by more than 5 percent, clearly documenting the ongoing benefits from the geological feat of shale gas mining. In 2015, shale gas production represented 53 percent of U.S. dry gas production, up from 10 percent in 2007.[4]

In Canada, "ultimate potential" and conventional natural gas resources are estimated at 1,087 Tcf, of which nearly 80 percent (855 Tcf), is found in the WCSB.[5]

[4] *The Growth of U.S. Natural Gas*, EIA presentation, June 15, 2015. http://www.eia.gov/conference/2015/pdf/presentations/staub.pdf

[5] *Canada's Energy Future 2016: Energy Supply and Demand Projections to 2040, Chapter 6,* NEB, January, 2016.

The U.S. and Russia have long been the largest producers of natural gas in the world, with the U.S. most often chasing Russia for bragging rights as Number 1. In recent years, Russian production appears to be on the wane while U.S production volumes are mind-boggling. According to the EIA and Statistics Canada, total North American marketable production averaged a record high of 99.5 Bcf/day in February, 2016. Average North American production for the year in 2015 was 93.4 Bcf/d, an increase of 4.3 Bcf/d or almost 5 percent over 2014.[6]

These production increases occurred in spite of a sharp drop in active drilling rigs. According to Baker Hughes' North America Rig Count, there was an average of 1,840 natural gas drilling rigs operating in the U.S. and Canada in September 2008. (This excludes oil rigs; the primary distinction between the two rig types is the targeted resource, however both produce natural gas.) In September 2015, there was an average of 308 natural gas rigs operating in the U.S. and Canada. That number had declined to 131 natural gas rigs as of the week of July 8, 2016.

In its July 2016 Short Term Energy Outlook, the EIA expects that natural gas production will increase 1 percent in 2016 and by 2.4 percent in 2017. Over the longer term, the EIA forecasts production to increase more than 50 percent by 2040.[7] As a result, the U.S. is expected to switch from a modest importer to a net exporter of natural gas in 2017.

What's going on here? Drilling technologies continue to advance at a dizzying pace, enabling producers to cost-effectively squeeze out more molecules of gas from every well. For example, producers in the Haynesville Shale play were recently successful in implementing "supersizing" techniques – extending the lateral portion of a well by thousands more feet.[8] Besides boosting volume and efficiency, which allows producers to realize profits even in a low price environment, this technology reduces the need to build more wellheads and further minimizes the industry's environmental footprint. Simply put, there's plenty of innovation going on beneath the surface.

8 *Modern Gas Drilling is Likely to Ensure Low Prices for Years*, Wall Street Journal, Sept. 2, 2015.

The Pacific Northwest is served by two prolific sources of supply: the WCSB and the U.S. Rockies, predominately, Colorado, Utah and Wyoming. Together these regions produced an average of 24.3 Bcf/d in 2015,[9] or more than 30 percent of North America's total natural gas supply. Production from these two areas is projected to approach a combined 30 Bcf/d by 2025.[10]

Northwest consumers benefit from access to different supply basins because shippers are able to flow from the regions that offer the best value at the time. Figure S5 is not a complete picture as it documents flows on one of the two pipelines serving the region, but it is nonetheless representative. For instance, in 2007 more than half the gas delivered to Northwest Pipeline shippers was sourced from the Rockies. The share of Canadian gas serving the Northwest has increased over the last several years as the price differential between Rockies and Canadian gas has widened, due in part to the growth in northern BC production.

Supply Variables

Key issues identified in prior Outlooks as having the potential to affect natural gas supplies are still relevant. They include:

- Development of new or improved well-completion technologies and techniques.
- The effect of the current low natural gas and oil prices environment on future production.
- The potential impact environmental concerns may have on natural gas production and pipeline expansions.
- Adequate access to gas supply, e.g., pipeline expansions and their timing.
- Local and national legislation or regulations affecting production/extraction processes.

Responsible Gas Production

The arrival of new and abundant natural gas supplies has changed the nation's energy picture. It also has brought new attention to gas production methods. Fracking – an abbreviation for hydraulic fracturing – is now a common term in our country's energy debate.

In fact, hydraulic fracturing isn't new: oil and gas developers have been using it for more than 60 years. Hydraulic fracturing uses water, sand and small amounts of chemicals to break open solid rock, releasing trapped fuels. According to the U.S. Department of Energy (DOE), more than 2 million wells have been hydraulically fractured to date and about 95 percent of new wells drilled today are fractured.

So, why are we only hearing about it now?

In the last 10 years, engineers learned how to combine hydraulic fracturing with another time-tested construction practice: horizontal drilling. Conventional drilling uses fracturing along the length of a vertical well. Now it's possible to send fracturing equipment horizontally along a shale deposit, releasing natural gas in larger volumes than ever before.

The combination of these technologies has helped the U.S. become the world's largest natural gas producer.

As with any industrial process, gas producers experienced a learning curve in terms of environmental protection. But as the industry and regulators have learned more about these processes, drillers are continually improving their operations. Some areas of interest are:

- **Water use.** Increasingly, gas producers are recycling the water they use to fracture rock. Some are starting with non-potable water, and the industry is studying ways to eliminate water entirely from the fracturing process.
- **Groundwater.** Groundwater protection is one of the highest priorities of drilling engineers. Without proper well casings, drilling fluids and natural gas can leak into the groundwater. That's why the American Petroleum Institute has established detailed standards for well casings, and state regulators closely inspect well construction. It's important to note that hydraulic fracturing itself has not been associated with groundwater contamination.
- **Disposal.** The industry and regulators have established practices to prevent spills from water emerging from wells and to protect municipal water treatment facilities.
- **Methane.** The industry has been working hard to reduce methane emissions from gas production. A recent U.S. Environmental Protection Agency (EPA) study found that total methane emissions from gas production are 38 percent lower than they were in 2005 – although gas production grew by 26 percent during that time.
- **Earthquakes.** Increased gas production has been associated with new earthquake activity. The technology exists to help well developers avoid earthquakes and government oversight is increasingly helpful. For instance, BC has robust regulations concerning seismic activity related to well-drilling and completion. Additionally, the industry has backed new regulations in gas-producing states to reduce earthquake potential, and a new working group through the Interstate Oil & Gas Compact Commission and the Ground Water Protection Council is now focusing on this issue.

The rapid growth of gas production has spurred regulators and academics to learn more about the environmental impact of gas development. NWGA looks forward to emerging information and continued cooperation between the natural gas industry and state and federal regulators.

2016 GAS OUTLOOK – Prices

Key Conclusions

1. Spot prices and futures contracts for natural gas continue to reflect the sustained growth of North American natural gas production.
   - Northwest consumers continue to benefit from low natural gas prices, with forecasts below Henry Hub for the foreseeable future.
2. Long-term price forecasts are sharply lower than those made prior to the advent of shale.
3. Natural gas remains a price-competitive transportation fuel.

Summary

According to EIA historical data, the spot price of natural gas averaged $4.40/Dth from 1981 to 2000 when adjusted for inflation ($2015). The average spot price was $2.62/Dth in 2015 and is currently (as of July) $2.36/Dth in 2016, 46 percent lower than the 2014 average of $4.37/Dth. Monthly Henry Hub spot prices are forecast to remain at or below $3/Dth until 2017.[11] Residential and commercial natural gas customers in the Northwest saved almost $2 billion in 2014 compared to what they would have paid in 2007 (adjusted for inflation).[12] These prices demonstrate a continuing surplus of natural gas supply across North America due mostly to the unprecedented production from shale formations noted earlier.

Analysts continue to be bullish on the ability of the U.S. and Canada to develop and deliver low-priced natural gas for years to come, notwithstanding periodic weather related volatility and spikes during periods of high demand. That means consumers can expect to enjoy good economic value from natural gas for years to come. In fact, Henry Hub prices are not expected to rise much above $5/Dth ($2015) through 2040[13] and the long range outlook is sharply lower than it was prior to the advent of shale gas. (Figure P2). Furthermore, Northwest supply sources typically trade at a discount to North American benchmarks like the Henry Hub. The Northwest Power and Conservation Council corroborates this concept in its Fuel Price Forecast for the 7th Power Plan (Figure P2).

FIGURE P1. Historic Natural Gas Prices

[13] *EIA, 2016 Annual Energy Outlook*

Despite the recent sharp drop in oil prices, natural gas has maintained a roughly 3:1 price advantage over oil on a Btu basis. The differential has been as much as 8:1 (Figure P3). And natural gas is expected to become even more price competitive with diesel and gasoline as a transportation fuel into the future (Figure P4).

Price Variables

NWGA members are tracking a number of market dynamics that could influence natural gas prices going forward:

1. North American economic growth.
2. Pace of natural gas adoption for generation, industrial and transportation uses.
3. Future costs and/or permitting constraints resulting from new energy policies, environmental legislation and regulation.
4. Effect of new and improved production technologies.
5. Effect of infrastructure constraints on regional pricing.
6. Benefits and costs of North American natural gas (such as LNG) exports to premium overseas markets.

FIGURE P3. Natural Gas/Crude Oil Comparison

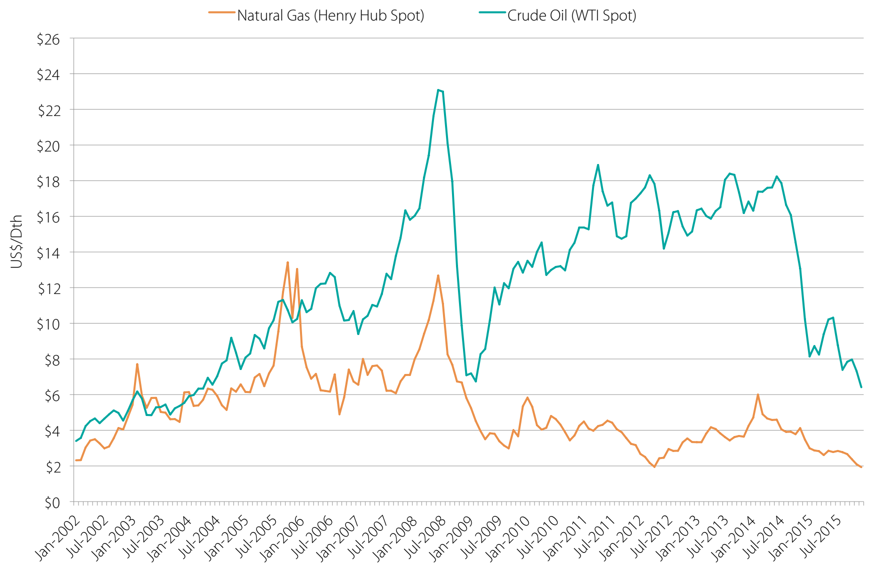

FIGURE P4. EIA Transportation Fuel Price Forecast, 2016 AEO Early Release

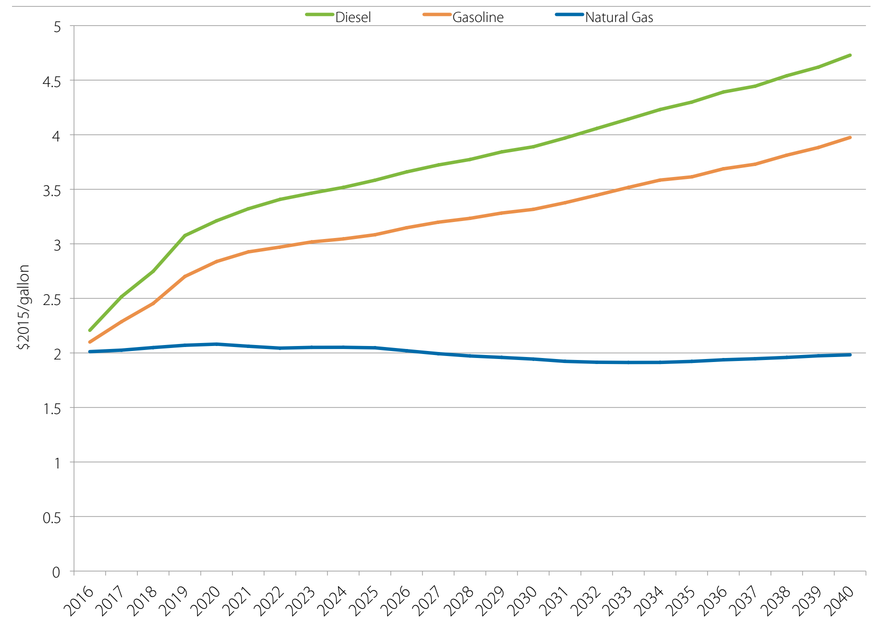


Oil Price Volatility

The downward trend in global oil prices that began in 2014 continued through the 2015-16 winter with a precipitous drop to under $30 a barrel – a 70 percent decline in 18 months and the lowest since 2003.

Persistent oversupply, made worse in January by Iran's increase in production following the removal of U.S. sanctions, combined with economic stagnation in Europe and economic slowing in China, created the perfect storm to make crude oil prices plummet. Drivers have certainly benefited at the pump, while producing companies and state/provinces dependent on oil revenues find themselves squeezed. Chevron, Royal Dutch Shell and BP have all announced layoffs; Alaska, Alberta, North Dakota and Texas are among those grappling with significant budgetary challenges.

The EIA predicts a decline in non-OPEC production globally in 2016, mainly due to American and Russian reductions, but increases in OPEC production, mainly from Iran. Still, it expects global oil inventory to continue to rise in the short term and prices to recover only slowly. According to the EIA's July 2016 Short-Term Energy Outlook, Brent oil prices (a global benchmark) are forecast to average $44 a barrel in 2016 and average $52 a barrel in 2017, presuming a slight uptick in demand and reduction in the supply glut. Nevertheless, industry analysts think it could be years before oil returns to $90 or $100 a barrel, the price that has been the norm over the last decade.

What do oil prices have to do with natural gas?Depressed oil prices cause companies to cut investments in production. Natural gas production is also affected since it is often associated with oil production. While natural gas volumes are expected to continue rising, the trend is for slower growth over the next few years (see Supply Section). Another impact is on natural gas as a transportation fuel. As noted in this section, the differential between natural gas and diesel/gasoline is expected to hold up and grow over time. Nevertheless, the precipitous decline in oil prices chilled the transition to natural gas as payback periods for investing in new and more expensive equipment lengthened.

2016 GAS OUTLOOK – Demand

Key Conclusions

1. Growth rates in the Pacific Northwest over this forecast period are a little lower than the 2015 Outlook.
2. A number of variables could significantly affect demand during the forecast period. This Outlook explores two plausible scenarios: some natural gas replacement of regional coal-fired generation along with accelerated industrial and transportation loads; and significant demand growth from LNG exports and major petrochemical developments.

Summary

Moderate economic growth in the Pacific Northwest is not translating into natural gas demand growth in the region. In fact, at 0.8 percent growth per year, we are projecting the slowest rate of growth since we began publishing the Outlook in 2004 (Table D1). This translates to cumulative growth of about 62 million Dth over the 10-year forecast horizon.

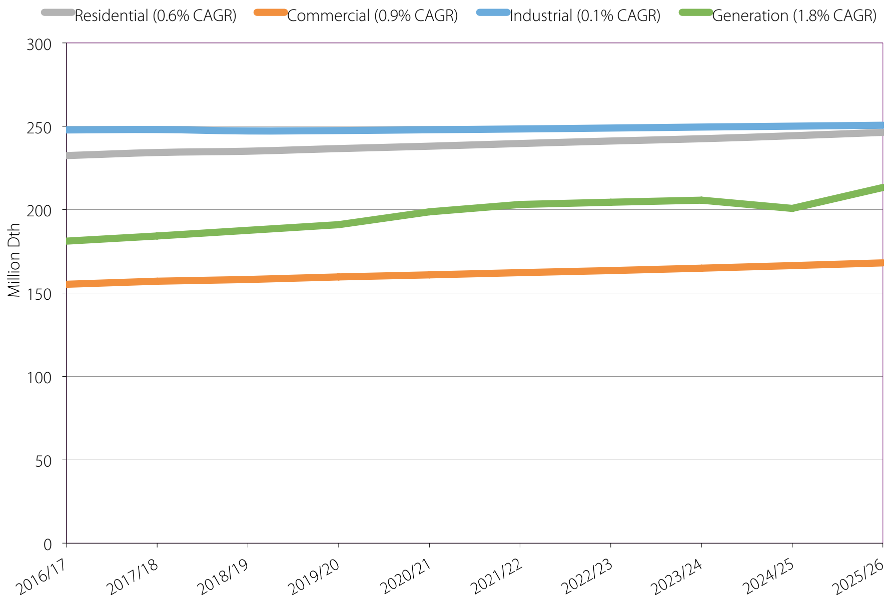
Figure D1 depicts forecasted natural gas load growth by economic sector. Core market (residential, commercial) demand is characterized by modest growth, as new customer additions are partly offset by declining use per customer of natural gas due to tighter building standards and more efficient appliances.

The "Great Recession" cost the region more than 20 percent of its industrial gas load between 2007 and 2012, although industry remains the largest user (Figure D2). Overall, there is almost no organic industrial demand growth throughout the forecast horizon (0.1 percent), reflecting both efficiency gains and a stable manufacturing sector. Proposals to add new industrial loads in the region continue to advance but associated volumes are not accounted for in the expected, low or high forecasts. Instead, we examine the potential impacts of these projects through a separate, accelerated demand scenario at the end of this section.

TABLE D1. Projected Regional Demand Growth through 2026

	Low		Expected		High	
	Annual Rate	Cumulative	Annual Rate	Cumulative	Annual Rate	Cumulative
Total	**0.4%**	**3.4%**	**0.8%**	**7.0%**	**1.0%**	**11.0%**
Residential	0.4%	3.7%	0.6%	5.6%	1.1%	9.1%
Commercial	0.5%	4.7%	0.9%	7.6%	1.4%	11.4%
Industrial	-0.3%	-2.6%	0.1%	1.1%	0.5%	4.2%
Generation	1.1%	9.2%	1.8%	15.1%	1.3%	11.0%

FIGURE D1. Projected Load Growth by Sector Through 2026



New gas-fired generation demand continues to account for the majority of forecast load growth in the region, though at a slower pace than in years past. While demand for natural gas to fuel generation is projected to grow year over year, this year's Outlook documents a downward adjustment in gas-fired generation demand of about 17 percent compared to the 2015 Outlook. We attribute this adjustment primarily to improved modeling that more accurately depicts the likely utilization of gas-fired generation plants in the region.

Public policy and regulatory initiatives in Washington and Oregon have compelled the pending closure of two coal-fired generation facilities in the region: TransAlta's Centralia units and the Boardman plant operated by PGE. In addition, a recent court settlement mandates the closure of Colstrip Units 1 and 2 in Montana by 2022. Although no commercial agreements have yet been executed, we expect that some portion of the output of these plants will be replaced with gas-fired generation. Therefore, we include a simple expanded generation demand scenario at the end of this section.

Demand Composition – Regional natural gas loads are more sensitive to weather variations today than when gas was first delivered to the region. Currently, variable weather-sensitive loads make up more than two-thirds of the region's natural gas use (Figure D3). Consequently, the region's infrastructure is being utilized differently today than when it was first built. Then, less than 50 percent of the region's annual load was subject to weather patterns.

System Planning – Planning standards are designed to meet demand on the coldest day likely to occur in a gas utility's service territory. While each company approaches this forecasting requirement a little differently, "peak" or "design" days are typically based on actual 24-hour average temperatures recorded at representative locations. A comparison of the NWGA member company weather design standards can be found in Appendix B. Peak day loads are 2.7 percent lower on average than the 2015 forecast (Figure D4).

FIGURE D2. Historic Demand by Sector

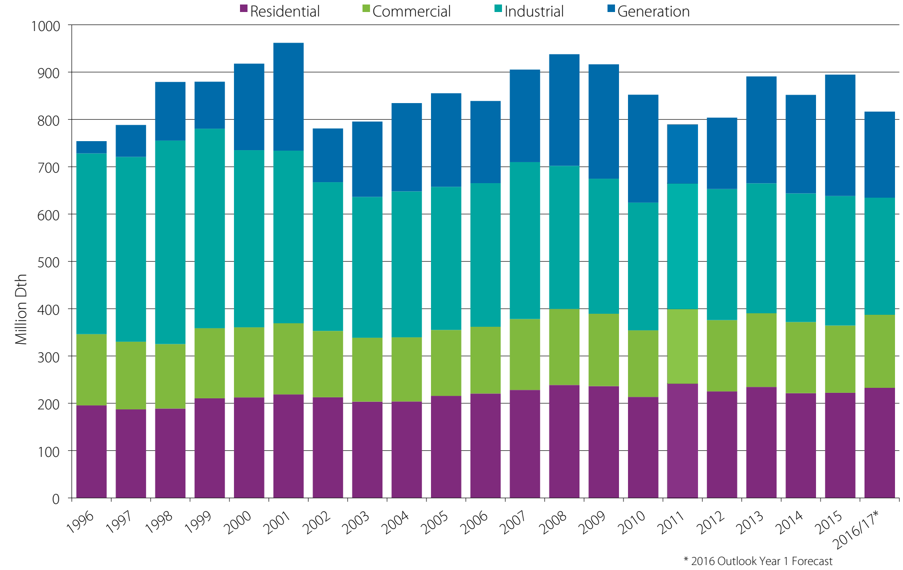


FIGURE D3. Demand Composition

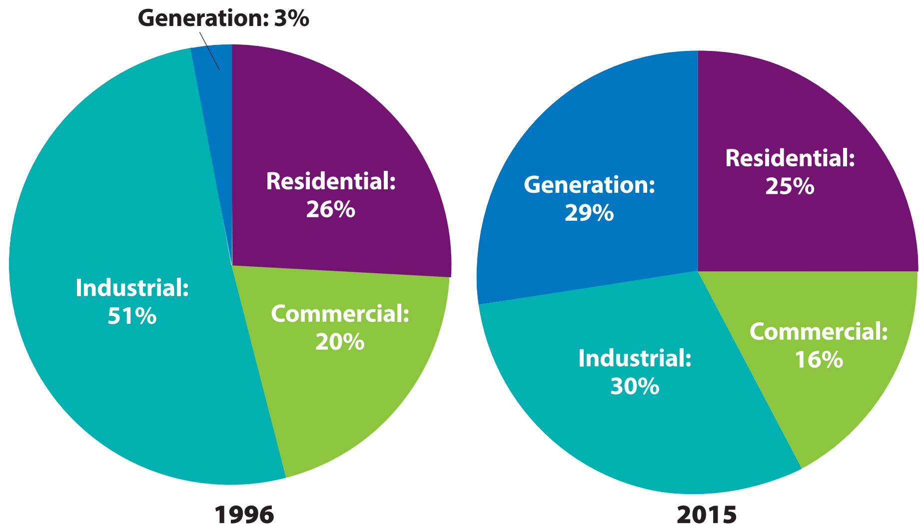

FIGURE D4. 2015-16 Peak Day Forecast Comparison

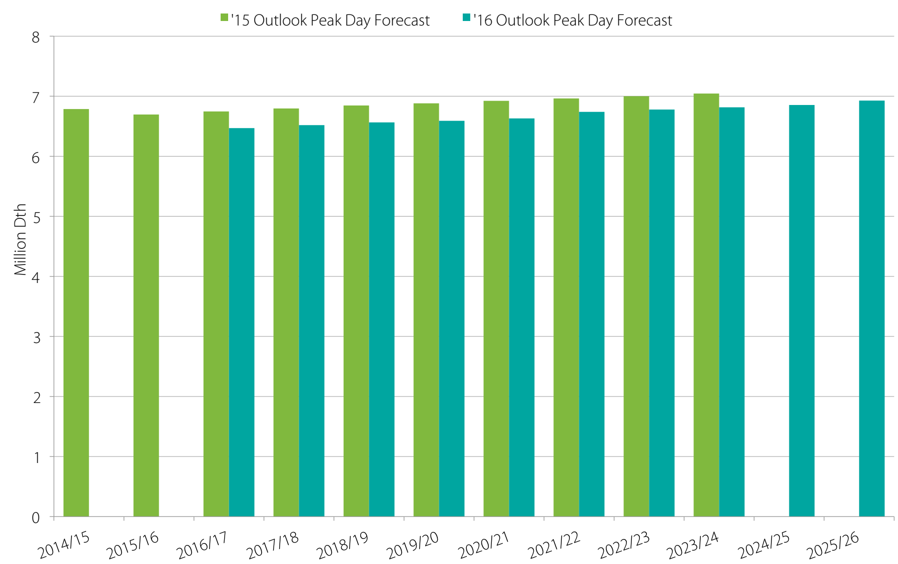


Clean and Efficient: Benefits of Direct Use of Natural Gas

For many years, energy agencies have alerted Americans to the importance of energy efficiency. A variety of tags and certifications, backed by financial incentives, encourage us to understand our equipment buying options. We know that it makes sense to spend a little more on a product so that we can save money and energy throughout its useful life.

These efforts continue to reduce per capita energy use for both natural gas and electric customers. And the more energy we save, the lower our impact on the environment.

But focusing on product efficiency only reveals half the story. To get the whole picture, it's important to look at what's called the full fuel cycle. That means understanding how much energy is retained – or lost – from the energy's source until its final use in your water heater, oven or home heating system.

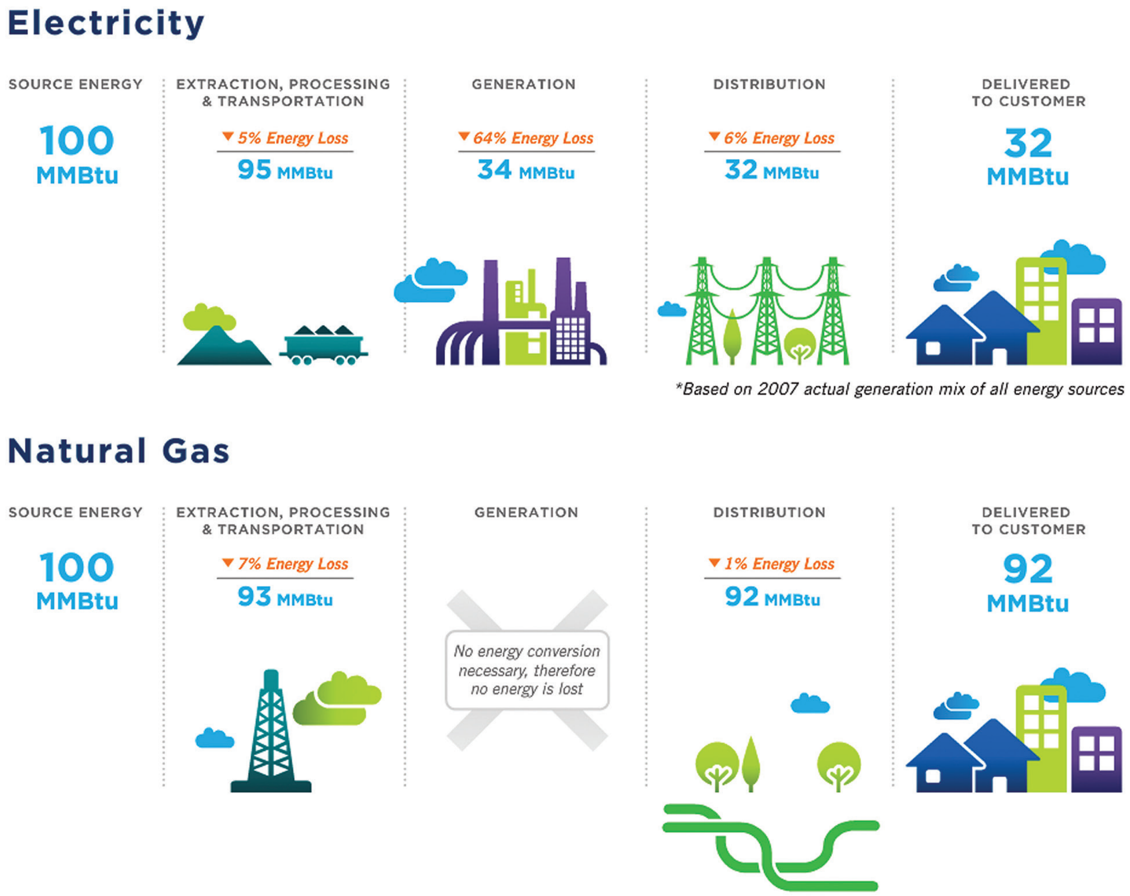
And with the full fuel cycle in mind, direct use of natural gas comes out a winner in the energy efficiency race. For instance, by the time you turn on your electric appliance, up to 68 percent of the energy value from the original fuel has been lost. So the full fuel cycle efficiency is about 32 percent. The full fuel cycle efficiency of a natural gas appliance is about 92 percent – a substantial difference.

Here's how it works:

1. Even with advances in renewable power, most electricity in the U.S. is generated by either coal or natural gas.
2. We lose some of the energy benefits of those fuels as they are transported to the power plant.
3. The major energy loss occurs during generation itself when potentially useful energy is lost in the form of heat as the fuel is burned to crank an engine or turn a turbine.
4. Finally, we lose more energy over the electric transmission lines. So for every 100 MMBtu of fuel that leaves the mine or well, only 32 MMBtu is left to power our electrical appliances.

These fuel choices have important environmental implications. On average, the house fueled by natural gas is responsible for about one third fewer greenhouse gas emissions than a comparable all-electric home (*American Gas Association, Dispatching Direct Use: Achieving GHG Reductions with Natural Gas in Homes and Businesses,* Nov 2015). Furthermore, the more fuel we waste, the more we need to produce and transport – processes that also affect the environment.

We are approaching a future when a combination of wind, solar, wave energy and usable storage will reduce our reliance on fossil fuels. Until then, one of the most effective ways we have to save energy and reduce carbon emissions today is to use natural gas directly in our homes, businesses, and vehicles wherever gas is available. We have the ability to maximize these benefits using today's technologies.



Possible Regional Demand Scenarios

We have developed two scenarios to explore the impact that plausible but currently unaddressed growth could have on regional demand and capacity utilization. They include a coal replacement scenario and an accelerated industrial growth scenario.

NOTE: These scenarios are created wholly by the NWGA. In developing them, we accessed public information and tested whether our assumptions were reasonable with a number of regional stakeholders. They are solely intended to illustrate a possible future outcome. To our knowledge, neither scenario reflects any actual negotiations or commercial agreements, nascent or otherwise, except as can be found publicly.

SCENARIO 1: Coal Replacement

In response to policy and regulatory requirements, PGE agreed to cease coal-fueled generation at the Boardman plant in 2020. Likewise, TransAlta will phase out its Centralia plant, closing Unit 1 by 2020 and Unit 2 by 2025.

Depending on market conditions, TransAlta intends to replace its coal-fired facility with a clean-burning natural gas plant as part of a planned Centralia 3. Per TransAlta: "The Centralia 3 project develops replacement power for the current 1,340-MW capacity Centralia coal-fired plant…[t]he proposed new natural gas plant is assumed initially as a roughly one-for-one replacement of Centralia's 670-MW coal-fired Unit 1."[14] Similarly PGE, while keenly focused on developing renewable fuel alternatives to replace as much of the 550-MW capacity of the Boardman plant as possible, has not dismissed the possibility that natural gas may play some role in its new generation portfolio.

In addition, Grays Harbor Energy (GHE) sought and received approval from Washington's Energy Facility Site Evaluation Council (EFSEC) to add 650 MW of gas-fired generating capacity to its existing 650-MW facility (construction period of up to 22 months to begin no later than December, 2020).[15]

This scenario assumes 800 MW of new combined-cycle gas combustion turbine (CCCT) generation above our expected case forecast (which already accounts for the new PGE Carty plant). Six hundred (600) MW will be added to Western Washington loads in 2019-20 replacing TransAlta and 200 MW to Eastern Oregon loads in 2020-21 replacing a portion of Boardman. Further assumptions include current turbine technology with a heat rate of 7,000 Btu/kilowatt-hour[16] operated 75 percent of the time (utilization rate). Under this scenario, 300 MW of generation equals an annual gas load of 13.8 MMDth and a daily load of 37,800 Dth.

SCENARIO 2: Accelerated Industrial Demand

A number of industrial projects have been proposed for the region. We classify them into two types of industrial load: general and large load projects.

The general category includes a number of proposed local projects like Woodfibre LNG near Squamish, BC, FortisBC's Tilbury LNG expansion, Puget Sound Energy's Tacoma LNG, as well as some generic U.S. and Canadian industrial loads not otherwise accounted for in the Outlook forecast. For the general category of prospective load, NWGA adjusted the base case industrial load by adding 35,000 Dth/day starting in the 2017-18 heating year, 200,000 Dth/day in 2019-20 and another 200,000 Dth/day in 2021-22.

We are using the methanol plants being proposed for the region by Northwest Innovation Works (NWIW) as a scalable proxy for the large load scenario. Together, the two proposed NWIW methanol plants are expected to consume about 550,000 Dth/day of natural gas. The methanol plants are proposed for two locations in the region. The Port Westward site is not expected to require as much on-site generation as Kalama, which explains the differential in projected loads shown below. The plants' expected load and service dates are:

Methanol Plant	Expected Load	In-Service
Kalama, WA	300,000 Dth/day	2020-21
Clatskanie, OR	250,000 Dth/day	2023

The average daily load for the entire region in 2015 was almost 2.5 million Dth (more during the winter months, less during the summer). If fully built out as proposed, the two methanol plants will consume almost one quarter of the region's current average daily load.

[14] www.transalta.com/us/2011/12/growth-2/
[15] EFSEC, *Amendment 5 to Grays Harbor Energy Center Site Certification Agreement*, Dec. 21, 2010
[16] A heat rate of 7,000 is representative of the newest CCCT generating units operating in the region (e.g., Port Westward, Mint Farm, etc.).

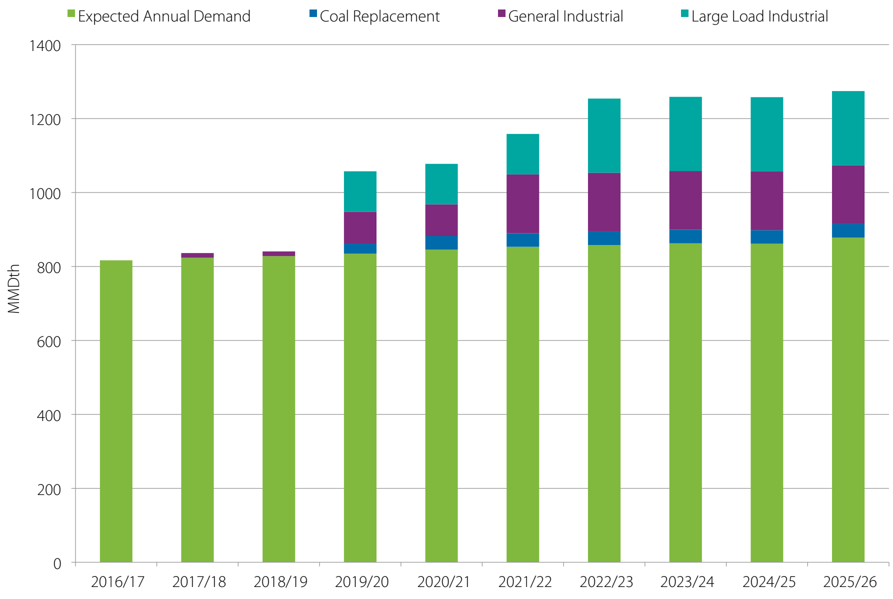
Combined Results – If both scenarios were fully realized, the total annual demand in the last year of the forecast would include an additional 396 MMDth per year over the base case, for a total of almost 1,300 MMDth; an increase of about 45 percent. The overall annual growth rate would increase from 0.8 percent to 5.1 percent. As discussed in more detail in the following section, these results suggest an accelerated need for additional capacity in the region.

Demand Variables

The demand for natural gas in the region is changing and NWGA members continue to watch a number of demand drivers that have yet to be quantified, including:

1. The magnitude and nature of the use of natural gas for generating electricity.
2. The possibility of new significant industrial loads (including exports).
3. The regional growth potential for natural gas as a transportation fuel.
4. The adequacy of natural gas infrastructure to support regional growth opportunities.
5. The impact of future energy policies and plans on demand, particularly GHG legislation. (See sidebar on page 16.)

FIGURE D5. Growth Scenarios



A Closer Look: Regional Policies/Plans that Could Impact Demand

Climate Policy Initiatives

Throughout the Northwest, there are several initiatives being considered to cut carbon emissions. Here are some of the proposals we are closely tracking:

In Oregon, two energy bills were considered during an interim legislative session in spring 2016. The first, a Clean Air and Coal Transition Plan (HB4036, later inserted into SB1547), requires the state's major electric utilities to forego coal-fired generation by 2030 and serve half of customers' demand with renewables by 2040. A collaborative effort by utilities and environmentalists, the bill was meant to fend off a similar measure poised to appear on the November ballot. Despite concerns raised by the state's Public Utility Commission about its actual effectiveness reducing carbon and shifting of costs and risks to ratepayers, the bill was passed. One possible implication of the new law could be an increase in the amount of gas-fired generation serving the region, both as a base-load resource and as a reliable backup to support intermittent renewable generation.

The other Oregon bill, intended to enforce the state's earlier adopted climate goals to reduce carbon emissions 75 percent below 1990 levels by 2050, called for the state to establish a cap-and-trade system with phased carbon emissions limits. It died in committee.

In Washington state, the legislature considered a number of carbon limiting proposals, all of which ultimately died. In response to the Legislature's lack of action in this regard, Gov. Jay Inslee directed the Department of Ecology to develop and implement a binding carbon cap. The highly controversial rule would establish a cap on emissions of the state's largest stationary sources (e.g., factories, power plants, oil refineries) that provide the gasoline used in the state and region, and the more than 1 million households and businesses that use natural gas. The rule is currently under development and expected to go into effect in January of 2017.

In addition, Washington voters will decide this fall whether to levy a carbon tax on themselves. Initiative 732 proposes to start the tax at $15 per ton of carbon, escalating to a cap of $100 per ton over 40 years. (If successful, this would be the first carbon tax enacted by a U.S. state.)

In BC, a diverse Climate Leadership Team is leading the task to update the province's 2008 GHG reduction plan. Climate Action Plan 2.0 seeks to expand the use of carbon pricing and identify new programs to achieve provincial GHG targets (33 percent reduction from 2007 emission levels by 2020 and 80 percent reduction by 2050).

How these initiatives affect our member utilities, their customers, and overall demand is uncertain. Do they raise rates and/or provide disincentives for large-scale industry to locate or expand here? Do they effectively reduce GHG or, in the case of renewables, drive the need for more gas-fired generation plants for backup? Of key importance to us is that our industry and customers are treated fairly.

Northwest Power Plan

In February 2016, the Northwest Power and Conservation Council (NPCC or Council) adopted its seventh Northwest Power Plan, which addresses the many variables affecting the region's power network and provides guidance on which resources can help ensure a reliable and economical regional power system for the next 20 years.

According to the Plan, the Council expects energy efficiency improvements and deployment of "demand response resources" (such as technology that enables voluntary curtailment of power usage, with price incentives) to provide the most economically sound means for meeting the region's electricity needs through 2035. Then, increased use of existing natural gas-fired generation and new gas-fired units are the most cost-effective resources, the plan says.

The Plan also states that natural gas generation is the lowest cost option for reducing regional carbon emissions. Even without additional carbon control policies, the Council's modeling found that the mix of aggressive efficiency standards, expanded gas-fired generation and planned coal plant retirements would reduce power system carbon emissions nearly 40 percent by 2035, achieving the carbon emission limits set out in the U.S. Environmental Protection Agency's Clean Power Plan (currently in limbo due to court action).

While the Plan encourages investment in renewables, it favors research and development of "more consistent output" resources such as ocean wave and geothermal sources (and methods of storing energy) over expansion of "variable output" renewables such as wind and solar beyond that already mandated. However, the NPCC acknowledges the costs of utility-scale wind and solar generation are becoming more cost-competitive and will continue to play a role in the resource mix, as long as gas-fired generation is present to provide backup and winter-peaking capacity.

In an email provided to *The Oregonian* in December 2015, Tom Eckman, director of NPCC's power division, summarized the council's approach: "We (are) evaluating policies that would reduce carbon emissions at the lowest cost, not how to increase the use of renewable resources… The best policy option involves the use of multiple tactics, which include retiring coal plants and substituting lower carbon-emitting gas, then building renewables only to the extent needed."

The plan can be accessed at http://www.nwcouncil.org/energy/powerplan/7/draftplan/.

2016 GAS OUTLOOK – Capacity

Key Conclusions

- The existing system of natural gas pipelines and storage facilities has reliably served the load requirements of the Pacific Northwest for decades and is sufficient to meet today's needs, though recent cold weather events have approached system limits.
- Additional capacity is likely to be required within the forecast horizon to serve growing demand for natural gas, particularly on a peak design day. Additional generation demand and industrial loads materially above the expected case will amplify and accelerate the need for incremental capacity required to serve the region.
- The timing, location and type of future capacity expansions or additions, whether pipelines or storage, and use of existing infrastructure, will depend on the changing nature of regional natural gas demand. For example, if large industrial loads expand or locate here, the resulting change in daily baseload demand will alter how current and new pipeline systems are used, while also making gas flows more consistent on a year-round basis compared to a largely winter-peaking profile of most systems.

Summary

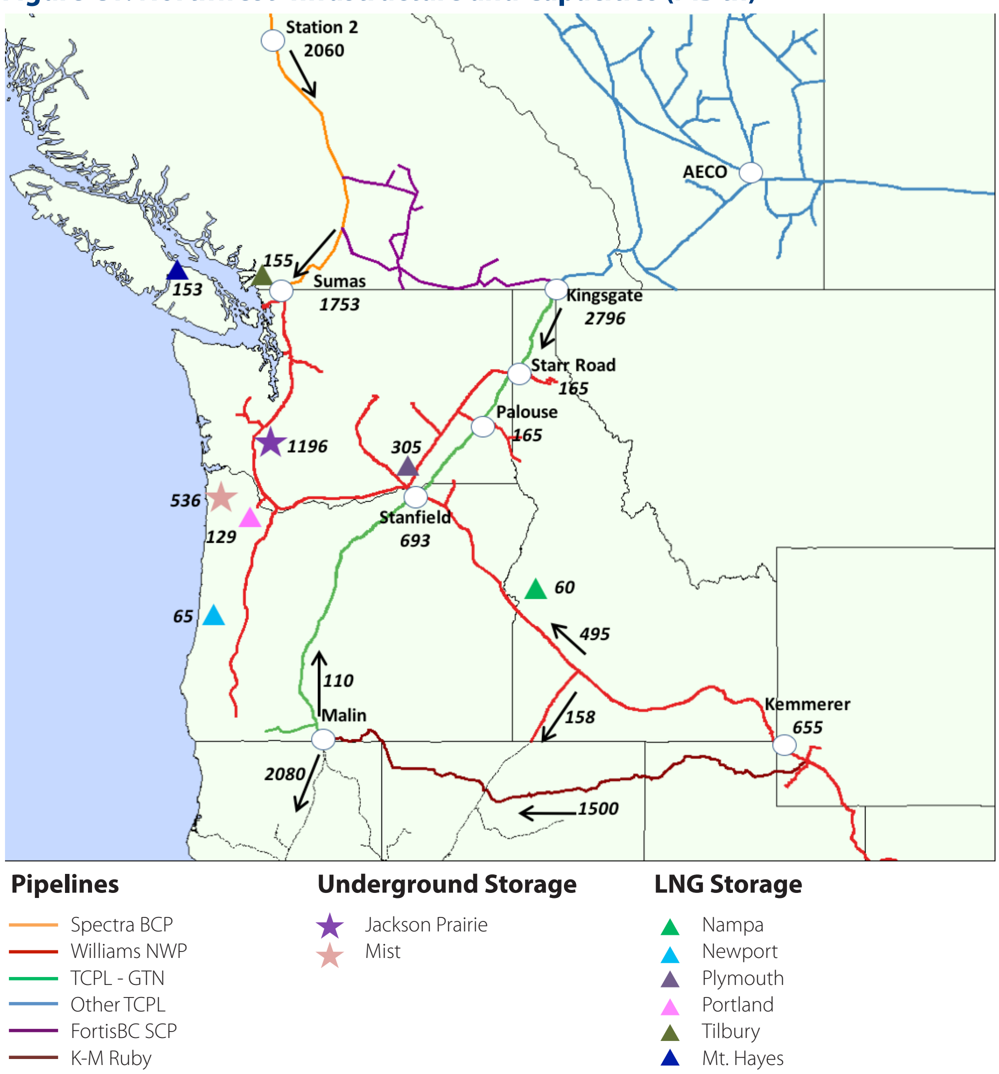
The Pacific Northwest's 48,000-mile network of transmission and distribution pipelines safely and reliably serves 3.2 million natural gas homes and businesses. The pipelines that transport natural gas from production areas in Alberta, BC, and the U.S. Rockies can deliver more than 4 MMDth/day to the region.

TABLE C1. Regional Storage Facilities

Facility	Owner	Type	Capacity* (MDth)	Max Withdrawal** (MDth/day)
Jackson Prairie, WA	Avista, PSE, NW Pipeline	Underground	25,448	1,196
Mist, OR	NW Natural	Underground	16,572	536
	Underground Subtotal		**42,020**	**1,732**
Plymouth, WA	NW Pipeline	Peak (LNG)	2,388	305
Tilbury, BC	FortisBC Energy	Peak (LNG)	591	155
Mt. Hayes, BC	FortisBC Energy	Peak (LNG)	1,530	153
Portland, OR	NW Natural	Peak (LNG)	644	129
Newport, OR	Intermountain Gas	Peak (LNG)	980	65
Nampa, ID	Intermountain Gas	Peak (LNG)	588	60
Swarr Station, WA	PSE	Peak (LNG)***	130	30
Gig Harbor, WA	PSE	Peak (LNG)	13	3
	Peak Storage Subtotal		**6,864**	**900**
Total Storage			**48,884**	**2,632**

*Working gas capacity; gas that can be used to serve the market
** Start of season or full rate; underground storage withdrawal rates decline as working gas volumes decline.
*** LPG: Liquid Propane Gas and Air mixture.

Figure C1. Northwest Infrastructure and Capacities (MDth)



Peak Day Capabilities – Because natural gas utilities are obligated to serve their customers at all times, even during the coldest weather conditions, they design their systems to accommodate extreme, but plausible, conditions called peak or design days (see Appendix B for a comparison of NWGA member company weather design standards). Figure C2 aggregates the projected design day volumes of NWGA gas utility members and plots them against available capacity. Under the expected and high demand cases, peak day loads could stress the system, approaching or exceeding the region's infrastructure capacity within the forecast horizon.

The probability of design days occurring on every distribution system across the entire region on the same day ("coincidental peak day") is small. However, the possibility of very cold weather occurring simultaneously along the I-5 Corridor is reasonably high. Figure C3 plots projected design day volumes along the I-5 Corridor against the pipeline and storage resources available to serve the area. The expected and high demand cases along the I-5 Corridor approach system capabilities within the forecast horizon.

FIGURE C2. Region-wide Peak Day Resource/Demand Balance[17]

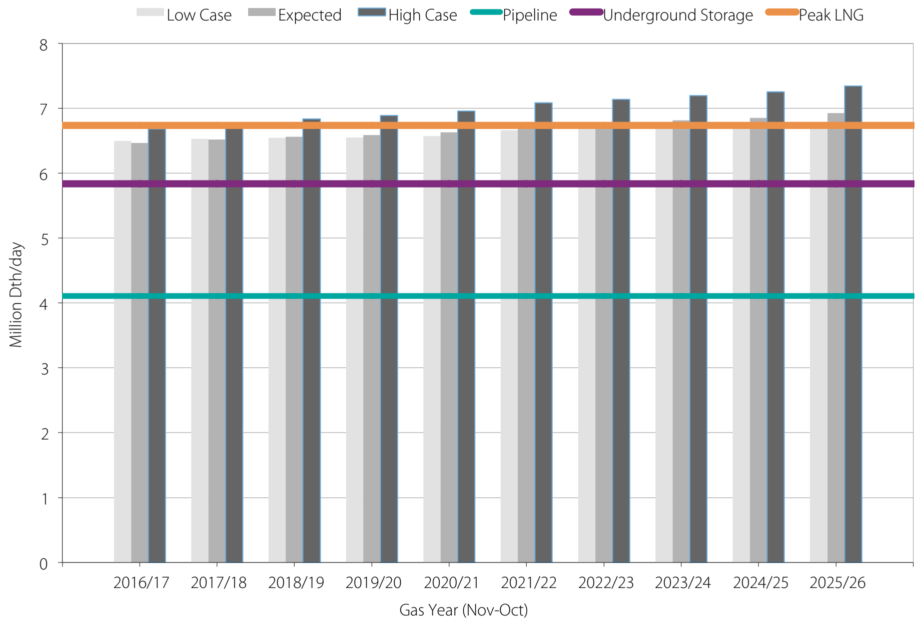


FIGURE C3. I-5 Peak Day Resource/Demand Balance[17]

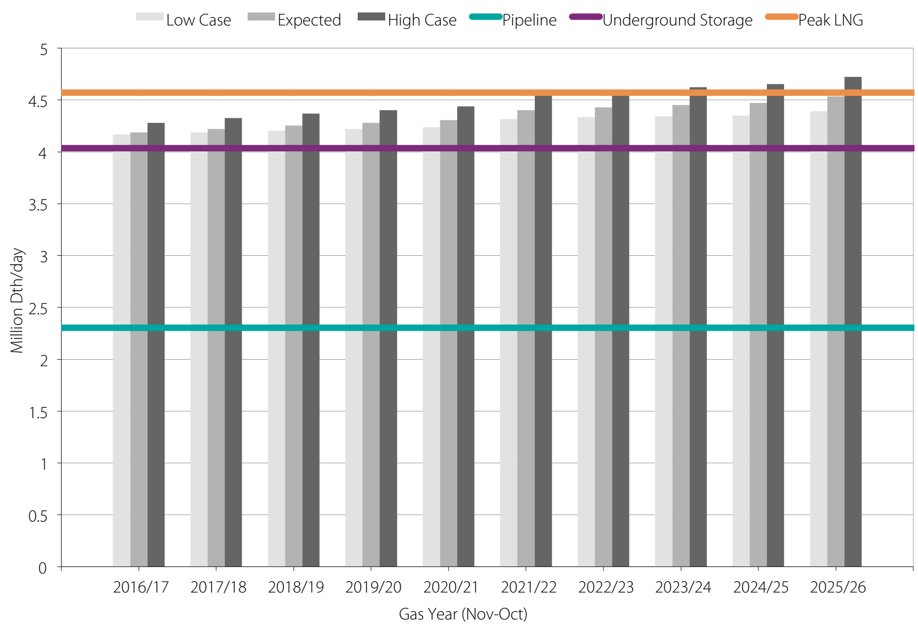

[17] Figures C2 and C3 assumptions include: a design weather day occurs simultaneously across the depicted region; existing infrastructure will deliver 100 percent of its capability; and gas will not flow to customers without firm pipeline transportation contracts (e.g., industrial users or electricity generators with alternate fuels).

Accelerated Demand Scenario – Regional capacity has served the Northwest's needs under severe circumstances, including the winter of 2013-14. That same winter, however, demonstrated that demand approached the system's capacity on cold weather days. The clear lesson is that the region's delivery infrastructure may require augmentation to accommodate growth. This is especially true if load growth exceeds expected levels. For instance, it's worth keeping an eye on the increased use of natural gas in place of coal and/or to support increased intermittent renewable generation.

Two potential scenarios are outlined in the Demand Section of this report, including accelerated industrial demand and coal-fired generation replacement. Figure C4 includes the projected incremental loads from these scenarios plotted against the resources available to serve the region. Quicker deployment of new capacity will be required to serve the region if these scenarios are realized.

Analyses such as these help send signals to the market of an impending need for additional capacity. Market participants weigh the probability of disruptions against the costs of various infrastructure options to make decisions about what is needed and when. In response to these market signals, projects are typically proposed to serve future delivery capacity needs. Several Infrastructure expansions have been proposed in the Pacific Northwest (Figure C5).

However, reductions in projected demand, a slow economic recovery and the new reality of a vast North American supply of natural gas have all combined to change the nature of projects now being considered within the region (see Appendix D). Today's market for regional infrastructure capacity has evolved from valuing diversity to equally valuing reliability; from providing market access for imported LNG to accessing the Asian LNG export markets; from serving a rapidly growing core market to serving potential industrial and electric generation demand growth; and from once-diminishing Canadian supplies to the need to find new markets for abundant supplies.

FIGURE C4. Accelerated Demand Peak Day Resource/Demand Balance[18]

FIGURE C5. Proposed Natural Gas Infrastructure Projects

[18] Figure C4 assumes that the entire load generated by the accelerated demand scenario will require, and contract for, firm transportation and/or storage capacity. In fact, potential shippers have options including less costly interruptible service contracts that can be curtailed as necessary by the capacity operator.

Still, it is only a matter of time before new capacity within the region will be required. If major industrial loads increase, for example, the region will require infrastructure expansions that provide both diversity and reliability of gas supply for the new base load. The location of new large natural gas loads may drive gas supply sourcing decisions, which will in turn determine the nature and location of capacity enhancements.

Capacity Variables

NWGA members continuously monitor a number of dynamics to ensure that regional natural gas consumers have the gas they need when and where they need it, including:

1. When, where and how much natural gas the region will require to generate electricity, meet peak load, and balance variable renewable resource generation.
2. Whether, when and where large industrial and/or LNG export loads proposed for the region materialize.
3. The impact of the legal, regulatory environment, as well as environmental and community groups, on the ability to build new or expand existing infrastructure in a timely manner to meet future needs. Projects take three to five years to develop, making foresight imperative.

Appendix B: IRP Characteristics

Company	Region/Area	Customer Classes	Forecast Period	Econometrics	Economic Source
Avista	2 Divisions (WA/ID, OR); 4 Service Territories (WA/ID, Roseburg/ Medford, Klamath Falls, La Grande); 8 demand areas according to available pipeline capacity	Residential, commercial, industrial, core interruptible.	20 years	Separate forecast for customers and use per customer. Key drivers: Population growth, service area residential permitting; U.S., California, and service area employment growth; average household size; U.S. industrial production; U.S. GDP growth; non-weather seasonal factors; and real natural production; and real natural gas prices. Normal weather is based on a 20-year moving average.	IHS Global Insight; Bureau of Labor Statistics; U.S. Census; Bureau of Economic Analysis; NOAA; University of Oregon Economic Indicator; Construction Monitor; U.S. Federal Reserve; The Economist; Wall Street Journal; IMF; World Bank; Bloomberg; Blue Chip Consensus, Washington Office of Financial Management
Cascade	CNGC will forecast at its city gates starting with 2016 IRP. 6 regions; West, Central and East for market share; by county for economic forecasting.	Residential, commercial, Industrial, core interruptible.	20 years	Customer Counts: Population growth, economical employment rates, weather, natural gas price and other regional economic market intelligence	Woods & Poole, FHLMC, Federal Reserve, Schneider Electric, Wood Mackenzie and other regional economic market intelligence.
Fortis	4 service regions: Lower Mainland; Vancouver Island; Northern Interior; Southern Interior.	Residential; commercial; industrial.	20 years	Forecasts based on third party housing starts forecast and market capture. New dwellings, commercial floor space and industrial plant capacity added based on account growth rates. Anticipated 'natural' efficiency improvements incorporated in both existing buildings and new construction. Anticipated changes in the saturation and gas shares for specific end-uses also included. Recent uptick in industrial consumption assumed to continue for the short-term, then level off.	Conference Board of Canada, user surveys (industrial customers)
IntGas	6 regions (includes an "all other" category); West, Central, and East for market share rates; by county for economic forecasting.	Residential, commercial, and industrial (potato processors, other food processors, chemical and fertilizer, manufacturers, institutions, and all other).	5 years	Customer growth forecast: New residential construction customers, # of residential customers who convert to natgas fr/ an alt fuel, and number of small commercial customers (assuming a new household = a new dwelling needed). The annual change in households by county x IGC's market penetration rate in that region = the additional residential anticipated % of conversion customers relative to new construction customers in those locales = # of expected res. conversion customers + residential new construction #s = total expected additional residential customers across the periods, by county.	Church 2016 Forecast; NOAA.
NW Natural	12 Regions based on topology of the gas distribution system	Residential existing, new construction single family, new construction multi-family and residential conversion; commercial existing, new construction and conversions; industrial firm sales; firm transport; interruptible sales.	20 years	Customer growth by region and category. Recent usage data for customer base use + heat use behavior response to historic weather and gas rates.	Oregon Office of Economic Analysis; Northwest Power & Conservation Council; Woods & Poole.
Pacific Power	By state (California, Oregon, Washington, Idaho, Utah, and Wyoming) which is allocated to 37"bubbles," including 10 load bubbles	Residential, commercial, industrial, irrigation, and Public Street and Highway Lighting.	20 years, but IRP discussion focuses on first 10 years.	Forecast by state and customer class. Key drivers: New technologies/end use, demographics, employment, income, weather, DSM, and energy efficiency mandates.	PacifiCorp's 2014 DSM potential study, conducted by Applied Energy Group.
Portland General	Single contiguous service area.	2017-2050 (20 years required).	2017-2050 (20 years required)	Precarious economic conditions, demographic trends such as in-migration and life expectancy, a business environment that favors future growth; Oregon's position as a magnet state, the presence of prominent industry leaders, continued gains in productivity, and emerging sectors sustaining and creating new growth; and the high tech sector.	Oregon Office of Economic Analysis economic forecast and Energy Information Administration.
Puget Sound Energy	Single contiguous service area.	Firm: residential, commercial, industrial, large volume commercial, large volume industrial. Interruptible: commercial and industrial.	20 years	Regional and national economic growth, demographic changes, weather, prices, seasonality, housing starts, and demand side management (DSM) for customer growth and use per customer forecasts; Stochastic approach for developing Low and High growth scenarios.	Moody's Analytics US Macroeconomic Forecast, PSE's regional and economic forecasts, US Bureau of Economic Analysis, US Bureau of Census, Washington State
Questar	Utah and Wyoming (Idaho rolled into Utah).	Residential by state; small commercial by state; large commercial, industrial, and electric generation gas demand all together; firm customer and transportation. All rate classes are forecasted by state, but non-GS (all but residential and small commercial) is only presented system-wide in the IRP document.	11 years for demand forecast; 21 years for SendOut model	Population, personal income, housing starts, and unemployment rate are used in forecasting by state.	University of Utah (Bureau of Economic & Business Research); UT Governor's Office of Planning and Budget; U.S. EIA, U.S. Census Bureau, HIS Global Insight.

Company	Scenarios Developed	Price Forec ast	Weather Design
Avista	An Average Case, Expected Case, Expected Case with Low Price, High Growth with Low Price, Low Growth with High Price, and an Alternate Weather Standard.	Wood Mackenzie – first four years modified to include Nymex forward prices	Coldest day on record, historic peak, and average weather data for each demand region.
Cascade	Low, Medium, High, High Growth with Low Price, Low Growth with High Price, Moderate CO2 costs, High CO2 costs.	A blend of public and private sources (EIA 20 yr, Bentek 5yr, Wood Mackenzie, NYMEX strips, Texas Comptroller)– based onCascade's general portfolio mix	System-weighted 56 HDD, based on coldest day in past 30 years.
Fortis	Reference Case, High and Low (driven by customer addition forecasts); scenarios by region.	Henry Hub forecasts using GLJ, Wood Mackenzie and US EIA along with NYMEX futures.	1-in-20-year day determined through extreme value analysis based on weather data from the last 60 years; result may vary from the actual coldest day in last 20 years.
IntGas	Low, base and high combined with other variables to yield 18 demand scenarios.	NYMEX & 2 proprietary five year forecasts	81 HDD weighted by customers in each district; several distinct laterals and areas of interest are assigned unique HDDs.
NW Natural	High Customer Growth; Low Customer Growth; Carbon Prices; Regional Pipeline Availability.	IHS CERA	Most extreme weather last 30 years (Feb 3, 1989).
Pacific Power	2015 IRP studied 34 core cases, including 3 different regional haze approaches, incorporated draft EPA 111(d) alternatives and additional CO2 taxes. 15 sensitivities focusing on low, high, and 1-in-20 load growth; low/high DG penetration; two types of storage addition; 1-in-20 load growth, low and high DG penetration, as well as two types of storage additions; solar cost sensitivities; two transmission sensitivities; PTC extension; Class 3 DSM; east/west balancing areas	Third-party proprietary data & forecasting services. Low, medium, and high Henry Hub natural gas prices and CO2 prices determined/used in IPM® and AURORAxmp® models. IPM® simulates North American system resulting in plant retirements and renewable resource builds. IPM® results are input in the AURORAxmp® model, which simulates the Western Interconnection and produces unique price projections for the cases analyzed in the 2015 IRP.	1-in-20 weather occurrence included in alternative load forecast to determine resource type and timing impacts.
Portland General	Reference (likely) case, high load and low load, assuming normal weather. 26 portfolios represent either a single resource or a mix of resources. Assess and test total expected portfolio costs using 21 futures.	Wood Mackenzie for natural gas prices long-term fundamental forecast from 2021 through 2035 for long-term Henry Hub price and basis differentials to Sumas, AECO, and other WECC (for electric) supply hubs. PGE extrapolates from the fundamentals forecast for dates after 2035.	Expected normal weather w/50% probability–PGE's reserve cover ~ 80% of a 1-in-5 weather event. Historically winter peaking but summer demand growing; PGE's system will shift to summer peaking by the end of the decade
Puget Sound Energy	Base, Low, High, Base + Low Gas Price, Base + High Gas Price, Base + Very High Gas Price, Base + No CO2, Base + High CO2, Base + Low Demand, Base + High Demand.	Prices for 2016 through 2019 represent 3-month average forward marks. Beyond 2019, natural gas forward prices represent the long-term forecast per Wood Mackenzie. Also generated Low, High & Very High gas prices using Wood Mackenzie forecasts.CO2 prices are based on Northwest Power & Conservation Council's estimated California CO2 prices under the California Global Warming Solutions Act of 2006	52 HDD daily average.
Questar	Stochastic modeling yielding mean, median and base cases; normal weather case also reported to inform quarterly variance reporting and pass through cases.	Means and standard deviations associated with historical data from 9 area price indices; average of 2 price forecasts including PIRA (19 months) and IHS CERA (252 months) as basis for stochastic modeling inputs.	1-in-20-year weather occurrence: 70 HDD at SLC coincident across service territory.

Appendix C: Regional Resource Deficiencies and Preferred Resource Options

Company	IRP File Date	Jurisdiction	Year of Peak Day Deficiency	Preferred Supply Resources Selected
Avista	August 29, 2014	Idaho; Oregon; Washington	No deficiency in planning horizon	N/A
Cascade	July 17, 2015	Oregon; Washington	2013 (OR), 2021 (WA)	Realign delivery rights; incremental GTN, NWP and other upstream pipeline capacity; incremental storage capacity.
FortisBC	March 25, 2014	British Columbia	2017 – Interior Transmission System; 2026 – Coastal Transmission System. To be reassessed in 2017 IRP.	Pipeline looping or LNG storage.
IntGas	January, 2015	Idaho	No deficiency within 5-year planning horizon	N/A
NW Natural	August 29, 2016	Oregon; Washington	2020	Mist Recall; North Mist Expansion; Additional Pipeline Capacity (specific pipeline dependent on scenario).
Puget Sound Energy	November 30, 2015	Washington	2017	Swarr propane air facility upgrade, PSE LNG, Mist Storage and pipeline expansions including the NWP Sumas Express, the Spectra T-South West coast expansion and the NWP N-MAX/ Trail West Cross Cascade expansion.

Developing a sufficient and efficient regional delivery system can be achieved by looking at the total needs of the region, the resources available, and future resource options. While current analysis shows sufficient resources to serve regional demand, they may not fully capture potential demand, both in magnitude and timing, or the future availability of existing resources.

Due to risks inherent in the forecasting process, changing needs and uses for natural gas, limited existing resources, and the lengthy permitting and construction time frames required to bring new resources on line, it is imperative to comprehensively assess regional resource adequacy and future resource needs.

NWGA member utilities strive to understand the planning issues, competitive environment and resource requirements for others in the region because of the region's reliance on a common infrastructure to serve both electricity and natural gas demand. Preparing a plan in isolation of these external considerations could mask potential resource utilization constraints, ignore operational synergies, discount project economies of scale, and result in over-reliance on existing resources.

For example, LDCs may plan to rely upon existing unsubscribed or under-utilized pipeline capacity to meet a future deficit. That same capacity may be relied upon by electric utilities that need gas for power generation sooner than the LDC. In this case, the LDCs' preferred resource would not be available. Therefore, evaluating who needs what, when and where can highlight potential problems and hone in on regional solutions.

This table summarizes the identified deficiencies and preferred supply resource portfolios of the NWGA member utilities from their most recently filed IRPs. It is apparent from the data in the table that near-term deficiencies can be handled with existing resources. Longer-term deficiencies are likely to be met with some combination of currently unsubscribed capacity, future capacity expansions and additional on-system storage including satellite LNG. There are several planning cycles in which to evaluate resource options for deficits far out into the future.

What has not been fully incorporated, however, are the resources regional electricity generators plan to access to meet growing and increasingly variable generation demand. The Outlook has captured future gas-fired generation loads to the extent they are planned, known and available. However, it is difficult to project how and when those resources will be required. The NWGA will continue working with the Pacific Northwest Utilities Conference Committee (trade association of regional electric utilities) to plan accordingly.

Appendix D: Proposed Regional Natural Gas Infrastructure Project Descriptions

Today's market for regional infrastructure capacity has evolved from valuing diversity to equally valuing reliability; from providing market access for imported LNG to accessing the Asian LNG export markets. It is only a matter of time before new capacity within the region will be required. Figure C5 on page 19 in the Capacity Section illustrates active regional infrastructure proposals, which include:

Spectra T-South Expansions: Spectra Energy continues to evaluate expansion of its T-South system to provide incremental delivery options for growing Western Canada gas supply to markets in the Pacific Northwest. All expansions on T-South would require pipeline looping and compression and can be brought into service between 2018-2020.

FortisBC Southern Crossing Expansion: FortisBC's existing Southern Crossing pipeline system enables bidirectional gas flow between Spectra's T-South system at Kingsvale, BC and TransCanada's BC system just upstream from the interconnection with GTN at Kingsgate, ID. The proposed expansion involves a 150 kilometre pipeline looping project on the segment between Kingsvale and Oliver BC and would facilitate access to an additional 300-400 MMcf/d of bi-directional capacity. This expansion would provide for greater market access to Station 2 supply by moving gas west to east or moving Alberta-sourced gas east to west to serve several new large industrial projects proposed for the BC Lower Mainland and the I-5 corridor.

Northwest Pipeline (NWP) Sumas Express: Williams NWP continues to assess the regional benefits of expanding its system along the I-5 corridor from Sumas, WA to the market areas in WA and OR. NWP believes that expanding in its existing corridor is both economical and permittable and can be accomplished in a scalable manner to meet anticipated regional growth. Depending on the size of the ultimate market needs, NWP can meet demand growth through adding additional loop and compression at its existing compressor stations in the corridor.

Gas Transmission Northwest (GTN) Trail West/N-MAX: Project sponsors TransCanada GTN is working with NW Natural and NWP to develop Trail West in conjunction with an expansion of the existing NWP system. The Trail West project would consist of a 106-mile, 30-inch diameter pipeline that would run from GTN's mainline in central Oregon to a NW Natural/NWP hub near Molalla — enhancing delivery capacity to the I-5 Corridor. Trail West's initial design capacity is 500 MMcf/d, expandable to 1,000 MMcf/d. It would be linked to the N-MAX project on the NWP system to deliver gas to other markets along the I-5 corridor. This integrated project is projected to be in service during the fourth quarter of 2021.

Veresen/NWP Pacific Connector Gas Pipeline Project (PCGP): The PCGP is a 232-mile 36-inch diameter pipeline extending from Malin to Coos Bay, OR. Veresen, Inc. and Williams NWP are proposing PCGP to serve the Jordan Cove LNG export terminal, as well as potential regional markets between Malin and Coos Bay. PCGP includes 41,000 horsepower of compression to be installed near Malin yielding a total project design capacity of 1.06 Bcf/d. PCGP will provide access to supplies from Western Canada and the U.S. Rockies via interconnections with GTN and the Ruby Pipeline. Williams NWP will operate PCGP.

About the NWGA:

The NWGA is a bi-national trade organization of the Pacific Northwest natural gas industry. Its mission is to promote natural gas as a cornerstone of the region's energy, economic and environmental foundation. The NWGA produces timely and regionally relevant information relating to natural gas; shapes and communicates the industry's perspective, and engages in policy analysis and advocacy. NWGA members serve more than three million consumers in communities throughout Idaho, Oregon, Washington and British Columbia.

Choosing natural gas

Natural gas offers valuable benefits for your home or business's budget and comfort. If you switch your home's space or water heating from electricity to natural gas, you may qualify for up to **$3,550 in fuel conversion rebates**.

Benefits of natural gas

- Convenience »

  Natural gas furnaces distribute heat more evenly than electric heating. Natural gas water heaters heat up to 40 percent faster than electric models. Natural gas ranges cook food faster with better heat control. And natural gas dryers produce less static cling. Plus, you'll never have the hassle of wood with a natural gas fireplace.

- Comfort »

  Natural gas heating delivers air faster and warmer than heat produced by other electric heating equipment. A natural gas fireplace can warm a room much faster than a wood-burning fireplace.

- Savings »

  Natural gas costs less than electricity, heating oil or propane when used to heat your space or water. Electricity can cost up to twice as much.

- Environmentally-friendly »

  In most applications, natural gas produces less chemical emissions and particulates which can cause acid rain or smog. And the majority of natural gas for domestic use is produced in the U.S. and Canada.

- Energy-efficient »

  Direct use of natural gas for space and/or water heating is twice as efficient as using natural gas to produce electricity and transmitting it to a home. And with the use of energy-efficient gas appliances, even greater efficiency is achieved.

- Versatility »

  Natural gas can not only heat your sparce, but it can be used for water heating, clothes drying, cooking, and fireplaces. It can also be used outdoors for barbecuing, gas lighting, and even to heat your swimming pool or hot tub.

- Reliability »

  Natural gas service is piped directly to your home or business site and is always there when you need it. You'll never have to worry about running out of fuel, and many gas appliances will operate during a power outage.

- Value-added »

  Adding natural gas service to your home or business, along with high-efficiency gas appliances, will pay dividends down the road. From a resale standpoint, homes with natural gas offer more appeal to prospective buyers.

- Safety »

  Natural gas is one of the world's safest energy sources. It's lighter than air, nontoxic, odorless and colorless in its natural state. Mercaptan, a harmless odorant, is added to create a clearly detectable scent.

Simple steps to switching to natural gas

1. Determine natural gas availability and costs »
Start by confirming that natural gas is available for your home or business. Please fill out this inquiry request and we will respond within 2-3 business days or call PSE's Customer Construction Services at 1-888-321-7779 (Monday through Friday, 7 a.m. to 5 p.m.). We can let you know availability and costs, if any, within two to four business days.

2. Select a contractor for estimates »
PSE can help you find a pre-screened, qualified independent contractor. They will inform you of your high efficiency equipment options and provide a free on-site estimate based on your needs. And you can be assured that it will be installed professionally and in compliance with your local codes.

3. Check for energy efficiency rebates, incentives and financial assistance »
Be sure to check out PSE's energy-efficiency rebates to help save you more money. If you are switching from PSE electricity to natural gas at your home, you may qualify for up to $3,550 in fuel conversion rebates. Additionally, you may qualify for competitive financing for your equipment and installation costs. A PSE Energy Advisor can assist you with all of this information.

4. Submit a Natural Gas Service Contract »
Once we confirm that natural gas is available for your home or business, you will receive/complete a Gas Service Agreement which will provide PSE useful information such as your intended natural gas use and meter location.

5. Schedule your meter and equipment installation »
A PSE representative will contact you to discuss details about your natural gas service installation, such as access requirements and permitting. An installation date can then be scheduled according to your needs and scope of work. Once your natural gas meter is installed, you can work with your contractor to schedule installation of your high-efficiency equipment and/or appliances.

6. Activate your natural gas service »
As soon as your natural gas equipment is properly installed, simply contact PSE to activate your service. In most cases, your contractor can contact us on your behalf.

Questions about switching to natural gas?

Once you know natural gas is available for your home or business, call a PSE Energy Advisor at 1-800-562-1482, Monday through Friday, 8 a.m. to 5 p.m., for more information about PSE's energy-efficiency rebates, efficient equipment options, energy cost savings estimates, financing referrals and PSE's Contractor Alliance Network.

Cost comparisons

Compare costs between natural gas and other heating fuels.

Financing options

In some cases, adding natural gas service is considered an energy-efficiency upgrade and can qualify for low-interest loans or federal tax credits. For more information, visit the website below or contact a PSE Energy Advisor.

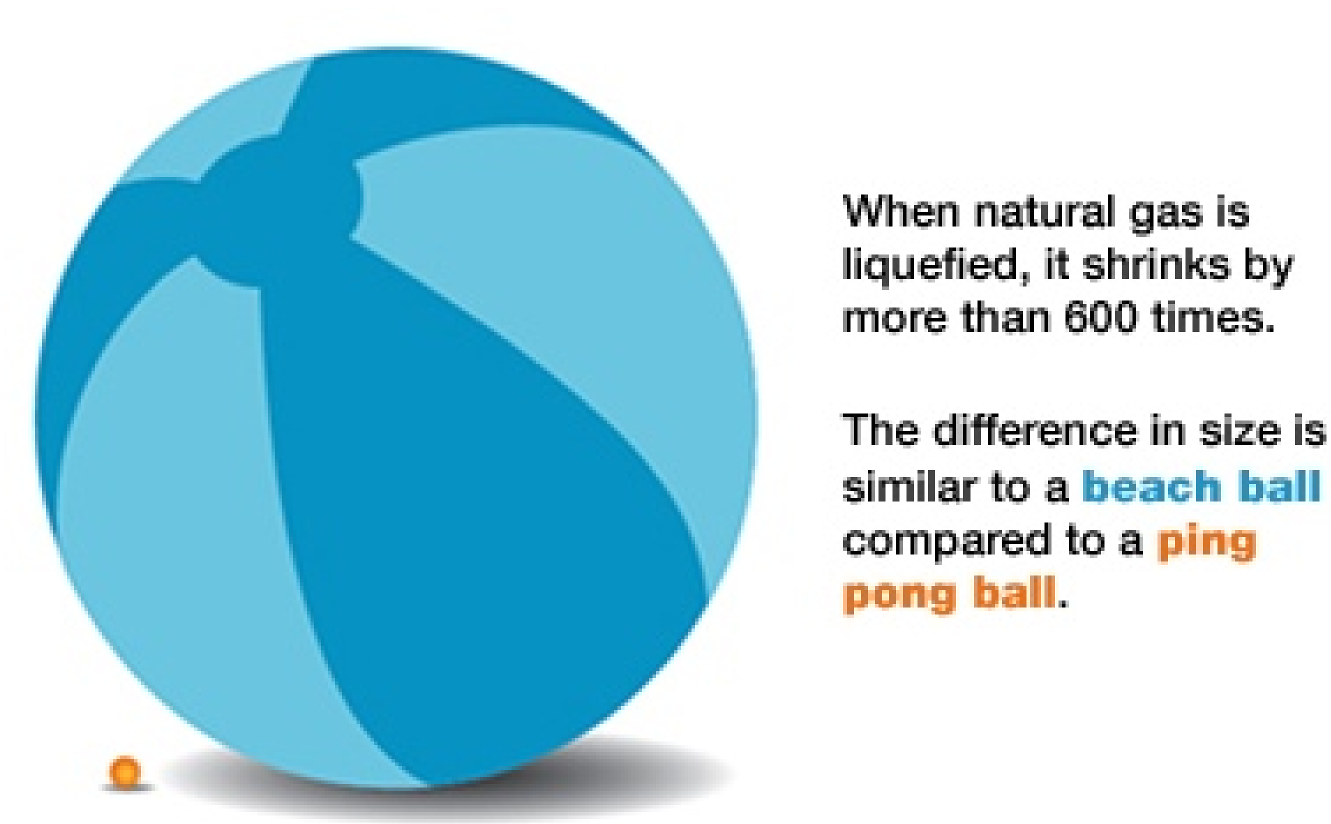
Natural gas conversion rebate

Natural gas safety

LNG is simply the liquid form of the natural gas used in millions of homes and vehicles.



Project Summary

Puget Sound Energy (PSE), Washington’s oldest energy utility, has begun construction of a $310 million Liquefied Natural Gas (LNG) facility at the Port of Tacoma. It will provide a clean and cost-effective gas supply resource for PSE's natural gas customers and a cleaner fuel alternative for maritime vessels owned by TOTE and other local employers. The project is expected to be completed and fully operational by late 2019.

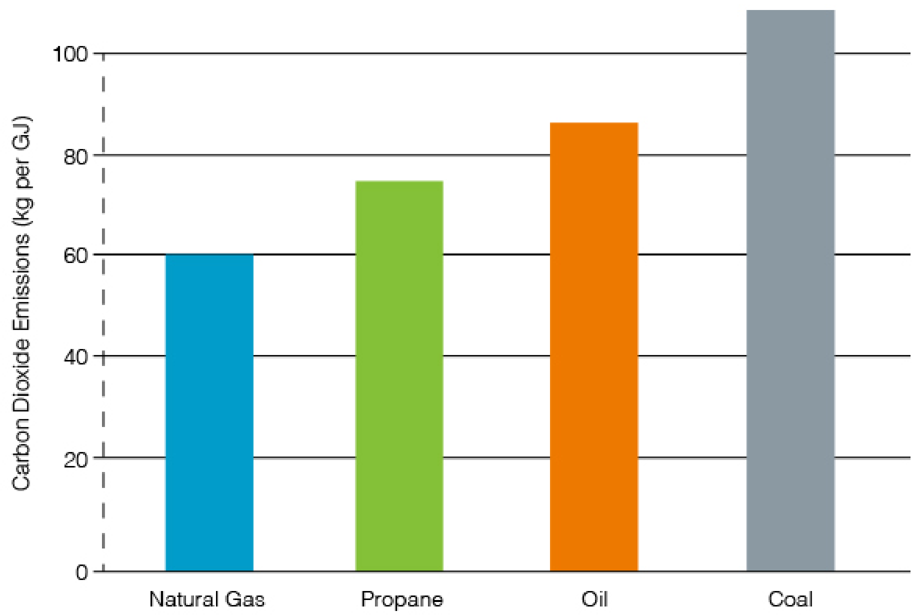
Local

PSE's LNG facility will serve our domestic natural gas customers and provide fuel for ships traveling between Tacoma and Alaska.

Safe

PSE has operated an LNG facility in Gig Harbor for more than a decade. The Tacoma facility will be operated in the same responsible way and built in accordance with the strictest federal guidelines.

LNG is simply the liquid form of the natural gas used in millions of homes and vehicles. When cooled, natural gas is reduced to a liquid that is one six-hundredth the volume, making it easier to store and transport. It is not explosive or flammable in its liquid state. When warmed, it returns to its gaseous state, and the same safe handling procedures are used as with natural gas. More than 100 LNG production, storage and fueling facilities currently operate in the United States.



Clean

Historically, many maritime vessels have used polluting bunker fuel or diesel. That's all changing. Switching from diesel to LNG reduces greenhouse gases more than 30 percent and dramatically reduces dangerous particulate emissions. This helps improve air quality and reduce health risks, and will help local employers like TOTE comply with new, stricter low-sulfur emission standards. Use of LNG also greatly minimizes the potential for harmful fuel spills that could damage the waters of Commencement Bay and Puget Sound.

Read Premier John Horgan's mandate letters to the new BC NDP government ministers

SHARE SHARE

Every new Premier delivers a mandate letter to the incoming Ministers and Ministers of State serving in their cabinet.

Premier John Horgan's government is no different. This week many of the 22 new Ministers and Ministers of State received their mandate letters from Premier Horgan.

Like the BC NDP platform and its three commitments, Premier Horgan's goals and expected outcomes are largely focused on improving the lives of everyday British Columbians. As he says in each letter: "It has never been more important for new leadership that works for ordinary people, not just those at the top."

In addition to their core responsibilities, all Ministers are expected to ensure members of the B.C. Green caucus are appropriately consulted on major policy issues, budgets, legislation and other matters as outlined in our agreement. After all, he continues, "British Columbians expect our government to work together to advance the public good. That means seeking out, fostering, and advancing good ideas regardless of which side of the house they come from."

Here are the highlights from the Mandate letters released yesterday:

1. The Honourable Melanie Mark, Minister of Advanced Education, Skills and Training

Key priorities for her Ministry include:

- Provide greater access to adult basic education and English-language learning programs by eliminating fees.
- Reduce the financial burden on students by eliminating interest on B.C. government student loans and establish a $1,000 completion grant program to provide debt relief to B.C. graduates.
- Encourage excellence in B.C.'s graduateschool programs by introducing a new graduate student scholarship fund.
- Work with the Minister of Education to support co-op, apprenticeship and work-experience programs for high school and undergraduate students.
- Work with the Minister of Transportation and Infrastructure to implement effective apprenticeship ratios on government-funded

infrastructure projects, and increase participation of equity-seeking groups in the skilled workforce.

Honourable Melanie Mark
Minister of Advanced Education, Skills and Training
Parliament Buildings
Victoria, British Columbia V8V 1X4

Dear Minister Mark:

Congratulations on your new appointment as Minister of Advanced Education, Skills and Training.

It has never been more important for new leadership that works for ordinary people, not just those at the top.

It is your job to deliver that leadership in your ministry.

Our government made three key commitments to British Columbians.

Our first commitment is to make life more affordable. Too many families were left behind for too long by the previous government. They are counting on you to do your part to make their lives easier.

Our second commitment is to deliver the services that people count on. Together, we can ensure that children get access to the quality public education they need to succeed, that families can get timely medical attention, and that our senior citizens are able to live their final years with dignity.

These and other government services touch the lives of British Columbians every day. It is your job as minister to work within your budget to deliver quality services that are available and effective.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone

2. The Honourable Lana Popham, Minister of Agriculture

Key priorities for her Ministry include:

- Revitalize the Agriculture Land Reserve and the Agricultural Land Commission.
- Establish Grow B.C. to help young farmers access land, and support fruit and nut growers and processors to expand local food production.
- Initiate Feed B.C. to increase the use of B.C.-grown and processed foods in hospitals, schools, and other government facilities.
- Bring back an enhanced Buy B.C. marketing program to help local producers market their products,and work with local producers to expand market access in the rest of Canada and abroad.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone

3. The Honourable David Eby, Attorney General

Key priorities for the Attorney General include:

- Introduce legislation to reform campaign finance laws to ban political contributions by corporations and unions, and set limits on individual contributions.
- Introduce legislation to hold a province-wide referendum on proportional representation in the fall of 2018.
- Introduce legislation to reform lobbying in BC.
- Re-establish the Human Rights Commission.
- Increase the number of court sheriffs, expand the use of duty counsel and increase staffing of the Court Services Branch to address court delays.
- Improve and support legal aid, including First Nations legal services, dispute resolution services for families and expanded poverty law services to increase access to justice.
- Conduct a comprehensive operating review of ICBC.

4. The Honourable Katrine Conroy, Minister of Children and Family Development

Key priorities for her Ministry include:

- Enhancing and improving child-protection services to ensure that all children grow up in safe andnurturing environments.
- Investing in child protection to hire additional social workers and staff to support social workers, and toimplement incentives to attract social workers to rural and underserved regions.
- Working to implement the recommendations from Grand Chief Ed John’s report and provide better supports to keep Aboriginal children at home and out of care.

5. The Honourable Katrina Chen, Minister of State for Childcare

Key priorities for her Ministry of State include:

- Work with all levels of government, child-care providers, the private and not-for-profit sectors to implement a universal child-care plan that provides affordable, accessible and high-quality care and early learning to every child whose family wants or needs it, starting with infant/toddler programs before gradually expanding.
- Provide additional investments in the Early Childhood Educator workforce through training, education and fair wages to enhance and ensure quality.
- Accelerate the creation of new child-care spaces in communities across the province as part of building a Better BC.

Our second commitment is to deliver the services that people count on. Together, we can ensure that children get access to the quality public education they need to succeed, that families can get timely medical attention, and that our senior citizens are able to live their final years with dignity.

These and other government services touch the lives of British Columbians every day. It is your job as minister to work within your budget to deliver quality services that are available and effective.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone,

17. The Honourable Judy Darcy, Minister of Mental Health and Addictions

Key priorities for her Ministry include:

- Work in partnership to develop an immediate response to the opioid crisis that includes crucial investments and improvements to mental-health and addictions services.
- Create a mental-health and addiction strategy to guide the transformation of B.C.'s mental-health-care system. As part of this strategy, include a focus on improving access, investing in early prevention and youth mental health.
- Consult with internal and external stakeholders to determine the most effective way to deliver quality mental-health and addiction services.

Honourable Judy Darcy
Minister of Mental Health and Addictions
Parliament Buildings
Victoria, British Columbia V8V 1X4

Dear Minister Darcy:

Congratulations on your new appointment as Minister of Mental Health and Addictions.

It has never been more important for new leadership that works for ordinary people, not just those at the top.

It is your job to deliver that leadership in your ministry.

Our government made three key commitments to British Columbians.

Our first commitment is to make life more affordable. Too many families were left behind for too long by the previous government. They are counting on you to do your part to make their lives easier.

Our second commitment is to deliver the services that people count on. Together, we can ensure that children get access to the quality public education they need to succeed, that families can get timely medical attention, and that our senior citizens are able to live their final years with dignity.

These and other government services touch the lives of British Columbians every day. It is your job as minister to work within your budget to deliver quality services that are available and effective.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone,

18. The Honourable Selina Robinson, Minister of Municipal Affairs and Housing

Key priorities for her Ministry include:

- Partnering with local governments and First Nations to develop a community capital infrastructure fund to upgrade and build sports facilities, playgrounds, local community centres, and arts and culture spaces.
- Through partnerships with local governments, the federal government, and the private and not-for- profit sectors, begin to build 114,000 units of affordable market rental, non-profit, co-op, supported social housing and owner-purchase housing.
- Amending the Residential Tenancy Act to provide stronger protections for renters, and provide additional resources to the Residential Tenancy Branch.
- With the Minister of Finance, delivering an annual renter's rebate of $400 dollars per rental household to improve rental affordability.

Our third key commitment is to build a strong, sustainable, innovative economy that works for everyone,

19. The Honourable Mike Farnworth, Minister of Public Safety and Solicitor General

Key priorities for his Ministry include:

- Provide more support to police efforts to disrupt the supply chain and advocate for increased penalties for drug dealers who knowingly distribute death-dealing drugs.
- Take action on gang and gun violence.
- Increase annual funding to support women who experience domestic violence, sexual assault and other crimes.
- Work with First Nations to set targets and take action to reduce the numbers of Aboriginal people involved in the justice system.
- Recognize culture for its role in rehabilitation and recovery and provide culturally diverse and appropriate programming in prisons, particularly for Aboriginal people.

LEVERAGING NATURAL GAS TO REDUCE GREENHOUSE GAS EMISSIONS

CENTER FOR CLIMATE AND ENERGY SOLUTIONS

June 2013

LEVERAGING NATURAL GAS TO REDUCE GREENHOUSE GAS EMISSIONS

June 2013

CONTENTS

ACKNOWLEDGEMENTS

Many individuals, companies, and organizations contributed to the development of this report. The Center for Climate and Energy Solutions (C2ES) wishes to acknowledge all those who volunteered their time and expertise, including James Bradbury of the World Resources Institute and the many members of the C2ES Business Environmental Leadership Council that provided comments and guidance throughout the research process. We would also like to thank the American Clean Skies Foundation and the American Gas Association for their generous support of the project.

EXECUTIVE SUMMARY

Recent technological advances have unleashed a boom in U.S. natural gas production, with expanded supplies and substantially lower prices projected well into the future. Because combusting natural gas yields fewer greenhouse gas emissions than coal or petroleum, the expanded use of natural gas offers significant opportunities to help address global climate change. The substitution of gas for coal in the power sector, for example, has contributed to a recent decline in U.S. greenhouse gas emissions. Natural gas, however, is not carbon-free. Apart from the emissions released by its combustion, natural gas is composed primarily of methane (CH_4), a potent greenhouse gas, and the direct release of methane during production, transmission, and distribution may offset some of the potential climate benefits of its expanded use across the economy.

This report explores the opportunities and challenges in leveraging the natural gas boom to achieve further reductions in U.S. greenhouse gas emissions. Examining the implications of expanded use in key sectors of the economy, it recommends policies and actions needed to maximize climate benefits of natural gas use in power generation, buildings, manufacturing, and transportation (Table ES-1). More broadly, the report draws the following conclusions:

- The expanded use of natural gas—as a replacement for coal and petroleum—can help our efforts to reduce greenhouse gas emissions in the near- to mid-term, even as the economy grows. In 2013, energy sector emissions are at the lowest levels since 1994, in part because of the substitution of natural gas for other fossil fuels, particularly coal. Total U.S. emissions are not expected to reach 2005 levels again until sometime after 2040.
- Substitution of natural gas for other fossil fuels cannot be the sole basis for long-term U.S. efforts to address climate change because natural gas is a fossil fuel and its combustion emits greenhouse gases. To avoid dangerous climate change, greater reductions will be necessary than natural gas alone can provide. Ensuring that low-carbon investment dramatically expands must be a priority. Zero-emission sources of energy, such as wind, nuclear and solar, are critical, as are the use of carbon capture-and-storage technologies at fossil fuel plants and continued improvements in energy efficiency.
- Along with substituting natural gas for other fossil fuels, direct releases of methane into the atmosphere must be minimized. It is important to better understand and more accurately measure the greenhouse gas emissions from natural gas production and use in order to achieve emissions reductions along the entire natural gas value chain.

TABLE ES-1: Sector-Specific Conclusions and Recommendations

POWER SECTOR
It is essential to maintain fuel mix diversity in the power sector. Too much reliance on any one fuel can expose a utility, ratepayers, and the economy to the risks associated with commodity price volatility. The increased natural gas and renewable generation of recent years has increased the fuel diversity of the power sector (by reducing the dominance of coal). In the long term, however, concern exists that market pressures could result in the retirement of a significant portion of the existing nuclear fleet, all of which could be replace by natural gas generation. Market pressures also could deter renewable energy deployment, carbon capture and storage, and efficiency measures. Without a carbon price, the negative externalities associated with fossil fuels are not priced by society, and therefore there will be less than optimal investment and expansion of zero-carbon energy sources.
Instead of being thought of as competitors, however, natural gas and renewable energy sources such as wind and solar can be complementary components of the power sector. Natural gas plants can quickly scale up or down their electricity production and so can act as an effective hedge against the intermittency of renewables. The fixed fuel price (at zero) of renewables can likewise act a hedge against potential natural gas price volatility.

TABLE ES-1: Sector-Specific Conclusions and Recommendations—continued

BUILDINGS SECTOR
It is important to encourage the efficient direct use of natural gas in buildings, where natural gas applications have a lower greenhouse gas emission footprint compared with other energy sources. For thermal applications, such as space and water heating, onsite natural gas use has the potential to provide lower-emission energy compared with oil or propane and electricity in most parts of the country. Natural gas for thermal applications is more efficient than grid-delivered electricity, yielding less energy losses along the supply chain and therefore less greenhouse gas emissions. Consumers need to be made aware of the environmental and efficiency benefits of natural gas use through labeling and standards programs and be incentivized to use it when emissions reductions are possible.
MANUFACTURING SECTOR
The efficient use of natural gas in the manufacturing sector needs to be continually encouraged. Combined heat and power systems, in particular, are highly efficient, as they use heat energy otherwise wasted. Policy is needed to overcome existing barriers to their deployment, and states are in an excellent position to take an active role in promoting combined heat and power during required industrial boiler upgrades and new standards for cleaner electricity generation in coming years. For efficiency overall, standards, incentives, and education efforts are needed, especially as economic incentives are weak in light of low natural gas prices.
DISTRIBUTED GENERATION
Natural gas-related technologies, such as microgrids, microturbines, and fuel cells, have the potential to increase the amount of distributed generation used in buildings and manufacturing. These technologies can be used in configurations that reduce greenhouse gas emissions when compared with the centralized power system as they can reduce transmission losses and use waste heat onsite. To realize the potential of these technologies and overcome high upfront equipment and installation costs, policies like financial incentives and tax credits will need to be more widespread, along with consumer education about their availability.
TRANSPORTATION SECTOR
The greatest opportunity to reduce greenhouse gas emissions using natural gas in the transportation sector is through fuel substitution in fleets and heavy-duty vehicles. Passenger vehicles, in contrast, likely represent a much smaller emission reduction opportunity even though natural gas when combusted emits fewer greenhouse gases than gasoline or diesel. The reasons for this include the smaller emission reduction benefit (compared to coal conversions), and the time it will take for a public infrastructure transition. By the time a passenger fleet conversion to natural gas would be completed, a new conversion to an even lower-carbon system, like fuel cells or electric vehicles, will be required to ensure significant emissions reductions throughout the economy.
INFRASTRUCTURE
Transmission and distribution pipelines must be expanded to ensure adequate supply for new regions and to serve more thermal loads in manufacturing, homes, and businesses. Increased policy support and innovative funding models, particularly for distribution pipelines, are needed to support the rapid deployment of this infrastructure.

I. OVERVIEW OF MARKETS AND USES

By Meg Crawford and Janet Peace, C2ES

INTRODUCTION

Recent technological advances have unleashed a boom in natural gas production, a supply surplus, and a dramatically lower price. The ample supply and lower price are expected to continue for quite some time, resulting in a relatively stable natural gas market. As a consequence, interest in expanding the use of natural gas has increased in a variety of sectors throughout the economy, including power, buildings, manufacturing, and transportation. Given that combusting natural gas yields lower greenhouse gas emissions than that of burning coal or petroleum, this expanded use offers significant potential to help the United States meet its climate change objectives. Expanded use of gas in the power sector, for example, has already led to a decrease in U.S. greenhouse gas emissions because of the substitution of gas for coal. It is important to recognize, however, that natural gas, like other fossil fuel production and combustion, does release greenhouse gases. These include carbon dioxide and methane; the latter is a higher global warming greenhouse gas. Accordingly, a future with expanded natural gas use will require diligence to ensure that potential benefits to the climate are achieved. This report explores the opportunities and challenges, sector by sector throughout the U.S. economy, and delves into the assortment of market, policy, and social responses that can either motivate or discourage the transition toward lower-carbon and zero-carbon energy sources essential for addressing climate change.

CONTEXT: A NEW DOMINANT PLAYER

Throughout its history, the United States has undergone several energy transitions in which one dominant energy source has been supplanted by another. Today, as the country seeks lower-carbon, more affordable, domestically sourced fuel options to meet a variety of market, policy, and environmental objectives, the United States appears poised for another energy transition. Past energy transitions, for example, from wood to coal, took place largely without well-defined policies and were not informed by other big-picture considerations. Transitions of the past were largely shaped by regional and local economic realities and only immediate, local environmental considerations. The potential next energy transition can be more deliberately managed to achieve economic and environmental goals. The United States possesses the technological capacity and policy structures to do this. This report outlines, sector by sector, those technological options and policy needs.

The history of energy consumption in the United States from 1800 to 2010 moved steadily from wood to coal to petroleum (Figure 1). In the latter half of the 19th century, coal surpassed wood as the dominant fuel. Around 1950, petroleum consumption exceeded that of coal.

Petroleum still reigns supreme in the United States; however, due to a number of factors including improving fuel economy standards for vehicles, its use since 2006 is in decline. At the same time, for reasons that this report explores in depth, natural gas use is on the rise. As these trends continue, it is entirely possible in the coming decades that natural gas will overtake petroleum as the most popular primary energy source in the United States.[1]

Natural gas already plays a large role in the U.S. economy, constituting 27 percent of total U.S. energy consumption in 2012. Unlike other fossil fuels, natural gas has applications in almost every sector, including generating electricity; providing heat and power to industry, commercial buildings, and homes; powering vehicles; and as a feedstock in the manufacture of industrial products.

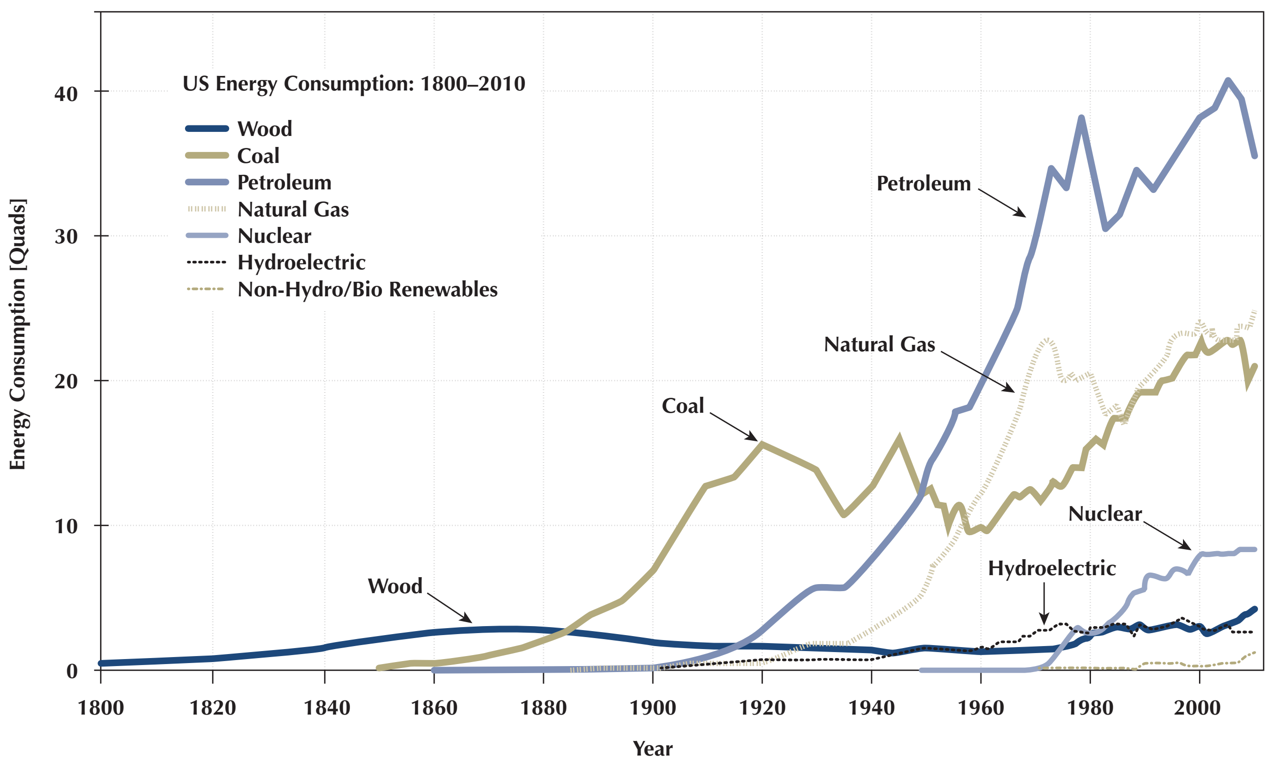
By all accounts, the existing increase in natural gas supply appears very certain, and the large domestic supply is expected to keep natural gas prices relatively low in the near to medium term. Furthermore, the domestic supply already has and is forecasted to deliver substantial benefits to the U.S. economy, providing jobs and increasing the gross domestic product. The primary uncertainties for the natural gas market are how quickly the expanded use will occur and the specific ways in which specific sectors of the economy will be affected. This report delves into the assortment of market, policy, and social responses that can motivate or discourage this transition. It places this energy transition firmly in the context of the closely related climate impacts of different types of energy use, and explores the interplay between economic opportunities and the pressing need to dramatically reduce the economy's emissions of greenhouse gases.

CLIMATE IMPLICATIONS

The expanding use of natural gas is already reducing emissions of carbon dioxide (CO_2), the primary greenhouse gas, at a time in which the U.S. economy is growing. In 2011, total U.S. CO_2 emissions were down by nearly 9 percent from peak levels of 6,020 million metric tons in 2007. This decrease is due to a number of factors, of which the increased use of natural gas in the power sector is prominent. Demand is increasing as new and significantly more efficient natural gas power plants have been recently constructed, existing natural gas power plants are being used more extensively, and fuel-substitution from coal to natural gas is taking place. Compared to coal, natural gas is considered relatively clean because when it is burned in power plants, it releases about half as much CO_2 (and far fewer pollutants) per unit of energy delivered than coal. As the fraction of electric power generated by coal has fallen over the last six years and been replaced mostly by natural gas-fueled generation and renewables, total U.S. CO_2 emissions have decreased.

According to several sources, including the U.S. Energy Information Administration (EIA), additions in electric power capacity over the next 20 years are expected to be predominantly either natural gas-fueled or renewable (discussed further in chapter 4 of

FIGURE 1: Total U.S. Energy Consumption, 1800 to 2010



Source: Energy Information Administration, "Annual Energy Review," Table 1.3. September 2012. Available at: http://www.eia.gov/totalenergy/data/annual/index.cfm#summary

Note: Wood, which was the dominant fuel in the United States for the first half of the 19th century, was surpassed by coal starting in 1885. Coal as the dominant fuel was surpassed by petroleum in 1950. Within one to two decades, natural gas might surpass petroleum as the dominant energy provider.

this report). Therefore, as coal's share of generation continues to diminish, the implications for climate in the near and medium term are reduced CO_2 emissions from the power sector. Further reductions in CO_2 emissions are possible if natural gas replaces coal or petroleum in other economic sectors. In addition, wider use of distributed generation technologies in the manufacturing, commercial, and residential sectors, namely natural gas-fueled combined heat and power (CHP) systems, has great potential to significantly reduce U.S. CO_2 emissions.

In the long term, however, the United States cannot achieve the level of greenhouse gas emissions necessary to avoid the serious impacts of climate change by relying on natural gas alone. Also required is the development of significant quantities of zero-emission sources of energy, which economic modeling shows will require policy intervention. Since many of these energy sources, such as wind and solar, are intermittent and current energy storage technology is in its infancy, natural gas will likely also be needed in the long term as a reliable, dispatchable backup for these renewable sources.

Crucially, natural gas is primarily methane, which is itself a very potent greenhouse gas. Methane is about 21 times more powerful in its heat-trapping ability than CO_2 over a 100-year time scale. With increased use of natural gas, the direct releases of methane into the atmosphere throughout production and distribution have the potential to be a significant climate issue. Regulations have already been promulgated by the Environmental Protection Agency (EPA) that address this key issue. For example, "green completion" rules for production will require all unconventional wells to virtually eliminate venting during the flow-back stage of well completion through flaring or capturing natural gas. Releases need to be carefully managed, and EPA regulation of the natural gas sector will ensure that the climate benefits from transitioning to natural gas are truly maximized.

ABOUT THIS REPORT

To examine the possible ways in which this energy transition might unfold and the potential implications for the climate, the Center for Climate and Energy Solutions and researchers at The University of Texas prepared 9 discussion papers looking at individual economic sectors, natural gas technologies, markets, infrastructure, and environmental considerations. Then, two workshops brought together dozens of respected thought leaders and stakeholders to analyze the potential to leverage natural gas use to reduce greenhouse gas emissions. Stakeholders included representatives of electric and natural gas utilities, vehicle manufacturers, fleet operators, industrial consumers, homebuilders, commercial real estate operators, pipeline companies, independent and integrated natural gas producers, technology providers, financial analysts, public utility and other state regulators, environmental nonprofits, and academic researchers and institutions.

This report is the culmination of these efforts. First, it provides background on natural gas and the events leading to the present supply boom. Next, it lays out the current and projected U.S. natural gas market, including the forecast price effects during the transition. It details the relationship between natural gas and climate change and then explores the opportunities and challenges in the power, buildings, and manufacturing sectors. It looks at technologies for on-site (distributed) electricity generation using natural gas, followed by prospects for increasing natural gas consumption in the transportation sector. Finally, the report examines the state of natural gas infrastructure and the barriers to its needed expansion.

This report offers insight into ways to lower the climate impact of natural gas while increasing its use in the electric power, buildings, manufacturing, and transportation sectors, and looks at infrastructure expansion needs and what future technologies may portend for low-emission natural gas use. This report is the product solely of the Center for Climate and Energy Solutions (C2ES) and may not necessarily represent the views of workshop participants, the C2ES Business Environmental Leadership Council or Strategic Partners, or project sponsors.

BACKGROUND

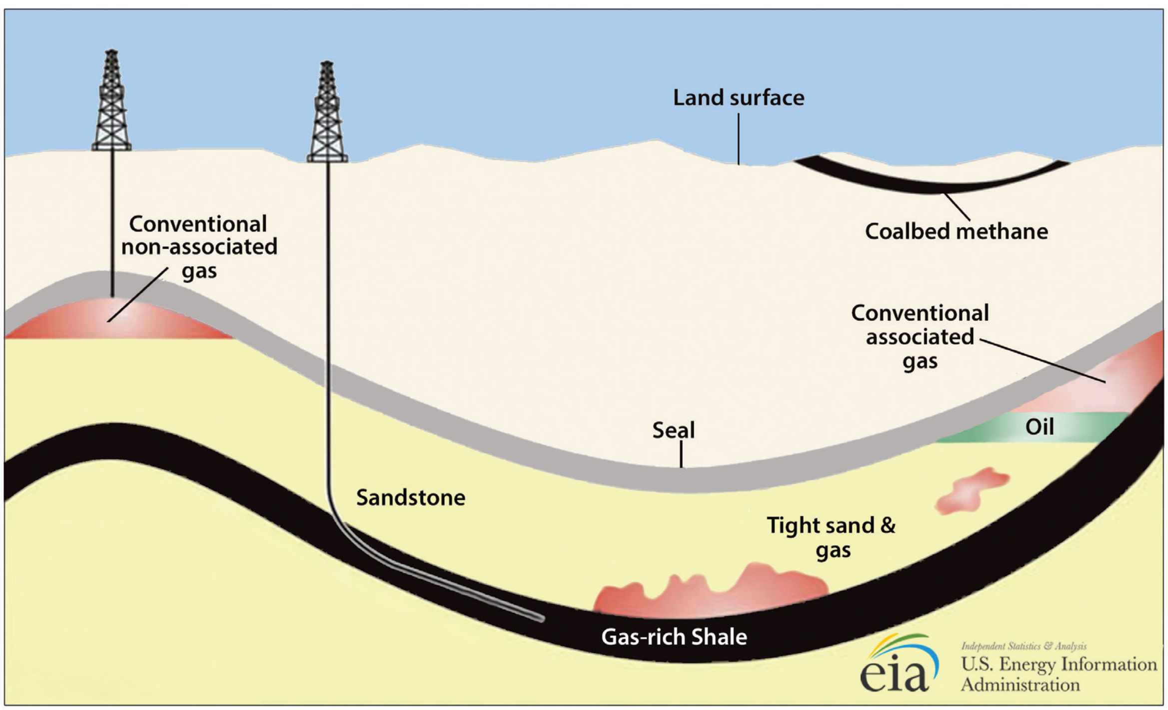
Natural gas is a naturally occurring fossil fuel consisting primarily of methane that is extracted with small amounts of impurities, including CO_2, hazardous air pollutants, and volatile organic compounds. Most natural gas production also contains, to some degree, heavier liquids that can be processed into valuable byproducts, including propane, butane, and pentane.

Natural gas is found in several different types of geologic formations (Figure 2). It can be produced alone from reservoirs in natural rock formations or be associated with the production of other hydrocarbons such as oil. While this "associated" gas is an important source of domestic supply, the majority (89 percent) of U.S. gas is extracted as the primary product, i.e., non-associated.[2]

With relatively recent advances in seismic imaging, horizontal drilling, and hydraulic fracturing, U.S. natural gas is increasingly produced from unconventional sources such as coal beds, tight sandstone, and shale formations, where natural gas resources are not concentrated or are in impermeable rock and require advanced technologies for development and production and typically yield much lower recovery rates than conventional reservoirs.[3] Shale gas extraction, for example, differs significantly from the conventional extraction methods. Wells are drilled vertically and then turned horizontally to run within shale formations. A slurry of sand, water, and chemicals is then injected into the well to increase pressure, break apart the shale to increase permeability, and release the natural gas. This technique is known as hydraulic fracturing or "fracking."

The remarkable speed and scale of shale gas development has led to substantial new supplies of natural gas making their way to market in the United States. The U.S. EIA projects that by 2040 more than half of domestic natural gas production will come from shale gas extraction and that production will increase by 10 trillion cubic feet (Tcf) above 2011 levels (Figure 3). The current increase was largely unforeseen a decade ago. This increase has raised awareness of natural gas as a key component of the domestic energy supply and has dramatically lowered current prices as well as price expectations for the future. In recent years, the abundance of natural gas in the United States has strengthened its competitiveness relative to coal and oil,

FIGURE 2: Geological Formations Bearing Natural Gas



Source: Energy Information Agency, "Schematic Geology of Natural Gas Resources," January 2010. Available at: http://www.eia.gov/oil_gas/natural_gas/special/ngresources/ngresources.html

Notes: Gas-rich shale is the source rock for many natural gas resources, but, until now, has not been a focus for production. Horizontal drilling and hydraulic fracturing have made shale gas an economically viable alternative to conventional gas resources.

Conventional gas accumulations occur when gas migrates from gas rich shale into an overlying sandstone formation, and then becomes trapped by an overlying impermeable formation, called the seal. Associated gas accumulates in conjunction with oil, while non-associated gas does not accumulate with oil.

Tight sand gas accumulations occur in a variety of geologic settings where gas migrates from a source rock into a sandstone formation, but is limited in its ability to migrate upward due to reduced permeability in the sandstone.

Coalbed methane does not migrate from shale, but is generated during the transformation of organic material to coal.

has expanded its use in a variety of contexts, and has raised its potential for reducing greenhouse gas emissions and strengthening U.S. energy security by reducing U.S. reliance on foreign energy supplies.

A HISTORY OF VOLATILITY: 1990 TO 2010

U.S. natural gas markets have only been truly open and competitive for about 20 years, when U.S. gas markets were deregulated and price controls were removed in the early 1990s. Before that time, government regulation controlled the price that producers could charge for certain categories of gas placed into the interstate market (the wellhead price) as well as pipeline access to market and in some cases specific uses of natural gas. The results were price signals that periodically resulted in supply shortages and little incentive for increased production. Since deregulation, price fluctuations have been pronounced, ranging from less than $2 to more than $10 per thousand cubic feet (Mcf) (Figure 4). Periods of high market prices have resulted from changes in regulation, weather disruptions, and broader trends in the economy and energy markets—but also from perceptions of abundance or scarcity in the market. A number of supply-side factors also affect prices, including the volume of production added to the market and storage availability to hedge against production disruptions or demand spikes. Looking forward, the average wellhead price is expected to be much less volatile and remain below $5 per Mcf through 2026 and rise to $6.32 per Mcf in 2035, as production gradually shifts to resources that are less productive and more expensive to extract.[4]

SUPPLIES

Since 1999, U.S. proven reserves of natural gas have increased every year, driven mostly by shale gas advancements.[5] In 2003, the National Petroleum Council estimated U.S. recoverable shale gas resources at 35 Tcf.[6] In 2012, the EIA put that estimate closer to 482 Tcf out of an average remaining U.S. resource base of 2,543 Tcf,[7] and in 2011, the Massachusetts Institute of Technology's mean projection estimate of recoverable shale gas resources was 650 Tcf out of a resource base of 2,100 Tcf.[8] By comparison, annual U.S. consumption of natural gas was 24.4 Tcf in 2011.[9] So, these estimates represent nearly 100 years of domestic supply at current levels of consumption.[10]

FIGURE 3: U.S. Dry Natural Gas Production, 1990 to 2040

Game-Changing Technologies

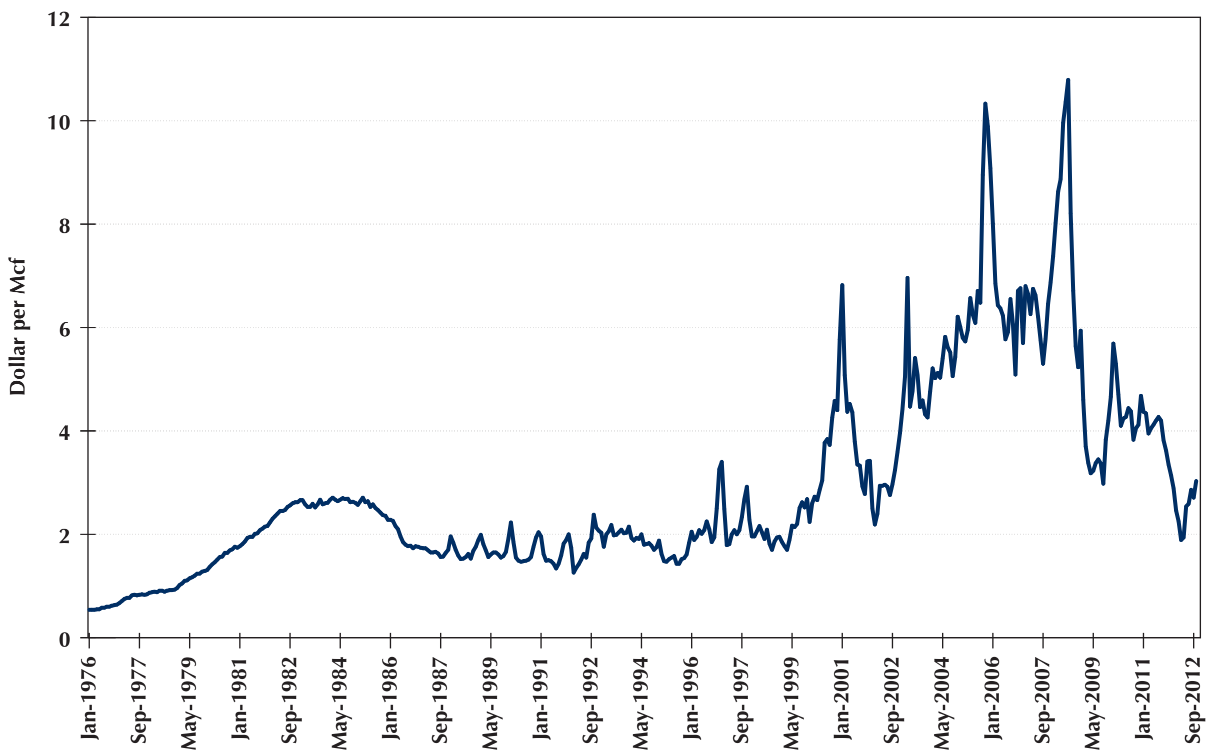
Rising natural gas prices after deregulation offered new economic incentives to develop unconventional gas resources. Advances in the efficiency and cost-effectiveness of horizontal drilling, new mapping tools, and hydraulic fracturing technologies—enabled by investments in research and development from the Department of Energy and its national labs along with private sector innovations—have led to the dramatic increase in U.S. shale gas resources that can be economically recovered.

Even as supply estimates have increased, the cost of producing shale gas has declined as more wells are drilled and new techniques are tried. In one estimate, approximately 400 Tcf of U.S. shale gas can be economically produced at or below \$6 per Mcf (in 2007 dollars).[11] Another estimate suggests that nearly 1,500 Tcf can be produced at less than \$8 per Mcf, 500 Tcf at less than \$8 per Mcf, and 500 Tcf at \$4 per Mcf.[12]

The Geography of Shale Gas Production

Shale gas developments are fundamentally altering the profile of U.S. natural gas production (Figure 3). Since 2009, the United States has been the world's leading producer of natural gas, with production growing by more than 7 percent in 2011—the largest year-over-year volumetric increase in the history of U.S. production.[13] The proportion of U.S. production that is shale gas has steadily increased as well. In the decade of 2000 to 2010, U.S. shale gas production increased 14-fold and comprised approximately 34 percent of total U.S. production in 2011.[14] From 2007 to 2008 alone, U.S. shale gas production increased by 71 percent.[15] Shale gas production is expected to continue to grow, estimated to increase almost fourfold between 2009 and 2035, when it is forecast to make up 47 percent of total U.S. production.[16] The geographic distribution of shale gas production is also shifting to new geologic formations with natural gas potential, called "plays," such as the Barnett shale play in Texas and the Marcellus shale play

FIGURE 4: **U.S. Natural Gas Monthly Average Wellhead Price History, 1976 to 2012**



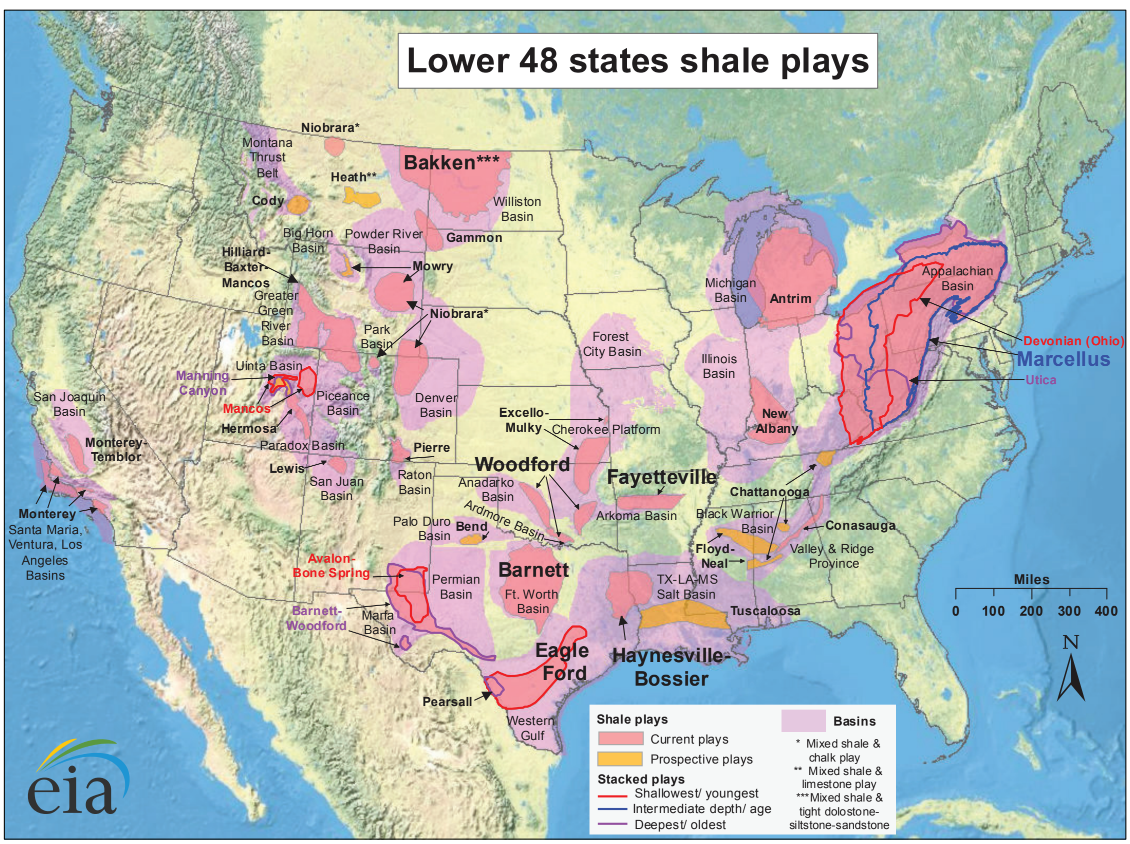
Source: Energy Information Administration, "Natural Gas Prices," 2013. Available at: http://www.eia.gov/dnav/ng/ng_pri_sum_dcu_nus_m.htm in the Midwest (Figure 5).[17] Natural gas is currently produced in 32 states and in the Gulf of Mexico, with 80.8 percent of U.S. production occurring in Texas, the Gulf of Mexico, Wyoming, Louisiana, Oklahoma, Colorado, and New Mexico in 2010. An increasing percentage of production is coming from states new on the scene, including Pennsylvania and Arkansas. This new geography of production has particularly large impacts for the development of natural gas infrastructure, as examined in chapter 9.

These dramatic increases in production, in combination with a weak economy and the accompanying decrease in demand for energy, are reflected in unexpectedly low and less volatile market prices, prices that encourage energy consumers to look at new uses for the fuel. Yet uncertainties remain that could hinder future development and production. For one thing, very low prices may result in producers temporarily closing down wells, particularly if the associated liquids produced along with the gas are not sufficient to make up for low natural gas prices and make well production economically viable.[18] In the long term, the dynamic nature of natural gas supply and demand will determine the price levels and volatility. Of particular importance is the extent and speed of demand expansion, a topic explored in the following section.

DEMAND

Just as supply has implications for the price path of natural gas, so does the demand. Natural gas is consumed extensively in the United States for a multitude of uses: for space and water heating in residential and commercial buildings, for electricity generation and process heat in the industrial sector, and as industrial feedstock, where natural gas constitutes the base ingredient for such varied products as plastic, fertilizer, antifreeze, and fabrics.[19] In 2012, natural gas use constituted roughly one-quarter of total U.S. primary energy consumption and was consumed in every sector of the

FIGURE 5: Lower 48 Shale Plays



Source: Energy Information Administration, "Lower 48 States Shale Plays," May 2011. Available at: http://www.eia.gov/oil_gas/rpd/shale_gas.pdf

U.S. economy (Figure 6). Total U.S. consumption of natural gas grew from 23.3 Tcf in 2000 to 25.4 in 2012.[20] Within the overall growth, consumption in several sectors held steady, while consumption in the industrial sector declined (due to increased efficiency and the economic slowdown) and consumption in the power sector grew at an annual average rate of 3.5 percent.

In the U.S. power sector in 2010, natural gas fueled 23.9 percent of the total generation. From 2000 to 2010, electricity generation fueled by natural gas grew at a faster rate than total generation (5.1 percent versus 0.8 percent per year) (Figure 7). This growth can be attributed to a number of factors, including low natural gas prices in the early part of the decade that made natural gas much more attractive for power generation. In addition, gas-fired plants are relatively easy to construct, have lower emissions of a variety of regulated pollutants than coal-fired plants, and have lower capital costs and shorter construction times than coal-fired plants. Transportation has remained the smallest sectoral user of natural gas, with natural gas vehicles contributing to a significant percentage of the total fleet only among municipal buses and some other heavy-duty vehicles.

FIGURE 6: U.S. Natural Gas Consumption by Sector, 2012

LARGELY REGIONAL NATURAL GAS MARKETS

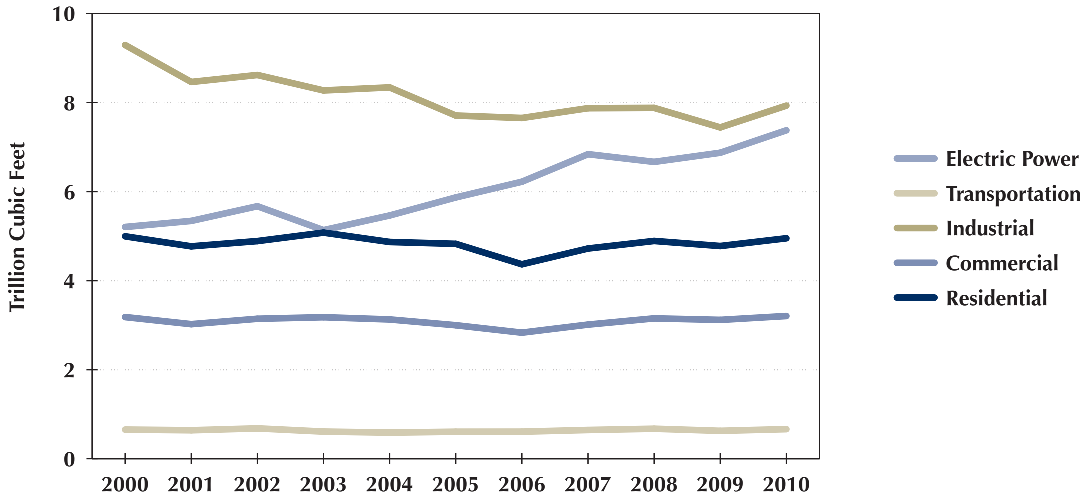
In contrast to oil, which is widely traded across national boundaries and over long distances, natural gas has been primarily a domestic resource. The low density of natural gas makes it difficult to store and to transport by vehicle (unless the gas is compressed or liquefied). (See chapter 8 for an extended discussion of liquefied and compressed natural gas.) Natural gas is therefore transported via pipelines that connect the natural gas wells to end consumers. Trade patterns tend to be more regional (particularly in the United States), and prices tend to be determined within regional markets. On the world stage, resources are concentrated geographically. Seventy percent of the world's gas supply (including unconventional resources) is located in only three regions—Russia, the Middle East (primarily Qatar and Iran), and North America. Within the United States, 10 states or regions account for nearly 90 percent of production: Arkansas, Colorado, Gulf of Mexico, Louisiana, New Mexico, Oklahoma, Pennsylvania, Texas, Utah, and Wyoming. Significant barriers exist to establishing a natural gas market that is truly global. While most natural gas supplies can be developed economically with relatively low prices at the wellhead or the point of export,[21] high transportation costs—either via long-distance pipeline or via tankers for liquefied natural gas (LNG)—have, until recently, constituted solid barriers to establishing a global gas market.

In 2011, net imports of natural gas, delivered via pipeline and LNG import facilities, constituted only 8 percent of total U.S. natural gas consumption (1.9 Tcf), the lowest proportion since 1993.[22] Of this amount, about 90 percent came from Canada.[23] (By contrast, 45 percent of U.S. oil consumption was imported in 2011, of which 29 percent came from Canada.[24]) Net imports of natural gas have decreased by 31 percent since 2007, with U.S. production growing significantly faster than U.S. demand. These trends and greater confidence in U.S. domestic gas supply suggest that prices between crude oil and gas will continue to diverge, establishing a new relationship that may fundamentally change the way energy sources are used in the United States.

THE RISE OF AN INTEGRATED GLOBAL MARKET

Although most of the world's gas supply continues to be transported regionally via pipeline, the global gas trade is accelerating because of the growing use of LNG. Natural gas, once liquefied,[25] can be transported

FIGURE 7: Trends in U.S. Natural Gas Consumption by Sector, 2000 to 2010



Source: Energy Information Administration, "Natural Gas Consumption by End Use," 2013. Available at http://www.eia.gov/dnav/ng/ng_cons_sum_dcu_nus_a.htm

---

by tanker to distant destinations and regasified for use. Between 2005 and 2010, the global market for LNG grew by more than 50 percent,[26] and LNG now accounts for 30.5 percent of global gas trade.[27] From 2009 to 2011 alone, global capacity for gas liquefaction increased by almost 40 percent, with global LNG trade set to rise by 30 percent by 2017.[28]

In the United States, prospects for exports of LNG depend heavily on the cost-competitiveness of U.S. liquefaction projects relative to those at other locations. During 2000 to 2010, new investments were made in the United States in infrastructure for natural gas importation and storage, prompted by lower supply expectations and higher, volatile domestic prices. Since 2000, North America's import capacity for LNG has expanded from approximately 2.3 billion cubic feet (Bcf) per day to 22.7 Bcf per day, around 35 percent of the United States' average daily requirement.[29] However by 2012, U.S. consumption of imported LNG had fallen to less than 0.5 Bcf per day, leaving most of this capacity unused.[30] The ability to make use of and repurpose existing U.S. import infrastructure—pipelines, processing plants, and storage and loading facilities—would help reduce total costs relative to "greenfield," or new, LNG facilities. Given natural gas surpluses in the United States and substantially higher prices in other regional markets, several U.S. companies have applied for export authority and have indicated plans to construct liquefaction facilities.[31]

The EIA projects that the United States will become a net exporter of LNG in 2016, a net pipeline exporter in 2025, and a net exporter of natural gas overall in 2021. This outlook assumes continuing increases in use of LNG internationally, strong domestic natural gas production, and relatively low domestic natural gas prices.[32] In contrast, a study done by the Massachusetts Institute of Technology presents another possible scenario in which a more competitive international gas market could drive the cost of U.S. natural gas in 2020 above that of international markets, which could lead to the United States importing 50 percent of its natural gas by 2050.[33] Yet while increased trade in LNG has started to connect international markets, these markets remain largely distinct with respect to supply, contract structures, market regulation, and prices.

The increase in domestic production (supplies) of natural gas, low prices, and forecasts of continued low prices have not gone unnoticed. The implications for energy consumption are far-reaching and extend across all sectors of the economy. This report examines how each sector may take advantage of this energy transformation and evaluates the greenhouse gas emission implications of each case.

II. PRICE EFFECTS OF THE LOOMING NATURAL GAS TRANSITION

By Michael Webber, The University of Texas at Austin

INTRODUCTION

Given technology developments that have fundamentally altered the profile of U.S. natural gas production and recent low prices that have pushed demand for natural gas in all sectors of the economy, the importance of natural gas relative to other fuels is growing. If recent trends continue, it seems likely that natural gas will overtake petroleum as the most-used primary energy source in the United States. in the next one to two decades.

Such a transition will be enabled (or inhibited) by a mixed set of competing price pressures and a complicated relationship with lower-carbon energy sources that will trigger an array of market and cultural responses. This chapter seeks to layout some of the key underlying trends while also identifying some of these different axes of price tensions (or price dichotomies). These trends and price tensions will impact the future use of natural gas in all of the sectors analyzed later in this report.

NATURAL GAS COULD BECOME DOMINANT IN THE UNITED STATES WITHIN ONE TO TWO DECADES

For a century, oil and natural gas consumption trends have tracked each other quite closely. Figure 1 shows normalized U.S. oil and gas consumption from 1920 to 2010 (consumption in 1960 is set to a value of 1.0). These normalized consumption curves illustrate how closely oil and gas have tracked each other up until 2002, at which time their paths diverged: natural gas consumption declined from 2002 to 2006, while petroleum use grew over that time period. Then, they went the other direction: natural gas consumption grew and oil production dropped. That trend continues today, as natural gas pursues an upward path, whereas petroleum is continuing a downward trend.

The growing consumption of natural gas is driven by a few key factors:

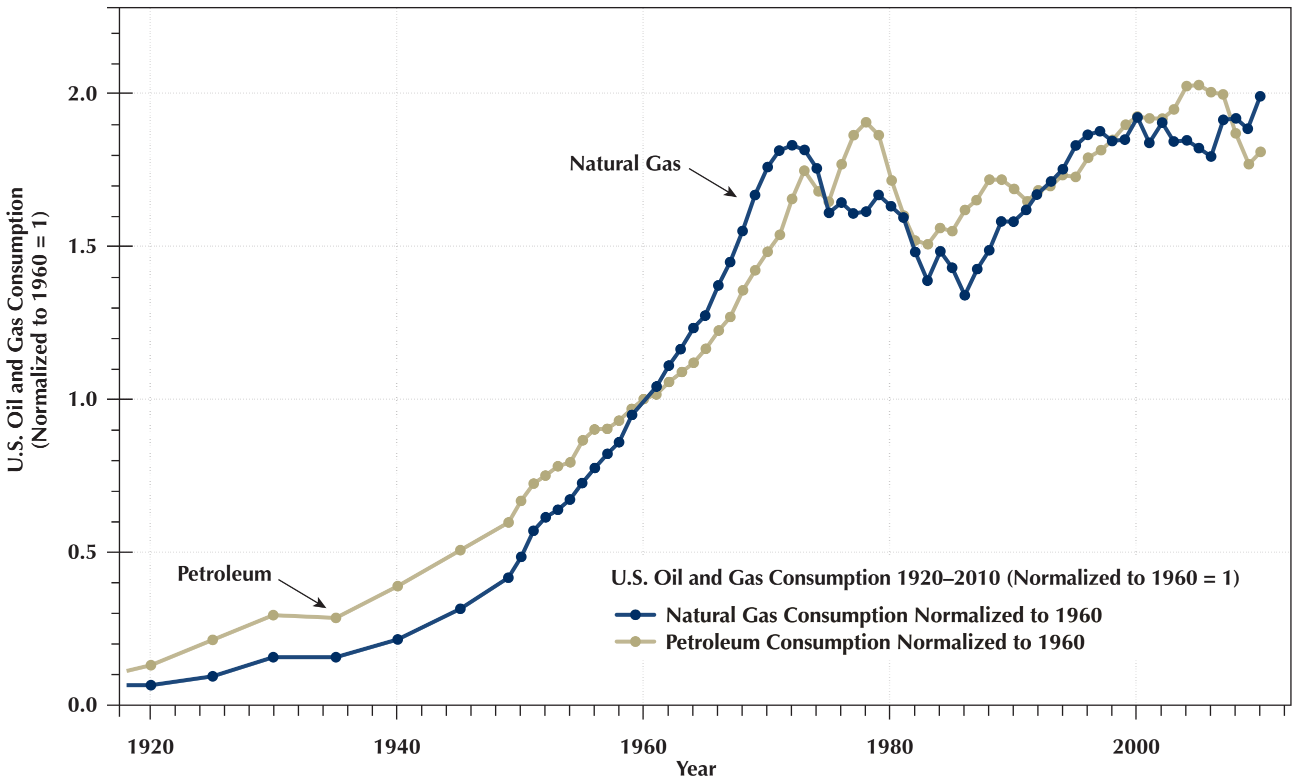
1. It has flexible use across many sectors, including direct use on-site for heating and power; use at power plants; use in industry; and growing use in transportation.
2. It has lower emissions (of pollutants and greenhouse gases) per unit of energy than coal and petroleum
3. It is less water-intensive than coal, petroleum, nuclear, and biofuels
4. Domestic production meets almost all of the annual U.S. consumption

By contrast, the trends for petroleum and coal are moving downwards. Petroleum use is expected to drop as a consequence of price pressures and policy mandates. The price pressures are triggered primarily by the split in energy prices between natural gas and petroleum (discussed in detail below). The mandates include biofuels production targets (which increase the production of an alternative to petroleum) and fuel economy standards (which decrease the demand for liquid transportation fuels). At the same time, coal use is also likely to drop because of projections by the EIA for price doubling over the next 20 years and environmental standards that are expected to tighten the tolerance for emissions of heavy metals, sulfur oxides, nitrogen oxides, particulate matter, and CO_2.

Petroleum use might decline 0.9 percent annually from the biofuels mandates themselves. Taking that value as the baseline, and matching it with an annual growth of 0.9 percent in natural gas consumption (which is a conservative estimation based on trends from the last six years, plus recent projections for increased use of natural gas by the power and industrial sectors), indicates that natural gas will surpass petroleum in 2032, two decades from now, as depicted in Figure 2. A steeper projection of 1.8 percent annual declines in petroleum matched with 1.8 percent annual increase in natural gas consumption sees a faster transition, with natural gas surpassing petroleum in less than a decade.

While such diverging rates might seem aggressive, they are a better approximation of the trends over the

FIGURE 1: U.S. Oil and Gas Consumption, 1920 to 2010



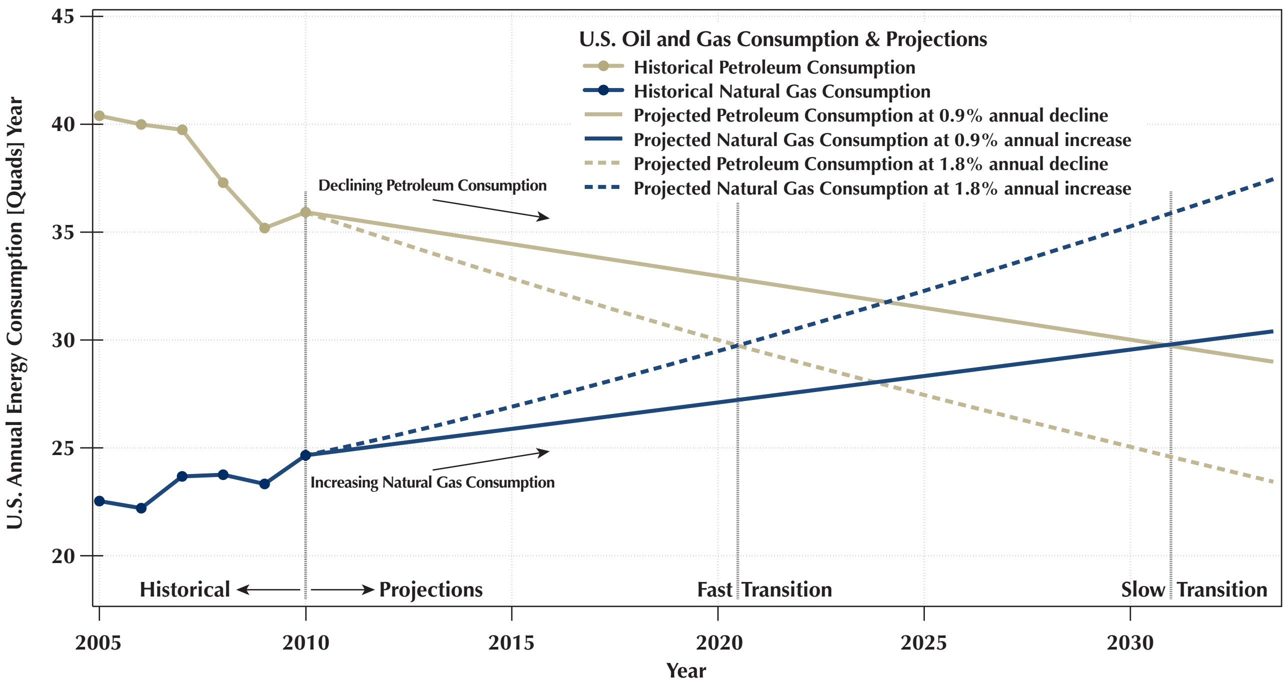
Source: Energy Information Agency, "Annual Energy Review 2010" Technical Report, 2011.

Note: U.S. oil and gas consumption from 1920 to present day (normalized to a value of 1 in 1960) shows how oil and gas have tracked each other relatively closely until 2002, after which their paths diverge. Since 2006, natural gas consumption has increased while petroleum consumption has decreased.

last six years than the respective 0.9 percent values. An annual decline in petroleum of 1.8 percent is plausible through a combination of biofuels mandates (0.9 percent annual decline), higher fuel economy standards (0.15 percent annual decline), and price competition that causes fuel-switching from petroleum to natural gas in the transportation (heavy-duty, primarily) and industrial sectors (0.75 percent annual decline). Natural gas growth rates of 1.8 percent annually can be achieved by natural gas displacing 25 percent of diesel use (for on-site power generation and transportation) and natural gas combined-cycle power plants displacing 25 percent of 1970s and 1980s vintage coal-fired power plants by 2022. While this scenario is bullish for natural gas, it is not implausible, especially for the power sector, whose power plants face retirement and stricter air quality standards. Coupling those projections with reductions in per-capita energy use of 10 percent (less than 1 percent annually) over that same span imply that total energy use would stay the same.

These positive trends for natural gas are not to say it is problem-free. Environmental challenges exist for water, land, and air. Water challenges are related to quality (from risks of contamination) and quantity (from competition with local uses and depletion of reservoirs). Land risks include surface disturbance from production activity and induced seismicity from wastewater reinjection. Air risks are primarily derived from leaks on site, leaks through the distribution system, and flaring at the point of production. Furthermore, while natural gas prices have been relatively affordable and stable in the last few years, natural gas prices have traditionally been very volatile. However, if those economic and environmental risks are managed properly, then these positive trends are entirely possible.

FIGURE 2: U.S. Oil and Gas Consumption and Projections



Source: Energy Information Agency, "Annual Energy Review 2010" Technical Report, 2011.

Note: Natural gas might pass petroleum as the primary fuel source in the United States within one to two decades, depending on the annual rate of decreases in petroleum consumption and increases in natural gas consumption. Historical values plotted are from EIA data.

THERE ARE SIX PRICE DICHOTOMIES WITH NATURAL GAS

In light of the looming transition to natural gas as the dominant fuel in the United States, it is worth contemplating the complicated pricing relationship that natural gas in the United States has with other fuels, market factors, and regions. It turns out that there are several relevant price dichotomies to keep in mind:

1. Natural Gas vs. Petroleum Prices,
2. U.S. vs. Global Prices,
3. Prices for Abundant Supply vs. Prices for Abundant Demand,
4. Low Prices for the Environment vs. High Prices for the Environment,
5. Stable vs. Volatile Prices, and
6. Long-Term vs. Near-Term Prices.

The tensions along these price axes will likely play an important role in driving the future of natural gas in the United States and globally.

DECOUPLING OF NATURAL GAS AND PETROLEUM PRICES

One of the most important recent trends has been the decoupling of natural gas and petroleum prices. Figure 3 shows the U.S. prices for natural gas and petroleum (wellhead and the benchmark West Texas Intermediate (WTI) crude at Cushing, Oklahoma respectively) from 1988 to 2012.[34, 35] While natural gas and petroleum prices have roughly tracked each other in the United States for decades, their trends started to diverge in 2009 as global oil supplies remained tight, yet shale gas production increased. This recent divergence has been particularly stark, as it's driven by the simultaneous downward swing in natural gas prices and upward swing in petroleum prices. For many years, the ratio in prices (per million BTU, or MMBTU) between petroleum and natural gas oscillated nominally in the range of 1–2, averaging 1.6 for 2000–2008. However, after the divergence began in 2009, this spread became much larger, averaging 4.2 for 2011 and, remarkably, achieving ratios greater than 9 spanning much of the first quarter of 2012 (for example, natural gas costs approximately $2/MMBTU today, whereas petroleum costs $18/MMBTU).

This spread is relatively unprecedented and, if sustained, opens up new market opportunities for gas to compete with oil through fuel-switching by end-users and the construction of large-scale fuel processing facilities. For the former, these price spreads might inspire institutions with large fleets of diesel trucks (such as municipalities, shipping companies, etc.) to consider investing in retrofitting existing trucks or ordering new trucks that operate on natural gas instead of diesel to take advantage of the savings in fuel costs. For the latter, energy companies might consider investing in multi-billion dollar gas-to-liquids (GTL) facilities to convert the relatively inexpensive gas into relatively valuable liquids.

DECOUPLING OF U.S. AND GLOBAL PRICES

Another important trend has been the decoupling of U.S. and global prices for natural gas. Figure 4 shows the U.S. prices for natural gas (at Henry Hub) compared with European Union and Japanese prices from 1992 to 2012.[36, 37, 38, 39] In a similar fashion as discussed below, while natural gas prices in the U.S. and globally (in particular, the European Union and Japan) have tracked each other for decades, their price trends started to diverge in 2009 because of the growth in domestic gas production. In fact, from 2003–2005, U.S. natural gas prices were higher than in the EU and Japan because of declining domestic production and limited capacity for importing liquefied natural gas (LNG). At that time, and for the preceding years, the U.S. prices were tightly coupled to global markets through its LNG imports setting the marginal price of gas.

Consequently, billions of dollars of investments were made to increase LNG import capacity in the United States That new import capacity came online concurrently with higher domestic production, in what can only be described as horribly ironic timing: because domestic production grew so quickly, those new imports were no longer necessary, and much of that importing capacity remains idle today. In fact, once production increased in 2009, the United States was then limited by its capacity to export LNG (which is in contrast to the situation just a few years prior, during which the United States was limited by its capacity to import gas), so gas prices plummeted despite growing global demand. Thus, while the United States was tightly coupled to global gas markets

FIGURE 3: U.S. Oil and Gas Prices, 1988 to 2012

Note: While natural gas and petroleum prices have roughly tracked each other in the U.S. for decades, their price trends started to diverge in 2009.

for well over a decade, it has been decoupled for the last several years. At the same time, the European Union and Japan are tightly coupled to the world gas markets, (with the European Union served by LNG and pipelines from the Former Soviet Union, and Japan served by LNG). How long these prices remain decoupled will depend on U.S. production of natural gas, U.S. demand for natural gas, and the time it takes for these isolated markets to connect again. In fact, LNG terminal operators are now considering the investment of billions of dollars to turn their terminals around so that they can buy cheap natural gas in the U.S. that they can sell at higher prices to the EU and Japan. Once those terminals are turned around, these geographically-divergent market prices could come back into convergence.

PRICES FOR ABUNDANT SUPPLY VS. PRICES FOR ABUNDANT DEMAND

Another axis to consider for natural gas prices is the tension between the price at which we have abundant supply, and the price at which we have abundant demand. These levels have changed over the years as technology improves and the prices of competing fuels have shifted, but it seems clear that there is still a difference between the prices that consumers wish to pay and producers wish to collect. In particular, above a certain price (say, somewhere in the range of $4–8/MMBTU, though there is no single threshold that everyone agrees upon), the United States would be awash in natural gas. Higher prices make it possible to economically produce many marginal plays, yielding dramatic increases in total production. However, at those higher prices, the demand for gas is relatively lower because cheaper alternatives (nominally coal, wind, nuclear and petroleum) might be more attractive options. At the same time, as recent history has demonstrated, below a certain price (say, somewhere in the range of $1–3/MMBTU), there is significant demand for natural gas in the power sector (as an alternative to coal) and the industrial sector (because of revitalized chemical manufacturing, which depends heavily on natural gas as a feedstock). Furthermore, if prices are expected to remain low, then demand for natural gas would increase in the residential and commercial sectors (as an alternative

to electricity for water heating, for example) and in the transportation sector (to take advantage of price spreads with diesel, as noted above).

The irony here is that it is not clear that the prices at which there will be significant increases in demand will be high enough to justify the higher costs that will be necessary to induce increases in supply, and so there might be a period of choppiness in the market as the prices settle into their equilibrium. Furthermore, as global coal and oil prices increase (because of surging demand from China and other rapidly-growing economies), the thresholds for this equilibrium are likely to change. As oil prices increase, natural gas production will increase at many wells as a byproduct of liquids production, whether the gas was desired or not. Since the liquids are often used to justify the costs of a new well, the marginal cost of the associated gas production can be quite low. Thus, natural gas production might increase even without upward pressure from gas prices, which lowers the price threshold above which there will be abundant supply. At the same time, coal costs are increasing globally, which raises the threshold below which there is abundant demand. Hopefully, these moving thresholds will converge at a stable medium, though it is too early to tell. If the price settles too high, then demand might retract; if it settles too low, the production might shrink, which might trigger an oscillating pattern of price swings.

LOW PRICES FOR THE ENVIRONMENT VS. HIGH PRICES FOR THE ENVIRONMENT

Another axis of price tension for natural gas is whether high prices or low prices are better for achieving environmental goals such as reducing the energy sector's emissions and water use. In many ways, high natural gas prices have significant environmental advantages because they induce conservation and enable market penetration by relatively expensive renewables. In particular, because it is common for natural gas to be the next fuel source dispatched into the power grid in the United States, high natural gas prices trigger high electricity prices. Those higher electricity prices make it easier for renewable energy sources such as wind and solar power to compete in the markets. Thus, high natural gas prices are useful for reducing consumption overall and for spurring growth in novel generation technologies.

However, inexpensive natural gas also has important environmental advantages by displacing coal in the power sector. Notably, by contrast with natural gas prices, which have decreased for several years in a row, prevailing coal prices have increased steadily for over a decade due to higher transportation costs (which are coupled to diesel prices that have increased over that span), depletion of mines, and increased global demand. As coal prices track higher and natural gas prices track lower, natural gas has become a more cost-effective fuel for power generation for many utility companies. Consequently, coal's share of primary energy consumption for electricity generation has dropped from 53 percent in 2003 to less than 46 percent in 2011 (with further drops in the first quarter of 2012), while the share fulfilled by natural gas grew from 14 percent to 20 percent over the same span. At the same time, there was a slight drop in overall electricity generation due to the economic recession, which means the rise of natural gas came at the expense of coal, rather than in addition to coal. Consequently, for those wishing to achieve the environmental goals of dialing back on power generation from coal, low natural gas prices have a powerful effect.

These attractive market opportunities are offset in some respects by the negative environmental impacts that are occurring from production in the Bakken and Eagle Ford shale plays in North Dakota and Texas. At those locations, significant volumes of gases are flared because the gas is too inexpensive to justify rapid construction of the pricey distribution systems that would be necessary to move the fuel to markets.[40, 41] Consequently, for many operators it ends up being cheaper in many cases to flare the gas rather than to harness and distribute it.

And, thus, the full tension between the "environmental price" of gas is laid out: low prices are good because they displace coal, whereas high prices are good because they bring forward conservation and renewable alternatives. This price axis will be important to watch from a policymaker's point of view as time moves forward.

STABLE VS. VOLATILE PRICES

One of the historical criticisms of natural gas has been its relative volatility, especially as compared with coal and nuclear fuels, which are the other major primary energy sources for the power sector. This volatility is a consequence of large seasonal swings in gas consumption (for example, for space and water heating in the winter) along with the association of gas production with oil, which is also volatile. Thus, large magnitude swings in demand and supply can be occurring simultaneously, but in opposing directions. However, two forces are mitigating this volatility. Firstly, because natural gas prices are decoupling from oil prices (as discussed in above), one layer of volatility is reduced. Many gas plays are produced independently of oil production. Consequently, there is a possibility for long-term supply contracts at fixed prices. Secondly, the increased use of natural gas consumption in the power sector, helps to mitigate some of the seasonal swings as the consumption of gas for heating in the winter might be better matched with consumption in the summer for power generation to meeting air conditioning load requirements.

Between more balanced demand throughout the year and long-term pricing, the prospects for better stability look better. At the same time, coal, which has historically enjoyed very stable prices, is starting to see higher volatility because its costs are coupled with the price of diesel for transportation. Thus, ironically, while natural gas is reducing its exposure to oil as a driver for volatility, coal is increasing its exposure.

LONG-TERM VS. NEAR-TERM PRICE

While natural gas is enjoying a period of relatively stable and low prices at the time of this writing, there are several prospects that might put upward pressure on the long-term prices. These key drivers are: 1) increasing demand, and 2) re-coupling with global markets.

As discussed above, there are several key forcing functions for higher demand. Namely, because natural gas is relatively cleaner, less carbon-intensive, and less water-intensive than coal, it might continue its trend of taking away market share from coal in the power sector to meet increasingly stringent environmental standards. While this trend is primarily driven by environmental constraints, its effect will be amplified as long as natural gas prices remain low. While fuel-switching in the power sector will likely have the biggest overall impact on new natural gas demand, the same environmental and economic drivers might also induce fuel-switching in the transportation sector (from diesel to natural gas), and residential and commercial sectors (from fuel oil to natural gas for boilers, and from electric heating to natural gas heating). If cumulative demand increases significantly from these different factors but supply does not grow in a commensurate fashion, then prices will move upwards.

The other factor is the potential for re-coupling U.S. and global gas markets. While they are mostly empty today, many LNG import terminals are seeking to reverse their orientation, with an expectation that they will be ready for export beginning in 2014. Once they are able to export gas to EU and Japanese markets, then domestic gas producers will have additional markets for their product. If those external markets maintain their much higher prevailing prices (similar to what is illustrated in Figure 4), re-coupling will push prices upwards.

Each of these different axes of price tensions reflects a different nuance of the complicated, global natural gas system. In particular, they exemplify the different market, technological and societal forces that will drive—and be driven by—the future of natural gas.

CONCLUSION

Overall, it is clear that natural gas has an important opportunity to take market share from other primary fuels. In particular, it could displace coal in the power sector, petroleum in the transportation sector, and fuel oil in the commercial and residential sectors. With sustained growth in demand for natural gas, coupled with decreases in demand for coal and petroleum because of environmental and security concerns, natural gas could overtake petroleum to be the most widely used fuel in the United States within one to two decades. Along the path towards that transition, natural gas will experience a variety of price tensions that are manifestations of the different market, technological and societal forces that will drive—and be driven by— the future of natural gas. How and whether we sort out these tensions and relationships will affect the fate of natural gas and are worthy of further scrutiny.

III. GREENHOUSE GAS EMISSIONS AND REGULATIONS ASSOCIATED WITH NATURAL GAS PRODUCTION

By Joseph Casola, Daniel Huber, and Michael Tubman, C2ES

INTRODUCTION

Natural gas is a significant source of greenhouse gas emissions in the United States. Approximately 21 percent of total U.S. greenhouse gas emissions in 2011 were attributable to natural gas.[42] When natural gas is combusted for energy, it produces carbon dioxide (CO_2), which accounts for most of greenhouse gas emissions associated with this fuel. Natural gas is composed primarily of methane (CH_4), which has a higher global warming potential than CO_2. During various steps of natural gas extraction, transportation, and processing, methane escapes or is released to the atmosphere. Although this represents a relatively smaller portion of the total greenhouse gas emissions associated with natural gas production and use, vented and leaked or "fugitive" emissions can represent an opportunity to reduce greenhouse gas emissions, maximizing the potential climate benefits of using natural gas.

Total methane emissions from natural gas systems (production, processing, storage, transmission, and distribution) in the United States have improved during the last two decades, declining 13 percent from 1990 to 2011, driven by infrastructure improvements and technology, as well as better practices adopted by industry. This has occurred even as production and consumption of natural gas has grown. Methane emissions per unit of natural gas consumed have dropped 32 percent from 1990 to 2011. Since 2007, methane emissions from all sources have fallen almost 6 percent, driven primarily by reductions of methane emissions from natural gas systems. Nevertheless, given its impact on the climate, emphasis on reducing methane emissions from all sources must remain a high priority. This chapter discusses the differences between methane and CO_2, emission sources, and state and federal regulations affecting methane emissions.

GLOBAL WARMING POTENTIALS OF METHANE AND CO_2

On a per-mass basis, methane is more effective at warming the atmosphere than CO_2. This is represented by methane's global warming potential (GWP), which is a factor that expresses the amount of heat trapped by a pound of a greenhouse gas relative to a pound of CO_2 over a specified period of time. GWP is commonly used to enable direct comparisons between the warming effects of different greenhouse gases. By convention, the GWP of CO_2 is equal to one.

The GWP of a greenhouse gas (other than CO_2) can vary substantially depending on the time period of interest. For example, on a 100-year time frame, the GWP of methane is about 21.[43] But for a 20-year time frame, the GWP of methane is 72.[44] The difference stems from the fact that the lifetime of methane in the atmosphere is relatively short, a little over 10 years, when compared to CO_2, which can persist in the atmosphere for decades to centuries.

Since models that project future climate conditions are often compared for the target year of 2100, it is often convenient to use 100-year GWPs when comparing emissions of different greenhouse gases. However, these comparisons may not accurately reflect the relative reduction in radiative forcing (the extent to which a gas traps heat in the atmosphere) arising from near-term abatement efforts for greenhouse gases with short lifetimes. Whereas near-term reductions in CO_2 emissions provide reductions in radiative forcing benefits spread out over a century, near-term abatement efforts for methane involve a proportionally larger near-term reduction in radiative forcing. In light of potential climate change over the next 50 years, the control of methane has an importance that can be obscured when greenhouse gases are compared using only their 100-year

GWPs. Accordingly, reducing methane emissions from all sources is important to efforts aimed at slowing the rate of climate change.

EMISSIONS FROM NATURAL GAS COMBUSTION

On average, natural gas combustion releases approximately 50 percent less CO_2 than coal and 33 percent less CO_2 than oil (per unit of useful energy) (Figure 1). In addition, the combustion of coal and oil emits other hazardous air pollutants, such as sulfur dioxides and particulate matter. Therefore, the burning of natural gas is considered cleaner and less harmful to public health and the environment than the burning of coal and oil.

The U.S. Energy Information Administration (EIA) has projected that U.S. energy-related CO_2 emissions will remain more than 5 percent below their 2005 level through 2040, a projection based in large part on the expectation that: 1) natural gas will be steadily substituted for coal in electricity generation as new natural gas power plants are built and coal-fired power plants are converted to natural gas, and 2) state and federal programs that encourage the use of low-carbon technologies will continue.[45] The EIA predicts that natural gas—fired electricity production in the United States will increase from 25 percent in 2010 to 30 percent in 2040, in response to continued low natural gas prices and existing air quality regulations that affect coal-fired power generation.

VENTING AND LEAKED EMISSIONS ASSOCIATED WITH NATURAL GAS PRODUCTION

In 2011, natural gas systems contributed approximately one-quarter of all U.S. methane emissions (Figure 2), of which over 37 percent are associated with production.[46] In the production process, small amounts of methane can leak unintentionally. In addition methane may be intentionally released or vented to the atmosphere for safety reasons at the wellhead or to reduce pressure from equipment or pipelines. Where possible, flares can be installed to combust this methane (often at the wellhead), preventing much of it from entering the atmosphere as methane but releasing CO_2 and other air pollutants instead.

These methane emissions are an important, yet not well understood, component of overall methane emissions. In recent years greenhouse gas measurement and reporting requirements have drawn attention to the need for more accurate data. This uncertainty can be seen in the revisions that have accompanied sector emission

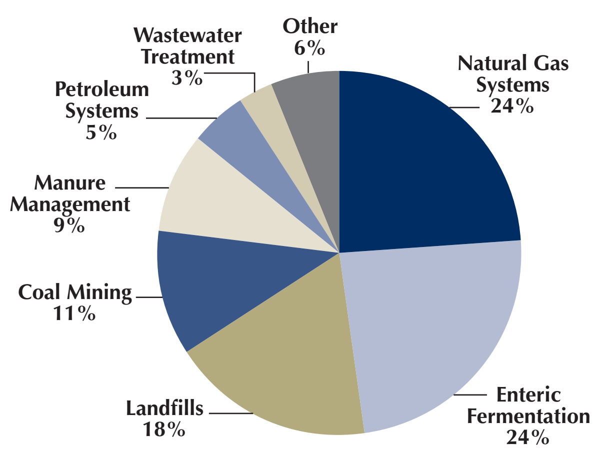
FIGURE 2: **Sources of Methane Emissions in the United States, 2011**



Source: Environmental Protection Agency, Draft U.S. Greenhouse Gas Inventory Report, 2013. Available at: http://www.epa.gov/climatechange/ghgemissions/usinventoryreport.html estimates. Just recently for example, EPA revised downward the estimated level of methane emissions attributable to production of natural gas. In 2010, it estimated about 58 percent of methane emission in the natural gas system came from production. In 2013, EPA reduced that number to 37 percent. A major reason for this revision was a change in EPA's assumption about emission leakage rates. Based on EPA's GHG inventory data, the assumed leakage rate for the overall natural gas system was revised downward from 2.27 percent in 2012 to 1.54 percent in 2013.[47] Independent studies have estimated leak rates ranging from 0.71 to 7.9 percent.[48, 49, 50] EPA and others are trying to better understand the extent of leakage and where this leakage is occurring.

Given the climate implications of methane, considerable effort is also being focused on reducing leakage and methane emissions overall. According to EPA, methane emissions from U.S. natural gas systems have declined by 10 percent between 1990 and 2011 even with the expansion of natural gas infrastructure.[51] This decline is largely the result of voluntary reductions including greater operational efficiency, better leakage detection, and the use of improved materials and technologies that are less prone to leakage.[52] In particular, the EPA's Natural Gas Star Program has worked with the natural gas industry to identify technical and engineering solutions that minimize emissions from infrastructure, including zero-bleed pneumatic controllers, improved valves, corrosion-resistant coatings, dry-seal compressors, and improved leak-detection and leak-repair strategies. The EPA has tracked methane reductions associated with its Natural Gas STAR program (Figure 3) and estimates that voluntary actions undertaken by the natural gas sector reduced emissions by 94.1 billion cubic feet (Bcf) in 2010. Notably, many of the solutions identified by this voluntary program have payback periods of less than three years (depending on the price of natural gas).[53] The success of the Natural Gas STAR program further highlights the importance of understanding where emission leakage is occurring because without accurate data, it is difficult to prioritize reduction efforts or make the case for technologies and processes like those highlighted by the program.

REGULATION OF LEAKAGE AND VENTING

Regulations applicable to methane leakage and venting from natural gas operations have been implemented at both the federal and state level. Although air pollution from natural gas production has been regulated in various forms since 1985 (e.g., toxic substances such as benzene and volatile organic compounds that contribute to smog formation), over the past few years, due to the recent increase in natural gas production and the use of new extraction methods (particularly hydraulic fracturing), natural gas operations have come under renewed scrutiny from policy-makers, non-governmental organizations, and the general public. In response to potential environmental and climate impacts from increased natural gas production including deployment of new technologies, new state and national rules are being developed.

FEDERAL REGULATIONS

EPA released new air pollution standards for natural gas operations on August 16, 2012. The New Source Performance Standards and National Emissions Standards for Hazardous Air Pollutants are the first federal regulations to specifically require emission reductions from new or modified hydraulically fractured and refractured natural gas wells. The New Source Performance Standards require facilities to reduce emissions to a certain level that is achievable using the best system of pollution control, taking other factors into consideration, such as cost.[54] Under the National Emissions Standards for Hazardous Air Pollutants program, EPA sets technology-based standards for reducing certain hazardous air pollutant emissions using maximum achievable control technology. The regulations target the emission of volatile organic compounds, sulfur dioxide, and air toxics, but have the co-benefit of reducing emissions of methane by 95 percent from well completions and recompletions.[55]

Among several emission controls, these rules also require the use of "green completions" at natural gas drilling sites, a step already mandated by some jurisdictions and voluntarily undertaken by many companies. In a "green completion," special equipment separates hydrocarbons from the used hydraulic fracturing fluid, or "flowback," that comes back up from the well as it is being prepared for production. This step allows for the collection (and sale or use) of methane that may be mixed with the flowback and would otherwise be released to the atmosphere. The final "green completion" standards apply to hydraulically fractured wells that begin construction, reconstruction, or modification after August 23, 2011, estimated to be 11,000 wells per year. The "green completion" requirement will be phased-in over time, with flaring allowed as an alternative compliance mechanism until January 1, 2015.

While the "green completion" regulations are expected to reduce methane emissions from natural gas wells, concern has been expressed that the regulations do not apply to onshore wells that are not hydraulically

FIGURE 4: Venting Regulations by State

Available at: http://www.rff.org/centers/energy_economics_and_policy/Pages/Shale_Maps.aspx fractured, existing hydraulically fractured wells until such time as they are refractured, or oil wells, including those that produce associated natural gas.[56] However, geologic and market barriers may limit the applicability of this type of rule to other sources of natural gas.

STATE REGULATIONS

Numerous states have also implemented regulations that address venting and flaring from natural gas exploration and production. Some states with significant oil and gas development, such as Colorado, North Dakota, Ohio, Pennsylvania, Texas, and Wyoming, already have venting and/or flaring requirements in place. For example, Ohio requires that all methane vented to the atmosphere be flared (with the exception of gas released by a properly functioning relief device and gas released by controlled venting for testing, blowing down, and cleaning out wells). North Dakota allows gas produced with crude oil from an oil well to be flared during a one-year period from the date of first production from the well. After that time period, the well must be capped or connected to a natural gas gathering line.[57] These regulations may be changed or upgraded as the national "green completion" rules come into effect. Maps produced by Resources for the Future, show the diversity of state regulations that apply to venting and flaring in natural gas development in 31 states (Figures 4 and 5).

CONCLUSION

The climate implications associated with the production and use of natural gas differ from other fossil fuels (coal and oil). Natural gas combustion yields considerably lower emissions of greenhouse gases and other air pollutants; however, when methane is released directly into the atmosphere without being burned—through accidental leakage or intentional venting—it is about 21 times more powerful as a heat trapping greenhouse gas than CO_2 when considered on a 100-year time scale. As a result, considerable effort is underway to accurately measure methane emission and leakage. Policy-makers should continue to engage all stakeholders in a fact-based discussion regarding the quantity and quality of available emissions data and what steps can be taken to improve these data and accurately reflect the carbon footprint of all segments of the natural gas industry. To that end, additional field testing should be performed to gather up-to-date, accurate data on methane emissions. Policy-makers have begun to create regulations that address methane releases, but a better understanding and more accurate measurement of the emissions from natural gas production and use could potentially identify additional cost-effective opportunities for emissions reductions along the entire natural gas value chain.

IV. POWER SECTOR

By Doug Vine, C2ES

INTRODUCTION

The U.S. power industry produces electricity from a variety of fuel sources (Figures 1 and 2). In 2012, coal-fueled generation provided a little more than 39 percent of all electricity, down from 50 percent in 2005. Nuclear power provided around 19 percent of net generation. Filling the gap left by the declining use of coal, natural gas now provides nearly 29 percent of all electricity and renewables, including wind and large hydroelectric power, provide about 12 percent. Petroleum-fueled generation is in decline, providing less than 1 percent of electricity in 2012.

Natural gas use in the power sector during the 1970s and 1980s was fairly consistent and low, contributing a declining share of total electricity generation as coal and nuclear power's share of total electricity significantly increased. In 1978, in response to supply shortages (the result of government price controls), Congress enacted the Power Plant and Industrial Fuel Use Act.[58] The law prohibited the use of oil and natural gas in new industrial boilers and new power plants, with the goal of preserving the (thought to be) scarce supplies for residential customers.[59] As a consequence, the demand for natural gas declined during the 1980s, contributing to an oversupply of gas for much of the decade. The falling natural gas demand and prices spurred the repeal in 1987 of sections of the Fuel Use Act that restricted the use of natural gas by industrial users and electric utilities.[60] (For an overview of key policies impacting natural gas supply, see Appendix A). Continued low natural gas prices in the 1990s stimulated the rapid construction of gas-fired power plants.[61] In the early 2000s, the building boom in natural gas-fired generation was tempered

FIGURE 1: U.S. Electricity Generation by Fuel Type, 1973 to 2012

somewhat by price spikes, although natural gas-fired generating capacity continues to be added more than any other fuel type. Since 1990, electricity generation from natural gas has increased from around 11 percent to 29 percent of the total net generation in 2012 (Figure 1). In 2006, natural gas surpassed nuclear power's share of the total generation mix, and in April 2012, natural gas and coal each contributed a little more than 32 percent of total generation.

This chapter explores the combination of factors driving change in the power sector. It examines the advantages and disadvantages of natural gas use, the competitive nature of alternative energy sources, and the synergy between natural gas and renewable energy generation. Finally, it explores relevant policy options that could lower greenhouse gas emissions in the sector.

ADVANTAGES AND DISADVANTAGES OF NATURAL GAS USE IN THE POWER SECTOR

From the perspective of an electrical system operator, a power plant owner, or an environmental perspective, natural gas-fueled power generation has many advantages. Natural gas can provide baseload, intermediate, and peaking electric power, and can thus meet all types of electrical demand. It is an inexpensive, reliable, dispatchable source of power that is capable of supplying firm backup to intermittent sources such as wind and solar.[62] Natural gas power plants can be constructed relatively quickly, in as little as 20 months.[63] Air emissions are significantly less than those associated with coal generation, and compared to other forms of electric generation, natural gas plants have a small footprint on the landscape. However, even though combustion of natural gas produces lower greenhouse gas emissions than combustion of coal or oil, natural gas does emit a significant amount of carbon dioxide (CO_2), and its direct release into the atmosphere, as discussed in chapter 3, adds quantities of a greenhouse gas many times more potent than CO_2. Finally, natural gas-fired power plants must be sited near existing natural gas pipelines, or else building new infrastructure may significantly increase their cost.

Cost of Building Natural Gas-Fired Power Plants

Natural gas-fired combined-cycle electricity generation (see Appendix B for a list of power plant technologies) is projected to be the least expensive generation technology in the near and mid-term, taking into account a range of costs over an assumed time period. These costs include capital costs, fuel costs, fixed and variable operation/maintenance costs, financing costs, and an assumed utilization rate for the type of generation plant (Figure 3). The availability of various incentives including state or federal tax credits can also impact the cost of an electricity generation plant, but the range of values shown in Figure 3 do not incorporate any such incentives. Based purely on these market forces, utilities looking at their bottom lines and public utility commissions looking for low-cost investment decisions will favor the construction of natural gas-fired technologies in the coming years.

Emissions

For each unit of energy produced, a megawatt-hour (MWh) of natural gas-fired generation contributes around half the amount of CO_2 emissions as coal-fired generation and about 68 percent of the amount of CO_2 emissions from oil-fired generation (Table 1).

While combustion of natural gas produces lower greenhouse gas emissions than combustion of coal or oil, natural gas does emit a significant amount of carbon dioxide (CO_2). In 2011, the power sector contributed about 33 percent of all U.S. CO_2 emissions.[64] Since 2005, total greenhouse gas emissions from the electricity sector have decreased, even as net electricity generation has remained steady, a result of natural gas-fired electricity

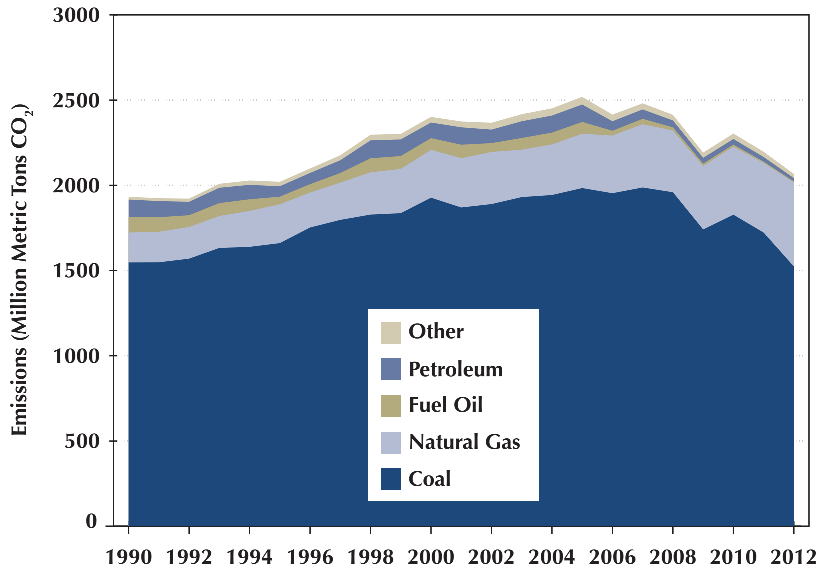
generation displacing petroleum- and coal-fired generation and an increase in the use of renewable generation. In 2012, CO_2 emissions from power generation were at their lowest level since 1993 (Figure 4).

Future Additions to Electricity Generation Capacity

There is strong evidence that the trends toward more natural gas in the power sector will continue in the near and medium term. With natural gas prices expected to stay relatively low and stable and the increasing likelihood of a carbon-constrained future, natural gas has become the fuel of choice for electricity generation by utilities in the United States.[65, 66] In 2012, the electric power industry planned to bring 25.5 gigawatts (GW) of new capacity on line, with 30 percent being natural gas-fired (and the remainder being 56 percent renewable energy and 14 percent coal.[67] Between 2012 and 2040, the U.S. electricity system will need 340 GW of new generating capacity (including combined heat and power additions), given rising demand for electricity and the planned retirement of some existing capacity.[68] Natural gas-fired plants will account for 63 percent of cumulative capacity additions between 2012 and 2040 in the Energy Information Administration (EIA) Annual Energy Outlook 2013 reference case, compared with 31 percent for renewables, 3 percent for coal, and 3 percent for nuclear (Figure 5).

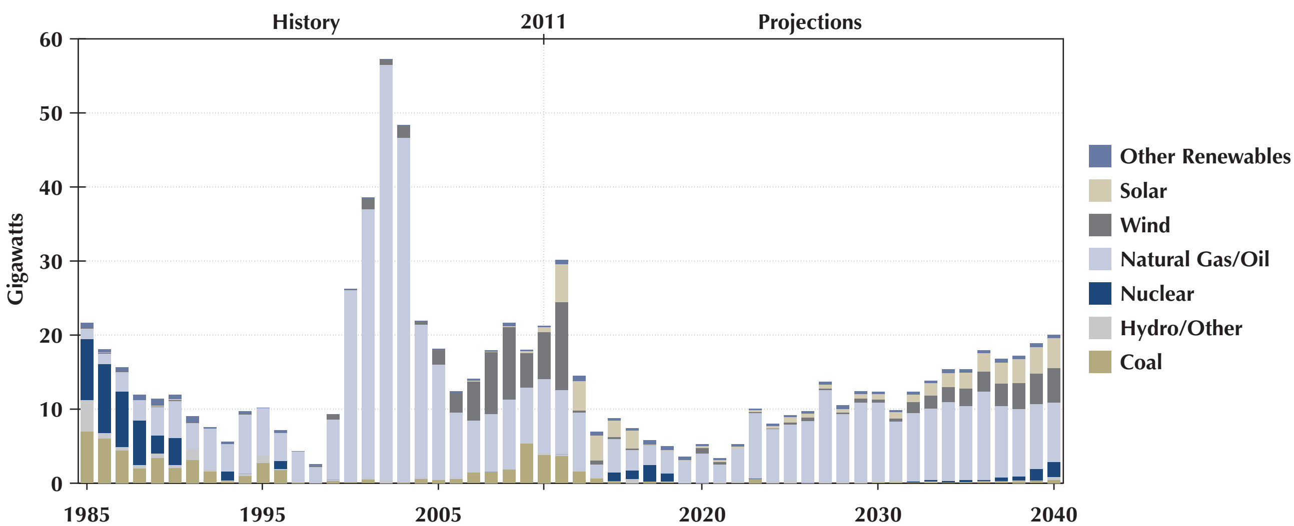
Federal tax incentives and state programs will contribute substantially to renewables' competitiveness in the near term.[69] For example, with the wind production tax credit, wind generation is expected to increase more than 18 GW from 2010 to 2015. Similarly

FIGURE 4: U.S. Emissions in the Power Sector, 1990 to 2012



Source: Energy Information Administration, "Monthly Energy Review," Table 12.6, March 27, 2013. Available at: http://www.eia.gov/forecasts/archive/aeo11/index.cfm

FIGURE 5: Additions to Electricity Generation Capacity, 1985 to 2040



Source: Energy Information Administration, "Annual Energy Outlook 2013," April 15, 2013. Available at: http://www.eia.gov/forecasts/aeo/MT_electric.cfm#cap_addition

with the solar investment tax credit, utility and end-use solar capacity additions are forecast to increase by 7.5 GW through 2016.[70] In addition to federal incentives, state energy programs mandate increased renewable energy capacity additions in thirty-eight states. These states have set standards specifying that electric utilities deliver a certain amount of electricity from renewable or alternative energy sources. Increasing the deployment of zero-carbon energy technologies such as renewables, nuclear, and carbon capture and storage needs to be a priority in order for the United States (and the rest of the world) to address climate change.

Fuel Mix Diversity

Since 1990 the share of generation from natural gas has increased from around 11 percent to 29 percent of the total net generation in 2012 (Figure 1), substantially increasing the diversity of the fuel mix. Natural gas-fired generation is expected to constitute just over 27 percent of the total generation mix in 2020, rising to 30 percent in 2035.[71] Fuel diversity is an important consideration for utilities looking to reduce their reliance on any particular energy source, as too much reliance on any one fuel can expose utilities or other power generation owners to the risks associated with price volatility. From a national perspective, fuel diversity is projected by EIA to remain about the same through 2040 with no single fuel being dominant.[72] Two things could change this outlook, however. One is a scaling back or reversal of the state and federal policies supporting zero-carbon generation, such as state renewable portfolio standards and federal tax incentives.[73] The other is a change in the outlook for the U.S. nuclear generation fleet. Competitive pressures from low natural gas prices have already caused one small, older (1974) plant—the 586 MW Kewaunee plant in Wisconsin—to announce its closure (even though its operating license does not expire until 2033).[74] Should more nuclear generation follow suit, these would likely be replaced by natural gas-fired generation. Given that 19 percent of U.S. electricity comes from nuclear power, there is concern that replacing these with natural gas and decreasing the emphasis on renewable energy deployment would push the U.S. power sector into a situation where fuel diversity is significantly reduced.

OPPORTUNITIES FOR FURTHER GREENHOUSE GAS REDUCTIONS

Beyond the increased use of lower-emitting fuels in the traditional, centralized power-generation system, certain fundamental changes in where and how electricity is generated have the potential to dramatically reduce greenhouse emissions from the sector. These opportunities and challenges are detailed below and are crucial if long-term emission reductions are to be made.

Distributed Generation

Generating electricity at or near the site where it is used is known as distributed generation. A common example is solar panels on the rooftops of homes and businesses, but natural gas is also used in conjunction with distributed generation technologies. For example, natural gas combined heat and power (CHP) systems in industrial, commercial, and residential settings are becoming a more commonplace type of distributed generation.

Traditionally, the power sector functions with centrally located power stations generating large quantities of electricity, which is transported to end users via electrical transmission and distribution lines. With distributed generation systems (also referred to as on-site generation or self-generation, and described in more detail in chapter 7), smaller quantities of electricity are generated at or near the location where it will be consumed, obviating the need for long electrical transmission lines. Additionally, natural gas CHP systems (discussed in more detail in chapter 6) are able to use waste heat from electricity production for practical purposes. Switching from a primarily centrally generated power generation system to a more efficient distributed system that captures waste heat avoids electrical transmission losses, requires less electricity to be generated, and uses less fossil fuel in aggregate, and therefore lowers greenhouse gas emissions.

Supply Side Efficiency

For a host of practical and economic reasons, centralized power generation will not be going away in the near or medium term. Basically, there are three categories of natural gas-fueled central power station: steam turbines, combustion turbines, and combined-cycle power plants (Appendix B). Each of these plant types has an average thermal efficiency. Thermal efficiency measures how well a technology converts the fuel energy input (heat) into electrical energy output (power). A higher thermal efficiency, other things being equal, indicates that less fuel is required to generate the same amount of electricity, resulting in fewer emissions. Steam turbines have the lowest efficiency at around 33 to 35 percent. Combustion turbines are around 35 to 40 percent efficient, and combined-cycle plants have thermal efficiencies in the range of 50 to 60 percent.

More efficient designs should be considered as new natural gas-fired capacity is added to the power sector. The Electric Power Research Institute (EPRI) asserts that it is technologically and economically feasible to improve the thermal efficiencies of steam turbine technology by 3 percent, increase combustion turbines to 45 percent efficient, and construct combined-cycle plants with 70 percent efficiency by 2030.[75] Higher thermal efficiencies translate into less fuel required to generate the same amount of electricity. EPRI's 2009 analysis estimates a potential CO_2 emissions reduction in 2030 of 3.7 percent from the power sector as a result of increasing the efficiency of new and existing fossil fuel-fired generation.[76]

Carbon Capture and Storage

In a carbon-constrained future, and with natural gas potentially playing a greater role in the future of the total generation mix natural gas plants with carbon capture and storage capability will need to be deployed to ensure greenhouse gas emissions are reduced over the long term. Carbon capture and storage projects have already been initiated, and several projects are planned in the next several years to demonstrate the feasibility of the technology, such as the Texas Clean Energy Project and the Kemper County integrated-gasification, combined-cycle (IGCC) project.[77] To date, these projects have been undertaken almost exclusively in conjunction with coal-fired power plants or industrial sources.[78] However, one international project in Norway, set to begin in 2012, endeavors to capture CO_2 from a natural gas CHP plant (similar to a combined-cycle plant) and sequester the CO_2 in an underground saline formation.[79]

In addition to sequestering CO_2 in saline formations, CO_2 is currently being injected into oil wells as part of tertiary, or enhanced, oil production (CO_2-EOR).[80] This storage option has the added benefit of providing an economic incentive, that is, compensation from the oil-field operator to the captured-CO_2 provider. In 2011, the National Enhanced Oil Recovery Initiative (NEORI) was formed to help realize CO_2-EOR's full potential as a national energy security, economic, and environmental strategy. In addition, NEORI suggests federal- and state-level action to support CO_2-EOR.[81]

Economics and Fuel Selection

For power plant operators, the economics of switching from coal to natural gas ultimately depend on underlying fuel prices, which in turn depend on individual location, operational and reliability requirements, and environmental regulations. In mid-2011, natural gas prices fell below coal prices on a dollar-per-energy-output basis. As the gap between the two fuels widened, the share of natural gas-fired power generation increased. However, by July 2012, natural gas prices had rebounded above \$3.10 per thousand cubic feet, the cost point for coal at the time. Accordingly, coal-fired generation increased relative to natural gas-fired generation.[82] Future fuel substitution will depend on the variable prices of both coal and natural gas.

Competitive electric power markets, in some form, exist in 43 states. In competitive power markets, electricity is bid into the market based on production costs. Typically, fuel cost is the main driver of production cost, but fuel costs can vary depending on a plant's location. Other factors such as plant efficiency will also affect production cost, with newer more efficient plants able to bid into the market at lower prices than older plants. Renewable technologies such as hydro and wind have the lowest production costs (Figure 6), and can be bid into a market at near zero dollars. Next in the merit or price order is nuclear power, followed by lignite, a cheaper, softer coal with a high moisture content. Hard coal plants and natural gas combined-cycle plants are in the middle of the supply curve or bid stack. Finally, natural gas combustion turbine plants and oil and diesel plants are the most expensive plants to run and are basically only used during times of peak demand. Electricity system operators employ a least-cost dispatch methodology. The point at which the quantity of electricity demanded at any point in time crosses the price-ordered supply curve is known as the marginal generator, and this sets the market price. Coal- or natural gas-fired plants are the marginal generator in most competitive power markets. Even though other suppliers such as wind and nuclear have bid into the market at a price lower than the marginal generator, all units receive the marginal or market price for that time period.

Lower natural gas prices and greater quantities of low variable cost renewables are contributing to lower prices in competitive electricity markets. Current and forecast low natural gas prices were cited as one of the reasons behind the recently announced decision to shut down a 556 megawatt (MW) Wisconsin-based nuclear power station.[83] Additionally, there is evidence to suggest that lower natural gas prices suppress the development of renewables.[84] In this situation, government policies are undoubtedly necessary to ensure that zero-carbon generation sources are a growing, rather than declining, share of the U.S. energy mix.

Relationship Between Natural Gas and Renewables

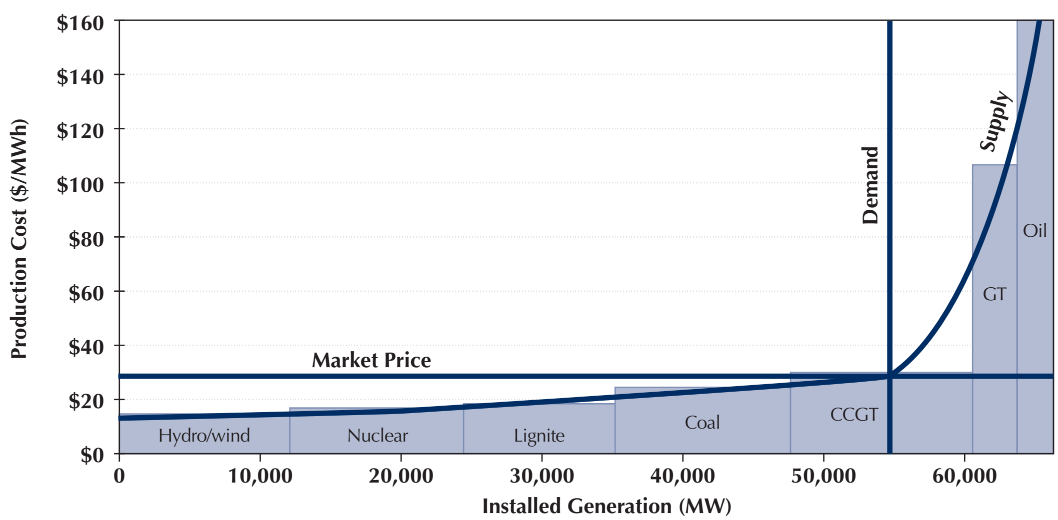
There is a complicated relationship between natural gas and renewables in the power sector, stemming from two aspects: 1) competition in the dispatch order between natural gas and renewables, and 2) the potential to produce renewable forms of natural gas.

For the most part, the relationship between natural gas and renewables is interpreted as competition in the power sector, by which renewables are seen as a threat to natural gas because they push natural gas-fired power plants off the bid stack. This phenomenon occurs because the power markets take bids on marginal costs rather than all-in costs. Because the marginal cost of wind is zero, it bids zero (or negative in some cases, reflecting the effect of production tax credits for wind power). Consequently, it is a price-taker in the markets, and it displaces the highest bidders, which are the price-setters. Historically, those price-setters are natural gas power plants, and so wind power displaces natural gas. Consequently, the relationship between gas and wind is one of rivalry. Natural gas interests audibly complain about this rivalry, with the criticism that policy supports for wind give it an unfair advantage in this competition. Renewable energy supporters counter that natural gas interests are not required to pay for their pollution (which is a form of indirect subsidy) and have enjoyed government largesse in one form or another for many decades.

Despite the perception that wind and natural gas are vicious competitors in a zero-sum game where the success of one must come at the demise of the other, the relationship is actually more nuanced. In fact, wind and gas benefit from each other because they both mitigate each other's worst problems. For wind, intermittency is a problem, and for natural gas, price volatility has been a problem historically. It turns out that the ability for natural gas power plants to serve as rapid response firming power is an effective hedge against wind's intermittency. And, it turns out the fixed fuel price (at zero) of wind farms is an effective hedge against natural price volatility. Thus, they are complementary partners in the power markets.

Almost all natural gas used today comes from geologic reserves formed many millions of years ago. Therefore, many people seeking a long-term sustainable energy option reject natural gas automatically because it is widely considered a fossil fuel that has a finite resource base. It is important to note that there are also renewable forms of natural gas, known as biogas or biomethane. This form of gas is mostly methane (CH_4) with a balance of CO_2, and is created from the anaerobic decomposition of organic matter. While renewable natural gas is a small fraction of the overall gas supply, it is not negligible. For example, landfill gas is already an important contributor to local fuel supplies at the local scale. And, recent studies have noted that the total potential supply available from wastewater treatment plants and anaerobic digestion of livestock waste is over 1 quadrillion British thermal units annually in the United States, which is more than 10 percent of the amount of renewable energy consumed in the United States in 2011.[85, 86, 87]

FIGURE 6: Generalized Representation of a Competitive Power Market



Source: Adapted from Rawls, Patricia, U.S. Department of Energy: National Energy Technology Laboratory, "The PJM Region: A GEMSET Characterization for DOE." December 13, 2002. Available at http://www.netl.doe.gov/energy-analyses/pubs/200220DecPJMregionHandout.pdf

KEY POLICY OPTIONS FOR THE POWER SECTOR

Significant policy decisions affecting the U.S. power sector today include regulations to address the interstate air pollution transport, the National Emissions Standards for Hazardous Air Pollutants, and the proposed New Source Performance Standards issued by the U.S. Environmental Protection Agency (EPA). For electricity generation plants to comply with the Cross State Air Pollution Rule and National Emissions Standards for Hazardous Air Pollutants, they will need to install pollution control technologies, a requirement that will affect coal-fired plants in particular.[88] PJM, the operator of the world's largest wholesale electricity market, located in the eastern United States, predicts that approximately 14 GW of coal-fired generation (out of an installed capacity of 78.6 GW of coal-fired generation) could be retired by 2015, largely due to these rules.[89] Questions have been raised about the implications of these retirements on the electricity system's capacity and ability to meet demand and specifically reserve margins. Reserve margins are the spare capacity that electricity system or market operators are required to maintain above the projected peak loads in order to ensure system reliability. While reserve margins appear sufficient in the short run, new, reliable baseload generation will be required in the next 10 to 20 years to fill the gap.

In late March 2012, EPA proposed CO_2 pollution standards for new electric power plants as part of its New Source Performance Standards program. The proposed standard is 1,000 pounds of CO_2 per megawatt-hour, and under this new standard all new power plants would need to match the CO_2 emissions performance currently achieved by highly efficient natural gas combined-cycle power plants. While new efficient natural gas, nuclear, or renewable energy plants would meet this standard easily, new coal-fired power plants could meet the standard only by capturing and permanently sequestering their greenhouse gas emissions using carbon capture and storage technologies. If adopted, this standard would favor new natural gas-fired generation over coal in the future.[90]

In the past few years, there has also been some interest in a federal-level renewable portfolio standard and, more recently, in a broader federal clean energy standard. Whereas a renewable portfolio standard typically credits only 100 percent-renewable generation such as wind, solar, geothermal, or new hydro power, a clean energy standard would create a mechanism to credit "cleaner" electricity generation as well, that is, generation that emits some CO_2 although less than a reference power plant technology such as a generic coal power plant. Under a clean energy standard proposal, credits would be available to new and incremental (upgrades and improvements to) natural gas-fired generation, natural gas with carbon capture and storage, and other relatively cleaner forms of electricity production.[91] Indiana and West Virginia have alternative energy portfolio standards, similar to a renewable portfolio standard; however, these standards allow natural gas-fueled generation to be a part of their clean energy goals. In this way, some policy-makers have recognized that there are significant emissions benefits to natural gas use.

There is a need, however, to continue moving the power generation sector to even cleaner generation (zero-emission sources), to reduce CO_2 emissions to levels that will stave off the worst effects of climate change.

A price on carbon is a highly effective policy that can provide an incentive for zero-emission sources but it is not the only option. Tax credits for renewable generation, carbon capture and storage, nuclear loan guarantees, and policies that promote energy efficiency are all being used, to some extent, in the United States to acccelerate the deployment of low-carbon energy.

CONCLUSION

Market forces are driving greater use of natural gas in the power sector, and the inherent qualities of natural gas combustion are leading to lower greenhouse gas emissions. Adoption of distributed generation technologies, more efficient technology, and carbon capture and storage with natural gas have the potential to lower greenhouse gas emissions further. Market forces are joined by policy decisions, enacted and pending, that impact coal-fired generation and will further discourage its use. In addition, some states' alternative energy portfolios count natural gas-fueled generation toward their medium-term clean energy goals.

Low natural gas prices are having an impact on the diversity of the fuel mix used in electricity generation. In the near term, the diversity of the fuel mix is increasing as fuel-switching from coal to natural gas proceeds; however, in the long term, a sustained low natural gas price may discourage investment in nuclear generation and renewables. Policy is necessary to ensure that the percentage of zero carbon-emission power generation is growing sufficiently to mitigate the most dangerous effects of climate change.

APPENDIX A: NATURAL GAS POLICY

1938	The Natural Gas Act of 1938 establishes federal authority over interstate pipelines, including the authority to set "just and reasonable" rates. It also establishes a process for companies seeking to build and operate interstate pipelines. Oversight of The Act is given to the Federal Power Commission.
1954–1978	Natural gas price controls eventually lead to scarcity and shortage.
1978	In response to supply shortages, Congress enacts the Power Plant and Industrial Fuel Use Act. The law prohibits the use of natural gas in new industrial boilers and new electric power plants. The goal is to preserve "scarce" supplies for residential customers.
1985	The Federal Power Commission is replaced by the Federal Energy Regulatory Commission, which issues Order 436, intended to provide for open access to interstate pipelines that would offer transportation service for gas owned by others.
1987	President Reagan signs into law the repeal of the remaining Fuel Use Act restrictions and incremental pricing, believing that the country's natural gas resources should be free from regulatory burdens, which some saw as costly and counterproductive.
1990	On April 3rd, trading on natural gas futures begins at the New York Mercantile Exchange.
2005	The Energy Policy Act 2005 is passed, a bill exempting fluids used in the natural gas extraction process of hydraulic fracturing from protections under the Clean Air Act, Clean Water Act, Safe Drinking Water Act, and Comprehensive Environmental Response, Compensation, and Liability Act. The Act exempts companies drilling for natural gas from any requirement to disclose the chemicals involved in fracking operations, normally required under federal clean water laws. The proposed Fracturing Responsibility and Awareness of Chemicals Act would repeal these exemptions.
2011	Tough pollution limits (Cross State Air Pollution Rule) and limits on mercury, sulfur oxides (SO_x), and nitrogen oxides (NO_x) emissions (National Emissions Standards for Hazardous Air Pollutants) begin to drive older inefficient coal plants out of the market.
2011	A proposed Federal Clean Energy Standard credits natural gas relative to a coal reference power plant.
2012	New Source Performance Standard for CO_2 is proposed by EPA.

APPENDIX B: POWER PLANT TECHNOLOGIES

Steam Turbines

A common method of generating electricity is with steam turbines (Figure B-1). A power plant uses a combustible fuel—coal, oil, natural gas, wood waste—or nuclear fission to heat water in a boiler, which creates steam. The high-temperature, high-pressure steam is piped toward turbine blades, which move and rotate the attached turbine shaft, spinning a generator, where magnets within wire coils produce electricity.[92] Steam units have a relatively low efficiency. Only about 33 to 35 percent of the thermal energy used to generate the steam is converted into electrical energy, and the remaining heat is left to dissipate. Baseload electricity generation commonly relies on large coal- and nuclear-powered steam units on the order of 500 to 1000 MW or greater, as they can supply low-cost electricity nearly continuously.

Combustion Turbine

Combustion turbines are another widespread technology for centralized power generation (Figure B-2). In a combustion turbine, compressed air is ignited by burning fuel (e.g., diesel, natural gas, propane, kerosene, or biogas) in a combustion chamber. The resulting high-temperature, high-velocity gas flow is directed at turbine blades, which spin a turbine driving the air compressor and the electric power generator. Combustion turbine plants are typically operated to meet peak load demand, as they can be switched on relatively quickly. Another advantage is their ability to be a firm backup to intermittent wind and solar power on the grid, if needed. The typical size is 100 to 400 MW, and their thermal efficiency is slightly higher than steam turbines at around 35 to 40 percent.

Combined Cycle

A basic combined-cycle power plant combines a combustion turbine and a steam turbine in one facility (although there are other possible configurations) (Figure B-3). Combined-cycle plants waste considerably less heat than does either turbine alone. As combustion turbines became more advanced in the 1950s, they began to operate at ever-higher temperatures, which created increasing amounts of exhaust heat.[93] In a combined-cycle power plant, this waste heat is captured and used to boil water for a steam turbine generator, thereby creating additional generation capacity from the same amount of fuel. Combined-cycle plants have thermal efficiencies in the range of 50 to 60 percent. Historically,

FIGURE B-1: Steam Turbine

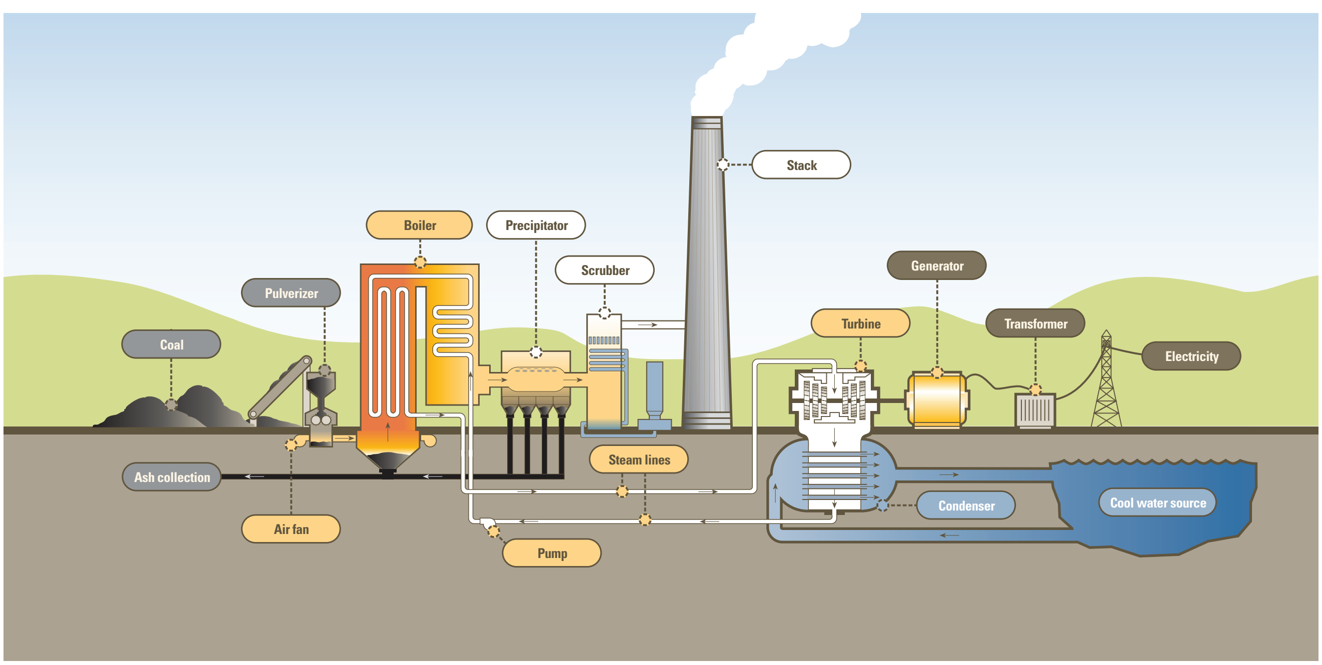


FIGURE B-2: Combustion Turbine

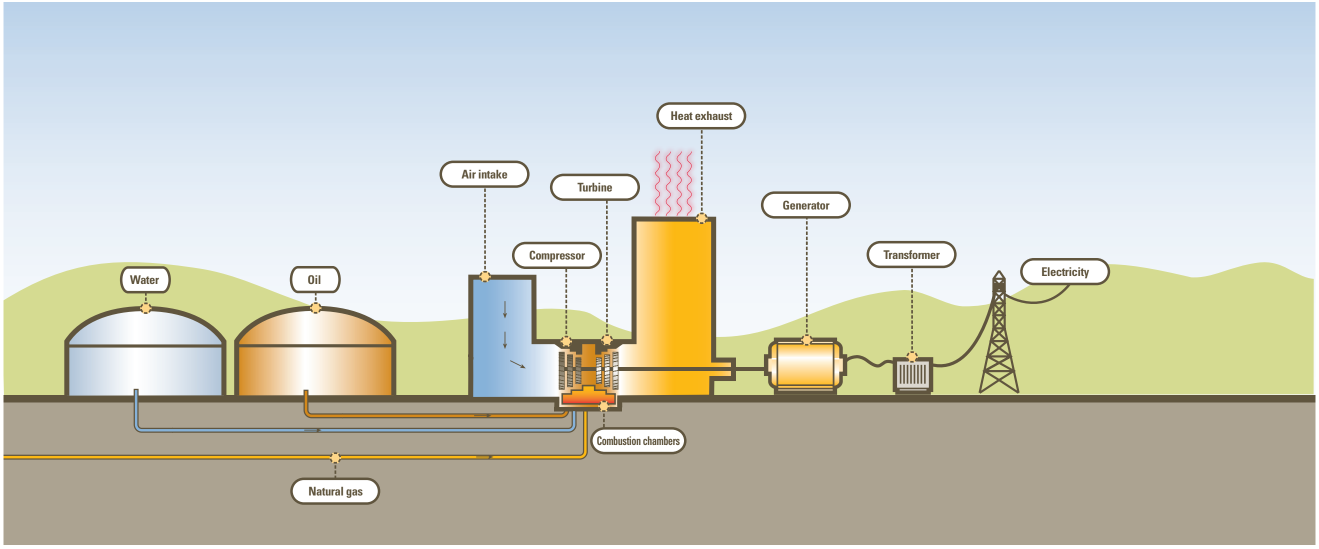

FIGURE B-3: Combined-Cycle Power Plant

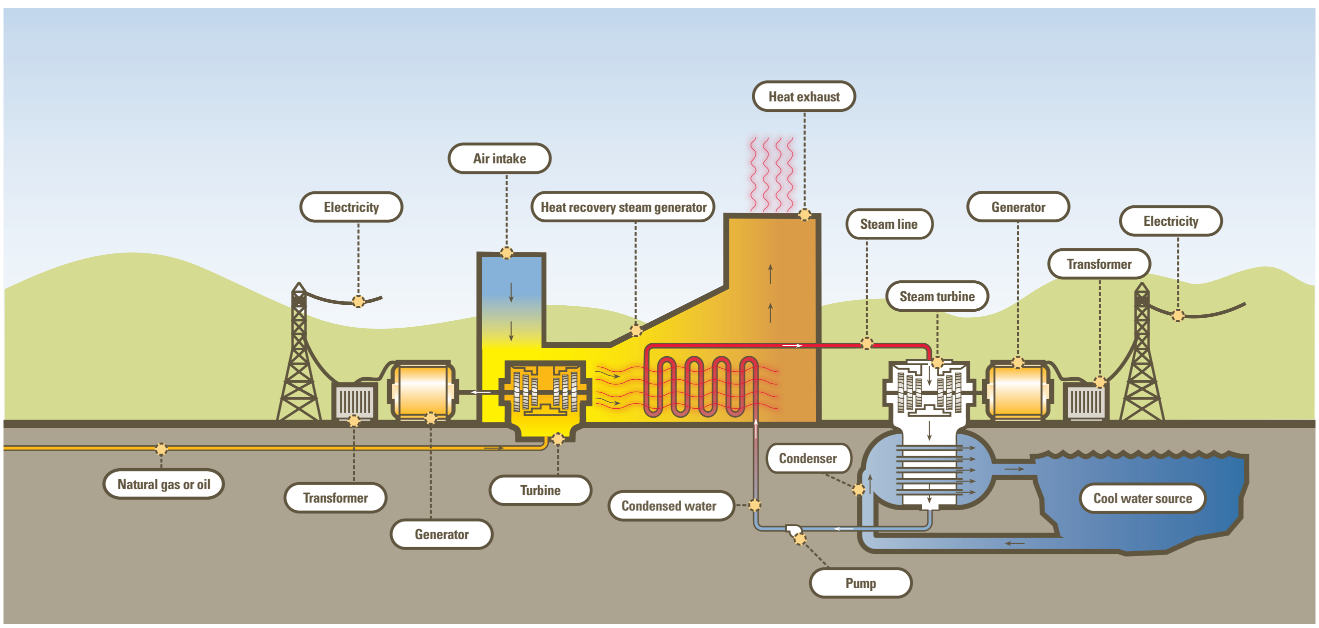

they have been used as intermediate power plants, supporting higher daytime loads; however, newer plants are providing baseload support. Cutting edge natural gas combined-cycle power plants are coming online with thermal efficiencies at 61 percent with a correspondingly smaller emission of greenhouse gases; these plants are able to cycle on and off more frequently (than most of the installed power plant fleet) to more efficiently complement intermittent renewable generation.[94]

V. BUILDINGS SECTOR

By Fred Beach, The University of Texas at Austin

INTRODUCTION

In 2009, the U.S. buildings sector accounted for about 41 percent of primary energy consumption.[95] Energy was delivered to more than 113 million residences and 4.8 million commercial and institutional buildings by four primary means: electricity, natural gas, district heat, and fuel oil. In both residential and commercial building sectors, natural gas and electricity have been the dominant fuel sources over the last 30 years. In the residential sector the proportion of electricity used has grown rapidly compared to other energy sources, largely driven by the proliferation of home electronics (Figure 1). In 2003 in the commercial sector, electricity and natural gas accounted for 87 percent of all energy used (Figure 2).[96] In 2011, residential and commercial buildings accounted for 34 percent of greenhouse gas emissions in the United States. Among fuels typically used in residential and commercial buildings, electricity usage accounted for 74 percent of carbon dioxide (CO_2) emissions from fossil fuel combustion, which accounts for the majority of greenhouse gas emissions from the buildings sector. Natural gas and other fuel combustion accounted for the remaining 26 percent.[97]

The fuel mix in the buildings sector heavily influences its greenhouse gas emissions. Natural gas consumed on site has relatively low emissions compared with the average emissions associated with liquefied petroleum gas (propane), fuel oil, or electricity. Electricity in particular typically has emissions far above those of natural gas. In 2011, more than 40 percent of U.S. electricity production came from coal-fired power plants, which create more CO_2 per unit of energy delivered than natural gas,

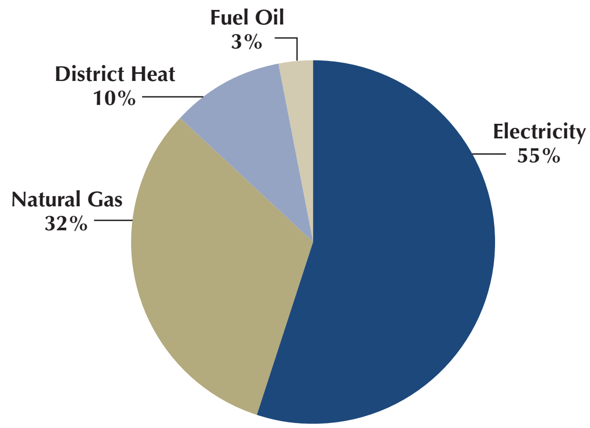
FIGURE 2: U.S. Commercial Energy Consumption by Source, 2003



Source: Energy Information Administration, "Overview of Commercial Buildings, 2003," 2003. Available at: http://www.eia.gov/emeu/cbecs/cbecs2003/overview1.html propane, and fuel oil used on site.[98] Coal-fired electricity also produces sulfur dioxide (SO_2), nitrogen oxides (NO_X), and mercury, which are associated with environmental damage and harmful health effects.

Because of the significant amounts of primary energy and greenhouse gas emissions associated with electricity generation and consumption, and the relatively higher greenhouse gas emissions footprint associated with fuel oil, switching from inefficient electricity or fuel oil to high-efficiency natural gas in buildings can yield significant emission reductions. This chapter provides an overview of energy consumption in residential and commercial buildings, which is driven by climate zone, business needs and activities, building size, and, in large part, consumer behavior. It explains why consideration of primary and "source-to-site" energy, a measure of energy consumption that occurs prior to consumer energy use on site, contributes to a more complete picture of energy consumed and emissions emitted. Accordingly, this chapter makes use of the concept of full-fuel-cycle efficiency, which is the appropriate energy and efficiency metric with which to compare consumer fuel choices and consequences for greenhouse gas emissions. It demonstrates how using natural gas appliances could lead to dramatic reductions in fuel consumption and greenhouse gas emissions. Finally, the chapter looks at how policy support, including efficiency programs, consumer information, and innovative funding models, can help to overcome the barriers to increased natural gas access and utilization in the buildings sector.

ENERGY USE IN RESIDENTIAL AND COMMERCIAL BUILDINGS

There are strong regional variations in the types of energy available to and used in buildings. A significant factor affecting energy use is where a building is located. Homes in colder climates tend to consume more energy, driven by heating (often called thermal) requirements. Nationally, 61 percent of residential energy is used for space heating and water heating (41 percent and 20 percent, respectively), while air conditioning (space cooling) consumes only 8 percent. Overall, thermal uses are dominant in all regions of the country (Figure 3). In the commercial sector as well, the dominant energy uses are thermal loads (space and water heating), followed by lighting (Figure 4).

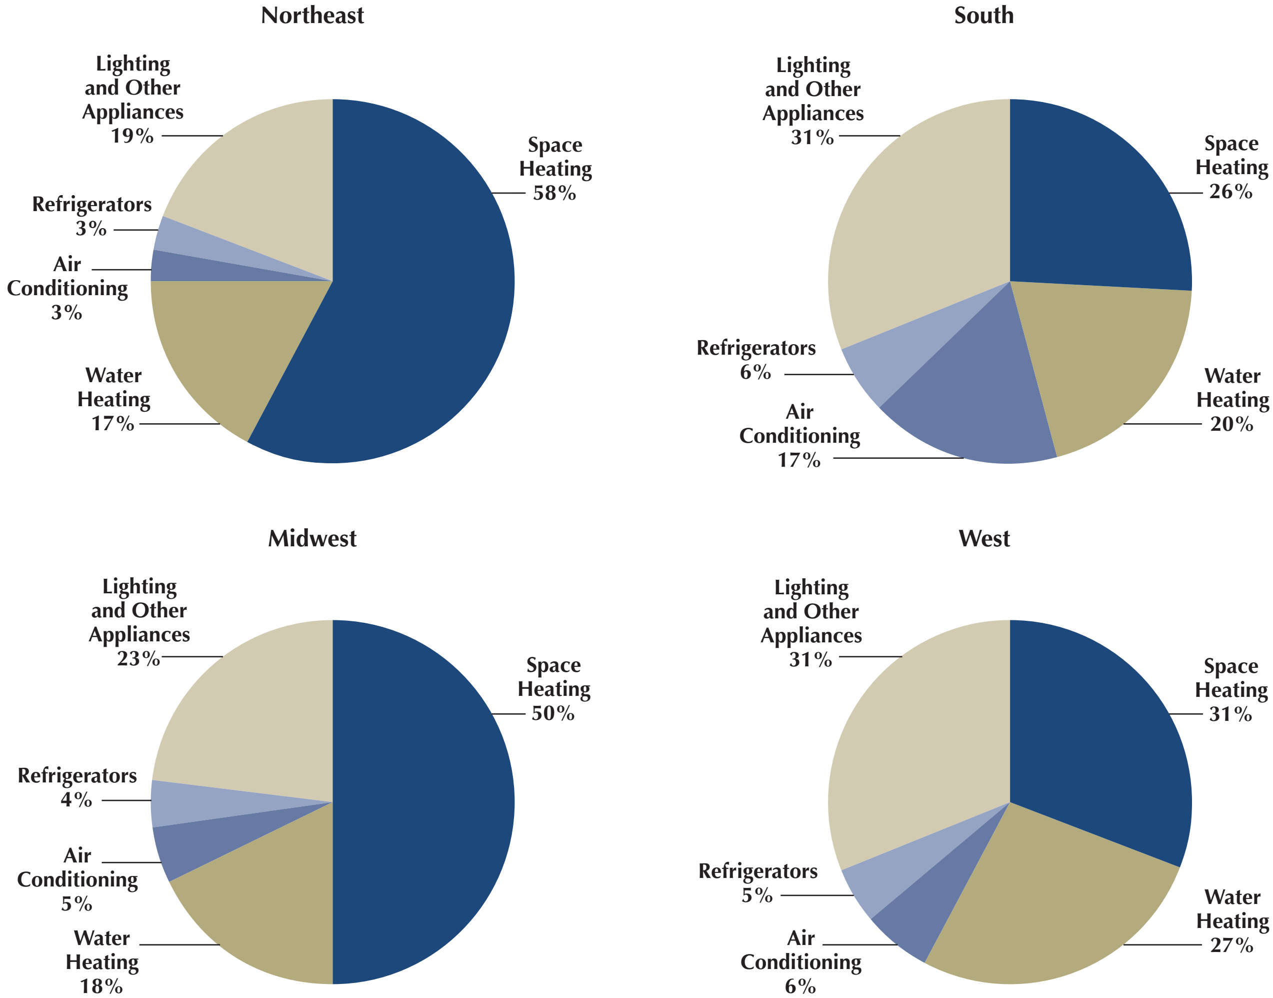
Energy Use in Commercial Buildings

Energy use among U.S. commercial buildings is quite diverse. Among commercial buildings, significant variation exists in the purpose and size of buildings, energy use, and emission profiles. Office space is the largest energy consumer, consuming 719 trillion Btu of electricity on site. Educational facilities are the second largest commercial consumer, using 371 trillion Btu of electricity on site. These two types of commercial buildings account for 36 percent of all the electricity used in buildings. Because they rely on relatively inefficient grid-delivered electricity rather than on-site generation (see below), they also have the highest emissions profiles.[99]

Commercial buildings vary in terms of energy intensity, measured in Btu consumption per square foot. The three most energy-intensive building sectors are food service, food sales, and health care, which use 258, 200 and 188 Btu per square foot per year, respectively.[100] While 84 percent of food service square footage is served by natural gas, only 60 percent of food sales square footage uses this fuel. The food service sector requires a large amount of thermal energy for cooking and cleaning, while energy use for food sales is predominantly for refrigeration. Thermal demands for in-patient healthcare are also heavy, with large amounts of food preparation, water heating, and cleaning. With these demands, 95 percent of building stock used for in-patient health care is served by natural gas, while only 59 percent of outpatient health care facilities use natural gas where are there are lower thermal loads.[101]

Building size also plays an important role in energy consumption and fuel source. Commercial buildings of more than 100,000 square feet account for only 2 percent of the total number of buildings, but they account for more than 34 percent of total floor space and more than 40 percent of total energy use (Figure 5). Clearly, this segment exhibits a higher concentration of high energy consumption, while being less fragmented in ownership than smaller buildings. Among large buildings of over 100,000 square feet, 77 percent use natural gas for space heating.[102, 103] The predominance of natural gas for heating in the largest of buildings, food service, and in-patient hospitals can be directly attributed to the greater overall efficiency and lower cost of natural gas over electricity for thermal applications such as space heating, water heating, and cooking.

FIGURE 3: U.S. Home Energy Consumption By End Use, 2005



Source: Energy Information Administration, "Annual Energy Review 2009," Table US12. Available at http://www.eia.gov/consumption/residential/data/2009/#consumption-expenditures

The types of activities carried out in commercial buildings also influence the type of energy used. Office buildings tend to utilize electricity rather than natural gas because many of their primary loads, such as lighting, elevators, personal computers, servers, scanners, and printers, cannot be served by natural gas. Lodging, health care, and food service, in contrast, can more easily use natural gas for cooking, hot water, cleaning, and laundry, and, consequently, they use proportionally more natural gas than office buildings.

Local climate plays a large role in determining what type of energy is used, and how. The majority of commercial (and residential) buildings are located in colder climate zones (zones 1 to 4), which encompass much of the country except for the Deep South and the Southwest. In colder zones, winters are cold enough for frequent, substantial space heating, and the average amount of energy needed to heat a building during the winter, measured in heating degree days, is two to four times the average amount of energy needed to cool a building during the summer (measured in cooling degree days) (Figure 6). Still, space and water heating account for the greatest energy use in buildings regardless of climate zone (Figures 3 and 4).

FIGURE 4: U.S. Commercial Energy Consumption by End Use, 2003

Energy Use in Residential Buildings

The prevalence of natural gas access and use in homes varies across U.S. climate zones, even though natural gas is a more efficient fuel choice for thermal loads. Natural gas appliances tend to be underrepresented in use, even when there is access to the fuel. In the two coldest regions in the country, natural gas is the preferred fuel for heating water in 23.7 million homes, while electricity is used in 10.8 million homes. The numbers suggest that nearly all of the homes using gas for space heating are also using it for water heating.[104] Nationwide, the story is different. Forty percent of households with natural gas access used electric appliances for space heating, water heating, or both in 2009, and that number has increased in recent years, with a four-million-household increase in residences with natural gas access using electric space heating.[105]

In warmer climates, natural gas use is less common than electricity for space heating—12.3 million residences use natural gas compared with 16.5 million using electricity.[106] However, natural gas and electricity are equally popular for water heating with an even split at 16 million homes each.[107] In these areas, more than 3 million homes had access to natural gas (as indicated by water heating usage) but did not use it for space heating.

Appliances, such as clothes dryers, ovens, and cooktops, are available in either electric, natural gas, propane, or fuel oil models, with electric and natural

5,001 to 10,000 square feet	948	6,585	563
1,001 to 5,000 square feet	2,586	6,789	685

Source: Energy Information Administration, "Natural Gas Consumption and Conditional Energy Intensity by Building Size for All Buildings, 2003" Table C31. Available at: http://www.eia.gov/consumption/commercial/data/archive/cbecs/cbecs2003/detailed_tables_2003/2003set16/2003html/c31a.html

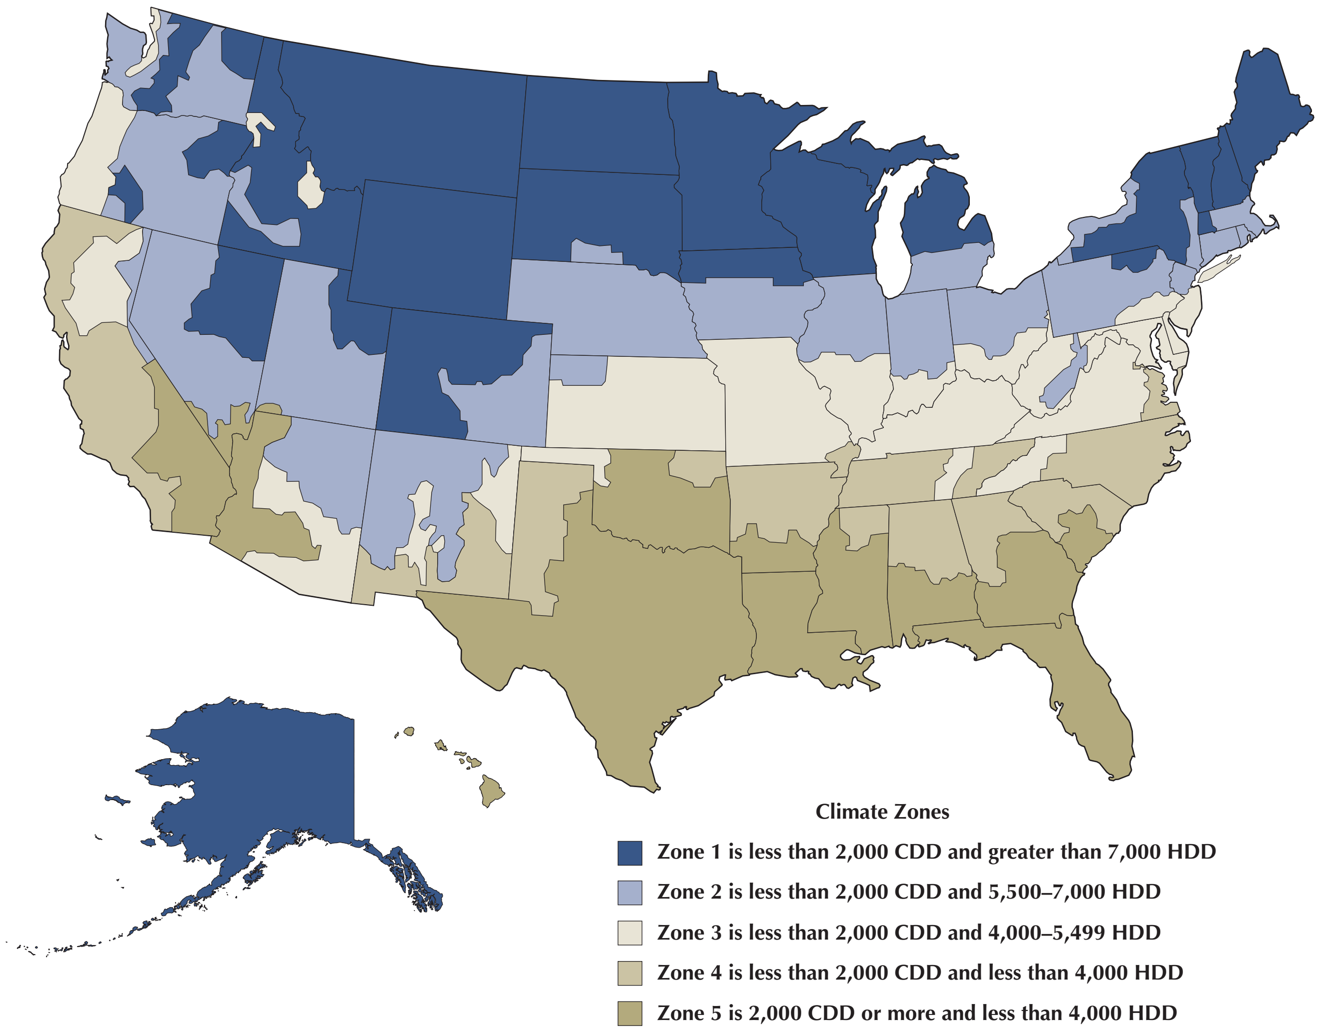
gas models being the most common by far (Figure 7). Nationwide, electric dryers outnumber gas models 4 to 1 (71.8 million compared to 17.5 million). For cooking appliances, whether ovens or cooktops, the ratio is almost 2 to 1 (68.1 million homes use electricity and 38.4 million use natural gas).[108] In theory, the use of these appliances should be independent of climate zone variations since they operate within the heated and cooled space of homes. Yet, natural gas appliances are significantly underrepresented in all climate zones.[109]

In the two coldest regions, zones 1 and 2, natural gas is the dominant space heating fuel, heating 24.8 million homes in 2005. In contrast, only 5.6 million homes used electric space heating in the same year (Figure 4).[110] Nationally, natural gas is also the chief fuel source for heating in commercial buildings. In 2003 in colder climate zones, it provided heat for 69 to 75 percent of all commercial floor space, but only 47 percent in zone 5, the warmest region.[111]

SOURCE-TO-SITE EFFICIENCY, SITE EFFICIENCY, AND FULL-FUEL-CYCLE EFFICIENCY

Building energy consumption can be measured in terms of fuel use on site: kilowatts of electricity, cubic feet of gas, and gallons of propane or fuel oil. This site energy is the total of all energy consumed at a building as measured by the electric and natural gas meters as it enters the building and/or by fuel oil or propane delivery. However, site energy does not tell the full energy story, because energy, whatever the source, must be extracted and delivered to the point of use, incurring losses along the way that are not reflected in the readings on customers' meters or delivery bills. As discussed in chapter 4, fossil fuels, such as coal or natural gas, are most often used to generate electricity. The term "source-to-site" generally refers to the total energy consumed in the course of extracting, processing, and delivering a unit of energy to a building, and in the case of electricity, energy associated with generation, transmission, and distribution. In other

FIGURE 6: **U.S. Climate Zones, Heating Degree Days vs. Cooling Degree Days**



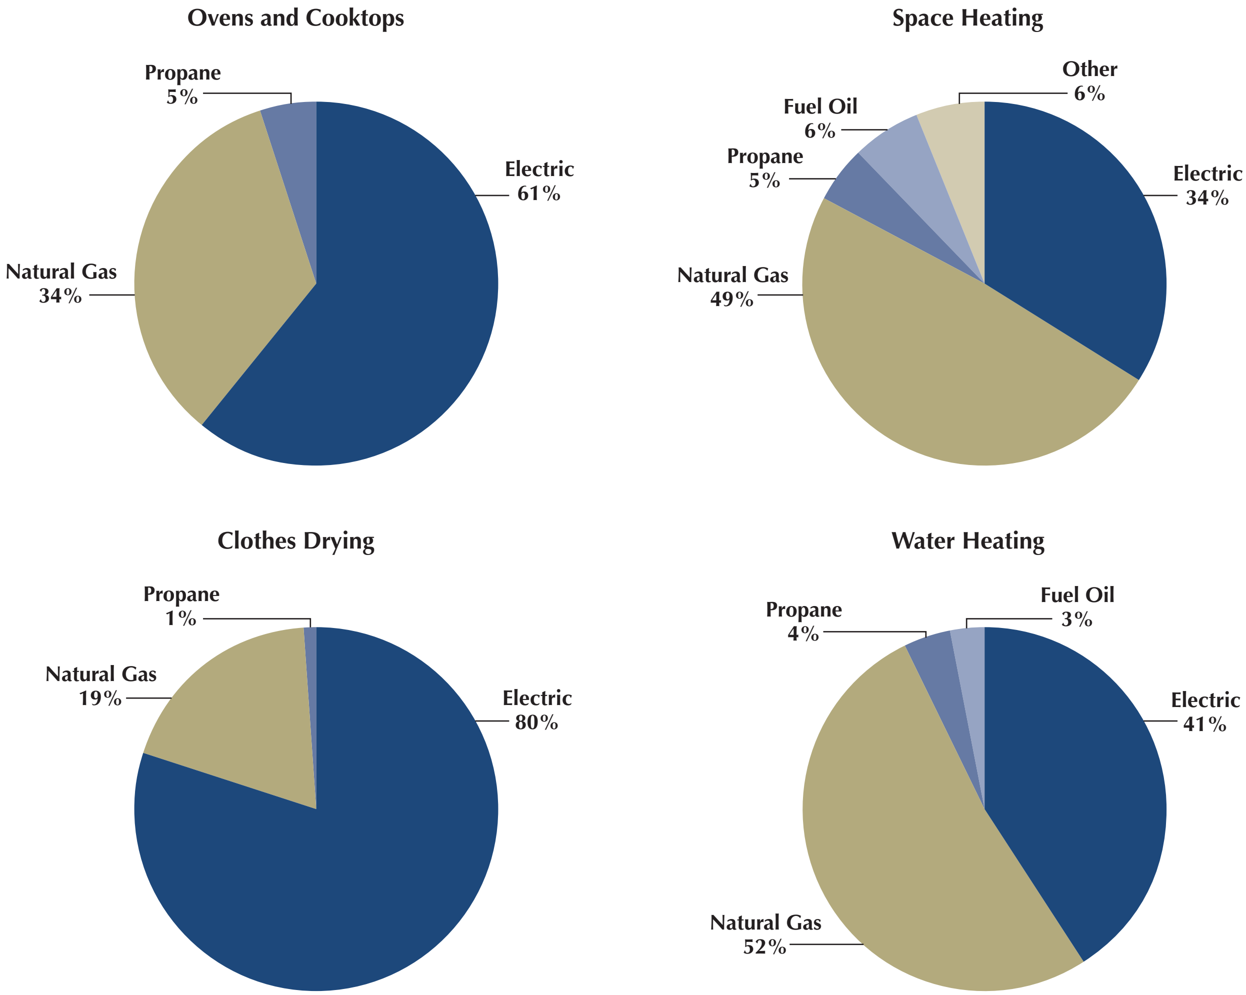
Source: Energy Information Administration, "U.S. Climate Zones," 2004. Available at http://www.eia.gov/emeu/recs/climate_zone.html

words, source-to-site efficiency is the energy required—accounting for losses—to bring usable energy to the consumer. Source-to-site efficiency varies widely by fuel. Often, direct fuel consumption has much higher source-to-site efficiencies compared with electricity, where energy is lost in the conversion and transmission of primary fuels to electrical energy. To assess the efficiency of total energy use, the source-to-site efficiency must be multiplied by the efficiency of the end-use appliances and equipment—the site efficiency. Combining source-to-site efficiency and site efficiency leads to the third—important and often overlooked—measure of efficiency, full-fuel-cycle efficiency.

Source-to-Site Efficiency

Electricity generation has the lowest source-to-site efficiency of all energy types. Centralized electricity generation and distribution through power lines is on average 32 percent efficient in the United States. The process of generating electricity incurs substantial losses, such that for every unit of electricity registered at a building's meter, three times the amount of primary energy was required to generate and distribute it. The majority of energy losses occur at the power plant, especially at cooling towers that emit waste heat into the atmosphere in the form of steam. The Western Electricity

FIGURE 7: Appliance Fuel Sources by Number of Units in U.S. Homes, 2009



Source: Energy Information Administration, "Residential Energy Consumption Survey 2009," Table HC3.1, Available at: http://www.eia.gov/consumption/residential/data/2009/

Coordinating Council, which covers the western United States, has the highest efficiency, at 38 percent, primarily due to its high percentage of hydropower, which has a higher conversion efficiency than coal- or natural gas-fired generation. The Midwest Reliability Council region in the Upper Midwest has the lowest efficiency, at 28 percent, due to a large percentage of coal plants using older, less efficient technology.[112] Transmission and distribution over power lines results in additional losses and reduces the source-to-site efficiency even further, by roughly an additional 7 percent, with longer lines experiencing greater losses. In total, up to two-thirds of the fuel that is burned for electricity production is wasted. In addition to providing no useful work in the economy, it releases significant greenhouse gas emissions in the process.

The production and distribution of natural gas, fuel oil, and propane also have inefficiencies. These fuels must be extracted from the ground, processed or refined to remove impurities and other liquids and gases, and finally transported to the building. During each of these steps, energy is used and a small amount of energy is lost but, in total, these losses are considerably less than the losses associated with electricity production and distribution. The source-to-site efficiency of natural gas is approximately 92 percent, around three times higher than the source-to-site efficiency of centrally generated electricity.[113] Other fuels commonly consumed onsite in residential buildings, fuel oil and propane, are also much more efficient than electricity. The average source-to-site efficiency of fuel oil is about 88 percent, and of propane, about 89 percent.[114]

Considering the source-to-site efficiency of different fuels offers a more accurate comparison of the fuel used in buildings. For example, in 2008, the total site consumption by residential and commercial buildings was 9.37 quadrillion Btu for electricity and 8.28 quadrillion Btu for natural gas. However, the amounts of primary energy consumed differed dramatically between electricity and natural gas, because of their different source-to-site efficiencies (compare Figures 8 and 9). About three times as much primary energy is used to generate and transmit electricity than is ultimately consumed onsite in buildings.

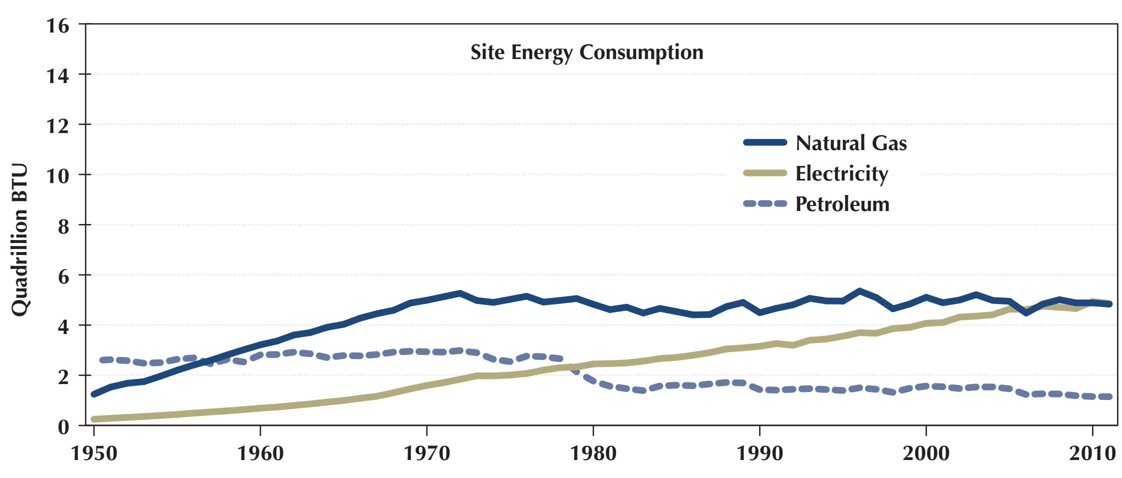
The relative efficiencies of on-site fuel use and grid-supplied electricity have major consequences for the greenhouse gas emissions associated with the U.S. building stock. Only accounting for site energy consumption misses energy losses and resulting greenhouse gas emissions associated with energy production and delivery. These losses account for a significant portion of total greenhouse gas emissions from the residential and commercial sector and should be accounted for when comparing fuel options. The use of grid-supplied electricity is growing, while direct natural gas consumption by residential and commercial buildings remains relatively flat. Increasing the amount of natural gas instead of electricity used in buildings would require fewer resources to provide the same amount of on-site energy and would lower the greenhouse gas emissions per unit of useful energy consumed.

Site Efficiency and Full-Fuel-Cycle Efficiency

Once energy is delivered to a building, it is used in an appliance or piece of equipment that has its own distinct efficiency level. Taken together, the source-to-site efficiency of the fuel delivered and the site efficiency of its use give a more complete picture of the total efficiency of consumer fuel and appliance choice and the resulting emissions. Source-to-site efficiency considered along with site efficiency yields an appliance's full-fuel-cycle efficiency.

To find the full-fuel-cycle efficiency of an appliance or piece of equipment, the efficiency of the source-to-site energy is multiplied by the efficiency of the appliance and associated equipment. For example, energy efficiency standards established in 2012 by the Department of Energy (DOE) for water heaters with storage tanks are 93 percent for electric-resistance units and 62 percent for natural gas models.[115] However, when these models' respective source-to-site efficiency is factored in, their full-fuel-cycle efficiencies are 30 percent for the electric model and 75 percent for the natural gas model. Therefore, despite the higher site efficiency rating of the electric-resistance water heater, it requires the use of significantly more primary energy

FIGURE 8: Residential Site Energy Consumption, 1950 to 2010



Source: Energy Information Administration, "Today in Energy," March 6, 2013. Available at: http://www.eia.gov/todayinenergy/detail.cfm?id=10251 and leads to the emission of more greenhouse gases than does the natural gas appliance for the same level of output in the building. Consequently, electric-resistance water heaters consume roughly twice the primary energy of the natural gas models.

Source efficiencies and site efficiencies can vary even further. Minimum efficiency standards for appliances promulgated by DOE are continuing to push the site efficiency ratings of new appliances higher. While this discussion compares widely used electric and natural gas water heaters, newer technologies such as electric heat-pump water heaters are also available that are two to three times more efficient than the conventional electric-resistance models analyzed here,[116] and solar water heating technologies offer high full-fuel-cycle efficiencies and can be a cost-effective option.[117] Furthermore, the source efficiencies and associated greenhouse gas emissions vary, because of the regional differences in source efficiency of power generation. It is clear that, despite geographic variation, a natural gas water heater yields significant energy savings compared with an electric-resistance water heater in every North American Electric Reliability Corporation Region in the country (Figure 10).[118]

EMISSIONS COMPARISON: NATURAL GAS VERSUS OTHER DIRECT FUELS

In addition to the energy savings delivered by the higher full-fuel-cycle efficiency of appliances using natural gas, there is also a large difference in greenhouse gas emissions. Residential energy use has been a growing contributor to CO_2 emissions for the last two decades, and the trend is expected to continue (Figure 11).[119] The negative consequences in terms of emissions of this upward trend in electricity use are exacerbated by the low average efficiency of grid electricity and the high average carbon fuel intensity of the U.S. electricity generation portfolio. Furthermore, given the high level of coal use in U.S. electricity production, increased electricity use leads to significant increases in sulfur dioxide, nitrogen oxides, and mercury emissions, where pollution controls are not in place.

Greenhouse gas emissions can be reduced by switching from lower-efficiency fuels and appliances such as an electric-resistance water heater to higher efficiency fuels and appliances such as a natural gas water heater. However, the reductions will vary by region. The relative percentage reductions of greenhouse gas emissions by switching appliances or fuels is a combination of the full-fuel-cycle efficiency of the appliances and the CO_2-emission intensity of the electricity generation portfolio in a given region. The varied carbon intensities of electric generation in each North American Reliability Council (NERC) region offer different relative benefits from switching an electric-resistance water heater to a natural gas model (Figure 12). The relative benefits are most clearly demonstrated in the following examples. In the NERC region overseen by the Northeast Power Coordinating Council in the northeast United States and Eastern Canada, where a large percentage of the electricity comes from

less carbon-intensive hydroelectric and nuclear power, switching from an electric to natural gas water heater results in CO_2 reductions of 30 percent. By contrast, the same switch results in emissions reductions of 70 percent in the Midwest Reliability Organization region in the Midwest where substantial amounts of older coal-fired power generation contributes to a significantly more carbon-intensive electric generation mix.

FIGURE 12: CO_2 Emissions from Water Heaters by North American Electric Reliability Corporation Region, 2005

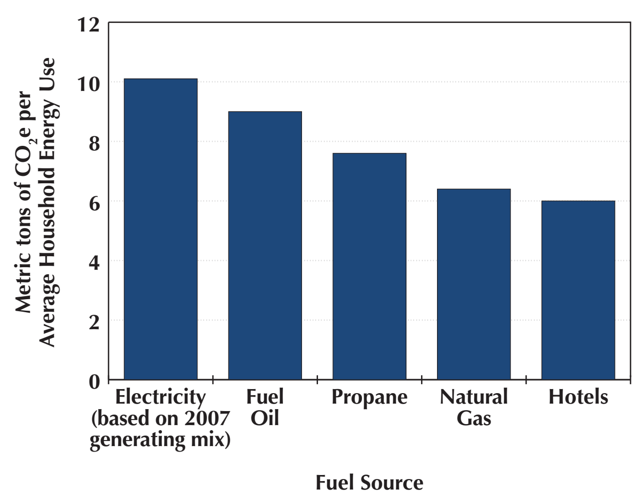
An average U.S. home using natural gas for space heating, water heating, cooking, and clothes drying is responsible for substantially fewer greenhouse gas emissions than homes using other fuel sources (Figure 13). In this example, natural gas use produces an average of 44 percent fewer emissions than electricity use.[120] Such a difference in energy use and CO_2 emissions is true for all energy uses in buildings where natural gas is an alternative to grid electricity as well as the direct use of propane and fuel oil. The two main factors determining the efficiency and emissions benefits from appliance to appliance are the full-fuel-cycle efficiency of the appliance and the emission-intensity of the primary fuel.

Emissions associated with natural gas use compared with electricity are lower for CO_2 and some pollutants. Considering the lower emissions of natural gas and its higher full-fuel-cycle efficiency, residential natural gas use results in 40 to 65 percent lower emissions of CO_2, 90 to 98 percent lower emissions of SO_2, and 50 to 88 percent lower emissions of NO_X. Residential natural gas use is free of any mercury emissions.[121]

FIGURE 13: Full-Fuel-Cycle Greenhouse Gas Emissions for Average New Homes



Source: Source: American Gas Association, "A Comparison of Energy Use, Operating Costs, and CO_2 Emissions of Home Appliances," October 20, 2009. Available at: http://www.aga.org/Kc/analyses-and-statistics/studies/demand/Pages/Comparison-Energy-Use-Operating-Costs-Carbon-Dioxide-Emissions-Home-Appliances.aspx

Note: Assumes fuel used for space heating, water heating, cooking, and clothes drying. All appliances are assumed to meet federal minimum efficiency standards. The fuel oil home assumes electricity is used for cooking and clothes drying. The new home assumes a one-story single-family detached home with 2,072 square feet of conditioned space and 4,811 heating degree days.

Reducing Emissions Through Fuel Substitution and On-Site Energy Production

Natural gas can provide a means to increase a building's total full-fuel-cycle efficiency and decrease its emissions profile in many cases. This improvement is most readily achieved in thermal applications, such as natural gas space heating and water heating. While buildings with older natural gas- or oil-fired boilers and furnaces can improve their efficiency and lower their emissions by upgrading to newer models, greater emission reductions may be achieved by removing electric appliances and replacing them with models using natural gas. While natural gas appliances have a comparable or slightly lower site efficiency than electric-resistance appliances, natural gas is often, on a full-fuel-cycle basis, two to three times more efficient than electricity.[122]

Significantly greater benefits can be realized when grid power is replaced by power produced on site. Combined heat and power (CHP) systems provide a means for buildings with high electrical demand to increase their efficiency and reduce emissions. A CHP system uses a fuel such as natural gas to generate electricity on site, capturing waste heat to meet on-site thermal loads (Table 1). (For a more extensive treatment of CHP see chapter 6.) Fuel cells and micro-turbine technologies provide another means for buildings to generate their own electrical power on site using natural gas. The waste heat generated by these devices can then be used for space heating, water heating, and other thermal loads to raise the overall full-fuel-cycle efficiency of these devices to greater than 80 percent.[123] (These technologies and others are explained in chapter 7.)

The potential for CHP in commercial settings may be quite large, with office buildings/retail, education buildings, and hospitals having the greatest potential (Figure 14). However, practical limits on thermal load matching and the utilization of waste heat may affect the potential of different building types. Hospitals are an ideal application, but hotels and other commercial buildings may be more difficult—though not impossible. The use of CHP microturbines has gained acceptance primarily in in-patient hospitals, hotels, and resorts. These facilities have large electrical loads and nearly as high thermal loads, for space heating, water heating, cooking, and laundry. These large and year-round thermal loads (in the case of all but space heating) provide a ready use for the waste thermal energy provided by the microturbine, allowing them to operate at near peak efficiency not only around the clock but 365 days per year. Nevertheless, there are many challenges to commercial CHP operations. To expand commercial CHP potential, policy is needed to support advanced technologies and innovative business models in this arena.

TABLE 1: Technology Comparisons

CATEGORY	10 MW NATURAL GAS CHP	10 MW PHOTOVOLTAIC ARRAY	10 MW WIND FARM	CENTRALIZED NATURAL GAS COMBINED CYCLE POWER PLANT (10 MW PORTION)
Annual Capacity Factor	85%	25%	34%	67%
Annual Electricity	74,446 MWh	21,900 MWh	29,784 MWh	58,692 MWh
Annual Useful Heat	103,417 MWht	0	0	0
Capital Cost	$24 million	$60.5 million	$24.4 million	$10 million
Annual Energy Savings	343,747 MMBtu	225,640 MMBtu	306,871 MMBtu	156,708 MMBtu
Annual CO_2 Savings	44,114 Tons	20,254 Tons	27,546 Tons	27,023 Tons

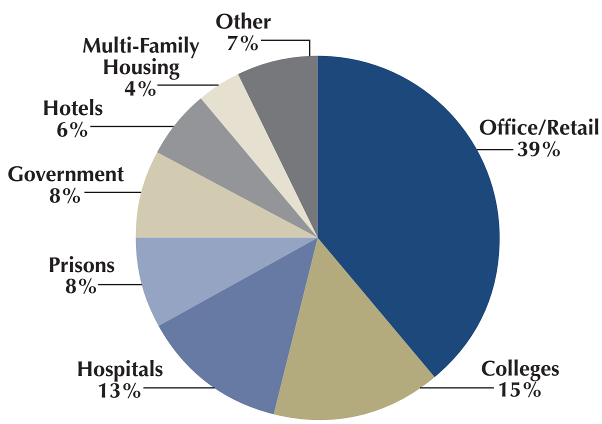
Source: ICF International 2012

Notes: A 10 MW Gas Turbine CHP –is assumed to have 30 percent electric efficiency and 70 percent total efficiency.

Electricity generation onsite is assumed to displace grid-supplied electricity generation of 9,720 Btu/kWh, with emissions of 1,745 lbs. CO_2/MWh; includes assumed 6 percent transmission and distribution losses.

Thermal generation on-site is assumed to displace an 80 percent efficient onsite natural gas boiler.

FIGURE 14: **CHP Potential for Systems Greater than 1 MW to 33 GW, Percent of Potential Capacity**



Source: ICF International 2012

Technological advances in gas-fired equipment are also needed. More affordable tank-less water heaters and combination space and water heating appliances can help reduce the market barriers to natural gas. Demonstration and deployment of such technologies can help natural gas utilities design the next generation of gas efficiency programs, provide whole-building solutions, and make natural gas service more attractive to customers and builders.

THE ROLE OF EFFICIENCY PROGRAMS AND STANDARDS

Current efficiency programs and federal efficiency codes and standards reduce greenhouse gas emissions from buildings in two important ways: by reducing the overall amount of energy used in buildings and by improving the baseline efficiency of specific appliances, equipment, and building stock. A third strategy could be to encourage the use of certain fuels, taking into account the total energy consumption of an appliance, the fuel used (full-fuel-cycle efficiency), and the associated greenhouse gas emissions. Historically, efficiency programs and standards have not considered full-fuel-cycle efficiency or the emissions reductions that could be achieved comparing across fuel types, although this is beginning to change, as in the case of appliance labeling described later in this chapter.

Conservation

At the broadest level, increasing the overall efficiency of new and existing buildings reduces the amount of fuel used of any type and is therefore beneficial. Energy efficiency minimizes energy use, and thus lowers greenhouse gas emissions. The United States has made remarkable progress in this regard. Energy use in buildings between 1972 and 2005 increased at less than half the rate of growth of gross domestic product, despite the growth in home size and the increased demand for energy from air conditioning and electronic equipment. But although great strides have been made, numerous untapped opportunities exist for further reductions in energy use and greenhouse gas emissions. Many of these require only modest levels of investment. Advances such as energy-efficient building designs and appliances provide quick payback to consumers through reduced energy bills. For example, new wall designs can minimize heat loss in buildings by as much as 50 percent by reducing the amount of framing used and by optimizing the use of insulated materials. The result is a diminished need for space heating—the largest energy use in a home.[124]

State and Local Building Codes

Building codes for new construction can improve the efficiency of buildings by ensuring that new technologies and methods are used that will reduce a building's energy use. Although new buildings constitute only 2 to 3 percent of the existing building stock in any given year, new construction practices have a compounding impact over time.[125] New construction can more easily incorporate novel energy efficiency technologies and is therefore often a harbinger of future trends. New building technologies are often introduced in the new construction market and then spill over into the arena of retrofits and renovation. Building codes can even affect a building's fuel options, for example, by encouraging or discouraging natural gas access by facilitating or slowing the approval of new, easier-to-install and less expensive indoor natural gas piping materials.[126.]

Low adoption rates for building codes are a barrier to the development of higher efficiency and lower emissions buildings. For example, in 1992 the commercial building code requirements of the Federal Energy Policy Act, which were based on 1989 industry standards, were met by only five states. By 2008, 40 states had statewide commercial building codes that met or exceeded the 1989 federal standards, but only 27 met the higher standards issued by DOE in 2004. This lead/lag effect in the setting and meeting of standards is indicative of a non-owner-operated building market that still places operating costs at a lower priority than construction costs. However, federal requirements are not the only drivers. California, for example, has set standards higher than those of the federal government, and some utilities, such as Austin Energy in central Texas, have worked with city governments to push standards and building codes beyond the industry norm.

Traditionally, building codes have been designed to look at the overall on-site energy usage of buildings. Accordingly, they are typically fuel-neutral, favoring neither natural gas nor electric appliances. As a result, building codes do little to take into consideration the full-fuel-cycle climate impacts of electricity versus natural gas and other fuels. Likewise, Leadership in Energy and Environmental Design (LEED) standards fail to take into account the relative full-fuel-cycle efficiencies of electricity, natural gas, and other fuels. LEED standards, developed by the U.S. Green Building Council, have been adopted by many municipalities, school districts, counties, and states for their new buildings, leading to an exponential growth in the number of LEED-certified buildings.[127] However, the U.S. Green Building Council is investigating ways to take these benefits into account, with particular focus on performance standards and nationwide applicability.

Appliance Standards

DOE is required by law to set minimum efficiency standards for appliances, and currently has standards that cover appliances and equipment responsible for 82 percent of home energy use and 67 percent of commercial energy use.[128] Appliance standards, first instituted in the 1980s and repeatedly strengthened since then, have greatly contributed to reducing appliance energy use and associated greenhouse gas emissions. However, appliance standards are based on the site efficiency of the appliance and do not consider the efficiency of the fuel. While this works well to encourage improved efficiency for each type of appliance, it does have implications for efficiency labeling programs and the ability of consumers to compare the true environmental performance of appliances using differing energy sources.

Appliance Labeling

Labeling programs such as ENERGY STAR strive to inform consumers about the energy consumption and energy cost implications associated with use of each appliance. ENERGY STAR uses a market-based approach having four parts: 1) using the ENERGY STAR label to clearly identify which products, practices, new homes, and buildings are the most energy efficient; 2) empowering decision-makers by making them aware of the benefits of products, homes, and buildings that qualify for ENERGY STAR, and by providing tools to assess energy performance and guidelines for efficiency improvements; 3) helping retail and service companies to easily offer energy-efficient products and services; and 4) partnering with other energy efficiency programs to leverage national resources and maximize impacts. The Environmental Protection Agency (EPA) estimates that in 2012 the ENERGY STAR program helped avoid more than 150 million tons of greenhouse gas emissions through encouraging the purchase of efficient products, with the amount of avoided greenhouse gas emissions increasing annually.[129]

While appliance labeling efforts like ENERGY STAR have educated consumers about the annual operating costs and site efficiency of appliances, current labels do not accurately or sufficiently connect consumers' economic interests with the environmental impacts of appliance use. Specifically, current labels do not inform consumers of the full-fuel-cycle efficiency of appliance models because the efficiency calculations are based on the appliance standards program, which again is based on site efficiency. As a result, consumers cannot compare the true quantity of energy required by each appliances or the true climate implications associated with using that appliance.

In 2009, the National Research Council released a report that recommended the gradual conversion of current labeling efforts to ones that would take full-fuel-cycle efficiencies into consideration. Full-fuel-cycle labeling will certainly be more challenging because it will require more data and analysis from appliance manufacturers, and the efficiency of an appliance will vary by geographical location because of different regional climates and power generation fuel mixes. However, as discussed earlier in this chapter, such information is essential to understanding the total amount of energy required to operate an appliance and the associated greenhouse gas emissions and will better equip consumers to make more informed choices when evaluating their appliance options.[130] In June 2011, DOE took the first steps toward a more regionalized labeling program with standards for furnaces and central air conditioning units that had a variable regional component.[131] In addition, in August 2012, DOE issued a policy amendment stating that it would begin consideration of full-fuel-cycle efficiency in setting future appliance standards and would work with the Federal Trade Commission to educate consumers about the full fuel cycle.[132]

While no appliance standards based on the full fuel cycle have yet been issued, if the success of current appliance standards and related labeling are any indication, moving to standards and labels based on full-fuel-cycle efficiency could move consumers to purchase appliances that use significantly less energy and provide a significant benefit to the climate.

ENERGY STAR for Buildings

In addition to having labels for appliances, EPA's ENERGY STAR program also assesses the efficiency of buildings and provides labels that allow comparison of energy usage across buildings. To be an ENERGY STAR-certified building, a variety of energy performance standards must be met and these differ by facility type. EPA provides tools to assess energy systems and management, building design, and a host of energy-related benchmarks to help building owners, architects, and even prospective tenants assess and make public the energy and cost implications of a building. In contrast to the appliance program, the ENERGY STAR program for commercial buildings does use primary or full-fuel-cycle efficiency to compare energy usage across building types.

Utility-Based Incentive Programs

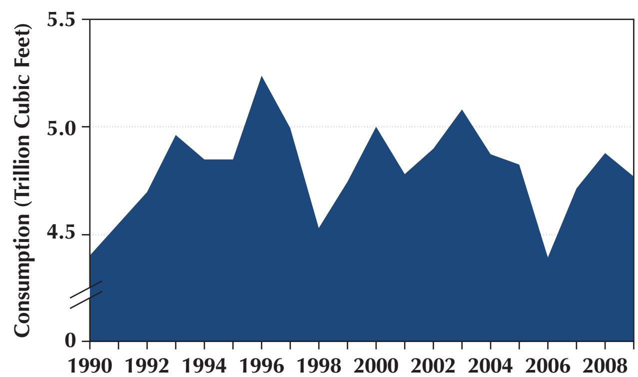
Utility-based financial incentive programs have been used since the early 1980s, when it became clear that information and education alone produced only limited energy and demand savings. Utilities have offered rebates, low-interest loans, and direct installation programs, and these have led to the accelerated market penetration of many energy-efficient building products such as attic insulation and high-efficiency appliances. However, these programs represent only a partial solution because not all states or all utilities offer such programs. More importantly, these incentives are based on site efficiency and are fuel-specific—since buildings are often served by separate electric and natural gas utilities, meaning that while incentive programs can encourage the efficient site use of a fuel, they do not allow consumers to compare fuel options based full-fuel-cycle efficiency. Thus, most utility-based incentive programs miss an opportunity to help consumers further reduce emissions.

BARRIERS TO INCREASED NATURAL GAS ACCESS AND UTILIZATION

The emissions benefits of natural gas use in homes and businesses will require greater access to the fuel for and within buildings. In 2005, 71 percent of U.S. homes had access to natural gas, and yet only 61 percent of U.S. homes made use of natural gas in an appliance. In addition, only 54 percent of new homes constructed in 2010 had natural gas service installed, and this access was primarily for heating and not necessarily for other natural gas appliances.[133] Similarly, in commercial buildings approximately half had natural gas access in 2003 (49 percent) and, as with homes, the use was primarily for heating.[134]

Annual consumption of natural gas in the residential sector has been declining since 1996 in spite of a growing residential customer base (Figure 15). Analysis by the Energy Information Administration suggests that the cause of this decrease is a combination of historically high natural gas prices from 2000 to 2009, which

FIGURE 15: Residential Natural Gas Consumption, 1990 to 2009



Source: Energy Information Administration, "Trends in U.S. Residential Natural Gas Consumption," 2010. Available at: http://www.eia.gov/pub/oil_gas/natural_gas/feature_articles/2010/ngtrendsresidcon/ngtrendsresidcon.pdf discouraged consumers from buying natural gas model appliances, a general migration of Americans to warmer climate zones with lower thermal loads, and an increase in home construction standards and appliance efficiency that reduced the amount of fuel consumed for the same purposes.[135]

Barriers to the Use of Natural Gas in Homes

The United States has, as a policy, pursued universal residential access to electricity for decades. Through taxpayer-funded rural electrification programs and customer-funded electric utility grid extension programs, the United States has achieved greater than 99.5 percent residential access to public or private electricity.[136] The same policy has not been implemented for natural gas.

When municipalities approve planning and development for new buildings, electric utility access is almost universally required through developer or utility funding, or a combination of the two. In contrast, running natural gas lines in new developments is often viewed as merely an option, and, as such, only 54 percent of new homes have natural gas access. In many cases, the decision is determined by financial analysis conducted by a local gas distribution company, or the combination local electric and gas utility, based on narrow first-cost criteria with little concern for the occupants' energy efficiency, operating cost, or greenhouse gas emissions. Prospective building owners often have little participation in this decision process. If the decision is made not to supply natural gas, retrofitted access to and within the building is significantly more expensive.

Even when natural gas infrastructure has been included in a new residential development, a homeowner may still be unable to choose how natural gas will be used in her home. Often, during architectural design and construction, the builder decides which appliances will have natural gas lines run to them, thereby "locking in" the decision and limiting consumer choice. In cases where the homeowner enters the process prior to construction, he may be offered a choice of appliance fuel options, but choosing natural gas may come at a cost premium for both the appliance and the cost of running the gas lines. In this choice, one between higher up-front costs of purchasing a home with gas appliances, on the one hand, and a lower long-term cost of operation (subject to gas prices), on the other, the immediacy of a slightly lower purchase price for electric appliances may prevail, even as low natural gas prices may lead to consumer savings in just a few years when compared to electric models.

Natural gas access, regulation, and price play important roles in residential fuel choice. The trend over the last decade, toward a lower percentage of new homes using natural gas, will have a long-term effect. Even though the trend was likely influenced by temporarily high gas prices, it effectively locks out the option for these "all electric" homeowners to benefit economically from what may be several decades of low natural gas prices as well as to benefit environmentally by lowering greenhouse gas emissions.

Moving beyond infrastructure constraints, an essential component shaping residential fuel choice is public education. For nearly a century, industry and government have portrayed electricity as a clean and efficient fuel, and it is—on site at the point of use.[137] Perceptions of natural gas are similarly affected by public opinion and government policy that focus on the point of use, which has not received the promotional policy that electricity has. This point-of-use perception is reinforced by the way in which most people interact with electricity and natural gas in their everyday lives: flipping a switch, turning on a burner, and paying a monthly bill. They rarely see or understand the generation side of electricity, the power plant, or the extraction and transportation of natural gas. Generally, the public has little basis for comparisons among fuels on issues of health, the environment, and the economy. Moreover, culture and family history can be important drivers of consumer choice, as individuals may be most comfortable with appliance types that they grew up with. Public education is critical for helping consumers understand the issues of efficiency and emissions and how they relate to common life choices, and to know what questions to ask when purchasing an appliance, renting an apartment, or buying a home.

Use of Natural Gas in Commercial Buildings

A significant barrier to the increased use of natural gas is the high percentage of non-owner-occupied commercial buildings, particularly office and warehouse floor space. On a floor-space basis, 49 percent of private commercial buildings are owner-occupied and 51 percent are non-owner-occupied.[138] Non-owner-occupied buildings are designed and built by real-estate developers who then rent or lease the space to tenants. The "for lease" building sector is extremely competitive, and rental cost per square footage is a key metric in attracting renters. In addition to paying rent, tenants may also pay utility or maintenance costs that may increase each year because of rising operating expenditures. Energy costs are a meaningful portion of these operating expenditures, but for billing purposes they are often combined with other costs, such as labor, water, and snow removal. Therefore, it can be difficult for tenants to discern specific financial benefits of energy efficiency upgrades, leaving building owners without a financial incentive to make such upgrades. This situation prevents lower operating costs from being reflected in market rental prices, since only exceptionally sophisticated tenants consider long-term gains from efficiency in rental decisions. In new buildings, owners' focus on achieving low rental costs can drive builders to prioritize construction cost over operating costs. This approach can preclude the installation of high-efficiency and lower-emission systems, including those that use natural gas on site for both electricity generation and heating applications.[139]

When energy efficiency upgrades are proposed for existing, occupied buildings, building owners may have the opportunity to recover capital outlays according to the terms of the leases. Most leases allow the installation of energy savings equipment or systems with cost recovery through amortization of the improvement over the life of the equipment installed. However, if a tenant does not renew her lease, a newly signed tenant cannot be charged the amortization; therefore, a portion of the cost of the project cannot be recovered. Since rents are based largely on market conditions and not by the operating costs incurred by the building owner, before owners undertake an energy efficiency project, they must evaluate what portion of the tenant base might leave before the project costs are recovered and what enduring benefits might accrue to the owner.[140]

Some low-cost energy efficiency upgrades can be treated as repair costs and added to the operating expenses within an existing lease. These stand-alone efficiency projects are very often subsidized with incentives from utilities. Projects of this nature usually have relatively short payback periods. The tenants see the benefit of the improvements very quickly, and the owner can justify the expense to the tenant regardless of whether the lease is renewed.[141]

In 2003, 46 percent of commercial buildings were owner-occupied, meaning they are designed and constructed for the owner's own use.[142] Compared to owners of leased buildings, owner-operators are more inclined to factor in the operating costs of their buildings because they have a long-term interest in the building and are concerned less with competitive rental markets. Therefore, they tend to install more energy-efficient systems and subsystem components as long as these have a payback period of 10 years or less. The government owners of 635,000 public buildings in the United States in 2003 share this focus on long-term operational costs and the advantage of higher efficiency systems; they may also have legal mandates or executive orders to reduce energy use and/or greenhouse gas emissions.[143] Owners constructing new buildings or performing retrofits, when faced with longer-term decisions about energy use and costs, will see expanded natural gas use as an attractive option, and large numbers of owner-occupied and government buildings using natural gas instead of electricity could yield significant emission reductions.

CONCLUSION

This chapter identified the full-fuel-cycle efficiency benefits and lower greenhouse gas emissions of the direct use of natural gas when compared to electricity, particularly for thermal loads. There is significant potential for increased direct use of natural gas in homes and businesses both in terms of increased access to new buildings and additional applications within buildings that already have access. In order for this potential to be fully realized, building standards, appliance standards, and appliance labels must take full-fuel-cycle energy use and associated emissions into account, and greater attention must be given to consumer education, regulatory changes, and increased access.

VI. MANUFACTURING SECTOR

By Michael Tubman, C2ES

INTRODUCTION

With prospects for cheap, abundant natural gas in the near and medium term virtually certain, demand for natural gas from manufacturing industries is expected to grow. In 2010, natural gas supplied 30 percent of the U.S. manufacturing sector's direct energy use, for combustion as well as non-combustion uses.[144] The U.S. Energy Information Administration forecasts that natural gas use in the industrial sector will increase by 16 percent between 2011 and 2025, from 6.8 to 7.8 trillion cubic feet.[145] Recent estimates indicate that $45 billion in new investment has recently occurred in chemical manufacturing alone. Lower natural gas prices are likely to provide a real economic advantage to U.S. manufacturing in the near and medium term.

The entire industrial sector (manufacturing and non-manufacturing industries combined) consumed 32 percent of all natural gas in the United States in 2011. This energy use emitted 401 million metric tons of carbon dioxide (CO_2).[146] This chapter examines the role of natural gas in the manufacturing sector today as well as its likely expansion, given forecasts of low and stable prices. With a resurgent and changing manufacturing sector comes the opportunity to reduce these emissions. This chapter also looks at promising strategies for reducing emissions include replacing older, less efficient industrial boilers and expanding the use of combined heat and power (CHP) systems.

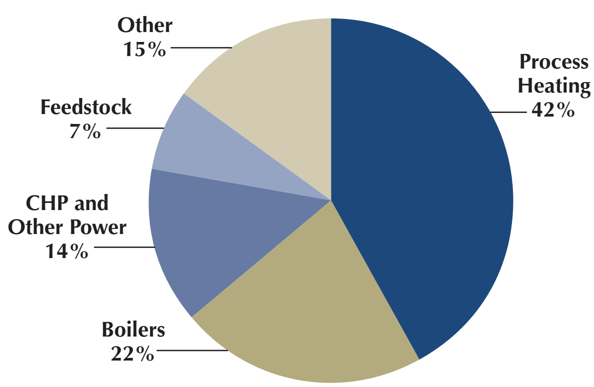
NATURAL GAS USE IN MANUFACTURING

The manufacturing sector includes diverse industries such as bulk chemicals, oil refining, and the production of steel, aluminum, cement, glass, paper, and food. It does not include the industrial activities of mining, construction, and oil and gas extraction. Natural gas usage within these industries varies significantly. It is used for heating and cooling; for process heat to melt glass, process food, preheat metals, and dry various products; and for on-site electricity generation (fueling boilers and turbines). Natural gas is also used as a feedstock (a material input) to make chemical products, fertilizers, plastics, and other materials.[147]

Overall, the largest direct use of energy by the manufacturing sector is for process heating, the production of heat directly from fuel sources, electricity, or steam that is used to heat raw material inputs during manufacturing. Natural gas is the dominant fuel used to generate heat, and process heating accounts for 42 percent of the natural gas use in the industrial sector overall (Figure 1). In 2010, process heating using all fuel sources produced 315.4 million metric tons of CO_2, which represents 40 percent of the CO_2 emissions for the entire manufacturing sector.[148]

Industrial boilers generating heat and steam are another large consumer of natural gas. Eighty-three percent of boilers run on natural gas, and they consume 22 percent of this fuel used in manufacturing.[149] While some are fueled by coal or other fuel, the dominant fuel

FIGURE 1: Natural Gas Use in Manufacturing, 2009

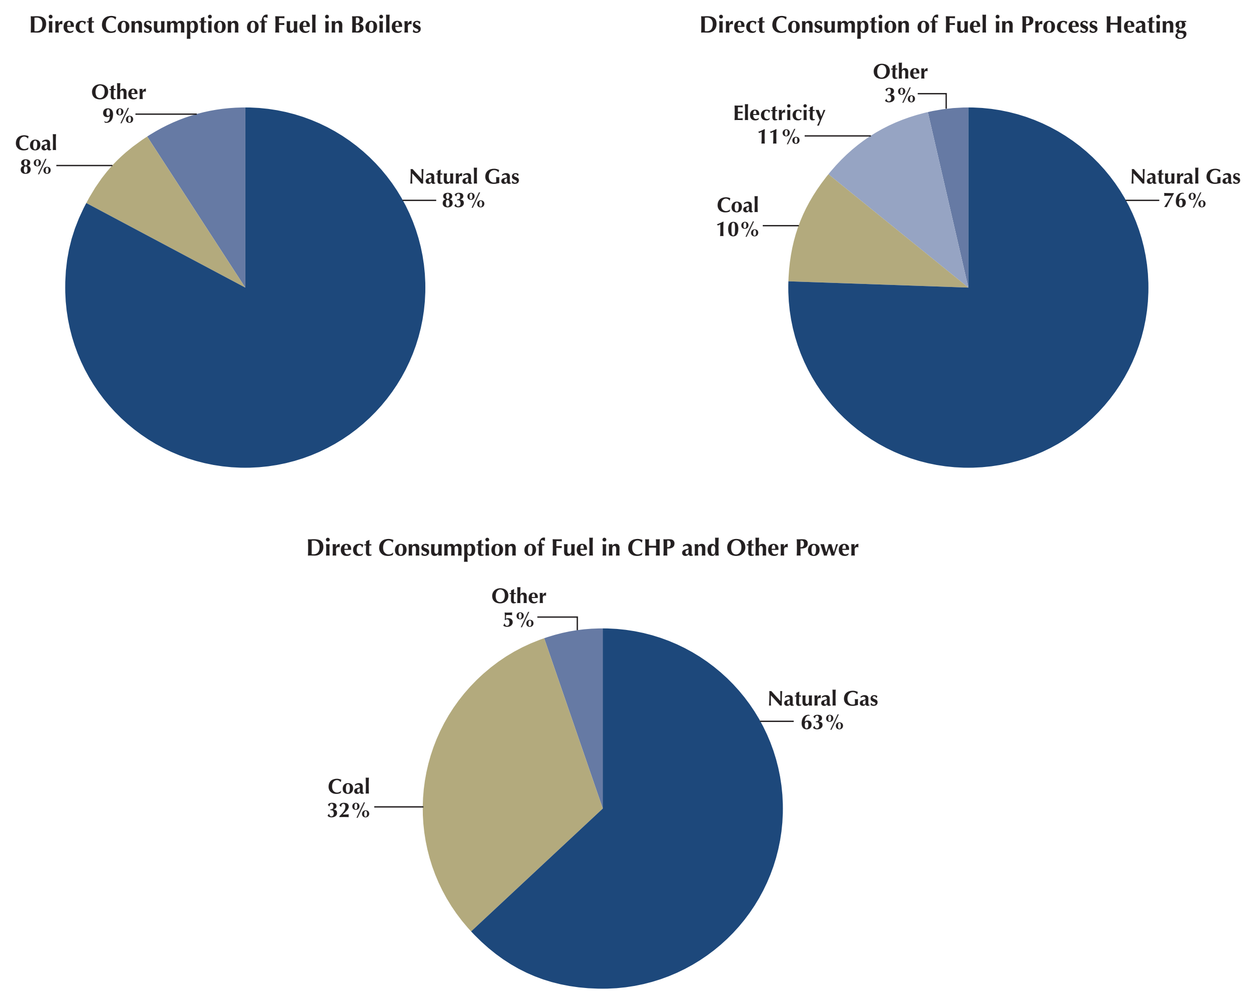


Source: Energy Information Administration, "Manufacturing Energy Consumption Survey," June 2009, Tables 2.2 and 5.2. Available at http://www.eia.gov/emeu/mecs/mecs2006/2006tables.html source is natural gas. Boilers are commonly used for a variety of purposes by chemical manufacturers, food processors, pulp and paper manufacturers, and the petroleum- and coal-derivatives industries (including chemicals, coke, and coal tar) (Figure 2).[150]

CHP—also known as cogeneration—is a third major use of natural gas in the manufacturing sector.[151] Natural gas is used to generate electricity on site, with the waste heat being captured and used for a variety of industrial purposes, greatly increasing the efficiency of the system overall. Additional efficiencies and emission reductions are also achieved through avoided transmission losses.[152] In 2010, 14 percent of natural gas used in manufacturing was consumed by CHP and other power systems. Natural gas is the most common fuel used for CHP systems. Nationwide, the added efficiencies of these systems avoid the emission of 35 million metric tons of CO_2 equivalent annually.[153]

Feedstock is raw material used as an input in manufacturing for creating value-added products. Natural gas production and its byproducts provide feedstock for the bulk chemicals industry, constituting a non-combustion use of natural gas. Methane—pure natural gas—is the source for hydrogen used in industrial processes, in fuel cells, and in the production of ammonia. Liquids extracted in association with natural gas, including ethane, propane, and butane, are processed and transformed to become other intermediate and final products including adhesives, insulation, paint, plastics, and vinyl.[154]

FIGURE 2: Direct Consumption of Fuels in the Manufacturing Sector, 2009



Source: Energy Information Administration, "Manufacturing Energy Consumption Survey," June 2009, Tables 2.2 and 5.2. Available at http://www.eia.gov/emeu/mecs/mecs2006/2006tables.html

Chemical companies are the largest consumers of natural gas-associated liquids, and they commonly use up to two-thirds of their delivered natural gas as feedstock.[155]

The emissions implications of using natural gas as a feedstock are very different from its other uses because feedstock use transforms hydrocarbon molecules into other products, rather than burning them. When natural gas is used as a feedstock, therefore, very low greenhouse gases emissions are produced. These low-emitting uses are enhancing U.S. competitiveness in the manufacturing sector. Whereas U.S. companies are reliant on low-cost natural gas liquids as a feedstock, European competitors use more expensive, oil-based naphtha.[156] In 2010, for example, domestic ethane sold at half the price of imported naphtha in Europe, and, consequently, U.S. chemical manufacturers have reaped a competitive advantage in international markets for intermediate and final goods.[157]

POTENTIAL FOR EXPANDED USE

Increased availability and low prices of natural gas have significant implications for domestic manufacturing. Large manufacturers dependent on natural gas for production are vulnerable to resource availability and price volatility. Accordingly, they have historically been concerned about policies or technologies that may impact these factors. Recently, abundant supply and low prices have led to greater confidence and an increase in domestic manufacturing, creating new jobs and economic value.[158] Numerous companies have cited natural gas supply and price in announcing plans to open new facilities in the chemicals, plastics, steel, and other industries in the United States,[159] including $41.6 billion worth of industrial investments that are planned between 2012 and 2018. One analysis has noted that the number of firms disclosing the positive impact of new gas resources for facility power generation and feedstock use increased substantially just between 2008 and 2011.[160] In 2010, exports of basic chemicals and plastics increased 28 percent from the previous year, yielding a trade surplus of $16.4 billion.[161] Continued low natural gas prices could have significant long-term economic benefits. A study by the American Chemistry Council estimates that a 25 percent increase in ethane supplies, for example, could yield a $32.8 billion increase in U.S. chemical production.[162]

EIA's Annual Energy Outlook 2013 Early Release of projections to 2040 reflects the expected increase in industrial natural gas demand. Total industrial consumption of natural gas for heat and power is projected to rise by 19 percent between 2010 and 2021 before increasing at a slower rate through 2040 (Figure 3). Efficiency measures are forecasted keep the amount of natural gas used per dollar of output declining over the same period (Figure 4).

Total industrial consumption of feedstock (natural gas liquids) is projected to rise by 23 percent between 2010 and 2023 before declining from peak levels (Figure 5). Feedstock growth will be tempered by long-term changes in the natural gas market, including higher prices and international competition in chemicals manufacturing and future energy efficiency improvements expected to offset increased demand for feedstock while maintaining output levels (Figure 6). The use of CHP is projected to increase by 113 percent over the same period (Figure 7). Increases in the use of on-site electricity generation through CHP systems would partially reduce facilities'

reliance on grid-supplied electricity while providing heat for industrial uses. CHP systems are designed to balance heat production with electric power needs within a facility; electricity can be bought from the grid if needed, or sold to the grid if there is excess on-site production.[163]

These changes in the manufacturing sector will have mixed impacts on greenhouse gas emissions. Absolute increases in natural gas used for heat and power operations are likely to increase total emissions coming from the sector. However, improvements in energy efficiency and especially the substantial deployment of CHP operations will allow the manufacturing sector to increase output with relatively smaller increases in the amount of natural gas input.

POTENTIAL FOR EMISSION REDUCTIONS

Even as the manufacturing sector expands, opportunities exist to reduce its emission intensity—the amount of CO_2 emitted per unit of output. Replacement of lower-efficiency boilers and greater deployment of CHP systems are ways to reduce emission intensity while using more natural gas.

Replacement of Lower-Efficiency Boilers

Improving the efficiency of industrial boilers is one such opportunity to reduce emission intensity. Boilers tend to have a low turnover rate, and older units are typically less efficient than newer ones. The pre-1985 fleet of boilers has an average efficiency of 65 to 70 percent, while new boilers have efficiency rates of 77 to 82 percent, and new, super-high-efficiency units can reach efficiencies of up to 95 percent.[164]

Source: Energy Information Administration, "Annual Energy Outlook 2013 Early Release," 2013. Available at: http://www.eia.gov/forecasts/aeo/er/pdf/tbla2.pdf

Analysis performed by the Massachusetts Institute of Technology found that replacing older natural gas boilers with high-efficiency or super-high-efficiency units would decrease CO_2 emissions by 4,500 to 9,000 tons or more per year per boiler. The analysis also found a strong economic incentive to make these replacements, highlighting annualized monetary savings of 20 percent (given certain assumptions, including 2010 natural gas prices) with a payback period for the new equipment of 1.8 to 3.6 years.[165]

While natural gas is the most commonly used fuel source for industrial boilers, 17 percent of boilers use coal or other fuels (Figure 2). Because of the air pollutants released from coal-fired boilers, these boilers are now subject to the U.S. Environmental Protection Agency (EPA) 2012 Maximum Achievable Control Technology standard (also known as the Boiler MACT). This standard requires the largest and highest-emitting boilers at industrial facilities, typically coal-fired boilers, to meet numeric pollution limits for the emission of air toxics, although it does not specifically require reductions in greenhouse gas emissions.[166] An analysis was performed to determine the results of replacing the Boiler MACT-affected coal boilers with efficient or super-high-efficiency natural gas boilers (natural gas boilers are not regulated under the new rule because of their already low emissions of the specified air toxics). This analysis found that replacement of coal boilers with natural gas boilers would reduce annual CO_2 emissions by 56 to 59 percent, or about 52,000 to 57,000 tons per year per boiler.[167]

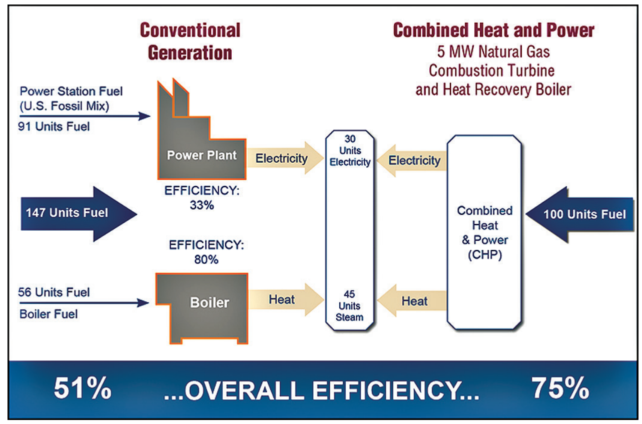
Expanded Use of Onsite CHP

Increasing the use of CHP also has the potential to reduce emissions produced in the manufacturing sector. An Oak Ridge National Laboratory study in 2008 calculated that increasing CHP's share of total U.S. electricity generation capacity from 9 percent in 2008 to 20 percent by 2030 would lower U.S. CO_2 emissions by 600 million metric tons compared with business as usual.[168] A study by McKinsey & Company in 2009 estimated that the potential exists for an additional 50.4 gigawatts of CHP capacity by 2020, which would avoid an estimated 100 million metric tons of CO_2 emissions per year compared with business as usual. Additionally, this study found that 70 percent of the potential cost-effective CHP capacity was through large-scale industrial cogeneration systems greater than 50 megawatts (MW).[169]

CHP units at industrial facilities have the added benefit of bolstering system reliability during a period of transition in the electric sector. Recent years have seen a wave of announced coal plant retirements, and power generation from natural gas-fueled CHP units could make up for some of this lost generation—with lower emissions than centralized coal power plants. A study from the American Council for an Energy-Efficient Economy found that natural gas-fueled CHP at industrial facilities could quickly and cost-effectively replace some of the electric power from retiring coal plants. In South Carolina and Kansas, it could replace all of the expected lost capacity, while in industrial, coal-dependent states such as Ohio and North Carolina, it could replace 16 and 56 percent of lost capacity, respectively.[170]

Figure 8 compares conventional, centralized power generation augmented with a boiler (left side) with a CHP system (right side). Each system is required to provide 30 units of electricity and 45 units of usable heat. However, the power station and boiler together require 154 units of fuel, and the CHP system requires only 100 units of fuel. Therefore, the power station is 49 percent efficient and the CHP unit is 75 percent efficient. At least 7 percent of the electricity delivered from the conventional power station to the industrial facility is lost during transmission. Although most of the losses occur as primary fuel-to-electricity conversion heat losses at the power plant, this heat is unable to be captured for useful purposes. Consequently, a boiler is required on the industrial site to create the necessary heat, which consumes additional fuel. In contrast, the CHP system is able to generate the electricity and heat together with far fewer losses. Since less fuel is required, overall emissions are lower. Some operations also use waste heat in an absorptive chiller to provide cooling services as well. Such operations are referred to as trigeneration or combined cooling, heating, and power. These operations offer even greater efficiencies and opportunities for emissions reductions.

FIGURE 8: CHP versus Conventional Generation



On the right, 100 units of fuel are converted into 30 units of electricity and 45 units of useful heat by a single CHP unit; 75/100 = 75 percent efficiency. On the left, 91 units of fuel are converted into 30 units of electricity by a large power plant and 56 units of fuel are converted into 45 units of useful heat by a separate boiler; 75/(91 + 56) = 51 percent efficient.

Source: Environmental Protection Agency, "Efficiency Benefits," 2012. Available at: http://www.epa.gov/chp/basic/efficiency.html.

BARRIERS TO DEPLOYMENT OF CHP SYSTEMS

Although CHP systems have dramatically higher efficiencies than grid power combined with simple natural gas combustion, and they result in much lower greenhouse gas emissions, barriers currently limit their application. Electric utilities often cite safety concerns as a barrier to deployment, specifically, perceived risks related to electricity being added to the grid outside of the central power plant. For example, some utilities cite the concern that miscommunication could occur between CHP operators and the utilities in the event of an emergency such as a storm causing downed power lines, which utilities say could lead to dangerous situations in which their line workers are not certain whether lines are energized or not. In addition, utilities may be concerned about risk and liability involved as their employees could be affected by safety and technical decisions of CHP operators, decisions they are concerned could be made independently of utilities.[171] Other concerns have to do with CHP systems' potential need for backup power. Many utilities are concerned about the need to provide backup power to industrial facilities if CHP systems are taken offline or are otherwise unavailable. For utilities, the ability to provide backup power requires capacity; to pay for investments in new or maintenance of existing capacity, utilities often charge CHP operators higher rates than other customers and additional interconnection fees to compensate for these necessary investments.

From the standpoint of industry, technical and economic considerations also may need to be taken into account when considering the installation of a CHP system. Some facilities may face shortages of trained CHP installers and operators. Another challenge is that CHP retrofits can be costly. Installation is easier during new construction or a major redesign of a facility. Lastly, some industrial users may face difficulties finding buyers for excess heat or power not needed for their own use. However, if buyers are found, the project may be not only environmentally sound, but economically viable as well.

Current regulatory and electric utility policies have inhibited the growth of CHP capacity, with its attendant climate benefits, because they prevent the alignment of financial interests between electricity producers and energy consumers. Power sector regulation in many states leads utilities to view CHP as unprofitable.[172] This negative view of CHP is often reflected in regulations established by public utility commissions that do not encourage new CHP deployment. However, innovative policy approaches can overcome this conflict between competing goals among utilities and CHP operators. One approach is decoupling, removing or modifying the link between a utility's volume of sales and its profits. Decoupling makes it profitable for utilities to encourage CHP systems.[173] Another potential policy solution is a lost-revenue adjustment policy, which compensates utilities through a charge on customer bills for revenues lost because efficiency measures were effective.[174, 175] State incentives can also encourage the use of CHP. State-level policies include standardizing grid-interconnection guidelines, offering tax incentives, and including CHP as a compliance mechanism for the state's clean-energy standards.[176] Some states have enacted these policies, and, as with many state-led policies, there is a diversity of approaches to (and success with) their implementation.[177]

An example of a state working to overcome barriers to CHP deployment is Ohio. The U.S. Department of Energy (DOE) estimates Ohio has a potential CHP capacity of up to 8,000 MW if CHP systems are installed and limited from selling power into the broader power market, and up to 11,000 MW if sales into the market are allowed. However, despite this vast potential, by 2011 only 766 MW of CHP was installed in the state.[178] Many of the boilers in Ohio will be affected by the new EPA 2012 Boiler MACT rule, making them candidates for upgrades or complete conversions to CHP systems. At the same time, new CHP facilities have the potential to address state regulators' concerns about several announced coal plant retirements affecting system reliability. In response to the benefits of CHP systems in Ohio at this time and to this technology's current underutilization, the Public Utilities Commission of Ohio launched a pilot project with DOE to encourage installation of CHP systems. This project identifies candidate systems and assists in the dialogue between potential CHP operators, utilities, and the electric market operator to facilitate installations while working to overcome regulatory and other barriers.[179] In 2012, the state legislature also added CHP systems as a qualifying resource in the state's clean-energy standard.[180]

CONCLUSION

The increased availability of low-priced natural gas has had positive economic impact on U.S. manufacturing and sector expansion is expected to continue. Given that natural gas is a feedstock and a fuel source for this industry, the efficient use of natural gas needs to be continually encouraged. Options to increase efficiency include the replacement of older boilers with more efficient ones and the expansion of CHP. CHP systems are highly efficient, as they use heat energy otherwise wasted. Policy is needed to overcome barriers to expanded deployment. States are in an excellent position to take an active role in promoting CHP when required industrial boiler upgrades and new standards for cleaner electricity generation are implemented.

VII. DISTRIBUTED GENERATION IN COMMERCIAL AND RESIDENTIAL BUILDINGS AND THE ROLE OF NATURAL GAS

By Doug Vine, C2ES

INTRODUCTION

Distributed generation is the production of electricity from smaller sources at or near the location where the energy will be consumed. Slightly more than 6.5 percent of electricity in the United States is generated at distributed locations outside of central generation plants.[181] Distributed generation using natural gas has a number of potential benefits, including the potential to capture heat associated with electricity generation that can be put to use on site. When waste heat is captured and used and/or highly efficient generation technologies are used, distributed generation decreases the total demand for primary fuels, thereby decreasing greenhouse gas emissions.

This chapter explores the potential climate-related benefits of distributed generation technologies as they apply to the residential and commercial sectors. (For a discussion of combined heat and power (CHP) systems in the manufacturing sector, see chapter 6.) The chapter discusses three major technologies for distributed generation: microgrids, fuel cells, and microturbines. Next, it explores policies that encourage the deployment of these technologies, and, lastly, it discusses barriers to deployment.

Electricity is the most widely used form of energy by residential and commercial buildings on a primary-energy basis (Figure 1). Since the majority of electricity generation emits greenhouse gases, it makes sense to consider technologies with lower emissions. Several promising technologies make use of natural gas as the primary fuel, and many of these technologies could significantly reduce greenhouse gas emissions from electricity use in the residential and commercial sectors. Distributed generation technologies either can be placed on site at a home or business or can be located a short distance away, serving several buildings together. While the majority of existing natural gas-fueled distributed generation technologies are not as efficient as central generation, the ones discussed in this chapter are highly efficient, can be used in highly-efficient configurations with CHP, and/or facilitate the deployment of renewable energy sources. Distributed generation technologies that supply power to multiple locations include microgrids. On-site or end-use technologies include natural gas-fueled electricity (and heating) devices such as fuel cells and microturbines, which can also be used as small CHP systems.

THE ADVANTAGES OF DISTRIBUTED GENERATION

In 2010, natural gas-fueled electricity comprised approximately 54 percent of the total net U.S. distributed generation (Figure 2). These figures are for industrial and commercial sector distributed generation only and represent approximately 3.5 percent of the total electricity generated in that year.

FIGURE 1: Projected U.S. Residential and Commercial Buildings Primary Energy Consumption, 2010

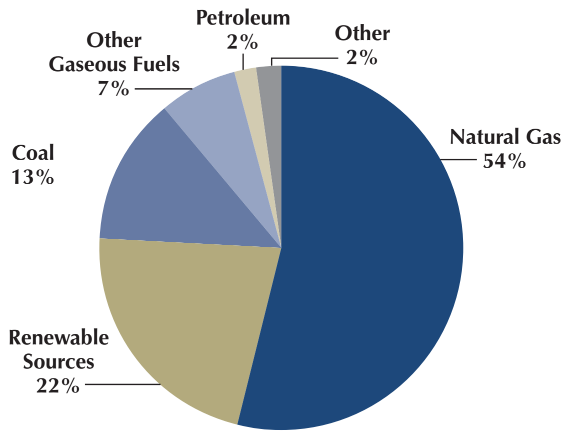
FIGURE 2: Distributed Generation by Fuel Source, 2009



Source: Source: Energy Information Administration, Residential Energy Consumption Survey, 2009. Available at http://www.eia.gov/consumption/residential/data/2009/

Distributed generation has many advantages over centralized electricity generation, including end-users' access to waste heat, easier integration of renewable energy, heightened reliability of the electricity system, reduced peaking power requirements, lower greenhouse gas emissions, and less vulnerability to terrorism due to more geographically dispersed, smaller power plants.[182] In addition, producing electricity closer to where it is used reduces the amount of electricity lost as it is delivered over long distances from power stations to end users. Annual electricity transmission and distribution losses in the United States average about 7 percent of the electricity transmitted.[183] Lowering transmission (or line) losses means less electricity generation (less fuel and fewer emissions) is required to serve the same electrical demand.

Generally, natural gas-fueled distributed generation technologies are not as efficient in producing electricity as natural gas-fired generation from the grid. In general, distributed generation only improves efficiency and reduces greenhouse gas emissions when it includes CHP. By definition, distributed generation is physically located close to loads, so use of heat is often an option. However, CHP requires tight matching, in space and especially in time, between power generation and thermal loads. This matching can make CHP technologies difficult to effectively install. Nevertheless, where possible, this technology is significantly more efficient and should be deployed.

MICROGRIDS

One increasingly employed distributed generation technology is the microgrid. A microgrid is a small power system composed of one or more electrical generation units that can be operated either in conjunction with or independently from the central power system (Figure 3).[184] Micrograms can serve a small grouping of buildings. Additionally, microgrids offer the potential to integrate renewable sources of electricity with fossil fuel-based backup power; they are able to integrate distributed, dispatchable natural gas-fueled electricity (or CHP systems) with local renewable power and energy storage. Furthermore, since the electricity is generated close to where it will be used, it becomes feasible to use the waste heat in a productive manner, such as for heating water or space in nearby homes and businesses. Microgrids can be particularly attractive if new or upgraded long-distance electricity transmission cannot be developed in a timely or cost-effective fashion.[185]

FUEL CELLS

Fuel cells are another promising distributed generation technology. Natural gas-powered fuel cells use natural gas and air to create electricity and heat through an

FIGURE 3: Microgrid Concept

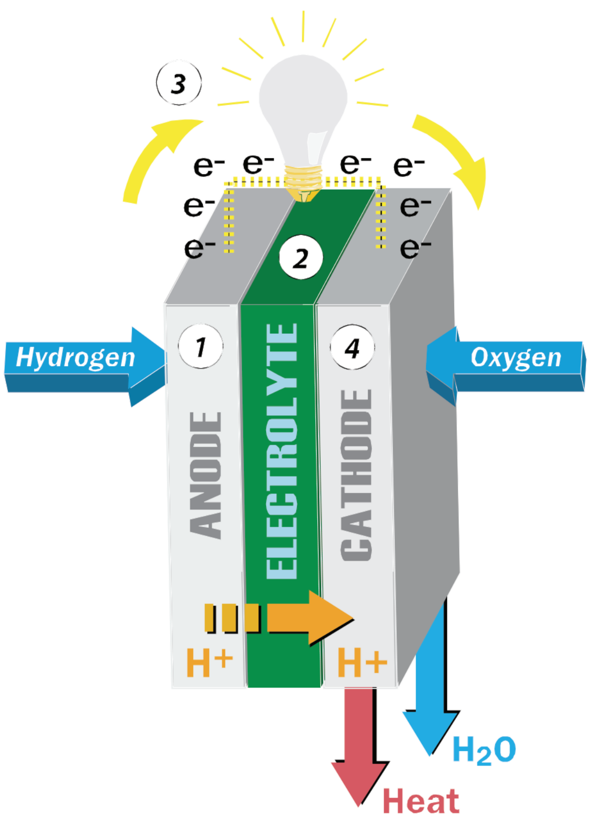
Note: Individual microgrid elements will vary.

electrochemical process rather than combustion.[186] First, natural gas is converted into hydrogen gas inside the fuel cell in a process known as reformation. When the hydrogen passes across the anode of the fuel cell stack (Figures 4 and 5), electricity, heat, water, and carbon dioxide (CO_2) are created.

Fuel cell technology has been around for many decades; it has been used by the National Aeronautics and Space Administration on space projects for nearly 50 years. Commercially available fuel cells operate in a

FIGURE 4: Fuel Cell Stack



1) Anode: As hydrogen flows into the fuel cell anode, a catalyst layer on the anode helps to separate the hydrogen atoms into protons (hydrogen ions) and electrons. 2) Electrolyte: The electrolyte in the center allows only the protons to pass through the electrolyte to the cathode side of the fuel cell. 3) External Circuit: The electrons cannot pass through this electrolyte and, therefore, must flow through an external circuit in the form of electric current. This current can power an electric load. 4) Cathode: As oxygen flows into the fuel cell cathode, another catalyst layer helps the oxygen, protons, and electrons combine to produce pure water and heat.

wide range of climates, from very cold to very warm (-20° to 110°F), and they have electrical efficiencies of around 40 to 60 percent (Table 1). They are quiet devices with a fairly small footprint. The only greenhouse gas emitted is a pure stream of CO_2, which could allow for capture and sequestration. Despite these benefits, skeptics question the durability, cost (see below) and reliability of fuel cells. In the past, materials have corroded within months or a few years. Bloom Energy estimates that its current devices will have a 10-year life as long as the fuel stacks are replaced at least twice. However, since Bloom's introduction is recent, there are currently no operational fuel cell systems that have approached this age.[187]

There are many types of fuel cells, each with its unique chemistry, operating temperature, catalyst, and electrolyte.[188] Phosphoric acid fuel cells, molten carbonate fuel cells, and solid oxide fuel cells, among others, have been commercialized for stationary electrical power generation. Since many units operate at high temperatures and contain corrosive materials, a key concern is their durability or stack life. For example, natural gas-fueled phosphoric acid fuel cells operate at temperatures of around 450°F, and solid oxide fuel cells operate at temperatures of about 1,800°F.[189] Phosphoric acid fuel cells are the most durable type in the less-than-one megawatt (MW) range and have a demonstrated stack life of more than 10 years, although designs of many other fuel cell types are improving rapidly.[190]

ClearEdge Power and Bloom Energy are among a handful of manufacturers of stationary fuel cells. Their main products are described below for illustrative purposes. There are an additional half-dozen or so manufacturers of non-stationary fuel cells (fuel cells for vehicles).

ClearEdge Power, based in Oregon and established in 2003, manufactures refrigerator-sized fuel cell units that generate baseload or backup electric power as well as provide useable heat for hot water and/or space heating in a CHP configuration. These units are scalable to suit the energy requirements of individual homes, apartment buildings, hotels, and other commercial businesses, and can be installed indoors or outdoors. They have efficiencies of up to 90 percent. They are 50 to 60 percent efficient in natural gas conversion to electricity, in addition to providing useful heat. Therefore, they require considerably less natural gas to generate the same amount of energy provided from a combination of centrally generated electricity and a heating appliance.[191] In February 2013, ClearEdge Power acquired UTC Power, an early pioneer in fuel cell research that conducted experiments with many types of fuel cells beginning in the late 1950s.[192] Stationary fuel cell products from UTC Power, now ClearEdge Power, are deployed in residential, commercial, and industrial applications around the world.[193]

Bloom Energy, based in California and founded in 2001, markets energy servers that consist of arrays of fuel cell boxes in various sizes that must be installed outdoors (Figure 6). The energy servers are scalable and are used by large corporate customers such as Wal-Mart, eBay, and FedEx, and not residential consumers.[194] These servers achieve conversion efficiencies above 60 percent. These are very high-temperature devices, but the heat is not used for water or space heating. The average emissions are 773 pounds of CO_2 per megawatt-hour (MWh), which is just below the average U.S. natural gas power plant at 800 to 850 pounds of CO_2/MWh.[195, 196]

FIGURE 6: Bloom Energy Server Outdoor Installation

Source: Bloom Energy

MICROTURBINES

Microturbines are small combustion turbines approximately the size of a refrigerator with individual unit outputs of up to 500 kilowatts (kW).[197] These devices can be fueled by natural gas, hydrogen, propane, or diesel. In a cogeneration configuration (Figure 7), the combined thermal-electrical efficiency can be as high as 90 percent.[198] Like fuel cells, microturbines can achieve much higher energy efficiencies, because the electricity is generated close to the location where it will be used, and the heat byproduct can be captured and utilized on site or nearby.

Microturbines are an established technology, and there are more than 20 companies worldwide involved

TABLE 1: Fuel Cells Summary

Fuel enters the combustor and the hot gases ejected from the combustor spin a turbine, which is connected to a generator that creates electricity. The exhaust gases transfer heat to the incoming air. A recuperator captures waste heat and helps improve the efficiency of the compressor.

Source: Capstone Turbine Corporation

in the development and commercialization of microturbines for distributed generation applications.

Los Angeles-based Capstone Turbine Corporation is a global market leader in the commercialization of microturbines.[199] The company offers individual units in the range of 30 kW to 200 kW, and greater quantities of power can be achieved by using multiple units, with electrical efficiencies from 25 to 35 percent (Figure 8). Using the heat produced by a microturbine for water or space heating, space cooling (in conjunction with absorption chillers) and/or process heating or drying, increases the efficiency of these units to 70 to 90 percent.[200] Capstone products service the commercial and industrial sectors, and they have installations all over the world, including universities, a winery, and a 35-story office tower in New York City (Figure 9).[201]

Flex Energy, also headquartered in California, is Capstone's main competitor. Its 250 kW microturbine has an electrical efficiency of 30 percent, and it too provides useful heat energy, which when used would improve the overall efficiency of the system.[202] Flex Energy and Capstone microturbines can use low-quality

FIGURE 8: Microturbine Unit

Source: Capstone Turbine Corporation

FIGURE 9: Microturbine Installation

Source: Capstone Turbine Corporation

and unrefined natural gas, making them capable of generating electricity at landfills and hydraulic fracturing sites.[203] Using unrefined natural gas at a well site for power requirements can reduce the need for diesel power generation and utilize natural gas that may have been flared otherwise.

Micro Turbine Technology, a company in the Netherlands, is developing a 3 kW electrical with 15 kW thermal microturbine CHP for homes and small businesses that is expected to be ready for market in early 2013.[204]

At 31 percent average electrical efficiency, much lower than a modern natural gas combined-cycle plant or fuel cell (both around 50 percent), microturbines produce 1,290 pounds of CO_2/MWh, about 50 percent higher emissions than a modern combined-cycle plant.[205] However, due to their ability to capture and use waste heat onsite, they are capable of achieving thermal efficiencies of up to 85 percent. When this heat is captured and used, the total efficiency of the system offsets the lower efficiency of electricity generation part of the system, reducing overall greenhouse gas emissions per MWh. Additional strengths of microturbines include their compact size, small number of moving parts, generally lower noise than other engines, and long maintenance intervals. Weaknesses include parasitic load loss from running a natural gas compressor and loss of power output and efficiency with higher ambient temperatures and elevation.[206] According to U.S. Environmental Protection Agency data, at an 80°F outdoor air temperature, the microturbines are about 3 percent less efficient than at a 50°F outdoor air temperature.[207]

RESIDENTIAL UNIT CHP

There are even smaller systems than the microturbines discussed that can provide CHP to individual residential units. At less than 50 kW, these microCHP units are small enough to provide electric power for a residential or commercial building while also supplying heat for thermal applications or absorption cooling (Figure 10). Common in Europe and Japan, microCHP is rare in the United States. These small units may use a variety of engine types, including combustion, steam, Brayton, and Stirling.[208] For example, the WhisperGen, developed in New Zealand, is a microCHP technology based on the Stirling engine. The company is currently headquartered in Spain, where the product is being marketed to European customers. The washing machine-sized technology is designed to produce hot water and space heating. Under normal operation the unit will provide around 1 kW of electrical power.[209] Other companies, such as Japan's Honda, also offer microCHP units to consumers.[210]

TABLE 2: Microturbine Summary

COMPANY	ELECTRICAL EFFICIENCY	USABLE HEAT	TOTAL EFFICIENCY FOR CHP SYSTEM	MARKETS

POLICIES TO ENCOURAGE THE DEPLOYMENT OF NEW TECHNOLOGIES

Although these new technologies have great potential to use less primary energy and to reduce greenhouse gas emissions from energy use in the residential and commercial sectors, there are some hurdles to overcome. Higher upfront capital costs hinder investment in distributed generation technologies overall. In addition, utility regulations often do not encourage, and in some case actively discourage, distributed generation technologies.

Some state and federal incentive programs help home- and business-owners with upfront costs. At least 10 states provide financial incentives for self-generation.[211, 212] The federal Investment Tax Credit, designed to help defray capital expenditure costs, applies to fuel cells, CHP, and microturbines for use in the commercial, industrial, utility, and agricultural sectors.[213]

Another potential incentive for consumer investment in on-site energy generation is net metering. Net metering allows customers to receive retail prices for their excess generation; the electricity meter turns backwards (literally or digitally) when the site generates more electricity than it consumes.[214] Forty-three states and the District of Columbia have rules enabling net metering.[215] Eligible generation technologies vary. Fuel cells using any fuel type often qualify, and CHP sometimes qualifies, although less often.

Sites using distributed generation often rely on a grid interconnection as a source of backup power. Establishing a connection between an on-site system and the power grid can be difficult, confusing for the on-site operator, and lengthy. Standard interconnection rules greatly simplify this process, establishing clear and uniform processes and technical requirements that apply to all utilities within a state. These rules reduce uncertainty and prevent delays that installers and operators of distributed generation systems can encounter when obtaining approval for electric grid connection, and thus make the prospect of installing a system less daunting to newcomers.[216] As of April 2012, 34 states had interconnection standards for fuel cells, and 29 states had such standards for microturbines.[217]

A final area where policies could encourage the installation of more distributed generation systems pertains to utility charges. As mentioned above, distributed generation systems rely on a grid connection for backup power during outages, whether scheduled or emergency. Standby rates are charges levied by utilities when a distributed generation system must purchase all of its power from the grid. These charges generally include an energy charge, reflecting the actual energy provided, and a demand charge, which is a way for the utility to recover its costs in maintaining the capacity to meet the facility's peak demand whenever that may be required. Utilities often argue that the demand charges act as a strong incentive for system owners to manage their peak demand. However, the likelihood of unplanned outages during times of peak demand is very low, and the use of demand charges likely discourages the expansion of distributed generation. Regulators should carefully weigh the discouraging effect of demand charges against the substantial benefits of distributed generation, including increased system reliability, reduced distribution losses, and the climate benefits of the higher system efficiencies.[218]

BARRIERS TO DEPLOYMENT

A variety of factors converge to discourage potential owners of distributed generation systems. First, consumers are largely unfamiliar with these technologies. Moreover, they are not compelled to search for innovative strategies to generate energy. Their utility bills are stable, due to low wholesale electricity prices (a result of lower natural gas prices). Local building and fire codes may also provide disincentives or even make it impossible for consumers to consider distributed generation. And the limited availability of many distributed generation products in the United States is a barrier to even those with natural gas access.[219]

Even if these hurdles are removed, the cost of many distributed generation technologies can be a barrier. According to the National Institute of Building Sciences, microturbine capital costs were $700 to $1,100 per kW in 2010, with installation costs adding 30 to 50 percent of the total installed cost. Combining heat recovery technology to units increased the cost by $75 to $350 per kW. A future cost below $650 per kW may be possible with future economies of scale.[220] Fuel cells could be cost-competitive with grid electricity if they were to reach an installed cost of $1,500 or less per kW; however, the current installed, unsubsidized cost is at least $4,000 per kW.[221] Nevertheless, a combination of state and federal incentives, low natural gas prices, and high grid-electricity prices could result in a 100 kW energy server making economic sense, as shown in an analysis by Seattle City Light (Figure 11). Similarly, natural gas microCHP units could be cost competitive with a 1.5- to two-year payback period at an installed cost of $1,500 for a 1 kW unit.[222]

CONCLUSION

To realize the potential of distributed generation technologies, policies such as financial incentives and tax credits will need to be more widespread. Additionally, net metering, grid interconnection requirements, and standby rate issues will need to be worked through. Also, low consumer awareness and higher costs of these emerging technologies will slow their deployment. Finally, utilities may perceive distributed generation technologies as a threat, as they have the potential to capture a large share of utilities' electricity sales business. Nevertheless, some supporters of distributed generation have claimed that their technology will replace the grid and have designed their business strategies accordingly.[223]

VIII. TRANSPORTATION SECTOR

By Fred Beach, The University of Texas at Austin

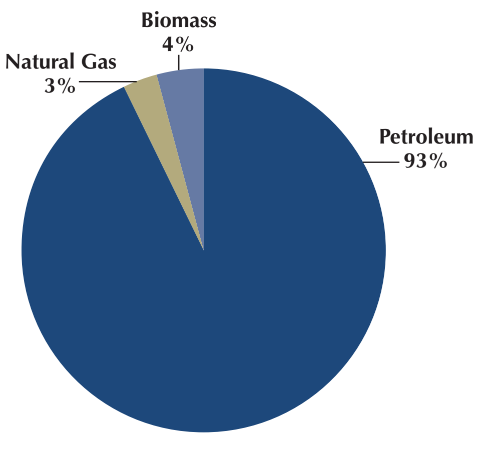
INTRODUCTION

Historically, natural gas has not been widely used as an energy source for transportation; rather, the sector has long been dominated by petroleum use. In 2010 (Figure 1), the U.S. transportation sector used 27.47 quadrillion British thermal units (Btu) of energy, of which 25.59 quadrillion came from petroleum and just 0.72 quadrillion came from natural gas—93 percent and 3 percent of the sector, respectively.[224] Natural gas used in the transportation sector resulted in the emission of just 40.1 million metric tons of carbon dioxide equivalent (CO_2e) in 2010, out of a total 1,746 million metric tons emitted by all fuel sources in the transportation sector.[225] As in other sectors of the economy, fuel substitution from other fossil fuels to natural gas in some parts of the transportation sector has the potential to yield climate benefits. In addition, it would benefit U.S. national security by decreasing reliance on the global oil market. Although the potential for natural gas use is less in the transportation sector than in others, the potential does exist, primarily for medium- and heavy-duty trucks as well as fleet vehicles and buses.

A main driver of the increased interest natural gas fleets and passenger vehicles is the relative abundance and low price of domestic natural gas in comparison to oil. On April 30, 2012, the national average price of diesel fuel was $4.07 per gallon and gasoline cost $3.83 per gallon,[226] while a gasoline-gallon-equivalent of natural gas cost only $2.09.[227] On the same day, the price of petroleum was $104.87 per barrel,[228] and the price of natural gas was only $12 on an energy-equivalent basis.[229] In recent years, oil prices rose while natural gas prices decreased, creating an ever-widening gulf (Figure 2). This differential has made natural gas vehicles increasingly economical.[230]

This chapter looks at the currently available natural gas technologies for vehicles. Next, it explores the barriers to adoption for various types of vehicles. Finally, it examines the potential implications of broader direct use of natural gas in the transportation sector for greenhouse gas emissions.

FIGURE 1: Energy Sources in the U.S. Transportation Sector, 2010



Source: Energy Information Administration, "Annual Energy Review," Table 2.1e. October 2011. Available at: http://www.eia.gov/totalenergy/data/annual/showtext.cfm?t=ptb0201e

AVAILABLE NATURAL GAS TRANSPORTATION TECHNOLOGIES

A variety of available vehicle technologies allow natural gas to be used in light-, medium-, and heavy-duty vehicles. Most commonly, natural gas is used in a highly pressurized form as compressed natural gas (CNG) or as liquefied natural gas (LNG). While CNG and LNG are ultimately burned in the vehicle, natural gas can also power vehicles in other ways. Natural gas can be converted into liquid fuel such as gasoline and diesel (distinct from LNG) that can be used in conventional internal combustion engines, reformed into hydrogen for use in fuel-cell vehicles, or be used to generate electricity for electric vehicles. Despite the existence of these technologies, only about 117,000 of the more than 250 million vehicles on the road in 2010 (about 0.05 percent) were powered directly by natural gas.[231] The majority of natural gas-powered vehicles are buses and trucks.[232]

Compressed and Liquefied Natural Gas

CNG is the most common natural gas fuel used in transportation today. There were 115,863 compressed-natural gas vehicles on U.S. roads in 2010, using 988 fueling sites.[233] The majority is found in larger transportation fleets. Although Honda offers a CNG passenger vehicle, only 4,000 vehicles were scheduled for production in 2012.[234] Public transit buses are the largest users of natural gas in the transportation sector, with about one-fifth of buses running on CNG or LNG. Some commercial fleets use natural gas-powered trucks, including thousands of trucks at FedEx, UPS, and AT&T.[235, 236] Waste Management has the largest fleet of natural gas vehicles in the country with 1,700 trucks that can run partially on biogas supplied from its own landfill assets.[237] The low cost and environmental benefits of this biogas are encouraging the company to continue conversions and to open some of its refueling infrastructure to the public.

To a lesser extent than CNG vehicles, vehicles powered by LNG (primarily heavy-duty trucks) are also used on U.S. roads and a fueling infrastructure has begun to develop. LNG is created by chilling natural gas to -260°F at normal pressures, at which point it condenses into a liquid that occupies 0.0017 percent of the volume of the gaseous form.[238] The conversion of natural gas to LNG removes compounds such as water, carbon dioxide (CO_2), and sulfur compounds from the raw material, leaving a purer methane product whose combustion results in less air pollution.[239] The stable, non-corrosive form also makes LNG more easily transportable, and it can be moved by ocean tankers or trucks.[240] Use of LNG requires large, heavy, and highly insulated fuel tanks to keep the fuel cold, which adds a significant cost to the vehicle.[241] Today, LNG is mainly used as a replacement for diesel fuel in heavy-duty trucks because they can accommodate this hefty storage system and can use LNG fueling infrastructure currently limited to trucking routes.[242] In 2010, there were only 40 public and private LNG refueling sites,[243] serving 3,354 LNG vehicles.[244] Recently, the Clean Energy Fuels network launched the development of an interstate LNG refueling network, mainly taking advantage of existing diesel fueling

stations along highways and trucking distribution centers. Seventy stations were opened in 2012, with plans for 70 to 80 more in 2013.[245]

CNG and LNG are less dense forms of energy than conventional gasoline and diesel fuel (Figure 3), requiring vehicles running on them to have larger fuel tanks in order to store the same amount of energy. CNG requires special storage because the gas is compressed to less than 1 percent of its volume at standard atmospheric pressure.[246] Vehicles use cylindrical storage tanks capable of fuel pressures of up to 3,600 pounds per square inch. These tanks are significantly larger and heavier than conventional gasoline or diesel fuel tanks, and their placement in passenger vehicles can take up valuable passenger or trunk space.[247, 248] The energy density of CNG is so low that CNG vehicles with ranges greater than 300 miles are unlikely to be produced unless current space and weight limitations are overcome. Therefore, CNG is primarily suitable for fleet passenger vehicles, municipal buses, and other vehicles where travel distances are shorter. The greater energy density of LNG, however, makes it practical for long-haul tractor-trailers that can accommodate larger fuel tanks.[249] Despite being less energy-dense than gasoline or diesel, both CNG and LNG can be an attractive fuel source for certain applications, from both an economic and environmental perspective.

Fuel Cell-Powered Vehicles

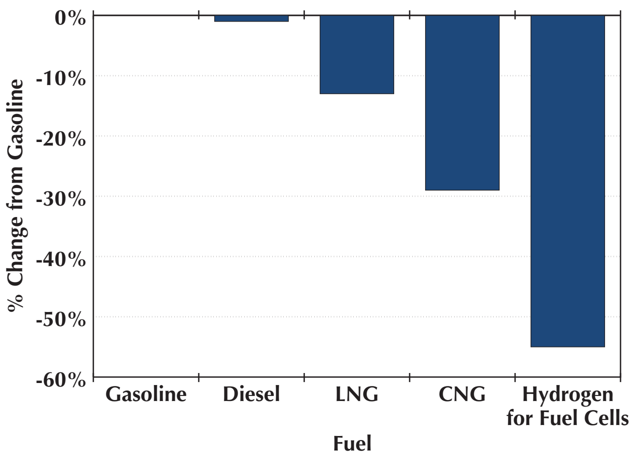
Natural gas also plays a role in supplying fuel cell vehicles (see chapter 7 for a discussion of stationary fuel cells in distributed generation). Fuel cells produce electricity through an electrochemical process rather than through combustion, resulting in heat and water and far lower emissions of greenhouse gases and other pollutants. Fuel cells are fueled by hydrogen, and the most common source of hydrogen today is natural gas. Hydrogen can be extracted on board the vehicle using a reformer, or it can be externally extracted and subsequently added to the vehicle.[250] Today, no light-duty fuel cell vehicles are commercially available in the United States, although there are certain test vehicles on the road as well as rudimentary hydrogen fueling infrastructure in California.[251] Companies are working to introduce fuel cell vehicles to the market. In the United States, Hyundai plans to build 1,000 fuel cell vehicles for distribution in 2013,[252] and Toyota has suggested that production costs are decreasing such that it should be able to sell fuel cell vehicles for $50,000 by 2015.[253]

Gas to Liquids

While CNG and LNG are today the most common forms of natural gas fuels in vehicles, other available technologies could increase the use of natural gas in the broader transportation system. Gas-to-liquids technology refines natural gas into gasoline or diesel hydrocarbons, which can be used in existing vehicles and moved through existing infrastructure. Gas-to-liquids products have energy densities similar to those of traditionally produced gasoline and diesel, properties that allow for better engine performance and potentially fewer emissions of greenhouse gases and regulated pollutants,[254] although more empirical study is needed on emissions.

Conversion technologies typically require 10 thousand cubic feet (Mcf) of natural gas to produce one barrel of oil-equivalent product output, such as diesel, naphtha, and other petrochemical products.[255] Using $4 per Mcf of natural gas as inputs to this conversion, the outputs are equivalent to $40 per barrel of oil-equivalent. Gas-to-liquids products have been produced at facilities elsewhere in the world, and new facilities in the United States are being developed. Several companies are considering gas-to-liquids facilities on the Gulf Coast because of favorable natural gas supplies and current domestic prices.[256]

FIGURE 4: Full Lifecycle, Total Carbon Intensity of Selected Transportation Fuel Options as a Percentage Reduction from Gasoline Carbon Intensity



Source: California Air Resources Board, "Proposed Regulation to Implement the Low Carbon Fuel Standard," March 5, 2009. Table ES-8. Available at: http://www.arb.ca.gov/fuels/lcfs/030409lcfs_isor_vol1.pdf

Notes: The carbon intensities compared above were calculated specifically for California's Low Carbon Fuel Standard program using the GREET model.

Results from the GREET model rely on the assumptions included in the model. Other models may use other assumptions and yield different results. Models are useful for insights, but their results depend on the assumptions made.

Electric Vehicles

Natural gas also plays a role in electric vehicles, which are becoming more common on U.S. roads. These vehicles use electricity from the electrical grid, which is increasingly powered by natural gas as a fuel source. From January 2011 to December 2012, Americans purchased more than 60,000 plug-in electric vehicles, including Chevrolet Volts, Nissan LEAFs, and Toyota plug-in Priuses.[257] Additionally, plug-in electric vehicles are now available from BMW, Ford, Tesla, Mitsubishi, and Daimler.[258] When fueled by electricity generated by a combined-cycle natural gas power plant, such natural gas-powered electric vehicles offer significant efficiency and emissions benefits over conventional diesel- or gasoline-powered vehicles.[259]

GREENHOUSE EMISSIONS OF NATURAL GAS AS A TRANSPORTATION FUEL

Transportation accounts for more than 25 percent of U.S. greenhouse gas emissions and is an important focus of U.S. emission reduction efforts. Natural gas emits fewer greenhouse gases than gasoline or diesel when combusted or used in fuel cells (Figure 4). Fuel Cells offer the greatest potential emission reduction benefit but today are also the most expensive. CNG offers the next largest greenhouse gas reduction potential and can be used in many transportation options including fleets, heavy-duty vehicles and passenger vehicles. The barriers and potential for emission reductions associated with fuel switching to natural gas in major segments of the transportation sector are described below.

NATURAL GAS IN BUSES AND MEDIUM- AND HEAVY-DUTY VEHICLE FLEETS

Buses produce a very small share of overall greenhouse gases, contributing only 1 percent of emissions from on-road vehicle transportation in 2011, but as previously mentioned, they are the most common use of natural gas in vehicles today.[260] In contrast, long-haul tractor-trailers play a more important role in U.S. energy consumption and greenhouse gas emissions. These vehicles account for two-thirds of all fuel consumption for freight trucks (medium- and heavy-duty trucks), and freight trucks' emissions are increasing more rapidly than those of other transportation sources. Over time, freight trucks will likely account for an even larger percentage of the sector's greenhouse gas emissions, as they will take on a greater portion of deliveries for consumer products, using more vehicles for just-in-time shipping and taking advantage of lower labor costs and changing land use patterns.[261] Consequently, reducing the carbon intensity of freight trucks will be critical to reducing transportation sector greenhouse gas emissions, and increased natural gas use is one opportunity to do so.

Barriers to Expanded Natural Gas Use

Significant barriers exist for the expansion of natural gas use in medium- and heavy-duty vehicles. Currently, trucks utilizing CNG or LNG have shorter ranges, fewer refueling options, and lower resale value than traditional diesel-powered trucks. A diesel truck with a 150-gallon tank and a 6 to 7 miles-per-gallon fuel economy can travel about 1,000 miles on one tank, which is significantly more than its natural gas-powered counterparts. Depending on the mounting of the cylindrical storage tanks, CNG trucks can travel between 150 miles and 400 miles between fueling, while LNG trucks can travel around 400 miles.[262]

The limited availability of fueling infrastructure also hampers the deployment of natural gas-powered trucks, and better infrastructure is required for greater use.[263] In May 2012, there were 1,047 fueling stations for CNG and 53 fueling stations for LNG in the United States, and 53 percent of the CNG stations and 57 percent of the LNG stations were closed to the public.[264] Also, speed of fueling can be a barrier to deployment in certain fleet types, as the more common and less expensive fueling technology requires long filling times. On-time delivery operations of trucking fleets may not be able to accommodate long filling. Slow filling is more appropriate for trucks such as waste trucks or buses that may idle for long periods overnight or between uses.[265]

Fuel pricing differentials are a clear driver for natural gas conversions in the transportation sector since fuel costs are a significant portion of the overall operating budgets for fleet owners. Medium-duty trucks use about 6,000 gallons of fuel per year, while heavy-duty trucks use about 18,000 gallons. At $3.50 per gallon of diesel fuel, annual fuel costs are $21,000 for a medium-duty truck and $63,000 for a heavy-duty truck. Natural gas fuel costs are substantially lower than diesel fuel. At a price of $2.80 per diesel gallon equivalent—a typical price for LNG or retail CNG—annual fuel costs would fall to $16,800 per medium-duty truck and $50,400 per heavy-duty truck. At a slow-fill CNG cost of $1.00 per diesel-gallon-equivalent, costs drop to less than one-third the cost of diesel, to $6,000 per medium-duty truck and $18,000 per heavy-duty truck. These fuel savings offer great incentives for fuel-switching.[266]

However, fleet economics are often more complex, extending beyond just fuel costs. Natural gas trucks are about $30,000 to $50,000 more expensive than their diesel counterparts, a substantial additional capital cost. Adoption of natural gas trucks also requires fleet owners to invest in additional maintenance capacity for natural gas vehicles, requiring investments in new materials and job training. Complying with standards for maintaining natural gas trucks, such as those required under Occupational Safety and Health Administration regulations for compressed gases, adds costs.[267] These costs may further rise as regulations for this nascent industry develop and change. Resale value of natural gas trucks is another important factor for some fleet owners. Trucks from some large fleets may be resold in as little as three to four years, often to smaller trucking companies that may not be able to use natural gas vehicles due to a lack of available infrastructure or a skilled workforce. As a consequence, even with the potential fuel savings, many fleet owners may have little economic incentive to switch to natural gas trucks.

Overcoming Barriers

The cost-benefit ratio of CNG vehicles for fleet owners depends on the many variables inherent in the composition and use of vehicle fleets and the costs of refueling infrastructure. For fleet owners, range requirements may not be a significant issue, since fleet vehicles travel regular and known paths. Refueling can take place at a centralized facility or along a set route.[268] The U.S. Department of Energy's National Renewable Energy Laboratory conducted research into three different types of CNG fleets that might be used by municipal governments—transit buses, school buses, and refuse trucks—and possible refueling infrastructures. This segment was targeted based on the potential for long-term cost-effectiveness, consistency of operational costs, lower greenhouse gas emissions, and other factors.[269] The research led to the creation of a model for fleet profitability that highlighted the importance of fleet size and vehicle miles driven in calculating the cost and benefits of CNG vehicles. It estimated payback periods of three to 10 years that were sensitive to the costs related to refueling stations and vehicle conversion, operations, and maintenance.

This model includes the cost of building and operating centralized fleet-specific refueling infrastructure and thus avoids the "chicken versus egg" refueling quandary that is challenging to non-municipal fleet applications, such as small private trucking operations. The lack of a public CNG refueling infrastructure hinders fleet owners' decisions to convert heavy-duty vehicles to CNG. Conversely, the low numbers of heavy-duty vehicles converted to CNG dampens private and public sector investor motivation to build CNG refueling infrastructure. Were it not for the lack of a public refueling infrastructure, the rationale for fleet owners to convert heavy-duty vehicles would be much more compelling, as their high annual miles driven provide a much quicker

FIGURE 5: Emerging Megaregions with High Tractor-Trailer Usage

---

return on the upfront cost of vehicle conversion than do the annual miles driven of municipal fleet vehicles.

One approach that may help to overcome the vehicle-conversion-versus-refueling-infrastructure hurdle is to focus on one subset of the high-mileage, heavy-duty tractor-trailer industry segment, namely, intercity (as opposed to interstate) transport. In intercity regions with areas of high tractor-trailer usage, a very small number of public CNG refueling stations can serve a large number and percentage of the heavy-vehicle transportation segment. The United States has 11 "Megaregions" where tractor-trailers travel tens of thousands of miles annually but never leave the confines of a relatively small geographic area (Figure 5). Natural gas infrastructure can be built out in these Megaregions, such as through the proposed Texas Clean Transportation Triangle (Figure 6). Nearly 75 percent of the intrastate heavy and medium transport in Texas occurs within the triangle, making it an excellent candidate for CNG infrastructure.[270] Nominal public refueling infrastructure for CNG vehicles in the 11 Megaregions could also prove sufficient to service the interstate CNG tractor-trailer segment for a significant portion of the nation and create enough consumer demand to encourage the installation of refueling capability throughout the nation's network of commercial truck stops.

NATURAL GAS IN PASSENGER VEHICLES

Passenger vehicles account for nearly three-fifths of the total energy use and greenhouse gas emissions in the transportation sector. The lower price of natural gas and the energy security benefits of reducing U.S. consumption of oil have both contributed to recent interest in using natural gas in passenger vehicles.

FIGURE 6: Texas Clean Transportation Triangle

Barriers to Deployment

Potential barriers to wider deployment of natural gas-powered passenger vehicles include lack of access to refueling sites and the vehicles' limited ranges.[271] Home refueling is one way to potentially increase the number of refueling sites. While there are 159,006 retail gasoline stations in the United States,[272] more than 65 million U.S. homes have natural gas service.[273] Home refueling of a CNG vehicle requires the installation of a wall-mounted electric compressor to deliver the low-pressure gas from the residential system into the high-pressure CNG vehicle tank. The compressors are small and unobtrusive, but require several hours to fill the vehicle's tank.[274] Home refueling options may, in addition to providing lower fuel prices, persuade some consumers to consider purchasing CNG passenger cars or to convert existing ones from gasoline-powered cars. Yet, home fueling infrastructure has remained expensive. Home fueling appliances, such as Phil, can cost more than $4,000,[275] not including the construction and permitting costs of extending home natural gas pipe access to the garage or carport. Other barriers to adoption exist. CNG vehicles, when compared with conventional gasoline vehicles, have a reduced range because of CNG's lower energy density (the maximum range of the Honda Civic GX NG is 248 miles),[276] higher up-front costs, and smaller trunk capacity.

Fleets including taxis, business, and government vehicles may offer the greatest potential for natural gas use in passenger vehicles. In 2012, 22 states signed a memorandum of understanding to jointly solicit automaker proposals to produce seven categories of natural gas vehicles for purchase by state, local, and municipal fleets. The intention of this joint effort is to stimulate the market for natural gas vehicles and eventually expand opportunities for market growth in the private sector for passenger natural gas vehicles, as well as to decrease the fleets' associated air pollution.[277] Combined, the barriers associated with the deployment of light-duty natural gas vehicles are noticeably larger and more costly than those associated with CNG- and LNG-powered heavy-duty vehicles.

Energy Security

Increased use of these vehicles offers significant potential benefits to U.S. energy security. Energy security is the adequacy and resiliency of the energy system as it relates to energy production, delivery, and consumption. The U.S. transportation sector relies on a global oil market that is currently dominated by an oligopoly—the Organization of the Petroleum Exporting Countries (OPEC)—as well as national oil companies. OPEC's ability to constrain supplies results in oil prices higher than a competitive market would produce. Monopoly power, combined with oil price shocks, mean that the U.S. economy loses hundreds of billions of dollars per year in productivity. Researchers at the Oak Ridge National Laboratory estimate that the combined total of these costs has surpassed $5 trillion (in 2008 dollars) since 1970.[278] Moreover, most experts believe that rising demand in emerging market economies coupled with supply-side challenges can be expected to lead to future volatility in oil prices, which would be highly damaging for U.S. consumers and businesses. Replacing oil with domestically produced natural gas would have significant benefits for U.S. energy security.

CONCLUSION

The transportation sector has long relied on petroleum fuels for the vast majority of its energy needs. While utilizing natural gas as a fuel source in this sector offers greenhouse benefits, in total these benefits are less likely than in other sectors of the economy, given the difficulty, cost and speed of converting passenger vehicles to natural gas. Moreover, in the near and medium term, fuel economy for gasoline-powered passenger vehicles is set to rise due to new Corporate Average Fuel Efficiency Standards, which could reduce the emissions advantage of natural gas vehicles. Hybrid and electric passenger vehicles are also becoming more common, and given the widespread availability of electricity compared to the availability of natural gas, they require less infrastructure investment than do natural gas vehicles. These factors indicate that, considering the need for substantial long-term reductions in greenhouse gas emissions from the transportation sector, by the time a fleet conversion to natural gas would be completed for passenger vehicles, a new conversion to an even lower-carbon fuel will be required. A passenger vehicle fleet conversion to natural gas would be short-lived and yield a low return on investment from a climate perspective.[279]

As in other sectors of the economy, fuel substitution from other fossil fuels to natural gas in some parts of the transportation sector has the potential to yield climate benefits. In addition, it would benefit U.S. national security by decreasing our reliance on a global oil market dominated by outside forces. Although the potential for natural gas use is less in the transportation sector than in others, the potential does exist, primarily for medium- and heavy-duty trucks as well as fleet vehicles and buses.

IX. INFRASTRUCTURE

By Michael Tubman, C2ES

INTRODUCTION

The United States has the world's most extensive infrastructure for transporting natural gas from production and importation sites to consumers all over the country. This transport infrastructure is made up of three main components: gathering pipelines, transmission pipelines, and distribution pipelines.[280] Though fundamentally similar in nature, each type of pipeline is designed for a specific purpose, operating pressure and condition, and length. These components are linked in networks to form the U.S. natural gas infrastructure system (Figure 1).

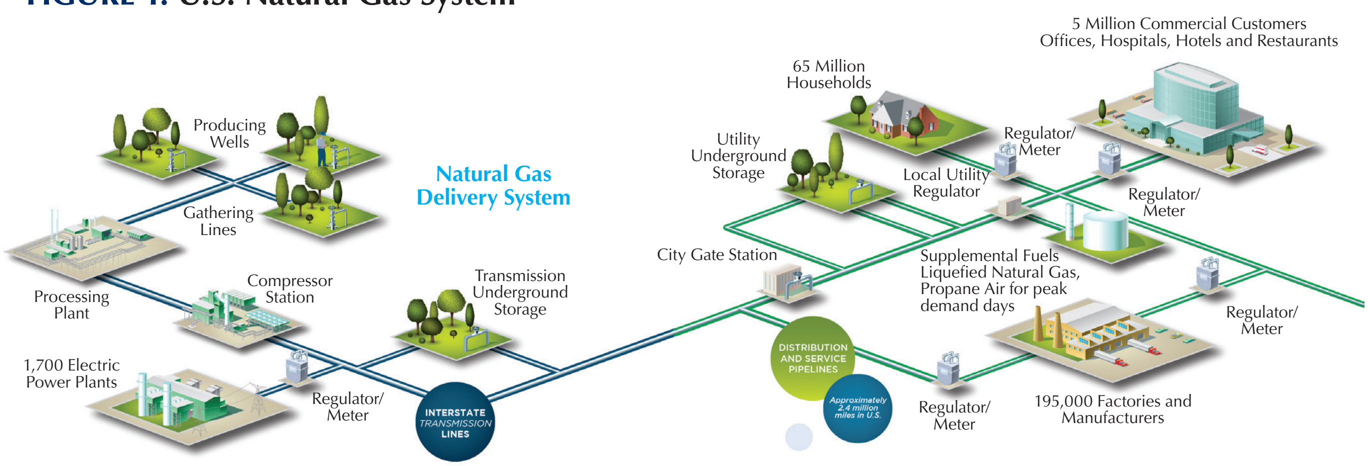
Rising demand for natural gas in the electric power, manufacturing, buildings, and transportation sectors requires significant expansion of the natural gas infrastructure system if these sectors are to reap the potential cost savings and energy security benefits. Increased use of natural gas, when substituted for other fuels, also can significantly reduce greenhouse gas emissions, as long as methane leakage emissions from natural gas systems are minimized. This chapter describes the elements of the U.S. natural gas system and how they function together. Next, it highlights the regional natural gas flows from producing basins to areas of consumption. Then, it discusses the critical issue of methane emissions. Finally, it explores the barriers to infrastructure development and outlines recent innovations in funding models.

ELEMENTS OF THE U.S. NATURAL GAS SYSTEM

Almost all natural gas consumed in the United States is produced in North America, from onshore or offshore wells or, to a much lesser extent, biogas production sites. Natural gas first enters the transport network through gathering pipelines that collect it from the point of production, most commonly the wellhead at the point of extraction, and carry it to processing facilities. Gathering pipelines are usually short and small in diameter and operate at low pressures. In 2011, there were almost 20,000 miles of gathering pipelines in the United States, originating at more than 460,000 wellheads.[281]

Once gathered from well sites, natural gas is processed to remove impurities such as sulfur and carbon dioxide

FIGURE 1: U.S. Natural Gas System



Source: American Gas Association, "About Natural Gas," 2013. Available at: http://www.aga.org/Kc/aboutnaturalgas/Pages/default.aspx

(CO_2) and is dehydrated to remove any water. It is then piped to where there is consumer demand, often hundreds of miles away, through transmission pipelines. Large-diameter (20- to 42-inch), high-pressure transmission pipelines, often called interstate pipelines or trunk lines, efficiently move the gas over vast distances. In 2011, there were 304,087 miles of transmission pipeline in the United States.[282] To ensure pressure in the pipeline and keep the natural gas flowing, compressor stations are placed every 40 to 100 miles. These stations apply pressure to the gas and often filter the gas again to maintain purity. Meters are placed along transmission pipelines to monitor the flow, and valves located at regular intervals can be used to stop flow if needed.[283]

At various points along the gathering and transmission networks, natural gas can be stored temporarily underground in depleted oil or natural gas fields, aquifers, and salt caverns. Storage is used to enhance supply reliability and serves as a physical hedge against the seasonality of natural gas demand. Traditionally, excess supplies of natural gas are stored during the summer and then withdrawn to serve heating demand during the winter or when there are unforeseen supply disruptions. However, as natural gas demand has increased for power generation, including for cooling needs in the summer months, the seasonality of natural gas demand has diminished to some extent. Natural gas can also be stored when purchased at low prices and withdrawn when prices rise, to be sold or consumed. In 2010, there were 400 storage facilities across the United States.[284]

To reach homes and businesses, natural gas leaves the transmission pipeline network and enters the "city gate station," where local distribution companies (local gas utilities) add odorant and lower the pressure before distributing it to residential and commercial customers. Local distribution companies move the gas through a series of larger distribution pipelines, called mains, throughout their service territory, and individual service lines branch off of the mains to reach each consumer. Natural gas regulators, devices in homes and commercial buildings, accept the incoming gas from the highly pressured pipelines and employ a series of valves to lower the pressure of the gas to meet appliance specifications. Distribution pipelines are much smaller pipelines, often only 0.5 to 2 inches in diameter, with pressures at a small fraction of those of the larger transmission pipelines. They may be made of plastic, which is less likely to leak than metal. Distribution networks used by local distribution companies are extensive, having more than 2 million miles of main and individual service pipelines as of 2011.[285]

Together, these components of natural gas infrastructure comprise an important asset that provides access to energy for all sectors of the economy. However, it is a large, dispersed asset that is mostly out of sight. Gathering and transmission pipelines are often in remote locations, while distribution pipelines, though located near the customers they serve, are buried underground. Some pipelines exist within rights-of-way occupied by other users, such as roads or private property, and pipelines often cross local, state, and even national boundaries. These factors make monitoring and regulating pipelines the responsibility of multiple jurisdictions and many levels of government.

Pipelines are regulated by both the federal and state governments. In 2007, 81 percent of natural gas in the United States flowed through transmission pipelines that cross state boundaries. The Federal Energy Regulatory Commission regulates the rates and services of these interstate pipelines as well as the construction of new interstate pipelines. Other pipelines located within states (intrastate pipelines) are regulated by state regulatory commissions. State regulatory commissions regulate both transmission lines and local distribution companies for pipeline siting, construction, operation, and expansion, as well as consumer rate structure.[286]

The federal government also regulates and enforces pipeline safety through the Department of Transportation, which works closely with state governments on pipeline inspection and safety protocols. Corrosion and defects can lead to leaks that have serious safety and environmental implications. Visual inspection of natural gas infrastructure is difficult, and complete replacements are nearly impossible given the vast extent of the network and its location underground. Instead, robotic inspection tools, often called "pigs," can be sent through pipelines to detect leaks, check pipeline conditions, and monitor for weaknesses.[287]

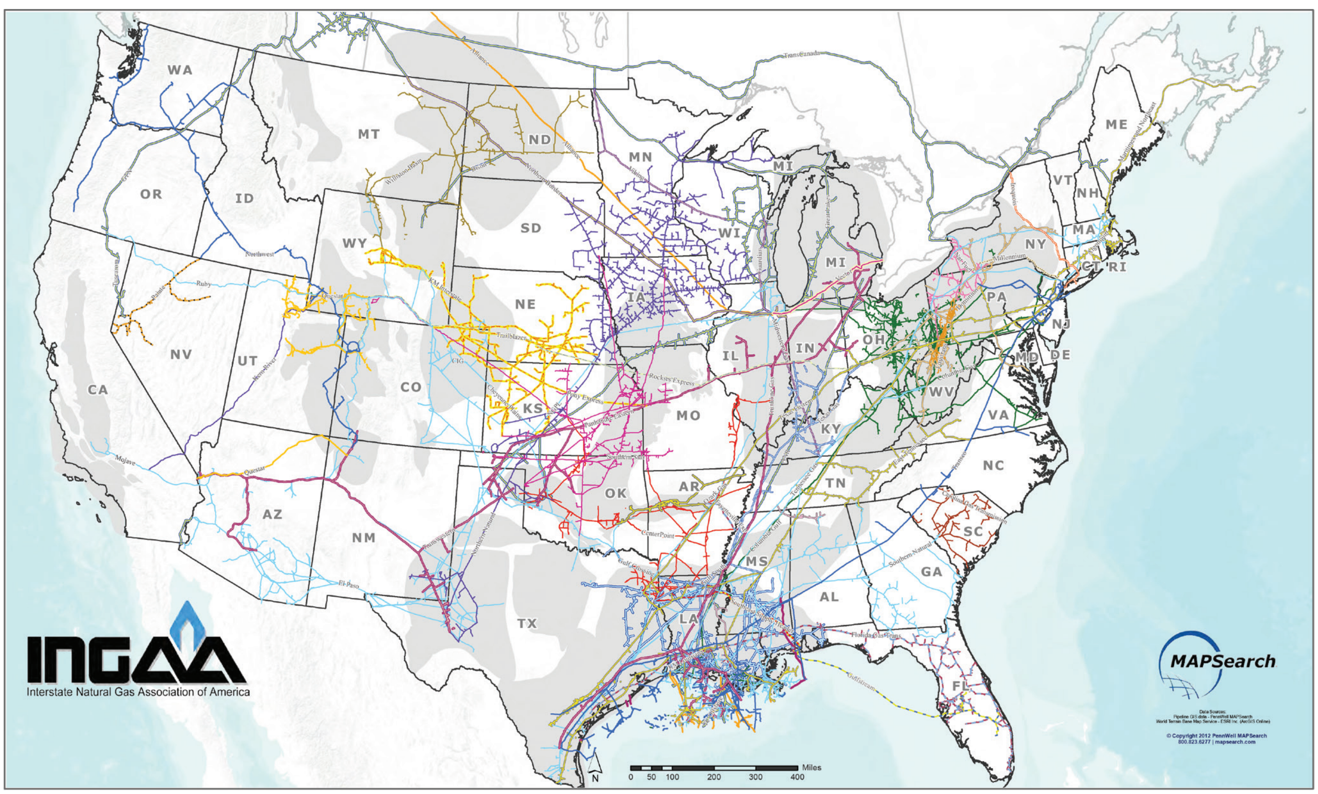
REGIONAL DIFFERENCES IN INFRASTRUCTURE AND EXPANSION

The capacity, extensiveness, and flow direction of existing natural gas infrastructure varies across the country, reflecting historical supply and demand for the fuel as well as disparate state and local policies that enabled infrastructure expansion. Gathering line networks are most extensive from wellheads in traditional gas-producing states such as Texas, Oklahoma, and Louisiana, and most existing intrastate transmission lines take the fuel from those states to manufacturers and consumers in the Midwest and Northeast (Figure 2).

Recent supply increases, lower prices, and increased demand have all led to a need for expanded infrastructure, including gathering, transmission, and distribution pipelines that can bring natural gas to users and may allow natural gas to replace higher-carbon fuel sources and achieve climate benefits. Changes in supply and demand will require that 28,000 to 61,900 miles of new pipelines be constructed in North America by 2030, and \$108 to \$163 billion worth of investment will be needed. Additional storage capacity of 371 to 598 billion cubic feet (Bcf) will also be needed over the same time period, at a cost of \$2 to \$5 billion.[288] Current trends in natural gas supply and demand indicate that expansion is likely to fall on the higher ends of these estimates.

Infrastructure needs related specifically to shale gas are growing across the country, reflecting the location of the shale gas resources. Significant investments related to shale gas have been made in states such as Texas and Louisiana that have historically been supply states for conventional gas deposits. Significant additional infrastructure expansion is also needed in parts of the country that have not historically produced natural gas but have been traditional destinations, such as Ohio, Pennsylvania, North Dakota, and West Virginia. Furthermore, new sources of biogas need infrastructure to collect, process, and either transport the gas to existing transmission infrastructure or use it on site. Although the potential of renewable biogas to reduce greenhouse gas emissions is large, further research is needed to ensure that it can be processed properly and safely added to the existing system, which was built specifically to withstand the constituents of geologically formed natural gas.[289] In sum, several of the new supply sources require new infrastructure, and in other cases, existing infrastructure may be repurposed and deployed to bring new sources to market. As more new sources are

FIGURE 2: Interstate Pipelines, 2013



Source: Interstate Natural Gas Association of America and PennWell tapped, the existing transmission pipeline infrastructure must continue to be creatively deployed and expanded to serve regional market needs.

Similarly, local distribution networks will need to be expanded, with new demand for natural gas appliances, industrial uses, distributed generation, and vehicle fueling in homes and businesses. Investments are necessary in new mains, service lines, meters, and regulators that can service new customers. Indirect investments will also be required to enhance the capacity of the overall system, including for control rooms, main reinforcements, and improved flow design.[290]

DIRECT EMISSIONS FROM NATURAL GAS INFRASTRUCTURE

In 2011, methane emissions from transmission pipelines and storage totaled 44 million metric tons of CO_2 equivalent (CO_2e), while emissions from distribution networks totaled 27 million metric tons CO_2e.[291] These figures have been fairly consistent over time as network expansion has been offset by better system management (including leak detection), more energy-efficient technology, and the replacement of equipment with new materials that are less subject to leakage, including replacing cast iron and steel pipe with plastics.[292, 293] While methane emissions from natural gas infrastructure are a very small portion of the nation's total greenhouse gas emissions (Figure 3 and Figure 4), methane is a potent greenhouse gas, as described in chapter 3. Given methane's potency, it is critical to reduce leakage to ensure that its climate benefits are maximized when compared with other fossil fuels that it may replace.[294]

Leaked Methane

Throughout the transportation of the fuel from gathering at the well to distribution to end-use consumers, there is potential for methane to leak into the atmosphere. Potential leakage points include production wells, valves, compressor stations, faulty seals, pressure regulators, and even broken pipes. Because methane leakage and accumulation can be an important safety issue, natural gas operators have robust safety programs in compliance with federal and state pipeline safety requirements to detect and repair leaks that pose safety risks. Methane emissions that do not pose safety concerns nevertheless can have significant implications for the climate and for the relative benefits of substituting natural gas for other fuel sources. At natural gas storage facilities, methane emissions may leak from compressors and dehydrators. At the local distribution level, methane emission leakage can occur at city gate station valves, seals, and pressure regulators, or from the joints of cast iron or unprotected steel pipe.[295] The majority of all greenhouse gas emissions from natural gas infrastructure are due to leaked emissions.[296]

Venting and Flaring

In addition to leaked emissions, methane can be intentionally released or vented as part of the production process at the wellhead or to reduce pipeline pressure. For safety and environmental reasons, however, intentionally-released methane is often burned off in a process called flaring. Flaring combusts the methane on site, forming CO_2, a less potent, though very significant, greenhouse gas.[297] (The climate implications of CO_2 and methane are compared in chapter 3.) Flaring of methane most often occurs when natural gas is found as a byproduct or co-product of other fossil fuel production and insufficient gathering pipeline infrastructure or market incentives exist to take the natural gas to market. In 2012 in Texas, where gathering pipeline networks are well developed, less than 1 percent of the natural gas produced was flared.[298] In North Dakota, where oil production from the Bakken Shale formation is a much newer phenomenon, almost 32 percent of the associated natural gas is flared, primarily because of a lack of gathering infrastructure.[299] With relatively low natural gas prices, there is less economic incentive for companies to build gathering infrastructure and monetize the resource.

In August 2012, a new federal requirement to minimize venting and flaring was established as part of the Environmental Protection Agency's New Source Performance Standards for oil and gas wells. The new regulations require that all new natural gas wells flare rather than vent, and as of 2015 use "green completion" technology that will allow excess natural gas from the well completion process to be taken to market. Many natural gas producers already use such technology.300 However, for the "green completion" rule to apply to the gathering of natural gas from the Bakken Shale or other primarily oil production sites, it would have to be expanded from its present form (see the discussion of "green completion" rules in chapter 3).

Reducing Emissions from Infrastructure

Many technologies and process improvements can reduce methane emissions from natural gas infrastructure. The federal Natural Gas STAR program, for example, has worked with industry to identify technical and engineering solutions to vented, leaked, and combustion-related emissions, including zero-bleed pneumatic controllers, improved valves, corrosion-resistant coatings, and dry-seal compressors, as well as improved leak detection and repair strategies. The solutions identified by this voluntary program often have payback periods of less than three years, depending on the price of natural gas. Participants in Natural Gas STAR reported that methane emissions from infrastructure were reduced by 15.9 Bcf in 2010, and overall, a total of 276.5 Bcf of greenhouse gases have been avoided since the program began in 1993.[301] Local distribution companies have reduced emissions from their low-pressure networks by continuing to replace cast iron and steel pipes with inexpensive and durable plastic pipes; however, this plastic is not strong enough to be used in high-pressure transmission lines.[302]

BARRIERS TO INFRASTRUCTURE DEVELOPMENT

As other chapters in this report explain, natural gas may be used to reduce greenhouse gas emissions in multiple sectors of the economy, including electric power, manufacturing, buildings, and transportation. While new pipelines are being built every day, there is a dramatic need for new pipeline investment to move new sources of natural gas supply to new regions and new users. Distribution pipeline networks, in particular, are challenged by financial and other barriers to expansion and improvement.

Funding Distribution Pipeline Expansion

For local distribution networks, the cost of expansion varies considerably depending on whether the network is being expanded to new or existing communities, the density of the neighborhood, and the terrain. For new distribution pipelines in urban areas, challenges include costly repairs of overlaying roads and landscaping, negotiations with entities holding surface and other subsurface rights-of-way, and public inconveniences. Accordingly, new urban pipelines can cost five times as much as rural ones.[303] Costs can be lowered when buildings are designed and constructed to be ready for natural gas access; retrofitting existing buildings with internal piping and hook-ups to natural gas supplies is more expensive.

Funding local distribution networks can be challenging and is typically dealt with through a formal regulatory proceeding called a rate case where public utility commissions determine allowable utility rates based on factors including utility operation costs, depreciation, investment, and consumer needs. Traditionally, expansion costs are considered during the rate case proceedings, but costs can only be recovered after investments are made. This time lag discourages or prevents utilities from investing in infrastructure. State-level regulatory innovations have provided some policy options to overcome these investment challenges. Some states, such as Nevada, allow the use of a deferred accounting mechanism so that costs can be better aligned temporally with ratemaking cases before state regulatory commissions. Seven southern states, including Texas, have decoupled gas consumption and cost recovery to create what is known as a "rate stabilization method." This method allows rates to adjust annually for infrastructure replacement and construction rather than simply the amount of natural gas throughput.[304]

Funding models that can foster greater access to natural gas are being explored throughout the country. For example, in North Carolina, rules established by the public utilities commission allow for dedicated funds for new distribution pipelines. A local distribution company may petition the public utilities commission to establish a Natural Gas Expansion Fund to help pay for the otherwise economically infeasible expansion of distribution pipelines. Additional money may be added to the Natural Gas Expansion Fund, including refunds from natural gas suppliers to the local distribution company, expansion surcharges, and other resources, and then, with approval by the public utilities commission, the company may pay for the specified distribution pipeline construction projects.[305] In 2011, the Vermont Public Service Board approved a plan by Vermont Gas Systems to use $17.6 million previously planned for ratepayer refunds to instead support expansion of its distribution network over four years, although these funds will cover only part of the needed finance.[306] This plan transferred some of the costs of expansion onto existing customers and offered the reduction of statewide greenhouse gas emissions as one rationale.[307] A 2012 law passed by the Maine Legislature authorizes the Finance Authority of Maine to issue up to $275 million in loans and $55 million in bonds for natural gas distribution system expansions. The funds will be available only if the applicant contributes at least 25 percent of the expected cost of the project.[308] Municipal utilities can also offer innovative solutions. For example, the municipal natural gas utility in Sunrise, Florida, will install main and service lines to neighborhoods at no cost as long as 25 percent of residents commit to installing a natural gas space or water heater, range, or clothes dryer within six months. Natural gas piping within the homes must be paid for by residents.[309]

Funding Upgrades and Replacements

Other innovative policy mechanisms are being developed to pay to upgrade and replace existing pipelines. Some states, such as Colorado, authorize tracker mechanisms allowing rates to change in response to the utility's operating costs and conditions outside of a complex rate case proceeding, specifically in response to federal and state safety requirements. A similar process outside the rate case in states such as Kentucky permits temporary surcharges for partial program cost recovery. The Georgia Public Services Commission has permitted Atlanta Gas Light Company to institute a surcharge on customer bills throughout its service territory to help fund pipeline replacement, improvement, and pressure increases through the Georgia Strategic Infrastructure Development and Enhancement (STRIDE) Program. The Georgia Public Services Commission reviews the surcharge and related plans every three years, thereby eliminating the need for rate cases and associated regulatory lag. Also, from 2009 to 2012, a pilot program called the Customer Growth Program was paid for through the STRIDE surcharge. It helped fund new pipeline construction and extensions, including strategic development corridors to regions far removed from existing Atlanta Gas Light Company infrastructure. It also helped overcome the barrier of high upfront costs for new natural gas pipelines.[310] However, the STRIDE program has not been renewed. The Atlanta Gas Light Company Universal Service Fund can also be used to pay for distribution pipeline expansion, and its monies may contribute up to 5 percent of Atlanta Gas Light Company's capital budget during a fiscal year.

Other Challenges

Beyond questions of funding, pipelines are affected by a number of project-specific requirements and regulations at the federal, state, and local levels. These requirements pertain to route selection, siting, and project approval by regulatory agencies that may all be affected by environmental, safety, community, operation, construction timing, and cost concerns. The size of the challenge for any individual project will vary significantly depending on the pipeline and the jurisdictions it crosses.[311] For natural gas to realize its climate benefits, infrastructure projects must meet these requirements, allowing the system to expand for greater low-emission use across the economy.

CONCLUSION

Natural gas is transported from areas of production to final consumers through networks of gathering pipelines, transmission pipelines, and distribution pipelines. These extensive networks are necessary to provide opportunities for low-emission end uses of natural gas. Given the recent surge in natural gas supply, the new source regions, and new uses, infrastructure must rapidly adapt. Gathering pipelines must be brought to more points of production, including areas where associated gas can be captured for use. Transmission pipelines must be expanded to ensure adequate supply can reach new regions of the country. Distribution pipeline networks must be built out to serve more manufacturing facilities, homes, and businesses. Increased policy support and innovative funding, particularly for distribution pipelines, are needed to support the rapid deployment of this infrastructure.

X. CONCLUSIONS AND RECOMMENDATIONS

Natural gas plays a role in all sectors of the U.S. economy, constituting 27 percent of total U.S. energy use in 2012. Its prominence is expected to grow as the supply boom unleashed by new drilling technologies continues in coming decades. Expectations of sustained abundance and correspondingly low and relatively stable natural gas prices are sparking widespread interest in additional ways that this domestic energy resource can replace oil and coal as the major fuel undergirding a growing economy. Indeed, natural gas is projected to displace petroleum as the dominant fuel used in the United States within a few decades.

In these early days of this energy transition, it is imperative to set a course for using this increasingly abundant domestic resource in ways that help meet, rather than aggravate, the challenge of climate change. This report examines ways that natural gas can be leveraged to reduce greenhouse gas emissions across a growing economy and reaches three crosscutting conclusions.

First, substitution of natural gas for other fossil fuels can contribute to U.S. efforts to reduce greenhouse gas emissions in the near to mid-term, even as the economy grows. At the beginning of 2013, energy sector emissions are at the lowest levels since 1994, in part because of the substitution of natural gas for coal in the power sector. Substitution of natural gas for coal, petroleum, and grid-supplied electricity is underway in other parts of the economy and will bring similar benefits to the climate and air quality. In the buildings sector, for example, a large reduction in emissions is possible through greater direct use of natural gas in an array of more efficient appliances and expanded use of CHP. The manufacturing sector also has a significant opportunity to reduce emissions even as it expands. Manufacturers can increase their consumption of natural gas as feedstock and an energy source, while reducing the emissions intensity of production. Finally, in the transportation sector, natural gas fuel substitution can reduce greenhouse gas emissions when used in fleets and heavy-duty vehicles.

Second, in the long term, the United States cannot achieve the reduction in greenhouse gas emissions necessary to address the serious challenge of climate change by relying on fuel substitution to natural gas alone. Low-carbon investment must be dramatically expanded. Zero-emission sources of energy such as wind, nuclear, and solar are critical, as are the use of carbon capture and storage technologies at fossil fuel plants and continued improvements in energy efficiency. Given that many renewable energy sources are intermittent, natural gas can serve as a complementary and reliable backup. In addition, because fossil fuels will likely be part of the energy fuel mix for the foreseeable future, carbon capture and storage will need to be deployed. Without a price on carbon emissions, alternative policy support will be needed to ensure optimal investment in zero-carbon energy sources and technologies.

Third, direct releases of methane into the atmosphere must be minimized. The primary component of natural gas is methane, which is a very potent greenhouse gas. Total methane emissions from natural gas systems in the United States have improved during the last two decades, declining 13 percent from 1990 to 2011. Nevertheless, given its impact on the climate, especially in the short term, it is important to better understand and more accurately measure the greenhouse gas emissions from natural gas production and use in order to achieve emissions reductions along the entire natural gas value chain.

The basis for these cross-cutting conclusions is a detailed examination of the current and potential role of natural gas in major sectors of the economy. Sector-specific conclusions and recommendations include:

Expanded use of natural gas has improved fuel diversity in the power sector. From 2003 to 2012, the share of primary energy consumption from coal for electricity generation dropped from 53 percent to 37 percent, while the share fulfilled by natural gas grew from 14 percent to 29 percent. Accordingly, the fuel mix in electricity generation has become more diverse in recent years. However, concern exists that some regions may become too dependent upon natural gas in the long term, especially as market pressures affect nuclear and renewable energy generation. Too much reliance on any one fuel can expose utilities, ratepayers, and the economy to the risks associated with commodity price volatility. Furthermore, natural gas-fired generation should not displace investment in zero-carbon generation, carbon capture and storage, and energy efficiency measures. If this occurs, the United States will not be able to meet its long-term goals for reducing greenhouse gas emissions.

Natural gas can be complementary with renewable energy. Instead of being thought of as competitors, natural gas and renewable energy sources such as wind and solar can be complementary components of the power sector. Natural gas plants have the ability to quickly scale up or down their electricity production and so can act as an effective hedge against the intermittency of renewables. The fixed fuel price (at zero) of renewables can likewise act as a hedge against potential natural gas price volatility. Low natural gas prices can also help facilitate an increase in renewable energy in some regions. In order for this mutually beneficial relationship to flourish, carefully designed policy that allows the addition of both sources to the grid in a complementary fashion must come into play and be encouraged by public utility commissions. Natural gas plants expansion should be leveraged to enable the expansion of renewable generation.

Natural gas can increase the overall efficiency of buildings through use of equipment with higher full-fuel-cycle efficiency. Thermal applications of natural gas in buildings have a lower greenhouse gas emission footprint compared with other fossil energy sources. Natural gas for thermal applications is more efficient than grid-delivered electricity, yielding less energy losses along the supply chain and therefore fewer greenhouse gas emissions. Information and incentives should be modified to inform consumers of the environmental benefits of natural gas use and to encourage its increased use when it has the potential to reduce greenhouse gas emissions—particularly its direct use in buildings and manufacturing settings. At present, labeling, building codes, and economic incentives are not aligned to maximize the use of natural gas in low-emitting ways.

Aligning incentives is particularly important in the building sector, as consumers and developers seeking to minimize up-front cost often do not realize that operating costs and environmental costs may be much higher for electric appliances. In addition, although current energy efficiency programs aim to reduce greenhouse gas emissions from appliances and buildings in two important ways—by setting standards and efficiency labeling programs—these standards are based solely on site efficiency, which is reflected in the energy and cost savings identified on efficiency labels. But efficiency labels based only on site efficiency do little to educate consumers about the total energy needed to power appliances and the greenhouse gases associated with that energy and, as such, often steer consumers toward electric appliances even if a natural gas appliance may be more efficient overall and produce fewer greenhouse gas emissions. It is important, therefore, that the source-to-site efficiency of an appliance also be taken into consideration, and in regions with fossil fuel-dominated grid electricity, natural gas appliances should be encouraged.

The efficient use of natural gas in the manufacturing sector needs to be encouraged. Replacing old coal-fired boilers with more efficient natural gas boilers can yield significant emissions benefits. CHP systems should also be deployed to make use of waste heat and avoid transmission losses. The incentives for CHP are often not properly aligned. Specifically, while CHP has significant environmental benefits, it can significantly decrease the demand for grid-supplied electricity, which can impact the rate base remaining on the grid. Policies are needed to overcome this and other barriers to expanded CHP deployment. States are in an excellent position to take an active role in promoting CHP during required industrial boiler upgrades and new standards for cleaner electricity generation in coming years.

Distributed generation technologies can offer options for using natural gas and reducing emissions. Distributed generation technologies, such as microgrids, microturbines, and fuel cells, can be used in configurations that reduce greenhouse gas emissions when compared with the centralized power system because they can reduce transmission losses and use waste heat onsite. Distributed generation has many other advantages over centralized electricity generation, including end-users' access to waste heat, easier integration of renewable energy, heightened reliability of the electricity system, reduced peaking power requirements, and less vulnerability to terrorism due to more geographically dispersed, smaller power plants. To realize the potential of these technologies and overcome high upfront equipment and installation costs, policies like financial incentives and tax credits need to be more widespread, along with consumer education about their availability.

Fuel substitution in fleets and heavy-duty vehicles offers the greatest opportunity to reduce greenhouse gas emissions in the transportation sector. Passenger vehicles, in contrast, likely represent a much smaller emission reduction opportunity even though natural gas emits fewer greenhouse gases than gasoline or diesel when combusted. The reasons for this include the smaller emission reduction benefit (compared to coal conversions), and the time it will take for a public infrastructure transition. By the time a passenger fleet conversion to natural gas could be completed, a new conversion to an even lower-carbon system, like fuel cells or electric vehicles, will be required to ensure significant emissions reductions throughout the economy.

Natural gas infrastructure expansion is needed to ensure access for low-emitting uses. New domestic supplies of natural gas require significant investment in infrastructure. Additional gathering and transmission pipeline capacity is needed in parts of the country that have not historically produced natural gas but have been traditional destinations, such as Ohio, Pennsylvania, North Dakota, and West Virginia. Expanded distribution pipeline networks are needed to serve greater numbers of commercial, industrial, and residential natural gas customers throughout the U.S. Moreover, expanding natural gas delivery systems within homes and businesses that have existing access will be necessary to support a greater number of end-use applications, such as natural gas-fueled space and water heating. Innovative funding models and support are needed to make the expansion and upgrading of natural gas infrastructure economically feasible for customers and utilities.

In the coming years, abundant natural gas will play an increasingly prominent role across all sectors of the U.S. economy. Increased availability of natural gas can yield economic opportunities and lower greenhouse gas emissions. Yet, natural gas is not carbon-free. A future with expanded natural gas use will require diligence to ensure that potential benefits to the climate are achieved.

ENDNOTES

1 Primary energy sources include petroleum, natural gas, coal, renewable energy, and nuclear power.

5 In economic terms, the supply of natural gas is often referred to as reserves and is classified with two primary categories, proven and unproven. Proven reserves are those that are economically recoverable from known resources using currently available technology. Unproven reserves are those considered not economically or technically recoverable or somehow not producible for regulatory reasons.

Note: In addition to the Barnett, since 2005 producers have begun intensively developing plays in the Woodford, north of the Barnett in Texas and Oklahoma; the Fayetteville in Arkansas; and the Haynesville in Louisiana/East Texas. During this time, development also began in the Marcellus Shale of the eastern United States.

18 Massachusetts Institute of Technology Energy Initiative, *The Future of Natural Gas: An Interdisciplinary MIT Study*, June 2011, page 33. Available at http://web.mit.edu/mitei/research/studies/natural-gas-2011.shtml.

Note: Natural gas and natural gas liquids are a principal feedstock in the chemicals industry and a growing source of hydrogen production for petroleum refining. Natural gas liquids products can add value for gas producers, especially important in a low-price environment. The liquid content of a gas—the "condensate ratio"—is expressed as barrels of liquid per million cubic feet of gas (bbls/MMcf). In a typical Marcellus well, assuming a liquids price of $80/bbl for a condensate ratio in excess of approximately 50 bbls/MMcf, the liquid production alone can provide an adequate return on the investment, even if the gas were to realize no market value.

25 The liquefaction process for natural gas involves removal of certain components, such as dust, acid gases, helium, water, and heavy hydrocarbons. The natural gas is then condensed into a liquid by cooling it to approximately -162°C (-260°F). The energy density of liquified natural gas is 60 percent that of diesel fuel.

96 2009 was the last time the US Energy Information Administration (EIA) conducted the Residential Energy Consumption Survey (RECS). 2003 was the last time that the EIA conducted the Commercial Building Energy Consumption Survey (CBECS) and the next survey is scheduled to begin in April 2013. These surveys provide data on building energy consumption and sources. However, data is gathered a multiyear intervals, unlike some other EIA data collected annually. This chapter uses relevant data from the years that the data were collected.

RTS No.:	11195
VanRIMS No.:	08-2000-20
Meeting Date:	July 12, 2016

TO: Vancouver City Council

FROM: Green Building Manager, Sustainability Group

SUBJECT: Zero Emissions Building Plan

RECOMMENDATION

A. THAT Council approve the Zero Emissions Building Plan (attached as Appendix A) and adopt a target to reduce emissions from new buildings by 90% as compared to 2007 by 2025 and to achieve zero emissions for all new buildings by 2030 including intermediary time-stepped GHG emission and thermal energy demand targets as described in the Plan.

B. THAT Council direct staff to report back with specific recommendations to reflect the first step of these limits in the Rezoning Policy for Green Buildings and Vancouver's Building Bylaw along with any synergistic updates to Neighbourhood Energy connection requirements by Q1 2017.

C. THAT Council direct staff to build all new City-owned and Vancouver Affordable Housing Agency (VAHA) projects to be Certified to the Passive House standard or alternate zero emission building standard, and use only low carbon fuel sources, in lieu of certifying to LEED Gold unless it is deemed unviable by Real Estate and Facilities Management, or VAHA respectively, in collaboration with Sustainability and report back with recommendations for a Zero Emissions Policy for New Buildings for all City-owned and VAHA building projects by 2018.

D. THAT Council direct staff, in consultation with industry, to develop a three year, $1.625 million Zero Emissions Home Program for detached and row houses ($325K in 2017 from the Climate Action Rebate Incentive Program Reserve, $650K in 2018 and $650K in 2019 from a funding source to be determined and reported back to Council), and report back to Council with specific recommendations for tools to catalyze leading builders to demonstrate cost effective approaches to building zero emissions homes by 2017.

E. THAT Council direct staff to engage partners, consult with stakeholders, and report back with recommendations in 2017 on the resources and tools required to catalyze leading developers to demonstrate cost effective approaches to building zero emissions multi-unit residential and commercial buildings.

F. THAT Council approves in principle $700,000 over three years ($300K in 2017, $200K in 2018, and $200K in 2019 from the City's 2017 Innovation Fund, subject to Council approval of the 2017 Innovation Fund budget) towards establishing a non-governmental Zero Emissions Building Centre of Excellence with the mission to facilitate the compilation and dissemination of the knowledge and skills required to design, permit, build and operate zero emission buildings in BC, and direct staff to engage partners, secure matching funding, consult with stakeholders and report back with recommendations for implementation in 2017.

G. THAT Council direct staff to review and recommend amendments to the City's bylaws, policies, and guidelines to incorporate "zero emission building related rules" including but not limited to Official Development Plans, the Zoning and Development By-law, Vancouver's Building Bylaw, the Subdivision by-law and all other applicable bylaws, policies and guidelines to remove barriers and facilitate the development of zero emission buildings and provide them with equal weight as other public policy objectives wherever such "zero emission building related rules" confer discretion to a City official or board, and report back with initial recommendations in 2017.

REPORT SUMMARY

This Plan lays out four action strategies to require the majority of new buildings in Vancouver use 100% renewable energy and have no operational greenhouse gas emissions by 2025 and that all new buildings achieve these outcomes by 2030.

These four strategies include:

1. Limits: establish GHG and thermal energy limits by building type and step these down over time to zero
2. Leadership: require City- owned and City managed building projects to demonstrate zero emission building approaches where viable
3. Catalyse: develop tools to catalyse leading private builders and developers to demonstrate effective approaches to zero emission new buildings; and
4. Capacity Building: establish a Centre of Zero Emission Building Excellence to facilitate the removal of barriers, the sharing of knowledge, and the development of the skills required to successfully achieve this goal

These strategies for achieving zero emissions new buildings were developed specifically to ensure comfortable and healthy indoor environments, maximize local economic development, ensure long-term building resilience, protect housing affordability and to facilitate achieving the City's Renewable City Strategy target to have all buildings in Vancouver (including those already built) use only renewable energy by the year 2050.

COUNCIL AUTHORITY/PREVIOUS DECISIONS

In July 2004, Council adopted the *Green Building Strategy*, demonstrating early leadership by setting high environmental standards for the construction of new civic buildings and special development projects such as Southeast False Creek (SEFC). The strategy mandated the use of the LEED Gold Green Building Rating System, and 30% lower energy consumption than current VBBL, with higher targets set for the Olympic Athlete's Village in SEFC. This neighbourhood and development were planned to be a model sustainable community, and by demonstration, contribute to a paradigm shift toward green buildings in private-sector developments across the city.

In June 2008, Council adopted a set of Building By-law amendments directed at reducing the environmental impacts of new one- and two-family dwellings. The amendments made Vancouver's Building By-law the greenest building code for one- and two-family dwellings in North America at the time.

In June 2008, Council also adopted a Building By-Law amendment to require the use of ASHRAE 90.1 2007, to improve the energy efficiency performance of all new Part 3 (large residential, commercial, industrial) buildings.

In July 2010, Council approved the *Green Buildings Policy for Rezonings*, which required all applicable developments applying for rezoning to achieve the LEED standard. In its current revised form, the policy requires meeting LEED Gold with additional energy reductions. This policy was developed to use a well-established City process (rezoning) to help transition industry toward more sustainable building practices.

In January 2011, Council adopted the revised *Greenest City Action Plan 2020* targets, which included the target to have all buildings constructed from 2020 onward will be carbon neutral in operations.

In October 2012, Council approved the *Vancouver Neighbourhood Energy Strategy and Energy Centre Guidelines*, to address the *Greenest City 2020 Action Plan* objective of reducing 120,000 tonnes carbon dioxide per year through the conversion of existing steam heat systems to low carbon energy sources and the deployment of sustainable energy systems for high-density neighbourhoods.

In April 2014, Council adopted a set of progressive Building By-law amendments as part of Vancouver's revised 2014 *Building By-law* that made great strides forward in terms of energy efficiency for one- and two-family dwellings and laneway houses. In sum, the new code required higher energy efficiency for walls, roofs, windows and skylights; energy efficient hot water tanks, boilers and furnaces; and improved air-tightness. As well, commercial and large residential buildings were required to meet the most up-to-date energy standards.

In November 2015, Council approved the *Renewable City Strategy* (RCS), detailing how Vancouver will achieve the target of 100% renewable energy use by 2050 and directed staff to bring forward recommendations for achieving zero emissions new buildings by 2030 and where possible, sooner.

CITY MANAGER'S/GENERAL MANAGER'S COMMENTS

The City Manager supports these recommendations as an effective approach for rapidly transitioning the local building industry towards higher quality and healthier new buildings that are highly energy efficient and rely only on renewable energy.

REPORT

Background/Context

Vancouver's Greenest City Action Plan (GCAP) includes targets to achieve carbon neutral new construction and to reduce emissions from existing buildings and industry by 20% from 2007 levels by 2020.

Changes to the City's Building Bylaw and the introduction of green building requirements for rezonings have successfully begun to transform construction practices in Vancouver. Emissions from newly constructed houses have been reduced by 48% as compared to 2007. Sixty seven large condominium, apartment, and commercial buildings representing over 8.5 million square feet of new development are under construction or have been built to achieve LEED Gold certification. These building are shifting standard construction approaches towards more efficient lighting, heating, and water systems along with improved ventilation system designs and the use of healthier materials for improved indoor air quality.

In addition, the increased production of renewable electricity in BC combined with recent trends towards warmer winters and City/energy utility programs to support and incentivise energy conservation have reduced GHG emissions from existing buildings and industry by 20% as compared to 2007, meeting the GCAP target for 2020.

Building on this success, Council established more aggressive and longer term targets in the fall of 2015 with the adoption of the Renewable City Strategy. This Strategy targets 100% of all energy used in Vancouver come from renewable sources by 2050.

Analysis undertaken in the development of the Renewable City Strategy estimated that of all the buildings (measured by floor space not number of structures) that are anticipated by 2050:

- 30% would be built prior to 2010
- 30% would be built between 2010 and 2020
- 40% would be built after 2020.

If all buildings are to use only renewable energy by 2050, the sooner new buildings achieve near zero emissions, the fewer buildings there will be that require costly and challenging deep energy retrofits to achieve the target.

Consequently, the Renewable City Strategy targeted new buildings to be zero emissions by 2030 by:

- Demonstrating zero emission standards in new City of Vancouver buildings
- Utilizing rezoning policy tools to lead the transition
- Incentivizing and streamlining development of near zero emission buildings
- Establishing and enforcing GHG intensity limits for new development
- Developing innovative financing tools
- Building partnerships to foster industry capacity
- Mandating energy use reporting

In adopting the Strategy, Council directed staff to bring forward a plan to action these measures that was to include recommendations on achieving zero emissions new buildings by 2030 or sooner where possible. This Zero Emissions Building Plan is staff's response to this direction.

Consultation

This is a Plan to fundamentally shift building practice in Vancouver in just under 10 years. It focuses building policy, catalyst tools, and an investment in capacity building on high performing building envelopes and transitioning to100% renewable energy for new buildings.

In order to succeed, it will be essential that other local governments, professional associations, academic institutions, non-governmental agencies, energy utilities and the development industry are aligned with and committed to the success of the shift articulated in this Plan. Consequently, it was developed not only in consultation with these stakeholders but through close collaboration with them.

Concurrent with the development of this Plan, the Province was working with local governments and these same stakeholders to develop recommendations on the structure and targets for a Provincial energy "stretch code" as well as for new actions for their Climate Leadership Plan. To foster alignment between the City's Near Zero Emissions Building Plan and recommendations for these Provincial plans, the City and Province actively shared research and undertook joint consultation exercises.

The full list of organizations actively involved in the development of this Plan is listed in Appendix B but key partners included:

- BC Hydro (co-funded research and consultation)
- Urban Development Institute (collaborated on establishing scope of research work and supported industry consultation to ensure representative voices from the designers, developers, builders, and suppliers for multi-unit residential buildings)
- Greater Vancouver Home Builders Association
- BC Ministry Responsible for Housing, Building and Safety Standards Branch
- BC Ministry of Energy and Mines, Electricity and Alternative Energy Division
- Staff from the cities of Richmond, New Westminster, and Surrey
- BC Housing and the Homeowners Protection Office
- International Building Performance Simulation Association - BC Chapter
- Fenestration Association of BC

- New Buildings Institute (one of the leading U.S. building energy code think tanks)
- Pembina Institute
- Canadian Passive House Institute

The Plan was also shaped and informed by ongoing discussions with the cities of New York and Brussels, whose involvement was made possible through a grant from the Carbon Neutral Cities Alliance.

Strategic Analysis

On average, 82% of new development in Vancouver is residential, 1-2% is office space and the remaining 16% is made up of a wide variety of building types. As per Council's direction in November 2015 when the Renewable City Strategy was adopted, this Plan includes detailed actions to reduce emissions in all new residential and office building to zero by 2025 with the exception of high-rise multi-unit residential buildings which do not go through a rezoning process; these will be required to achieve zero emissions in the Building Bylaw by 2030.

One key factor that will enable Vancouver to achieve this aggressive target is that electricity in BC is legislated to be at least 93% renewable and currently, 97% of electricity is provided from renewable sources. As a result the emphasis in this Plan is to reduce heating energy demand and to transition heating systems in new buildings to renewable energy such as waste heat, electricity, and bio-energy resources recovered from local waste (e.g. bio-methane from composting, clean wood waste).

Further research and analysis will be required before recommending detailed actions for achieving zero emissions in the dozens of other buildings types that make up the remaining 16% of new development in Vancouver as each of these buildings types has very unique energy usage and emissions profiles. Interim approaches for addressing all other building types will be recommended in the Rezoning Policy for Green Building later in 2016.

Past policy approaches to reduce energy use in new buildings combined with a gradual increase in the amount of renewable energy in electricity has resulted in a 33% reduction in greenhouse gas emission intensity (amount of GHG per unit area per year) in new buildings from 2007 requirements.

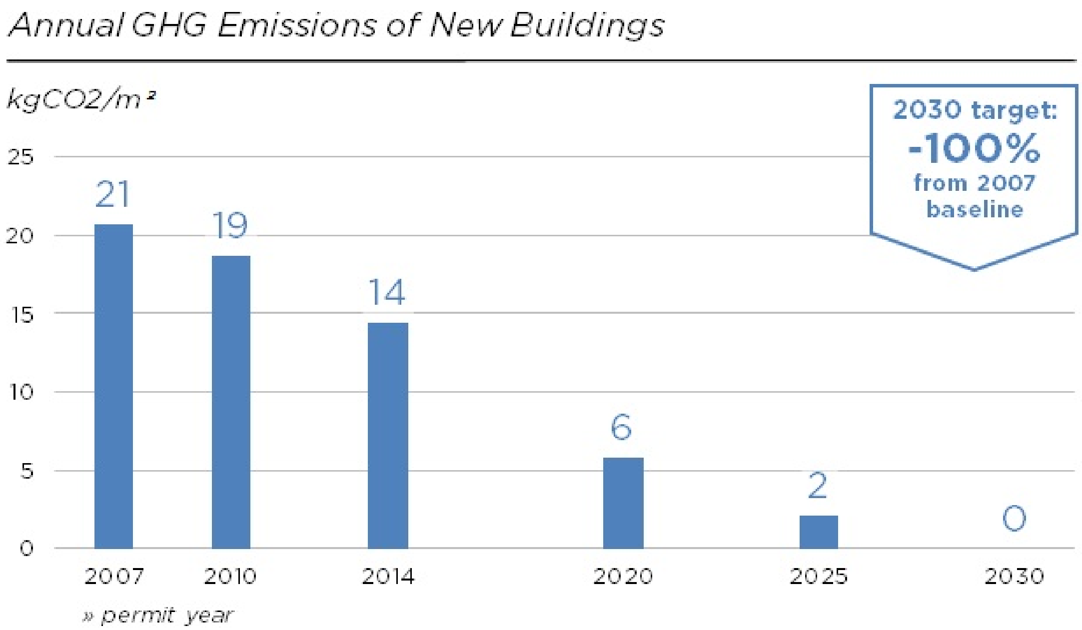

Figure 1: Weighted Average GHG Intensity for New Buildings in Vancouver

In accordance with the Renewable City Strategy, this plan sets a path to achieve significant reductions in energy demand in new buildings and increase the use of renewable energy. Beginning in 2016, new residential buildings will follow one of the following general paths towards achieving real and durable GHG emission reductions for new residential buildings in Vancouver:

1) First Path - Reduce Focused: where Neighbourhood Renewable Energy connections are not available, policy will initially focus on significant reductions in space heating and fresh air heating demand through greatly improved building envelope performance and highly efficient “passive” heat recovery ventilation. Once envelopes have improved significantly, requirements for renewable energy for hot water heating will be introduced in later years.

This Plan leverages the *Passive House* standard and its associated research, tools, training and verification processes to assist industry in successfully transitioning to highly energy efficient building envelope and ventilation system designs. Passive House is the leading global standard for high efficiency building envelopes and is supported by extensive designer and builder training (available locally), building science research, specialized energy modelling, third party design review and validation, and a strong Canadian and North American network of practitioners.

2) Second Path – Renewables Focused: new buildings connecting to a Neighbourhood Renewable Energy System (NRES) will also be required to reduce demand for space heating energy but the emphasis for these buildings will be on providing renewable heat energy for heating, ventilation air, and hot water. Neighbourhood Renewable Energy Systems are often viable in high density neighbourhoods such as Southeast False Creek and enable the use of a wide variety of local and renewable energy sources that are not otherwise feasible for individual buildings. In addition, these systems will make it possible for existing buildings that are already connected or can be connected in the future to transition to 100% renewable energy without requiring expensive and disruptive building renovations. Given the significant investment required to establish this shared infrastructure and the GHG benefits achieved, new buildings connecting to these systems will not be aiming to achieve passive house levels of performance and will require more modest improvements to building envelope performance in order achieve zero emissions. In addition, the City must collaborate with NRES utilities to ensure their continued success.

Office buildings and other building types where heating energy use is a less significant factor than it is in residential buildings will be required to pursue better envelopes while simultaneously transitioning to renewable energy.

The Plan includes four essential areas of action:

1. Limits: establish GHG and thermal energy limits by building type and step these down over time to zero
2. Leadership: require City-owned and city managed building projects to demonstrate zero emission building approaches where viable
3. Catalyse: develop tools to catalyse leading private builders and developers to demonstrate effective approaches to zero emission new buildings; and
4. Capacity Building: establish tools and a Centre of Zero Emission Building Excellence to facilitate the removal of barriers, the sharing of knowledge, and the development of the skills required to successfully achieve this goal

GHG and Thermal Energy Limits

This plan recommends establishing GHG Intensity (GHGI) targets for each major building type and stepping these down over time to zero by 2025, except for high-rise MURBs that do not go through a rezoning process which will be required to achieve zero emissions by 2030 in the Building Bylaw. These are to be complemented by Thermal Energy Demand Intensity (TEDI) targets to ensure real and durable reductions through building envelope performance improvements for all buildings.

These time-stepped GHG intensity reduction targets by building type will result in a 90% reduction in emissions from new buildings as compared to 2007 by 2025 and will ensure all new buildings permitted from 2030 onward will have zero emissions.

These targets are to be reflected as maximum GHGI and TEDI limits in the Rezoning Policy for Green Buildings and the Building Bylaw which are to be updated in 2016/2017, 2020, 2025 and 2030. Furthermore, requirements for buildings to be connectable to a Neighbourhood Energy System will need to be reviewed and updated to reflect only geographical areas where the City has certainty in a renewable energy source for the system supply.

Also note that, the requirements and limits established in the Rezoning Policy become Building Bylaw requirements 4-5 years later. Refer to the Plan (attached as Appendix A) for the specific targets by building type and date.

In summary:

- Detached Houses: Vancouver's 2014 Building Bylaw introduced aggressive new energy efficiency measures and emissions in these buildings have been reduced by 48% since 2007. Aside from establishing a cap on maximum allowed GHG emissions (effectively requiring large new houses to be more efficient than modestly sized ones) no *significant* new regulations will be imposed until 2020 and the immediate focus will be on the provision of catalyst tools and capacity building for early adopters of zero emission building approaches.
- Low-Rise Multi-Unit Residential Buildings (4-6 story MURBs): These buildings have not had significant new requirements imposed recently and provide an ideal form for Passive House levels of performance. Proposed amendments to the Building Bylaw and the Rezoning Policy for this form of development in 2016 will reduce emissions from this building type by nearly 50%, primarily by aligning insulation, window and ventilation system performance requirements with those for detached housing. The Plan targets 2020 updates to the Rezoning Policy to require Passive House performance for this form of development, thus emphasizing the immediate importance of catalyst tools and capacity building for early adopters of zero emission building approaches.
- High-Rise Multi-Unit Residential Buildings (MURBs): This Plan recommends establishing a GHGI limit in 2016 that would result in 64% lower emissions as compared to current rezoning policy outcomes (for buildings not connected to a renewable neighbourhood energy system). The incremental costs of improved envelope and ventilation systems will be offset by the savings from not being required to build a hydronic heated building.

Establishing these limits in policy and regulation will be undermined without also investing in clear and simple compliance processes supported with tools for both staff and industry, such as training, best-practice guides, etc.

City Leadership

In order to transition industry to building zero emissions by 2025 it is essential that the City demonstrate effective approaches in new building projects that it leads or influences so as to:

- inform what approaches work best under what conditions
- identify regulatory, permitting, and financing barriers so that these can be removed
- share real development experiences with private industry
- help catalyze the development of the required professional services, builder skills, and the supply of building components
- create opportunities for the public to experience the health and comfort benefits of these buildings

This Plan commits the City to build all new City facilities to the Passive House standard and certification, and use only low carbon fuel sources, or utilize equivalent near zero emission approach *wherever feasible* and to work with partners on other City influenced developments to assess and pursue opportunities to do the same. Given the magnitude of this shift in design and construction practice, feasibility of these approaches may be curtailed by financial, technical, schedule, and partner limitations that cannot be managed in the immediate term. This experience will enable the City to develop tools and processes to overcome challenges and will be used to inform a detailed policy for all City-led projects within two years.

Catalyst Tools

Rapid and effective transformation of the local building industry will require more than defined GHGI and TEDI reduction targets or City demonstrations of leadership. In order to achieve zero emissions for the majority of new buildings by 2025, the City must begin fostering zero emission design and building experience with numerous private sector leaders immediately. This will also stimulate local production and competition in the supply of highly efficient building elements while also improving the available selection and decreasing costs.

Initially, the development of zero emission new buildings will involve additional real or perceived risks and costs. New tools will be required in order to effectively catalyze private sector building innovation at the scale that will be required to enable zero emission building regulations within 9 years. Design and construction catalyst tools will target whole building performance and/or specific high performing building elements and practices.

The Plan describes key principles to guide the development of effective catalyst tools including appeal, clarity, timeliness to inform decision making, scale for impact, diversity of participants, and consistency of objectives/requirements.

Catalyst Tools for Detached and Row Houses

Given the relatively small size of detached and row house buildings, the fairly modest and reasonably well understood incremental costs of building these to near zero emissions, and a fairly consistent regulatory structure for the majority of these buildings, catalyst tools for this sector can be developed and launched relatively quickly.

The Plan outlines numerous catalyst tools that will be explored in further detail including expedited permitting, permit cost waivers, funding for case studies and design insight sharing, design competitions, and the potential for time limited relaxation of targeted City requirements such as those for minimum subdivision lot sizes or design guidelines for new homes in character neighbourhoods.

Preliminary research of the required costs to develop and provide catalyst tools at an adequate scale was undertaken and it was estimated that an incentive program of $325,000 for the first year and $650,000 for each of the next two years for a total of 1.625 million dollars would provide a meaningful start which could inform, and be re-evaluated in conjunction with, the proposed Building Bylaw updates proposed for 2020.

Catalyst Tools for Low-Rise MURBs

The Plan proposes that the 2020 Rezoning Policy for Green Buildings require 4-6 story MURBs achieve Passive House performance. In order to enable this, significant catalyst tools that can be launched in 2017 are required.

Given the far greater diversity of requirements and existing programs that impact the majority of these buildings, additional research is required to assess the cost to deliver and provide effective catalyst tools for this sector. That said, these same requirements and programs introduce additional opportunities to create meaningful catalyst tools.

In addition to exploring expedited permitting and permit fee waivers, staff will research options for the provision of required parking and potential, synergies with the Rental 100 Program, the Rezoning Policy for Green Buildings, and the green building requirements for large developments sites.

Significant delays in launching a meaningful incentive program may necessitate a delay in introducing the rezoning requirement for these buildings to meet Passive House levels of performance.

Catalyst Tools for High-Rise MURBs
Given their scale and the smaller pool of developers and design professionals who typically get involved in these large scale projects, only a few high-rise MURBs per year striving to attain Passive House like levels of performance would have a meaningful impact on our understanding of what is possible and would begin to lower the incremental costs for key building elements. Similar options as described for low-rise MURB catalyst tools will be explored. In addition to these, opportunities to introduce a design-build competition where entries could be judged on GHG performance, cost effectiveness, and public appeal will also be explored.

For all these incentives, and in particular those for the MURBs, the City should engage and seek support from higher levels of government given the transformative nature that a successful incentive program would have not only for the building industry in Vancouver but across BC and could help inform similar changes in major urban centres across Canada and the US.

Capacity Building
In order to successfully achieve zero emission for the majority of new buildings by 2025, the capacity of the building industry will need to be rapidly increased. This means providing resources and training, encouraging knowledge-sharing and supporting peer-to-peer learning. Capacity building will also include strengthening the relationship between the City and the building industry, with an emphasis on single-family-home builders to ensure that they are engaged and well supported with training and resources.

Not only will an investment in developing industry capacity for zero emissions buildings result in increased local jobs in design, construction, and manufacturing, it will increase business opportunities across North America as other jurisdiction adopt more energy efficient and lower emission building practices.

In developing this plan, staff conducted two workshops with industry stakeholders, held a meeting with leading architects and designers, and met with a number of the key stakeholders individually. Staff also researched leading capacity-building programs around the world, including multiple engagements with staff in Brussels and New York

City. The result of this research and consultation is a set of actions in the Plan aimed at rapidly increasing the capacity of Vancouver's building industry to design and build zero emissions buildings. These actions include:

- Providing funding to designers to share technical case studies and host tours of near-zero emission buildings;
- Requiring energy performance audits to be done after near-zero emission buildings are operating;
- Producing resources, guides to address industry-identified knowledge gaps;
- Hosting panel, exhibits and other networking events;
- Supporting training (primarily delivered by partner organizations) to help the industry gain needed skills, particularly those that are unique to zero-emission buildings;
- Removing barriers identified by the industry, such as permitting challenges;
- Showcasing Vancouver's leading developers, designers and builders through events and awards; and
- Engaging the public through tours and communication materials highlighting the aesthetics and liveability of near-zero emission buildings.

In order to coordinate the delivery of these actions, it is recommended that a neutral, arms-length Zero Emission Building Centre of Excellence be established:

Zero Emission Building Centre of Excellence
The proposed Centre is to be neutral and arms-length as Vancouver will not be acting alone to facilitate the development of zero emission building expertise – numerous other public sector and industry association groups have acknowledged the need for and advantages of establishing such an entity. The Centre will serve as a neutral space where developers, designers and builders can convene to learn, network and identify concerns or barriers to high-performance buildings. In this way, the Centre will help streamline the City's permitting processes.

The proposed Centre of Excellence will partner with professional and industry associations to host training events, courses, panels, and exhibits. In addition, the Centre could administer mission-related programs on behalf of partner organizations, such as energy-efficiency incentive programs. Several leading cities have established similar knowledge-sharing hubs for green buildings (see "New York's Building Energy Exchange") and they've proven to be highly effective in supporting the local building industry.

The Zero Emission Building Centre for Excellence is anticipated to be a physical space, centrally located, with a small staff trained in architecture and building science. Following best practices seen elsewhere, the centre is expected to be operated by an existing third-party organization with expertise in delivering training, education and communication materials and with a proven financial track record. This approach will ensure neutrality and a continued focus on the mission. Staff will be evaluating a number of potential host organizations in the coming months. Should there not be a suitable existing organization staff will consider other alternatives such as establishing a new arm's length non-profit.

Seed funding of $700,000 over the next three years is being requested to establish and begin operating the Centre, contingent upon receiving at least matching funds from external partners. A number of groups have expressed strong interest in partnering with the City, including BC Hydro, BC Construction Association, Wood Works BC, Simon Fraser Community Trust, other local governments, and the provincial government. While specific external funds have not yet been identified, the centre is expected to have impacts beyond the City and as such there are a number of potential funding sources, including but not limited to the Western Diversification Grant, Metro Vancouver Sustainability Grant, and Provincial Innovative Clean Energy funding.

Staff will report back to Council within six months with a detailed organization structure and funding strategy for the centre, including confirmed external funding sources.

Removing Barriers
Some existing City policies, regulations, bylaws, and guidelines make it challenging and more expensive to build to zero emission levels of performance. As the City and private leaders accelerate the development of zero emission buildings, the City will allocate dedicated staff to assess barriers and implement changes to minimize them. Ideally, adjusting how a policy is structured may enable its original public interest to be served while reducing the barrier to zero emission building. In more challenging instances, the benefits of reducing barriers to zero emissions buildings will need to be balanced against other public interests that a policy might be serving.

In addition, given the new, highly efficient approaches that designers and builders are already beginning to pursue, it is also critical that staff are provided with training and that internal processes are adjusted to ensure public safety is maintained while avoiding unnecessary delays in permitting for these buildings.

Implications/Related Issues/Risk (if applicable)

Financial

This report recommends a total of $1,625,000 be allocated over three years ($325,000 in 2017 from the Climate Action Rebate Incentive Program Reserve, $650,000 in 2018 and $650,000 in 2019 from a funding source to be determined and reported back to Council) to develop and provide tools to catalyze private sector leadership in demonstrating effective approaches to near zero emission detached and row housing.

In addition, staff will explore the development of similar catalyst tools multi-unit residential and commercial buildings and will report back to Council with specific resource requests and program recommendations in 2017.

This report also recommends approval in-principle for $700,000, contingent upon securing matching funding, to be allocated over three years with $300,000 in 2017, $200,000 in 2018 and $200,000 in 2019 from the City's 2017 Innovation Fund (subject to Council approval of the 2017 Innovation Fund budget) towards establishing an Zero

Emission Building Centre of Excellence with the mission to facilitate the compilation and dissemination of the knowledge and skills required to design, permit, build and operate zero emissions buildings.

The City's contribution of $700,000 towards a Zero Emission Building Centre of Excellence is expected to leverage at least $700,000 in direct matching funds plus over $100,000/year of in-kind contributions from a wide range of potential partners including, but not limited to: other BC local governments; the Provincial Government; Metro Vancouver; the Federal Government; energy utilities; and charitable foundations with strong commitments to climate protection.

Staff will report back with the sources of matching funding and recommendations for establishment of the Centre of Excellence in early 2017.

Additional financial implications such as those potentially required for new City-led buildings to demonstrate zero emissions as well as to develop and provide tools to catalyze early industry leaders to build zero emission multi-unit residential buildings to will be included in separate Council reports as additional research and consultation are completed.

CONCLUSION

Meeting the City's 2050 target to use only renewable energy will require the majority of new buildings be designed and built to achieve zero emissions by 2025 and all new buildings to achieve this target by 2030. Meeting these aggressive targets and timelines will require a restructuring of the City's policies and tools as well as leadership by the City and industry in demonstrating effective approaches for achieving this goal. It will also require a collaborative approach amongst many stakeholders to share knowledge, remove barriers, and ensure that the required skills are developed and widely available in BC.

This collaborative effort to transform how new buildings are designed and built will not only reduce their GHG emissions but will also make them healthier and more comfortable for their occupants. In addition, this innovation in the building industry will make buildings more resilient to changes in weather, climate and energy prices while providing significant opportunities for local professionals, trades, and industries.

Zero Emissions Building Plan

7/12/2016

Table of Contents

1 Exec Summary

This Plan lays out four action strategies to require the majority of new buildings in Vancouver to have no operational greenhouse gas emissions by 2025 and that all new buildings have no greenhouse gas emissions by 2030.

These four strategies include:

1. Limits: establish GHG and thermal energy limits by building type and step these down over time to zero
2. Leadership: require City-led building projects to demonstrate zero emission building approaches where viable
3. Catalyse: develop tools to catalyse leading private builders and developers to demonstrate effective approaches to zero emission new buildings; and
4. Capacity Building: build industry capacity through information sharing tools and the development of a Centre of Excellence for Zero Emissions Building to facilitate the removal of barriers, the sharing of knowledge, and the development of the skills required to successfully achieve this goal

These strategies for achieving zero emissions new buildings were developed specifically to ensure comfortable and healthy indoor environments, maximize local economic development, ensure long-term building resilience, protect housing affordability and to facilitate achieving the City's Renewable City Strategy target to have all buildings in Vancouver (including those already built) use only renewable energy by the year 2050.

2 Background

The Greenest City Action Plan includes a target to achieve carbon neutral new construction by 2020. More significantly the Renewable City Strategy targets 100% of all energy used in Vancouver come from renewable sources by 2050. In this Strategy, it was estimated that of all the buildings (measured by floor space not number of structures) that are anticipated by 2050:

- 30% would be built prior to 2010
- 30% would be built between 2010 and 2020
- 40% would be built after 2020.

If all buildings are to use only renewable energy by 2050, the sooner new buildings achieve near zero emissions, the fewer buildings there will be that require costly and challenging deep energy retrofits to achieve the target.

Consequently, the Renewable City Strategy targeted new buildings to be zero emissions by 2030 and where possible sooner.

2.1 New Building Emissions Trends

Operational greenhouse gas emissions from new buildings vary widely by building type, size, the carbon intensity and amount of the energy used, and policy or regulatory limits imposed on the building's design and construction. Building scale greenhouse gas emissions are measured in kg CO2e/m2 per year; since these are emissions per unit area they are referred to as emissions intensity or GHGI.

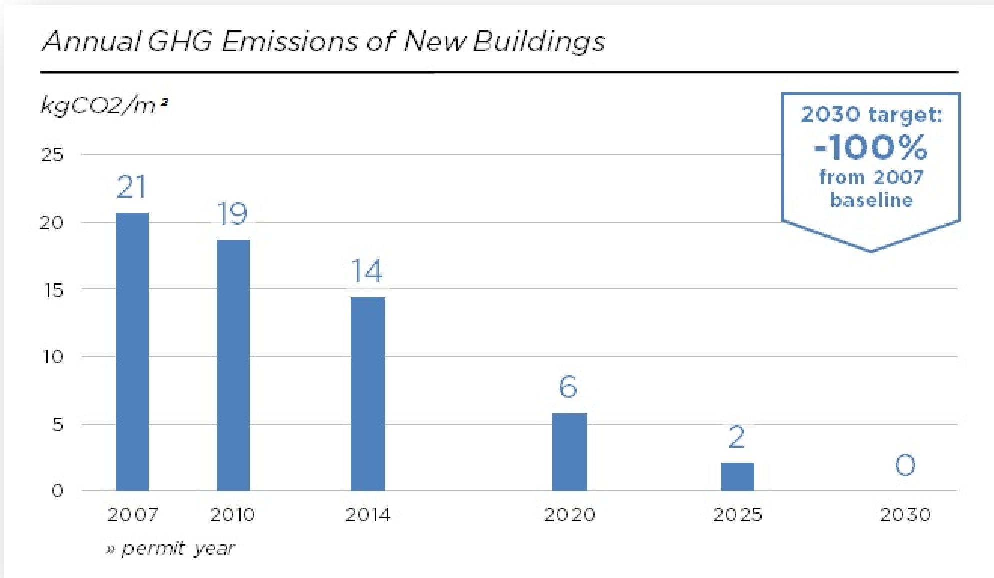

FIGURE 1: Aggregate GHG Emissions of All New Buildings Types

Total annual GHG emissions for a specific building type are calculated based on the modelled energy use of a typical sample building designed to its governing policy and/or regulatory requirements multiplied by the carbon intensity of the specific sources of energy sources used in that building.[1] Aggregate GHG emissions for all buildings types are based on a built area weighted average[2] of the emissions associated with each of the specific building types.

[1] Note that historic emissions for a specific building type are estimates only. Energy efficiency regulations do not *currently* control directly for GHG emissions so historic (and current) emissions by building type are based on modelled outcomes of *typical* design responses to energy efficiency regulations governing a building's design and construction in a given year.

[2] In 2007, only the Building Bylaw stipulated efficiency requirements (with the exception of a very limited number of buildings such as City facilities). Since then, rezoning policies as well as neighbourhood renewable energy system (NRES) connection requirements have introduced additional energy use limitations on large numbers of buildings in specific areas. GHG calculations (by building type) incorporate an estimate of how much new built area is impacted by rezoning conditions and/or NRES connection and therefore have lower GHG emissions than a building only impacted by the Bylaw.

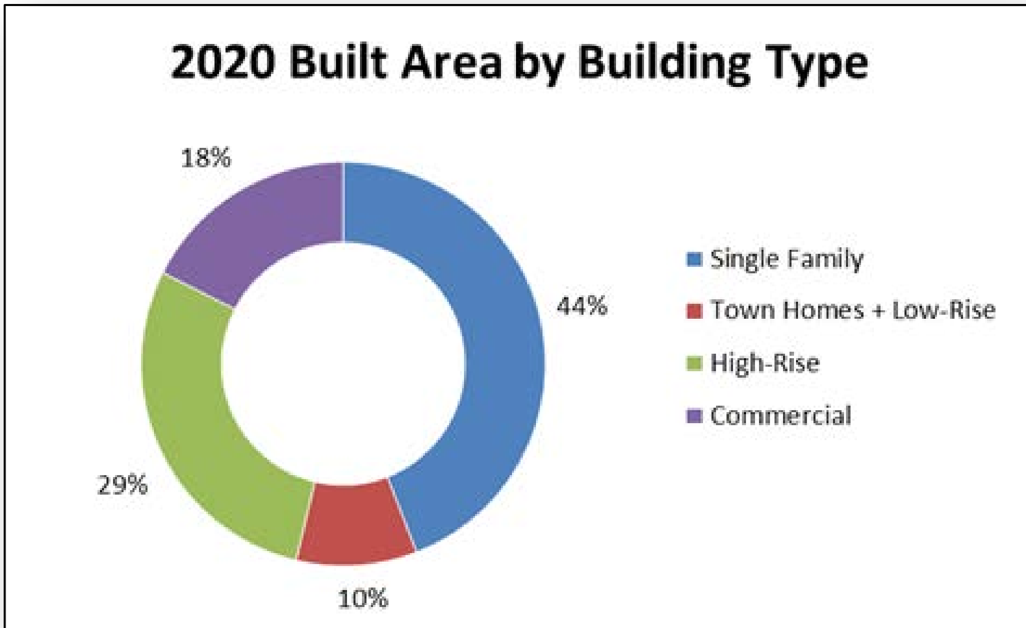

FIGURE 2: Built Area by Building Type

New development in Vancouver is predominantly residential with 82% of new building area being for houses, condominiums and apartments. Detached housing, referred to as "single family" but also including secondary suites, laneway houses and duplexes, represents the category of buildings with the most new development (by total floor area) per year. Even though significant and meaningful reductions in GHGI from new detached houses have been achieved since 2007, the significant amount of new development of this building type means additional improvements in performance must remain an important focus moving forward.

Mid and high-rise multi-unit residential buildings (over 6 stories in height) are the second most significant form representing 29% of new building area. Vancouver's efforts to reduce emissions from new mid and high-rise residential buildings have not been as successful in reducing emissions as they have been for houses and therefore must also be a form of development for particular focus. Fortunately, the expansion of neighbourhood renewable energy systems (NRES) and immediate changes outlined in this plan create two pathways to significantly reduce emissions from this critical form of development.

2.2 Renewable Energy in Vancouver

Unlike most jurisdictions around the world, Vancouver's electricity is already close to 100% renewable; Provincial legislation requires BC's grid to be supplied by a minimum of 93% renewable energy and the current mix is over 97% renewable and therefore has very low GHG emissions associated with its use. As a result, while electricity conservation remains important, the focus of this plan is on reducing the demand for fossil fuel based natural gas used primarily for space heating and hot water and transitioning these functions to renewable sources such as electricity (including heat pumps), bio-gas, and neighbourhood renewable energy systems (NRES).

In addition, because grid provided electricity is almost entirely renewable in BC, this Plan does not focus initially on mandatory building scale renewable energy technologies such as solar photovoltaic (PV) as is the case in a number of other leading jurisdictions. This Plan provides flexibility for builders and owners in determining how best to achieve the targeted GHG emission outcomes. One key element of providing flexibility for solutions is through removing barriers to good technologies and solutions such as solar PV.

When a building is required to achieve zero emissions if the electricity grid is not 100% renewable then the buildings will be obligated to install an on-site renewable energy system (or secure a share of Vancouver-based renewable power systems where on-site systems are not viable) that produces enough renewable energy to offset the small portion of grid power that comes from fossil fuel based generation.

2.3 Passive House

Passive House (also Passiv Haus) is the most rigorous and widely applied global standard that has been developed and refined specifically for ensuring highly energy efficient building envelope and ventilation system design and construction.

This standard is supported by:

- professional and trades training programs;
- customized energy modelling software to ensure strict energy limits are not exceeded, good ventilation is provided, and thermal comfort is maintained;
- third party verification processes (90% of which can be completed prior to construction start); and
- Canadian, North American, and global networks of designers, builders, equipment manufacturers and researchers.

Hundreds of millions of square feet, primarily of residential development but also including many schools, offices, hotels, firehalls, museums, etc., have been built and certified to the standard worldwide.

Throughout this Plan, reference is made to the Passive House standard as near zero emission because buildings meeting the standard’s criteria use virtually no space heating energy, limiting emissions to heating water and electricity use. While there is insufficient local data to conclude that this standard should be applied in its entirety to all building types under all conditions, the standard and its associated tools are seen as a key tool to effectively transform the building industry to greatly improved building envelopes and ventilations system approaches.

3 Stepping Down GHG Emissions to Zero

Zero emissions new buildings will be achieved by incrementally lowering the permitted GHG emissions for new construction in Vancouver`s Building Bylaw over time. Currently, no jurisdiction in North America has building code requirements that establish specific limits on GHG emissions. Experience has revealed that indirect approaches such as regulating energy cost efficiency as compared to a `reference` building (as is the standard approach under the North American building efficiency standard ASHRAE90.1 and in LEED) have not been as effective as anticipated in reducing emissions in Vancouver.

This Plan establishes greenhouse gas intensity (GHGI) targets (GHG emissions per unit area per year) by building type and includes a stepped reduction timeline to reflect these targets as maximum permitted limits in Vancouver`s building policies and Building Bylaw.

> *Clearly defining and quantifying desired outcomes and providing a schedule for performance changes will enable industry to plan appropriately and to focus building design and construction innovation towards achieving these objectives.*

3.1 Stepping Down GHG Emissions to Zero - Reduction Pathways

This Plan establishes two pathways by which GHGI limits for new buildings can be achieved in order to a) ensure reliable and durable emission reductions and to b) maximize co-benefits such as:

- local economic development
- healthy indoor building environments
- maximum occupant comfort
- protecting affordability
- future proofing to enable additional performance improvements post-occupancy
- resilience to climatic changes, extremes, and/or power outages.

3.1.1 Path One: High Performance Building Envelope and Ventilation Systems

A building envelope is like its skin – it includes surface elements such walls, windows, and the roof. Building envelope performance is primarily influenced by the amount and effectiveness of wall, roof and foundation insulation and the amount of windows and their energy efficiency. It is also impacted by how the building is designed to use the low angle of the sun in the winter to provide free heating while using shading strategies to keep out direct sunlight in the summer and avoid the need for air conditioning.

Ventilation `systems` are the means by which fresh air is provided for the building and stale air is exhausted.

Building envelope and ventilation system performance are interdependent. An efficient ventilation system cannot have warm air leaking out of the envelope in the winter (or cool air leaking out of the building during the hot summer) through poorly weather proofed walls and openings. At the same time, a healthy and durable building envelope depends on adequate airflow to avoid moisture accumulation which can lead to rot and mold. Very good draft proofing and the use of a `heat recovery ventilator` (HRV) that uses the energy of warm exhaust air to pre-heat fresh incoming air during the winter and vice versa during the summer are central to an energy efficient ventilation system.

A very efficient heat recovery ventilator (HRV) can pre-heat cold incoming fresh winter air from 0° C to 17 or 18° C just by recovering the heat energy from the exhaust air; because most of the fresh air heating is free, buildings can be well ventilated without concerns about the cost of doing so.

The first pathway to zero emissions buildings focuses on highly efficient building envelopes and ventilation systems because these systems do not depend on sophisticated maintenance staff or specialized contractors to ensure they are performing as designed. Given that 82% of the new development in Vancouver is residential and that most homeowners, strata councils, and apartment building operators are not building energy system experts, keeping the building systems simple is essential to reliable and durable building energy efficiency performance. In addition, these elements of a building are more difficult to upgrade once construction is completed. As the ultimate aim is to have all existing achieve 100% renewable energy or near zero emissions getting the envelope and ventilation systems right at the start are essential as these will be costly and disruptive to improve after the building is completed.

Co-Benefits of High Performing Building Envelopes and Ventilation Systems

High performing building envelopes result in more local jobs as insulation and windows are largely supplied from regional manufacturers. Installing these and weather proofing a building provide greater opportunities for local tradespeople than does the import of advanced energy system such as heat pumps or solar panels.

In addition, this pathway will result in increased occupant comfort and improved indoor air quality; buildings will be less drafty, there will be no chill from poorly performing windows, and a well-sealed and insulated building with triple-paned windows will be much quieter and easier to maintain.

3.1.2 Path Two: Neighbourhood Renewable Energy Systems

Neighbourhood energy systems are shared infrastructure platforms which provide heating and/or cooling for multiple buildings. In dense urban settings (as well as hospital or university campuses), these systems enable entire neighbourhoods to utilize nearly 100% renewable energy sooner than would otherwise be possible because of:

- economies of scale;
- incremental renewable energy technology costs can be amortized by a utility over 25+ years and repaid through operating cost savings due to free or low-cost energy sources such as sewer waste heat or clean wood waste;
- systems are continuously monitored to ensure performance objectives are met

Co-Benefits of Neighbourhood Renewable Energy Systems

- *Establishing and expanding neighbourhood renewable energy systems is essential to effectively reducing emissions from difficult-to-retrofit large occupied buildings; new buildings connecting to these systems help to expand RNES infrastructure and thereby increase the number of existing buildings that can be served with renewable energy*
- *New buildings that connect to a neighbourhood renewable energy system prior to the mandatory requirement for zero emissions new construction will be "zero emissions ready". They will not need to be retrofitted to achieve this objective at a future date because the neighbourhood system they are connected to can increase its mix of renewable energy over time;*
- *These systems foster overall energy resilience by utilizing a diversity of locally available free or waste energy sources such as sewer heat, commercial and industrial waste heat, or clean wood waste; creating a role for local energy or resources that would otherwise be wasted decreases Vancouver's overall dependence on imported sources of energy.*

One advantage of these systems is that they can provide renewable energy to all three building systems that require heat: space heating, ventilation air, and domestic hot water.

This pathway also results in reliable and durable GHG emission reductions by avoiding the need for complex mechanical systems in buildings. While this approach does depend on advanced renewable energy technologies, these systems are not operated or maintained by building owners but by an energy utility with professional and well trained staff. In this Plan, all buildings will be required to provide improved building envelopes and ventilation systems to improve occupant comfort and health but because neighbourhood renewable energy systems significantly reduce GHG emissions, envelope and ventilation system efficiency improvements required for buildings connecting to these systems will be more modest than for other buildings.

Given the importance of these systems in reducing emissions not only from new buildings but also from existing buildings, the City must continue to work with the NRES utilities to ensure these systems are successfully implemented and expanded.

3.2 Stepping Down GHG Emissions to Zero - Metrics

This Plan depends upon three metrics for it to be successful. They are described here in descending order of priority for Vancouver.

3.2.1 Greenhouse Gas Intensity (GHGI - kg CO2e/m2 annually)

Incrementally lowering GHGI limits in policy and regulation is the cornerstone of this Plan. GHGI is determined by the total amount of energy supplied to the building by type (electricity, natural gas, hot water or steam) multiplied by the energy's carbon intensity (a measure of how much greenhouse gas emissions are associated with its use). This overall operational GHG emission total is then divided by the building area to calculate GHGI.

> ***Carbon Accounting***
> *Vancouver follows global best practice for city-level carbon accounting which requires it to use provincially established carbon intensities for energy sources such as electricity, natural gas, and transportation fuels.*
>
> *Provincial changes to the accounting protocols for the carbon intensity of electricity are anticipated in the next year or two. If this occurs, the targets (as well as historic results) for new building GHGI established in this Plan will be revised to reflect this change.*

3.2.2 Thermal Energy Demand Intensity (TEDI kWh/m2 annually)

Thermal energy *demand* intensity is the amount of heat that is required to keep a building comfortably warm regardless of how efficiently or inefficiently that heat is produced. This metric reflects building envelope performance. In order to ensure continually improving envelope efficiencies, specific time-stepped limits for TEDI are required.

3.2.3 Energy Use Intensity (EUI)

Energy *use* intensity is the total amount of externally provided energy to a building including not only for heating, ventilation, and hot water (that are the primary sources of GHG emissions in buildings) but also for air conditioning, fans, pumps, lighting and expected energy use from appliances such as dishwashers and computers (referred to as plug loads). Time-stepped limits for EUI will ensure that even when energy provided to a building is renewable that it is being used efficiently and is not being wasted unnecessarily.

In jurisdictions where electricity is largely non-renewable, reducing overall energy use will effectively drive GHG reductions and is often the focus (directly or indirectly) of energy regulations and policy. As a result, there is significant global effort (public and private) to improve electrical efficiencies and reduce electricity use. Because overall energy use is not central to achieving GHG reductions in Vancouver (where we have more than 93% renewable electricity) and because the global electrical efficiency of lighting, devices and appliances is rapidly improving, it is not essential for Vancouver to drive innovation in this area.

For these same reasons, it is also not productive to establish *future,* time stepped EUI targets in this Plan. In order to ensure that energy is not being wasted, even if it is supplied from a renewable source, EUI limits reflecting established and proven good efficiency practices will be incorporated into rezoning and building bylaw updates at the time these are being developed.

3.3 Stepping Down GHG Emissions to Zero - Embodied Carbon

The City of Vancouver's green building and community-wide greenhouse gas emission reduction targets do not account for embodied (also referred to as upstream) emissions that occur as a result of energy used and GHGs emitted from building material resource extraction, production and transportation. In addition, under current policy and code requirements, the GHG emissions associated with the energy used in the operation of a building are significantly greater than the emissions embedded in the materials required for its construction. As result, this Plan is focused primarily upon reducing operational GHG emissions from new buildings.

That said, as this Plan is successfully implemented and operational emissions from buildings decline rapidly, the relative importance of addressing GHG emissions embodied in building materials will quickly become a significant consideration in efforts to reduce overall GHG emissions associated with buildings. Some building materials, such as wood, which is an abundant local and potentially renewable resource, can actually sequester carbon to reduce GHG emissions.

While historically it was difficult to quantify embodied emissions of building materials, new research and software tools have been developed specifically for the Canadian construction sector. These tools can be used quantify the embodied emissions from buildings on a detailed project basis for all building components and materials. In anticipation of the near term importance of measuring and reducing the embodied emissions of building materials, it is essential that the City begin collecting data from new developments on their estimated embodied carbon in order to inform future incentive, policy, and potentially regulatory mechanisms targeted at reducing the embodied emissions of new buildings as these become an increasingly significant portion of overall building lifecycle emissions.

3.4 Stepping Down GHG Emissions to Zero - Policy and Regulatory Tools

In this Plan, GHGI and TEDI targets are established for each major building type and step down starting in 2016 in roughly 5 year intervals until all buildings achieve zero emissions by 2030, and for many building types, by 2025. The Building Bylaw and the Rezoning Policy for Green Buildings will be updated to reflect these targets as firm limits for the prescribed milestone years. Time stepped EUI targets have not been established in this Plan but will be established to reflect established good electrical efficiency practices for each update to the Policy and Bylaw.

The City currently uses voluntary commitments from developers applying for rezoning to gradually drive improved green building outcomes. In general, GHGI and TEDI limits that will be required in the Rezoning Policy will be reflected in the Building Bylaw five years later. By aligning the limits for rezoning with the limits that will be required of all new construction within 5 years, the Rezoning Policy can help the industry evolve from one bylaw step to the next, and will provide demonstration projects for the building technologies and techniques that will soon be required by the Bylaw. This approach is often called a ‘stretch code’ or ‘reach code’. It has been used effectively by the City of Toronto Green Standard and the Ontario Building Code since 2006 to provide clarity and predictability to industry on upcoming energy code changes.

Prioritize Outcomes and Focus Policy Requirements

In order to enable industry to transform rapidly and successfully towards meeting these aggressive time-stepped GHGI and TEDI targets, it will be important to ensure that the Green Building Policy for Rezonings is structured to enable a focus on these high priority outcomes.

The effectiveness of the green building requirements in the current Rezoning Policy will be evaluated and outcomes will be prioritized. The 2016 update of the rezoning policy will include recommendations for achieving the highest priority green building outcomes.

It also aligns with the approach currently recommended by the BC Provincial Energy Efficiency Working Group, and is a key recommendation of the Pembina Institute for governments seeking to rapidly improve building performance.

3.5 Stepping Down Emissions to Zero - GHG and Energy Targets

Extensive research, energy modelling, and stakeholder consultation was undertaken to understand current building design and construction practices and to inform stepped reduction GHG and thermal energy demand targets for each major building type that were deemed ambitious yet achievable. Detailed construction and operating cost analysis of building changes required to meet the 2016/2017 targets were undertaken to ensure that the new requirements do not increase the cost of housing in Vancouver.

It is anticipated that building practices and the availability of cost competitive building systems will evolve quickly in response to the initial targets. The viability and cost implications of subsequent targets (2020 and later) will be assessed in detail and will be used to inform recommended changes to the targets should it be determined that they are overly aggressive.

The GHG emissions reduction benefit for new buildings connecting to a Neighbourhood Renewable Energy System (NRES) will be recognized if the NRES is City owned, or once the renewable energy supply is secured (e.g. by legally binding agreement or equivalent regulatory approach) even if the implementation of the renewable energy plant is not yet completed. In addition, while the GHG target for all buildings of a specific type are consistent, the thermal energy demand targets for RNES connected buildings will not be as stringent since these buildings will be paying for renewable energy infrastructure through utility rates and achieving reliable GHG reductions through their use of low-carbon energy.

In order to achieve zero emissions in new buildings by 2025 (or in some cases 2030), any portion of non-renewable energy in grid provided electricity will be required to be offset by the installation of an on-site renewable energy system such as photovoltaic solar panels. In the case of high-rise buildings with relatively small roof areas compared to the overall building size, the small portion of non-renewable energy in electricity will be allowed to be offset via a community-scale renewable power system. As grid power is required by legislation to be 93% renewable and is currently 97% renewable, the size of on-site renewable systems to make up the remaining 0-7% required to achieve 100% renewable power will be small in size and will be very modest in cost.

3.5.1 GHG and Energy Targets - Building Energy Performance Modelling

To support the establishment of GHGI and TEDI targets and to facilitate compliance as these targets are introduced to building policy and regulations, energy modeling guidelines have been developed. The intent of the guidelines is to clarify and standardize energy modeling assumptions to align with the parameters used in developing the established performance targets.

The energy modeling guidelines establish a consistent methodology around parameters such as operating schedules, non-regulated loads, air leakage, and others so that proposed building designs are measured in a consistent manner against the policy and code requirements. One key element is that the guidelines establish requirements for how to properly represent envelope heat loss by incorporating thermal bridging that has historically been ignored in code compliance modeling.

It is important to note that actual building energy use and emissions may vary from the modeled results; *energy models results based on standardized assumptions regarding building use are comparative not predictive*. A useful analogy is the fuel efficiency ratings of cars and standardized test conditions (speed, vehicle loading, road conditions etc) used to determine a vehicle's rating. The actual fuel efficiency of the vehicle can differ significantly from the test results given actual driving habits, road conditions, and vehicle usage (towing, number of passengers etc).

It is also important to note that different building energy modelling tools can generate fairly different results. The modelling tools used for detached homes, high rise MURBs and Offices, and for Passive House design are all different and therefore comparison of modeled outcomes between different building types can be misleading. What is important is that modelling tools enable relative comparisons for buildings of the same type to enable target setting and compliance.

As the GHGI and TEDI limits, targets and outcomes get closer to zero emissions, current modelling tools *may* no longer be effective. Research into the appropriateness of different modelling tools will be ongoing through the implementation of this Plan.

3.5.2 GHG and Energy Targets - Detached Housing

Detached houses (including secondary suites, laneway houses, and duplexes) represent the largest amount of new construction in Vancouver accounting for an average of 44% of new development by area. Over 90% of new houses are heated with natural gas and as a result have a significant opportunity to reduce greenhouse gasses by improving the building envelopes. These buildings are exposed to the weather on all sides and tend to have complex shapes, increasing the surface area to volume ratio which increases energy use. Since there are no rezoning for new one and two family homes, the City has historically lacked tools to encourage innovation and "better than code" energy performance.

Despite these challenges, Vancouver significantly reduced emissions and energy use in new homes with the 2014 Building Bylaw by prescriptively requiring better insulation, higher performing windows, increased air tightness requirements, the use of heat recovery ventilators, and requirements for more efficient equipment such as furnaces. As industry adapts to these significant changes, only minor improvements will be introduced between now and 2020.

One minor improvement will be setting a maximum allowed total GHG emission impact for new detached homes. The maximum allowed limit will be based on the average carbon footprint of a new home in Vancouver. Effectively, this will require larger than average homes to pursue greater energy efficiency or the use of additional renewable energy technologies sooner than the rest of the market. All grid connected space heating, domestic hot water heating, fireplaces (indoor and outdoor) and outdoor heating would be considered in setting the average. These larger than average projects will help drive innovation and the adoption of leading practices making improvements in more modest sized houses easier in the future.

While an envelope focus as the pathway towards zero emissions has been initially successful with the most recent changes to the Vancouver Building Bylaw, it is not envisioned that the Building Bylaw will mandate Passive House levels of performance for all new detached houses when zero emissions will be required in 2025. This is because achieving a Passive House level of envelope performance may be very challenging while still maintaining the complex building shapes required to maintain a early 20th Century housing character. A slightly higher TEDI combined with renewable energy based heating equipment, such as air-to-water heat pumps, will allow zero emissions to be achieved while still allowing for significant architectural variety.

Successfully transitioning detached homes to zero emissions will require the development of new incentive tools. This is because, unlike other building forms which have "better than code" requirements for rezoning, the City currently lacks tools to encourage innovations in energy efficiency performance for detached houses. In addition, the Vancouver homebuilding industry in comprised of a large number of small companies, many of them run by immigrants whose first language is not English, being responsible for no more than a few dozen homes out of the 1000 that are built each year. As a result, an ongoing investment in training, peer-to-peer exchanges, and capacity building is essential.

2007 Baseline		Current Bylaw		2020 Bylaw		2025 Bylaw	
GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI
23	113	12	84	7	55	0	30

GHG emissions for new detached houses, representing over 40% of all new development in the City, were significantly reduced as a result of improved envelope and efficiency requirements in the 2014 Building Bylaw; these emissions are almost 50% lower than the 2007 baseline. This Plan does not include any significant new regulatory requirements before 2020 but focuses on the provision of incentives for innovation and an investment in knowledge sharing and training.

3.5.3 GHG and Energy Targets - Low-Rise MURB Targets

Low rise MURB's (including rowhouses and 4-6 story multi-unit residential buildings) in Vancouver are predominantly wood framed, most have punched windows, they include relatively modest amounts of window area, and typically only have one or two sides exposed to the outdoor air. These factors, combined with the early adoption of the Passive House Standard by some rental apartment building developers, create an ideal opportunity to transition rapidly to high performing building envelopes and Passive House levels of performance.

The primary challenge in this transition is that these buildings have not historically been required to achieve high levels of energy efficiency, so success will depend upon immediate incentives for innovation, resources and tools to build the design knowledge and construction skills required. Because of the similarities in construction between 1&2 family homes and low-rise MURBs, aligning the requirements will help facilitate improved availability of high performing building elements such as windows, reduce confusion, and improve enforcement success. In addition, some design relaxations may be required to accommodate extra insulation and enable simplified building shapes.

Requirement Type	Current Bylaw		Current Rezoning		2016 Bylaw Updates		2016 Rezoning Update		2020 Rezoning Update		2025 Bylaw Requirement	
	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI
Bylaw or Rezoning	12.5	50	10.5	42	5.5	35	5	25	4.5	15*	0	15*
NRES Connected							5	35	4.5	35	0	TBD

* Passive House or equivalent performance

> Low-rise multi-unit residential buildings are the ideal building form and construction type for cost effective high performing building envelopes and ventilation systems. This Plan proposes immediate updates to the Building Bylaw targeting a reduction of nearly 50% in GHG emissions for new low-rise residential development and establishes the target for all low-rise MURB developments that are rezoned as of 2020 to achieve Passive House performance.

3.5.4 GHG and Energy Targets - High-Rise MURB Targets

High-rise MURBs represent the most significant challenge for achieving zero emissions given the changes from current design and construction practice required and the fact that it is the second most prevalent form of new development in the City representing 29% of new development floor area. These buildings typically include large amounts of glass and exposed concrete (slab ends and balconies), both of which result in significant heat losses and are leading to a growing reliance on air conditioning. In addition, they have historically used a ventilation approach that results in most of the conditioned air being lost to the outside (such as up the elevator shaft) before it reaches the units, which is very inefficient and can lead to poor indoor air quality. An unintended consequence of the City's 2011 and 2014 Rezoning Policy for Green Buildings is that it forced builders away from inexpensive to install, low carbon electric baseboard heat and led them to more expensive hydronic heating systems that use natural gas.

Despite these challenges, rapid improvements can be made immediately through the restructuring of the rezoning policy to reduce exposed concrete, improve window performance, shift towards direct ventilation and heat recovery ventilators, and allowing the use of electric heat once again. These requirements can each be stepped up while technologies for renewable creation of hot water at the scale required in MURBs are encouraged and then become normal practice.

Where low-carbon energy is available by connecting to a Neighbourhood Renewable Energy System, GHG reductions will be reliably and durably reduced. When starting from a context of low GHG emissions (RNES connection), requiring significant additional investment in the building envelope provides highly diminished return (in the form of additional GHG reductions) for the capital costs involved. As a result, the TEDI limits for these buildings, while require some improvements in the envelope and ventilation systems, will be less aggressive than the TEDI limits for buildings that are not connected.

Requirement Type	Typical Outcome of Current Requirements		2016 Limits		2020 Limits		2025 Limits	
	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI
Bylaw	20.0	55	20.0*	55*	6.0	32	5	TBD
Rezoning	16.5*	46*	6.0	32	5.0	18	0	TBD
RNES Connected	5.5	46	6.0	40	5.0	40	0	TBD

* Typical outcomes of the Rezoning Policy for Green Buildings which has been in place since 2011 will be reflected in the building bylaw in 2017.

This Plan targets an immediate reduction in GHG emissions of 64% for rezoned high-rise MURBs that are not connected to a RNES. This can be achieved by restructuring and updating of the rezoning policy in the fall of 2016 without increasing the cost of new development. The added expense of improved building envelopes and ventilation systems will be offset by the reduced construction costs cost of not forcing developers to install hydronic heating.

3.5.5 GHG and Energy Targets - Office

Office buildings tend to use more electricity and require less heating than residential buildings resulting in much lower GHGI impacts than high-rise MURBs under current policy requirements. This is due to very low use of hot water, ventilation systems with much lower distribution losses, and higher density of occupants and equipment which both emit heat and thereby lower heating system energy demands.

Despite their already relatively low GHGI, there are immediate opportunities for further improvement. This is due to the fact that office buildings typically have a different ownership structure than residential buildings and incremental constructions costs associated with higher energy efficiency requirements can be recovered through operating costs savings. In addition, office building tenants typical place a higher value on green building performance than residential building purchasers or tenants, possibly as a result of corporate social responsibility and/or recognition that green buildings typically foster more productive working environments. As a result, office developers have been demonstrating innovation in building envelope, heating, and ventilation system design that establish proven if not-yet-common approaches for energy and GHG emissions reductions.

Requirement Type	Typical Outcome of Current Requirements		2016 Limits		2020 Limits		2025 Limits	
	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI	GHGI	TEDI
Bylaw	9.5	40	9.5	40	3.0	27	0	21
Rezoning	7.5	30	3.0	27	1.0	21	0	TBD
RNES Connected	3.0	30	3.0	27	1.0	27	0	TBD

This Plan recommends an immediate 65% reduction in GHG emissions for office buildings. Unlike residential develop, new office buildings already rely upon complex mechanical systems and typically have trained and dedicated operations staff. As a result, improvements in this form of development will result from both improved building envelopes as well as a shift to renewable energy heating systems (either connection to a NRES or the use of heat pump technologies).

3.5.6 GHG and Energy Targets - Other Building Types

All other building types (excluding residential and office) such as food service, hotels, retail, light industrial, hospitals, schools, etc. represent an estimated 13% - 16% of new development by area in an average year. Given the wide diversity of building types, the specific energy use characteristics each type, and the small amount of new development of each type specific GHG and TEDI targets have not yet been developed. As better data becomes available and further research can be completed, specific targets will be proposed. In the interim, rezoning policy and building code updates will rely upon a "% better than" approach as compared to established standards. The most obvious shortfall of this approach will remedied by shifting from the existing energy cost efficiency requirements to energy use efficiency requirements.

3.6 Stepping Down GHG Emissions to Zero – Compliance with Targets

Building codes evolved historically to ensure health and safety outcomes. As a result, most compliance and enforcement tools are oriented to ensuring these outcomes. There is a growing awareness across North America that carefully constructed energy policies and regulation have been undermined by the absence of clear compliance processes and enforcement mechanisms. In addition, there are a number of prescriptive requirements for new buildings that do not directly result in reduced energy use or emissions but are essential to help ensure that design outcomes are actually achieved.

A number of tools will be used at different points in the building lifecycle to encourage and confirm compliance with the policy, as well as to assess whether the policy is delivering the intended outcomes. Compliance and measurement of outcomes should be demonstrated at each phase of the building lifecycle, throughout design, construction, and post-occupancy.

3.6.1 Compliance with Targets - Process and Tools

In order to facilitate compliance with building energy and emission performance policy and regulation, requirements and a process for demonstrating compliance must be clearly established and communicated with industry. This will include need to include clearly defined roles for suppliers, design professionals, commissioning agents, permit processing and inspections staff. Digital tools for submitting documentation and doing initial quality control checks, along with training sessions and videos regarding compliance expectations and process will greatly assist in streamlining this essential work for both applicants and staff.

Compliance of the proposed design with the targets described in the preceding sections will be demonstrated by applicants submitting project information in a standardized form that includes how the modeled intensities compare to the targets, as well as key design values that will allow staff to assess the application for possible anomalies or to seek more detail. Key values will include such metrics as overall ventilation rate, heat recovery effectiveness at rated and design conditions, assembly total effective R-value, window-to-wall ratio, and more. This format will serve as a quality control mechanism for applications for re-zoning, and should be updated at each phase of the permitting process.

In addition to requiring compliance of the design with the performance targets, applicants will be required to demonstrate compliance of the building construction through testing of the building air-barrier, commissioning of the building systems, and measurement and benchmarking of the building energy use once occupied.

3.6.2 Compliance with Targets - Air barrier testing

Air-tightness of the building is a critical factor in creating long-lasting, reliable energy performance. To ensure that buildings are designed and constructed to deliver this performance, a successful air-tightness test of the building will be required prior to occupancy permit being granted. There are different standards available in North America to draw from, including the Seattle standard, which has been in effect for over five years now, and the adoption of which would allow industry and officials to draw on local knowledge and expertise.

The Seattle standard requires whole-building air leakage testing to ASTM E779 with some modifications, and buildings must achieve a maximum air leakage of 2 L/s per m² of façade area, at a pressure of 75 Pascals. To help builders achieve this, there are also requirements for the individual components to meet maximum leakage rates, including windows, elevator doors, loading docks and others.

In the Seattle example, buildings that do not meet the standard are required to be re-inspected and re-sealed. In adopting this standard for Vancouver, additional compliance and enforcement measures could be considered, such as mandatory re-testing or re-training of the builder’s quality control staff.

3.6.3 Compliance with Targets - Commissioning

Commissioning is a quality control process of verifying that a building’s systems operate as intended, and is typically conducted by a third-party

Commissioning Agent. The commissioning agent works for the building owner or developer to verify that the building operates as designed, and validates that the design and operation meet the original requirements set out for the building at the beginning of the project. To do this, the commissioning agent periodically reviews the project during all phases of design, construction, and handover. They will focus particularly on active building systems such as the Heating, Ventilation, and Air-Conditioning (HVAC), plumbing, and lighting systems and their controls, to ensure that they operate as intended under a variety of conditions. This process will often include a follow-up review after the building is occupied in different seasons to ensure both heating and cooling system function correctly. Industry standards for commissioning include ASHRAE Guideline 0-2005 and Guideline 1.1-2007, and use of these guidelines are consistent with the requirements of LEED, as well as the City of Seattle Energy Code and California's Title 24 requirements.

Requiring commissioning be conducted by a Commissioning Agent according to these guidelines will support the policy goal of actually realizing modeled efficiency and reduced carbon performance in new buildings.

3.6.4 Compliance with Targets - Benchmarking

An important tool in measuring outcomes once buildings are built is the benchmarking of building energy use and emissions. Benchmarking involves the measurement and monitoring of key performance indicators of the building including energy use (of each major building system) and emissions, and comparing these metrics against those of other buildings in a common database, such as the US EPA's Energy Star Portfolio Manager. While the City is working with the Province and other interested local governments to develop energy benchmarking reporting regulation for all large existing buildings, updates to the rezoning policy will require energy metering of each major building system for new buildings, a benchmarking service contract is in place to ensure this data is compiled post-occupancy, and that a covenant on the property requires the owner to release non-personal data to the City.

> ***Essential Feedback Mechanism***
> *Modeled energy data is an imperfect tool to achieve real and durable GHG reductions. By metering and reporting the actual performance of new buildings, the outcomes of GHG and energy policies can be directly measured, and adjustments can be made to increase effectiveness and efficiency of the requirements. Equally important is that this data will help inform industry as to what building designs, systems, and construction approaches are most effective in achieving real GHG and energy savings.*

3.7 Carbon Neutral New Buildings

The Greenest City Action Plan includes a target to have all new buildings carbon neutral by 2020. Carbon neutrality is achieved through a combination of energy use reduction, transition to renewable energy sources, and/or by offsetting a building's operational GHG emissions with reductions in emissions elsewhere (typically through the purchase of a carbon offset).

This Plan establishes GHG limits by building type to be reflected in the building bylaw that step down to zero for most new building by 2025 and for all buildings by 2030. The Building Bylaw does not provide the flexibility to have a firm, non-zero carbon limit in 2020 (ie the GHGI limits in this Plan) and to also have a limit of zero that can be achieved through the purchase of an offset.

Staff will explore the potential of having GHGI limits in the rezoning policy, where the City has greater flexibility for establishing expectations for new buildings) along with the requirement for carbon neutrality where the latter might be achieved through the purchase of a carbon reduction credit. Carbon reduction credits could be achieved through City (or City recognized) programs that incrementally reduce GHG emissions in Vancouver. This rezoning requirement and the creation of a Carbon Reduction Credit Program could potentially generate an estimated $700,000/year for City (or City recognized) programs, such as home energy retrofit incentives, to generate the required carbon reductions to achieve carbon neutrality. Such a system could be in place between 2020 (carbon neutral requirement) and 2025 when near zero emissions will required in the building bylaw.

Stepping Down GHG Emissions to Zero - ACTIONS

Establishing and effectively transitioning the building bylaw and other City policies to require new buildings meet specific GHG and energy use targets is the cornerstone of this Zero Emissions Building Plan. This will require the following actions:

- Update the Building Bylaw in the fall of 2016 to reflect the targets described in Section 3.5.3 above for 4-6 story MURBs
- Restructure the Rezoning Policy for Green Buildings in the fall of 2016 to focus on key outcomes and reflect the targets for low-rise MURBs, high-rise MURBs, and office buildings as detailed in 3.5.3, 3.5.4, and 3.5.5 above
- Incorporate requirements for calculating and reporting embodied emissions in the restructured Rezoning Policy for Green Buildings
- Beginning in the fall of 2016, periodically review and revise as required NEU connection requirement zones to only mandate connection in areas where low-carbon outcomes capable of achieving these targets have been secured

- Undertake additional research and consultation and report back with recommendations on changes and approaches for embedding future stepped reductions prior to 2020 and 2025 respectively.
- Ensure that new policy and code requirements are supported with investment in the development of compliance processes, tools, and training for both staff and applicants prior to the requirements taking effect
- Incorporate air barrier testing, building energy system commissioning, and benchmarking in the Rezoning Policy for Green Buildings in the fall of 2016 and seek future opportunities to incorporate these into the building bylaw
- Research and consult with stakeholders on the viability of establishing a carbon reduction credit program for achieving carbon neutral buildings through the Rezoning Policy for Green Buildings and report back to Council with recommendations prior to 2020.

4 City Leadership

Achieving zero emissions for almost all new buildings permitted in Vancouver by 2025 will require early leaders to start demonstrating what is possible immediately. Large complex buildings often take 6 years or more from the initiation of permitting to the availability of occupied and operational building performance data to inform the real world effectiveness of the approaches taken. Building suppliers need local demand and lead time to enable their investment in the development, manufacture, and approvals for new products to meet industry needs in Vancouver. Finally, leading designers and builders must gain practical experience with zero emission buildings under a wide variety of conditions and building uses in order to learn what works (and what doesn't) and refine their approaches.

Similar to requiring LEED Gold for new civic facilities when the City first began to support a shift in the broader market towards green buildings, if the City wants to achieve zero emissions for most buildings by 2025, it is essential that it lead by example now.

City commitment to demonstrate that zero emission buildings are possible will:

- Inform what approaches work best under what conditions
- Identify regulatory, permitting, and financing barriers so that these can be removed
- Build real development experience that can be shown to and shared with private industry
- Help catalyze the development of the professional services, builder skills, and the supply of building components required to achieve zero emissions

- Enable the public to experience the benefits of these buildings beyond their operational cost savings

The City is involved in a wide variety of building projects. Some of these projects are already underway while for others, the design team and program have not yet been established. Some new projects are for City owned and operated facilities like branch libraries and swimming pools while a more significant amount of development involves City owned land or City Owned buildings being led by a development partner as an in-kind amenity for the neighbourhood. In these latter cases, negotiation with the development and operating partners will be required to demonstrate the value and secure their commitments to showcasing a zero emissions building approach.

In addition, some City facilities have the opportunity to connect to neighbourhood renewable energy systems and thereby greatly reduce their GHG emissions via this pathway while others must focus on high performing building envelopes.
This diversity of both building types and the nature of City involvement creates many opportunities to showcase leadership in zero emission buildings but it also creates complexity. In order to enable a focus on transformational change on building GHG emissions, City projects that pursue Passive House or a Zero Emissions approach will not also be mandated to achieve LEED gold certification.

4.1 City Leadership - City Owned and Operated Civic Facilities

City owned, developed, and operated new buildings provide the greatest flexibility for demonstrating zero emissions leadership as there are no partners involved with their own interests and limitations to accommodate. Incremental construction costs can be recouped through operational savings. Passive House Certification will be required for all city owned buildings, as well as the requirement to use only low carbon fuel sources unless both or either is deemed unviable. In the case of specialized facilities where the energy demand is less dominated by building envelope losses (such as outdoor pool), while Passive House Certification will be assessed for its suitability as zero emissions approach, other opportunities may be explored in lieu of Passive House Certification to demonstrate leadership with a method that does not include such a strong focus on the building envelopment improvements.

Fire hall 17, one of the next City owned and operated facilities to be built which is very similar to residential development for much of its programming, is being planned to achieve Passive House Certification, , and use only low carbon fuel sources to the greatest extent possible, in order to show early leadership in achieving near zero emissions.

4.2 City Leadership – In Kind Development Contributions

Developers often volunteer to develop a public amenity on behalf of the City such as rental housing or a day care when seeking to rezone a development; the City will work with these partners to assess the viability of these “in-kind” developments to demonstrate Passive House or another near zero emissions approach. This form of “in-kind” development represents a significant amount of new building area each year but complexity can arise when these developments are not stand-alone buildings but are incorporated into a portion of a larger building. While these building portions may need to share mechanical systems with the larger building and it may not be possible to certify just the City's portion to the Passive House Standard, the City will seek to require these elements to demonstrate zero emissions leadership to the extent possible given these limitations.

4.3 City Leadership - Affordable Housing Leadership

The Vancouver Affordable Housing Agency (VAHA) has a mandate to identify where the greatest impact can be made, and act as a catalyst for innovative housing ideas and models. VAHA sees zero emissions buildings and the Passive House standard in particular as an important opportunity for housing innovation.

VAHA has already incorporated the requirement to assess projects against Passive House standards as part of its RFP process and is assessing proponent team capacity and experience to successfully deliver Passive House projects as part of its proposal review. As a result of this "action while planning" VAHA is already aiming to deliver 3510 Fraser Street, one of its very first projects, as Passive House Certified.

In addition, the City has been working closely with BC Housing in the development of this Plan. BC Housing has been a leader in sustainable affordable housing for over a decade and has over 50 buildings registered with the Canada Green Building Council, 34 of which have achieved certification, almost all to LEED Gold. Given all of the

Passive House for Affordable Housing in the U.S.

As of this year, housing agencies in eleven US states have prioritized Passive House in their applications for affordable housing funding, with twenty four additional states actively working to develop similar programs.
The catalyst for this in 2014 when the Pennsylvania Housing Finance Agency (PHFA) and a group of 25 stakeholders including builders, architects and cities initiated a project with the target of all affordable housing in Pennsylvania be designed and constructed to a Net-Zero-Energy-Capable standard by 2030.

The standard proposed to achieve this was Passive House. By incorporating Passive House into its scoring criteria for the award of limited federal funding (via a 9% tax credit) available for affordable housing, nearly 40% of the 2015 affordable housing proponents in Pennsylvania applied as Passive House Projects. The construction cost premium calculated between Passive House projects and non-Passive House was less than 2%. 8 out of the 39 projects that were awarded 2015 funding were Passive House totaling 422 new affordable housing units.

The first state after Pennsylvania to announce a prioritization of Passive House was New York. This caught the attention of the White House, which has incorporated Passive House into their comprehensive plan to bring renewable energy and energy efficiency to households across the U.S.

sustainable new construction projects they completed, BC Housing has found that those with simple designs that rely primarily on passive elements rather than complex mechanical systems use less energy and are easier and more affordable to maintain. This discovery has led to BC Housing exploring other green building certification options including Passive House. They have targeted Passive House certification as a requirement in RFPs for several of recent new construction projects, and have shortlisted two projects in the City of Vancouver on which to pursue Passive House certification.

BC Housing believes that Passive House has the potential to help create affordable housing that is more energy efficient, and more affordable and easier to operate. Furthermore they have committed to compiling and sharing their experience on all Passive House (and other near zero emission) projects to facilitate capacity building in the BC development industry.

4.4 City Leadership - Procurement Process

Additional City leadership to demonstrate a more cost effective process to achieve high quality, highly energy efficient buildings that the City should explore and pilot is in new building design procurement. Constructing an innovative public building begins with the procurement process. As evidenced in places as diverse as The Netherlands and Edmonton, AB, changing the process by which governments procure their green buildings can have a significant impact on the architectural, lifecycle cost and energy performance outcomes of the buildings constructed. Through comparing the procurement changes that were implemented in jurisdictions seen as leaders in procuring exemplary and innovative buildings, a number of commonalities are present:

- Creating a multi-staged RFP process that creates a design competition focusing on a streamlined set of selection criteria that value architectural excellence, awards, and design;
- Transparently stating the project budget in the RFP and requesting that teams prepare their submissions to best demonstrate near zero emissions allows for greater creativity and typically requires an integrated team approach thereby helping to reduce risks;
- Creating the space for dialog with invited, shortlisted firms following the RFP in order to understand the proposed designs, and potential technical or economic risks; and
- In Europe, using Building Information Models (BIMs) as a requirement for project management and a part of the proposal submission package.

The BC Construction Association launched a “Construction Innovation Project” in 2016, with the goal of facilitating change in industry and government to meet the building and infrastructure needs of the 21st

Century. One component of this is a recommendation for government and industry to launch an Innovative Procurement Initiative, recognizing that the current status quo is stifling, rather than catalyzing innovation.

> *As it stands, the procurement process needs to be fixed. There has to be a shift from a culture of "lowest bid" to focus increasingly on quality and "whole-life" value.* – BC Construction Association, December 2015 [1]

City Leadership ACTIONS

In response to these opportunities and challenges, this Plan commits the City to:

- Build all new City owned facilities, and VAHA developments to be Passive House Certified and use only low carbon fuel sources, or other near zero emissions approach where technically, financially, and operationally feasible
- Require partners undertaking in-kind developments on behalf of the City to pursue Passive House Certification and use only low carbon fuel sources, or other near zero emission outcomes for the entire or City-portion of new developments where viable
- Direct City staff to investigate and pilot new procurement process(es) for City-led Passive House or alternate near zero emissions new development and assess/showcase the value of such a process as a tool for industry change
- Leverage the experience gained from the above actions to inform a more specific policy to define and govern outcomes for "City-led" projects by 2018.

5 Catalyzing Leadership

Rapid and effective transformation of the entire local development and building industry will require more than defined GHGI and TEDI reduction targets and government leadership. New design approaches must be learned, tried and refined. While technologies exist to achieve zero emissions buildings, many of the required elements such as super-efficient windows, prefabricated insulated wall panels, heat recovery ventilators, and air source heat pumps for domestic hot water are not readily available in our local market due to (current)

> *Supporting early innovators will signal market demand for super-efficient building components, support building design evolution, catalyze new training and education initiatives, and build broader industry confidence that zero emissions buildings are achievable.*
>
> *Ultimately, early showcase projects by public and private sector leaders will reduce the incremental costs of zero emission buildings and inform effective, streamlined, and flexible future regulations to ensure all buildings ultimately achieve these outcomes.*

[1] https://www.bccassn.com/media/bcca-report-construction-innovation-2016.pdf

low demand. Finally, it takes time for local industries to research, develop, and get approvals for new building products. In order to be competitive and to flourish; they need local demand for zero emissions buildings now in order to commit to these investments.

In order to achieve zero emissions for most building types by 2025, it is essential that the City develop tools to encourage innovation and offset incremental costs so as to catalyze voluntary leadership by private developers in demonstrating effective approaches for achieving zero emission new buildings as soon as possible.

5.1 Principles for Effective Catalysts

Preliminary staff analysis of effective (and less effective) approaches to catalyzing early leadership indicates that a range of tools tailored to the opportunities and challenges of specific building types will be required. The following principles will guide the development of these catalyst tools:

- Appeal and Clarity – catalyst tools must be tailored to local market conditions and priorities so as to provide clear and measurable appeal to builders and developers

- Timeliness –certainty on whether or not a proponent will qualify for and be able to access the catalyst must be provided in a timely manner in order to influence key project decisions

- Scale – in order to be effective, catalysts must help drive sufficient scale of demand for zero emissions buildings and their components to attract investment and competition to effectively reduce the incremental costs

- Diversity –experience and confidence in effective zero emission buildings must be fostered amongst multiple designers, developers, and builders before zero emissions can be expected for broad segments of the market

- Consistency –criteria and expectations regarding zero emissions buildings must remain fairly consistent from year to year to enable industry to focus on the desired outcomes and optimize their solutions by learning from prior projects

Underlying these principles is the understanding that market transformation does not begin to accelerate until leadership and innovation are supported; it is of paramount importance that effective tools to catalyze zero emission building leadership are made available as soon as possible, even if the catalyst program is not of sufficient initial scale or includes some imperfections. Early and visible success will attract not only participants but partner commitments and program details can be refined over time.

Note that while a catalyst program will be initially developed for zero emission new construction, consideration will be paid to the potential for expanding the partnerships and structures created to also deliver catalyst tools for deep building energy/emission reduction retrofits in the future.

5.2 Catalyst Approaches

Before describing possible catalyst tools (in Section 5.3) that will be considered for to reward private leadership, three general approaches have been identified and should be explored as standalone or a combination of options for each targeted building type.

A. Fixed Criteria: offering a benefit or reward for developers that commit to building to a specified set of criteria (such as Passive House). This approach is very useful when there is a high degree of certainty in viable and optimal outcomes as these can be clearly defined and there are no delays created in determining if a proponent qualifies.

B. Component Offers: offering a benefit or reward for building that utilize a defined building element such as a heat pump for domestic hot water or super-efficient windows. This approach has the benefit of generating high volumes of market demand and industry experience with a given technology to rapidly increase competition in its supply. Driving demand for key zero emission building elements can bring down the cost of a more complete building approach such as Passive House without limiting uptake to those proponents willing to make that full commitment. In addition, component offers can be structured to simultaneously support building energy or emissions retrofits when the same technology could easily be used in existing buildings.

C. Project Competition: offering a prize or benefit for winners of a call for projects competition assessed and judged against defined criteria. This approach can be very powerful when desired and potentially competing outcomes can be generally defined but when win-win solutions or the optimal balance between these outcomes requires testing and experimentation. This approach enables leading designers and builders to demonstrate what is possible (and what is not) to their industry peers and can be used to develop ground-tested, well informed policies with already built showcase projects.

As an additional benefit to this approach, competitions are inherently interesting to the public and would create an opportunity to engage and educate Vancouverites on the appeal and benefits of zero emission buildings. One notable disadvantage of this approach is that it can increase project timelines as proponents go through the call for competition submission, evaluation, and award process.

Brussel's BATEX Program

The Brussel's Region successfully partnered with their building industry to transition new buildings from amongst the least efficient in Europe to having all new residential and office buildings meet Passive House performance in just over seven years. This was achieved through the BATEX or Exemplary Buildings program.

BATEX offered a prize of up to 100 euros per square meter through 6 calls for projects judged to be of exemplary design and fit with their neighbourhood that achieved the highest levels of energy efficiency while remaining cost effective. The program aimed to stimulate innovation and demand for high performing buildings by encouraging private sector leaders to demonstrate what was possible and the best approaches for achieving these aims.

The BATEX program catalyzed private sector leaders to innovate and demonstrate to their peers as well as to the government how best to achieve multiple but clearly defined objectives. 243 projects representing over 6 million square feet of new development participated in the program over a period of seven years. BATEX built sufficient local industry confidence and capacity to deliver beautiful and high performing buildings to enable the introduction of effective legislation requiring all new buildings to achieve passive house performance levels beginning in 2015.

http://document.ibgebim.be/opac_css/elecfile/BRO_BE_Batex_EN_BR.pdf

5.3 Catalyst Tools

A wide range of tools are potentially available to the City to catalyze private leadership in demonstrating cost effective and attractive approaches to zero emission building. These should be explored in the context of the challenges and opportunities presented by specific building types and in consideration of the principles established in Section 5.1:

A. City Charges and Taxes: reducing or waiving City charges such as permit fees, development cost levies, or even property taxes would decrease the overall project costs and could be an effective tool to catalyze zero emission buildings. In considering these tools, administrative costs and the value of lost revenues will need to be addressed.

B. Expedited Permitting: developers and builders have indicated that decreased permitting times would reduce their costs and risks in a project and could be an effective catalyst tool. That said, this approach might be very complex and time consuming to establish as there are many steps to a permit approval and expediting each of these may be impractical; alternatively creating a whole new process could also be challenging especially for a time limited incentive program. In addition, large complex projects such as those going through a rezoning process involve complex back-and-forth negotiations which it may be difficult to expedite with certainty.

C. Public Benefit Negotiations: If the incremental costs for early adopters of Passive House or other zero emissions building approaches could be defined and taken into account when negotiating public benefit expectations for large new developments, the overall project costs and therefore the need for other catalyst tools would be reduced.

D. Parking Requirements: Below grade parking can be expensive to build and for small or unusually shaped sites, meeting the City's parking requirements can sometimes make development unviable. There may be opportunities to allow greater use of existing parking incentives such as those provided for additional bicycle parking or the provision of car sharing vehicles and parking for zero emission buildings.

E. Design Prize: A competition with a cash prize awarded for the winning submission for attractive, cost effective designs that effectively achieve near zero emissions for various building types could be a powerful catalyst tool. Design teams could be motivated by the offered prize and potential prestige to overcome design challenges. In addition designs could be made publicly available to showcase how to design zero emissions building and if the designs are flexible enough to be useful in a variety of contexts, they would reduce the overall cost of building a near zero emission building by avoiding the need for custom design expenses.

F. Exemptions to form of development and land-subdivision requirements: exemptions or partial relaxations of City requirements for land-division or form of development might be an effective catalyst with negligible negative impacts if carefully limited in scale and duration. For example, one builder recently offered to commit to build two Passive House certified homes if permitted to subdivide a 50' lot into two 25' lots (smaller than City standard sizing). In addition, design guidelines protecting neighbourhood character are developed to apply to an entire zoning area, typically in older single family neighbourhoods. These guidelines can result in very complex building shapes which make it more challenging and costly to build highly efficient envelopes such as those required to meet Passive House. A limited number of exemptions to these guidelines for early Passive House showcase buildings might be on avenue gain neighbourhood feedback on new, energy efficient building forms while learning what creative designers and builders can do to address neighbourhood fit.

G. Buildable Area: Allowing even modest amounts of additional buildable area for near zero emission buildings would be a very effective catalyst for private leadership. That said, doing so in an outright fashion would require extensive public engagement, could take a significant time to implement, and could lead to land speculation – a high cost for a temporary incentive. Enabling modest floor space exclusions at the Director of Planning discretion for passive design buildings or features might offer an opportunity to find an effective balance and create a catalyst for zero emission buildings.

5.4 Catalyst Tools for Targeted Building Types

5.4.1 Catalyst Tools - Detached and Row House Developments

The relatively small size and simplicity of detached and row housing make the scale and administrative ease of a permit discount program for early leaders in demonstrating near zero emissions building approaches like Passive House for these buildings viable and could be launched in the near future. For detached housing, it would be beneficial to explore the ideal balance between GHG reduction levels via envelope and simple mechanical solutions, cost, and neighbourhood fit. This form of development would be a good candidate for a design competition with a cash prize. Criteria for judging winners would include envelope performance, GHG reduction, replicability of solution (eg cost effectiveness), and neighbourhood fit.

Targeted technology incentives for domestic hot water heat pumps and highly efficient HRVs and windows may be complementary to the competition based approach. Given Vancouver's concurrent focus on supporting and piloting of incentives for detached home energy retrofits, targeted technology incentives might be supportive of both objectives and should be explored with other levels of government.

Additional opportunities to catalyze zero emission detached and row housing that need to be explored further include: limited and time bound relaxations to lot sub-division restrictions and neighbourhood design guidelines and/or expedited permitting (especially in outright zones).

Especially important in this sector are efforts to engage local builders from ethnic communities to inform the incentives offered for these building types to ensure universal appeal and access considerations are incorporated.

5.4.2 Catalyst Tools - Low-Rise MURBs

Low-rise (4-6 story) MURBs are an ideal building form for achieving Passive House. As this Plan recommends the 2020 update of the Green Building Policy for Rezoning's require these buildings meet the Passive House standard and given the body of global and rapidly developing local knowledge for how to cost effectively do so, catalyst tools for this form should be focused on meeting Passive House outcomes.

In addition to the catalyst tools to be explored for detached housing, the synergies demonstrated between Passive House and low-rise rental MURBs – both in built form and in the business case of their development, mean that opportunities for alignment between tools to catalyze zero emission buildings and the Rental 100 program need to be explored.

> ***Passive House MURBs Underway***
> *Presently there are 3 passive House Multi Family projects (comprising approximately 200 homes) under construction in Vancouver. In addition there are two multifamily projects in permitting comprising another 100 homes. Most projects are rental projects, with one market condo project and one market cohousing project.*

5.4.3 Catalyst Tools - High-Rise MURBs and Offices

Given the predominance of concrete and glass in the construction of high-rise MURBs combined with the limited amount of global data on the incremental costs, code barriers and constructability, establishing firm TEDI outcomes for zero emission buildings beyond those established for 2016 and 2020 will require additional research and pilot projects undertaken in partnership with private developers. A design competition to show case attractive, cost effective, near zero emission high rise building design approaches may be an important tool. In addition, understanding and proving out viable electric and heat pump solutions for domestic hot water in MURBs will be critical in order to achieve zero emissions for new MURBs by 2025.

Supporting early developer leadership will require tools to share in the risk and incremental costs of innovation. In addition to the tools to be described for detached housing, public benefit negotiations for high-rise towers may be a key tool in this sector.

Finally, while an envelope focused solution (beyond what is envisioned for the 2016 rezoning policy update) is less critical for the office sector to achieve zero emissions new buildings, it is also anticipated that the occupant comfort and productivity benefits combined with lower expected incremental costs of achieving Passive House envelope outcomes mean that a more modest incentive may be sufficient to catalyze leadership and innovation in this sector.

5.4.4 Catalyst Tools - Leadership on Special Sites

Some projects and sites in Vancouver present unique opportunities to demonstrate leadership in establishing neighbourhood renewable energy systems or building to Passive House performance outcomes. These are sites where, even though the City may not be leading the development, it is a key partner in the project moving forward or where environmental leadership (beyond general rezoning policy requirements) are already an expectation for the site. In these cases, the City should work collaboratively with the project developer to assess if there are mutually beneficial opportunities for developing the site to the Passive House levels or performance when an NRES is not viable.

Examples where there may be opportunities for the City to partner with a developer to demonstrate leadership might include:

- Vancouver Art Gallery
- Jericho Lands
- Some large development sites along the Cambie Corridor
- Etc

Even if the permitting and development of the site is still a number of years away, there are immediate benefits to committing to zero emissions leadership. Committing or establishing requirements to build to the Passive House standard for a large future development signals to industries such as window and prefabricated wall manufacturers that there will be a strong and ongoing local demand for high performance building products. Given that code and policy requirements will be evolving rapidly, early commitments such as these pose low risks given that by the time development occurs, bylaw or rezoning requirements may require near or zero emissions anyway.

5.4.5 Catalyst Tools – Financing Approaches

A key opportunity to catalyze developers of condominium projects to invest in meeting zero emission buildings before they are required to do so would be the creation of and/or increased use of innovative financing tools.

Smart investments in reduced energy use will pay for themselves over time. The challenge faced by condominium developers is that since they immediately sell the buildings they develop, they cannot recover their incremental capital costs spent on energy efficiency improvements through the resultant operating cost savings.

> ***Energy Efficiency Strata Loan for Condos with City Loan Loss Guarantee***
>
> *An energy efficiency loan program for new condos was first established in North America by the Toronto Atmospheric Fund (TAF) to overcome the energy efficiency split incentive. Condo developers in Toronto were previously unwilling to construct buildings that exceeded minimum energy standards because of the increased sale price due to higher construction costs and the resulting loss of competitiveness with other new developments. These barriers were overcome by TAF loaning the developer an amount equal to the incremental costs to construct a building that exceeds the building code energy performance by a specified percentage. The loan is assigned to the condominium home owners association to repay. Through energy modelling, the energy upgrade measures beyond code requirements were designed so that the monthly energy cost savings would exceed monthly loan repayment. Through marketing and the disclosure documentation required by law, potential buyers were made aware of the energy performance and the anticipated cost savings associated with the measures, as well as the loan that would be required to repay through their monthly condo fees. This tool holds significant potential for the voluntary construction of near zero emission condos in Vancouver, as it:*
>
> - *Removes the split incentive for energy efficiency in new construction;*
> - *Creates a clearer picture of energy costs for the buyer; and*
> - *Makes condo buyers able to afford a higher performing building for the purchase price of a code minimum alternative.*

Innovative tools exist where the incremental costs of efficiency are financed separately from the rest of the development costs. The loan for these costs is transferred to strata which repays this loan through a line item on the strata fees collected from owners.

Catalyst Tool ACTIONS

Developing and testing new design approaches, fostering the skills required to building to achieve zero emissions, and creating demand for new high performing building products to establish local production capability all require time. In order to require most buildings to achieve zero emissions by 2025, it is essential to begin providing catalysts for private sector leaders to demonstrate cost effective approaches to zero emissions building immediately. This will require catalyst tools for detached and row housing as well as multi-unit residential buildings, negotiations with developers of special sites with unique leadership opportunities, and the exploration of innovative financing tools as summarized by the following actions:

- Develop a program to provide catalyst tools such as design competitions, expedited permitting, permit fee reductions, or others for zero emissions detached and row house buildings targeting dozens of units per year for at least three years at which time the program should be reassessed
- Explore and recommend additional catalyst tools such as supplementary incentives for the Rental 100 Program for passive house low-rise multi-unit residential buildings targeting hundreds of units per year between now and 2020
- Explore and recommend catalyst tools for high-rise MURBs and office buildings structured to inform the ideal balance between high-performing building envelopes, renewable energy technologies, and cost effectiveness
- Engage developers of special sites in Vancouver to identify opportunities to develop these sites so that buildings achieve zero or near zero emissions

Explore and recommend required City actions to support the development and availability of innovative financing approaches for zero emissions or near zero emissions condominium buildings so as to decrease the need for other catalyst tools

6 Capacity Building

Designing and constructing near-zero emission buildings requires specialized knowledge and skills. To date, the local building industry has had limited experience in these types of buildings, particularly compared to our counterparts in areas of Europe. The local knowledge and skills that do exist are currently with a small group of early adopters who have pursued Passive House standards on a handful of very recent projects. Similarly, many Vancouver residents are unaware of zero emission buildings and the long-term benefits these buildings provide.

In order to rapidly transition to near-zero emission buildings in Vancouver, the capacity of the building industry will need to be increased. This means providing resources and training, encouraging knowledge-sharing and supporting peer-to-peer learning. Lessons learned by one designer can help another avoid similar pitfalls. Similarly, major energy savings realized on one project can be adopted by others to make similar gains. Capacity building will also include strengthening the relationship between the City and the building industry, with an emphasis on single-family-home builders to ensure that they are well supported with training and resources.

The following section outlines the recommended actions for rapidly increasing capacity in Vancouver's building industry to design, build and operate near-zero emission buildings. These actions recognize and build on the work already being done by various levels of government, industry associations, academic institutions and professional bodies. Many of the capacity-building actions recommended below will be delivered in partnership with other organizations.

6.1 Capacity Building - Generating knowledge

Near-zero emission buildings are already being built in Vancouver. These projects provide ideal quick-start learning opportunities. To maximize the learning potential, it's recommended that funding be offered to "early adopter" designers of near zero-emission buildings to produce written case studies that summarize their design methodology, design outcomes, successes and lessons learned on the project. Leading designers have told us they would be willing to "share their story" so that others can learn from them – replicating and building upon their successes and avoiding similar pitfalls. The specific terms of the case study would be refined through consultation with the design community, but would likely include design methodology, key design details (wall assemblies, mechanical equipment, etc.), challenges encountered, project costs, and modelled energy performance.

In addition to the written case study, designers will be required, as a condition of the design funding, to offer technical tours of their buildings and/or to present their project at a local knowledge-sharing conference or event. A technical tour is an ideal way for other architects, designers and engineers to see a zero emissions building first-hand and ask questions directly to the design team. This tour would look at the nuts-and-bolts of the building and would be geared towards peers in the industry. (Public tours of zero emissions buildings are discussed in Section 6.2).

Secondly, it's recommended that funding be provided to support the creation of new resource guides and training opportunities, to address industry-identified knowledge and skills' gaps. The production of resources such as reports, design details, and construction best practices, would be done through partnerships with existing organizations such as the Homeowner Protection Office, BC Hydro, the Architects Institute of B.C. The BC Construction Association, for example, has indicated that resources aimed at improving procurement practices would lead to more innovation and leading-edge construction. Similarly, this funding would support training that would be delivered through a partner organization (an example would be to offer subsidized rates for Canadian Passive House Institute's certification courses). While some knowledge and skills gaps are known today, it's expected that additional gaps will emerge as more designers and builders begin to tackle near-zero emission buildings. The case studies produced by designers will be specifically required to identify gaps.

Lastly, projects selected under the building incentive program will be required to provide post-occupancy energy performance reports, which will compare measured energy consumption with the modelled energy performance of the buildings. The energy performance report will include an audit, to identify the potential causes of difference between the modelled and actual performance. Through our consultation with the building industry, stakeholders identified actual building performance as a key knowledge gap today as virtually no publicly accessible post-occupancy monitoring information is available. The performance monitoring reports are intended to be public, though there may be some information that is private. The information gained through evaluating the operations of zero emissions buildings will be invaluable in determining if and when new design approaches are effectively in reducing GHG emissions and for refining design approaches going forward.

6.2 Capacity Building - Public Engagement

Stakeholders have told us that there is currently limited market demand for high-performance buildings, largely because of lack of awareness. Further, we've heard that there are persistent "urban myths" about the cost and performance of Passive House-like buildings. These urban myths persist in the public as well as amongst developers. A key piece of capacity building is therefore aimed at sharing information with the public about the real cost and performance of high-efficiency buildings, as well as promoting the other benefits of zero emissions buildings such as improved air quality, quietness and better temperature regulation.

As a condition of receiving design funding (Action 6.1.1), designers will be required to facilitate a public tour of their high-performance buildings. This tour will be geared toward the general public and not technical experts. The intent of the tour will be to showcase the aesthetic quality of the building, its high livability (quietness, natural temperature control, etc.) and its energy performance features.

A strong communication program is critical for engaging the public and raising awareness and demand for zero emissions buildings. Leading jurisdictions such as Brussels have implemented successful campaigns that featured regular high-profile zero emissions building ribbon cutting ceremonies, high-quality photography, glossy journals, and coffee table books to convey the aesthetic quality of Passive House buildings. These programs went beyond simply conveying information--they help build cachet around zero emissions buildings. It is recommended that a similar communications program be developed for the zero emissions building program, customized for the Vancouver market, which would include a variety of forms and mediums.

It's also recommended that innovative and aesthetically pleasing zero emissions buildings in Vancouver be recognized in both public and industry settings. This could be done in conjunction with existing building conferences and awards programs and/or through a dedicated Zero Emissions Award and Recognition Event. These showcases would provide opportunities to recognize leading developers, designers and builders. It would also raise the public profile of high-performance buildings (Wood Works BC's annual Wood Design Awards draws hundreds of attendees). These events could be coordinated to include public tours of the zero emissions buildings.

6.3 Capacity Building - Sharing knowledge

A key piece of the Zero Emissions Building Plan is ensuring that knowledge gained by early adopters is disseminated widely such that the capacity of the industry as a whole can be accelerated. It's particularly important to support designers and builders who in the past may not have been fully engaged. Single-family home builders, for example, will need new tools and training to successfully deliver zero emissions buildings. Focussing specific effort on these builders will mean a smoother transition and ultimately a more skilled workforce.

Peer-to-peer learning has been shown to be a one of the key ways to increasing knowledge in the building industry. For example, New York's Building Energy Exchange (BEEx), a non-profit created and partially supported by the City of New York, has helped build a strong green buildings' network in the city (focussed primarily on architects and designers) and facilitates ongoing peer-to-peer learning events and exhibitions. BEEx has become a hub for the zero emissions building industry in New York. Closer to home, Wood Works BC is a highly successful capacity-model with a strong educational and networking component. Over the past two decades, Wood Works BC has been particularly effective at identifying barriers to wood construction and working with stakeholders to remove those barriers.

Building on these successful models, it is recommended that a Centre of Excellence for Zero Emissions Building be established in Vancouver for near-zero emissions buildings. The Centre of Excellence will a central hub to disseminate case studies and resource guides, host panels and events, facilitate tours, share performance data from demonstration buildings, link with education partners to support and promote training, and identify barriers and knowledge gaps. The centre will serve as a neutral space where developers, designers, and builders can voice their concerns and work with City staff to resolve them. In this way, the centre will act as the "living room" for the local green building community, where relationships can be built. The Centre could also be used to deliver mission-related programs on behalf of the City and/or its partners. There is currently no such venue in Vancouver and this has been identified by stakeholders as a missing piece in the local green building industry.

The centre of excellence is envisioned as an independent entity focused on building industry capacity to design, build, and operate near zero emissions buildings. It would be supported by and serve a coalition of partners with a strong interest in transforming the building industry not just in Vancouver but across BC. A number of stakeholders including BC Hydro, BC Construction Association, Wood Works BC, SFU Properties Trust, BCIT, BC Housing, the provincial government and other local governments have expressed a strong interest in partnering with the City to create and support the ongoing success of a Centre of Excellence for Zero Emissions Building either through providing funding, sharing data, supporting programming and events, or partnering on training and resources. The Centre is expected to offer far-reaching benefits in terms of greenhouse reductions, education and skills training, and economic growth. The purpose, key roles, and organizational structure are outlined below.

Purpose

The Centre of Excellence for Zero Emissions Building will serve the building industry by compiling and sharing knowledge, identifying and facilitating the removal of barriers and building a community, with particular emphasis on groups that may not have been fully engaged in the past.

Key functions

The main functions of the centre of excellence for Zero Emission Building are as follows:

1. To provide a central source of information and resources, including case studies, performance monitoring reports, technical papers, and design details.

2. To ensure industry segments such as multicultural single-family home builders who often do not access new information and training through conventional means are engaged and supported in this transition.

3. To identify knowledge gaps and regulatory/permitting barriers to near-zero emissions building and work with partners to identify and implement solutions.

4. To serve a neutral space to facilitate dialogue between developers, designers, builders and the City and build relationship through networking events, panels, and exhibitions.

5. To showcase zero-emissions buildings to the public through a range of communications, tours, public space activations, and an annual awards event.

6. To administer mission-related programs, such as building incentive programs, on behalf of the City and/or partner organizations.

Organizational Structure

The Centre of Excellence for Zero Emission Building is envisioned as an independent entity accountable to dedicated board of directors for implementing its agreed-upon mission. Ideally, an existing third-party organization will operate the Centre of Excellence to minimize the start-up time required and to leverage existing organisational resources and staffing. The third-party organization will need to have a proven track record in delivering large projects, particularly in work related to sustainability and buildings, and be able to attract funding on an ongoing basis. The Centre will need a dedicated leader and several staff to administer the programming, serve as a knowledge hub, and ensure ongoing funding support. To this end, it is anticipated that an executive manager would be needed with training and experience in the field of architect and green buildings. This manager would oversee the operation of the Centre and guide the overall programming. It is anticipated that the Centre will need at least two additional staff with some background in the field of green buildings and strong communications skills. In order to ensure the centre is well managed, accountable for implemented it agreed to mission, and connected to key private and public sector partners, a separate board of directors or steering committee will be established. The board of directors or steering committee will include representatives from all major funding partners, as well as from key stakeholder groups.

The centre for excellence is intended to be a physical space. The space would provide office space for staff as well as exhibition space, to show green products and technologies related to near-zero emissions buildings as well as host training sessions, dialogues and networking events. Ideally the space would be able to accommodate speakers and small panel discussions. The physical space could be located within a building currently operated by a partner organization or in a building owned by the City. The space should be in a central located easily accessible by practitioners as well as the public (i.e., it should be visible).

In addition to a physical space, the Centre will have a comprehensive website, which will serve as a publicly-accessible repository for case studies, technical report, performance monitoring report and design details. The website would include a calendar of events and training, including courses offered by partner organizations such as AIBC, APEGBC, and HPO. In addition to the website, the Centre would include a variety of social media platforms to communicate with stakeholders and the public.

The organizational structure and financial model for the Centre of Excellence, including the physical space, staffing, board/steering committee, and funding sources, requires significant detailed planning. This planning will be done in partnership with key stakeholders over the next six months, at which time a detailed report will be brought back to Council for consideration.

NYC's Building Energy Exchange

The Building Energy Exchange (BEEx) was established in 2014 by the City of New York as a non-profit. The City provided seed funding and continues to provide office and exhibition space. BEEx currently has four full-time staff and is overseen by a board of directors made up of government and industry representatives and leading professionals.

Be-ex initially focused on lighting retro-fits but has since expanded to energy efficiency, specifically for commercial buildings larger than 50,000 square feet. They focus their capacity-building efforts on architects and designers as these professionals are involved in almost all projects..

Be-ex's capacity building work includes:

- *Hosting exhibits, panel discussions, speakers and networking events*
- *Serve as a resource hub for energy efficiency and lighting*
  - *Courses*
  - *Case studies*
  - *Technical reports*
- *Provide an online calendar of courses and training opportunities, many of which are delivered by partner organizations*
- *Act as a liaison between City and architects/designers*
- *Provide space for stakeholder engagement on City-led initiatives*
- *Establishing formal partnerships with industry stakeholders to share information and resources*

In a relatively short period of time, BEEx has established itself as a recognized hub for the local architectural and design community. They have built a sizable, engaged audience interested in near-zero emission and passive house buildings.

6.4 Capacity Building - Removing Barriers

Existing City of Vancouver regulations, policies, design guidelines, and requirements that establish expectations and requirements for new buildings can create challenges to building zero emission buildings.
For the past 5 years, the City has been working to identify and resolve barriers to higher performing buildings. One example was the provision of a wall thickness exclusion for highly insulated buildings so that they are not penalised with a loss of allowable building area. Recently Council approved amendments for detached houses in RS-1 zones (the majority of single family lots in Vancouver are in RS-1 zones) that provide the Director of Planning discretion to relax height and setback requirements for projects that achieve Certified Passive House to make use of the square footage gained from the wall thickness exclusion.

This approach must be expanded to other zones and building types as slightly thicker walls and higher roofs are required to provide highly efficient building envelopes.

More barriers have already been identified and more will emerge as the City and private sector leaders accelerate the development of near zero emission buildings. Resolving some of these barriers will be straightforward, such as accepting Passive House energy model results to show compliance with policy and bylaws while others will require the careful balancing of several public policy objectives.

Interdepartmental cooperation and accountability will be required to modify policies, bylaws and guidelines and create flexibility to resolve design challenges such as:

- Simple, cubic building forms are most energy efficient (and contribute to the ease of installing insulation and air barrier systems) but can conflict with step back, access to light, and "traditional character" requirements that increase building articulation and therefore roof and wall area as well as complexity
- Orientation for effective solar access and logical location of solar panel mounting can conflict with the form and material guidelines in some district schedules. The main conflict is where the guidelines speak to traditional roof forms and materials as seen from the street view, which may be the only aspect useful for solar installations.
- Policies that require builders to provide access to private outdoor space leads to the proliferation of cantilevered balconies which add cost and create complex heat loss challenges; alternative options for the provision of suitable private or semi-private outdoor spaces must be explored to balance affordability, sustainability and liveability outcomes.

Vancouver's Building By-law can also create barriers to zero emissions buildings. For example, the By-law requires a ducted kitchen exhaust from a range hood regardless of whether the range is gas or electric. In other jurisdictions, the use of a recirculating hood with charcoal filter paired with an electric range and a commissioned heat-recovery-ventilation unit is a permitted approach for maintaining indoor air quality. Similarly, the Bylaw considers wood buildings and some highly energy efficient window framing materials such fibreglass as to be fire hazards in buildings over 4-6 stories in height. There is growing a body of evidence that these materials can be safe if their use is properly regulated. Research into these challenges and alternate approaches is required to inform possible By-law changes.

Finally, the importance of City staff training on Passive House and zero emission building techniques and materials cannot be understated. Removing barriers in our regulations, policies and guidelines hinges upon City staff being able to understand this work and its intent, and feel comfortable implementing it.

Capacity Building ACTIONS

In order to successfully transition the majority of new buildings to zero emissions by 2025 while fostering the greatest opportunities for local economic development, it is essential that the City and other invested stakeholders work together to foster the capacity to design, build, permit, and produce components for zero emissions buildings. This will require investments to generate and share knowledge, increase public awareness, and to remove policy and permitting hurdles as summarized by the following actions:

- Provide funding for designers to prepare case studies and lead technical tours of zero emissions buildings
- Develop resource guides to document effective approaches to common challenges
- Invest in training programs for designers and trades
- Require post-occupancy performance evaluations of zero emissions buildings
- Organize opportunities for the public to learn about and experience the quality of zero emission buildings through the showcasing of beacon buildings, provision of public tours, and by making passive house units available for short term occupancy
- Establish a Centre of Excellence for Zero Emissions Building and website to foster the development and sharing of knowledge and skills regarding effective approaches to zero emissions buildings
- Identify and resolve City policy and process barriers to passive house and other near zero emission buildings
- Provide training and tools for City staff to facilitate permitting of zero emissions buildings

7 CONCLUSIONS

Meeting the City's 2050 target to use only renewable energy will require the majority of new buildings be designed and built to achieve zero emissions by 2025 and all new buildings to achieve this target by 2030. While meeting these aggressive targets and timelines is achievable, especially given that our electricity is almost 100% renewable already, it will require a restructuring of the City's policies and tools as well as leadership by the City and industry to demonstrate effective approaches for achieving this goal. It will also require a collaborative approach amongst many stakeholders to share knowledge, remove barriers, and ensure that the required skills are developed and widely available in BC.

This collaborative effort to transform how new buildings are designed and built will not only reduce their GHG emissions but will also make them healthier and more comfortable for their occupants. In addition, this innovation in the building industry will make buildings more resilient to changes in weather, climate and energy prices while providing significant opportunities for local professionals, trades, and industries.

Organizations Involved in the Development of the Zero Emissions Building Plan

Energy Utilities

- BC Hydro (cofounded research and consultation)
- FortisBC
- Creative Energy
- River District Energy

Industry and Professional Associations

- Urban Development Institute BC
- Greater Vancouver Homebuilders Association
- BC Construction Association
- Architectural Institute of BC
- Association of Professional Engineers and Geoscientists of BC
- International Building Performance Simulation Association – BC Chapter
- Fenestration Association of BC
- RealPAC

Public Sector

- BC Ministry Responsible for Housing, Building and Safety Standards Branch
- BC Ministry of Energy and Mines, Electricity and Alternative Energy Division
- Cities of Richmond, New Westminster, Surrey, Victoria, Burnaby, North Vancouver, New York, Seattle, and Brussels
- Metro Vancouver
- BC Housing and the Homeowners Protection Office

Non-Governmental Associations

- Pembina Institute
- Canadian Passive House Institute
- Building Energy Exchange (New York)
- Wood Works BC
- Canadian Green Building Council
- Lighthouse Sustainable Building Centre

Academic Institutions

- UBC
- SFU Community Trust
- BCIT

Consultant Team

- RDH Engineering

TIMES COLONIST

B.C. ferries will head to Poland for refits

Andrew Duffy / Times Colonist

March 25, 2016 06:01 AM

Spirit of Vancouver Island was built in 1994. Photograph By File, Times Colonist

With shipyards in Vancouver and Victoria both choked with work, B.C. Ferries will for the first time send vessels offshore for refits in 2017.

A Polish shipyard has won a $140-million contract from B.C. Ferries to conduct the mid-life upgrades of the two Spirit-class vessels.

Gdansk-based Remontowa, the largest ship-repair yard in Poland, won the contract after a competitive bidding process.

B.C. Ferries spokeswoman Deborah Marshall confirmed it is the first time the corporation has sent a vessel offshore for refit.

“But this isn’t just a refit, it’s a massive project, not the typical refit that we do,” she said.

The upgrades include converting the Spirit of Vancouver Island and Spirit of British Columbia to dual-fuel so that they can operate on liquefied natural gas in addition to diesel.

Both vessels will also have their safety features — marine-evacuation systems, rescue boats, fire-detection system, public-address system and fire-protection system — upgraded and their navigation and propulsion equipment renewed.

Passenger areas will also get an upgrade, with new designs, washrooms, expanded gift shops and new coffee bars.

Mark Wilson, B.C. Ferries’ vice-president of engineering, said during the last fiscal year, B.C. Ferries spent $118 million on diesel fuel, 16 per cent of which was consumed by the two Spirit-class vessels. “The conversion of the two largest ships in the fleet, along with the three new dual-fuel Salish-class vessels currently under construction, will go a long way to help with fare affordability for our customers, as LNG costs significantly less than marine diesel,” he said.

Wilson said the move will also reduce the corporation's environmental footprint, since using LNG in the two vessels will cut carbon-dioxide emissions by an estimated 12,000 tonnes annually.

Remontowa won the contract after being short-listed for the job alongside Seaspan's Vancouver Shipyard and another site.

Seaspan pulled out of the bidding process, however, since its three shipyards — Vancouver, Victoria and its drydock — are too busy to handle the work.

"We are at capacity at all three yards, and the National Shipbuilding Strategy work we are doing for the federal government is a major priority for us," said Seaspan Shipyards president Brian Carter in a statement. As part of that strategy, Seaspan is building new coast guard, fisheries and non-combat naval vessels.

The first ferry to be upgraded in Poland will be the Spirit of British Columbia, built in 1993. That work will start in fall 2017 and is expected to be completed in spring 2018.

The Spirit of Vancouver Island, built in 1994, will follow in fall 2018, with work expected to be completed in spring 2019.

Both vessels will sail to Poland and back under their own power, though B.C. Ferries will hire a professional ship-delivery company to crew the vessels.

Between 2007 and 2009, B.C. Ferries used Netherlands-based Redwise Global Ship Delivery to move the three Coastal-class vessels and the Northern Expedition to the Island from Germany.

The Spirit-class ferries will go through the Panama Canal, but Marshall said the precise route to Poland and back will be determined by the ship-delivery company.

Marshall said 45 days have been budgeted for the trip to Poland, which includes time to wait out bad weather. Temporary living quarters will be installed on both vessels to house B.C. Ferries staff and the ship-delivery crew.

Forward-Looking Information

Fortis Inc. ("Fortis" or, the "Corporation") includes "forward-looking information" in this presentation within the meaning of applicable Canadian securities laws and "forward-looking statements" within the meaning of the Private Securities Litigation Reform Act of 1995 (collectively referred to as "forward-looking information"). Forward-looking information included in this presentation reflects the expectations of Fortis management regarding future growth, results of operations, performance, business prospects and opportunities. Wherever possible, words such as "anticipates", "believes", "budgets", "could", "estimates", "expects", "forecasts", "intends", "may", "might", "plans", "projects", "schedule", "should", "target", "will", "would" and the negative of these terms and other similar terminology or expressions have been used to identify forward-looking information, which includes, without limitation: the expectation of regulatory stability in the near-term; the Corporation's consolidated and segmented forecast midyear rate base for 2017 and the period 2017 through 2021 and associated compound annual growth rate; targeted average annual dividend growth through 2021; the Corporation's forecast gross consolidated and segmented capital expenditures for 2017 and the period 2017 through 2021; the nature, timing and expected costs of certain capital projects including, without limitation, the ITC Multi-Value Regional Transmission Projects and 34.5kV to 69kV Conversion Project, the Central Hudson Gas Main Replacement Program, the FortisBC Lower Mainland System Upgrade and expansion to Tilbury 1A, the FortisAlberta Pole Management Program, and additional opportunities beyond the base plan including, without limitation, the Lake Erie Connector, the Wataynikaneyap Project and the pipeline expansion to the Woodfibre liquid natural gas site; the expectation that capital expenditures will exceed expectations; and the expected timing of filing of regulatory applications and receipt and outcome of regulatory decisions.

Forward-looking information involves significant risk, uncertainties and assumptions. Certain material factors or assumptions have been applied in drawing the conclusions contained in the forward-looking information. These factors or assumptions are subject to inherent risks and uncertainties surrounding future expectations generally, including those identified from time-to-time in the forward-looking information. Such risk factors or assumptions include, but are not limited to: uncertainty regarding the outcome of regulatory proceedings of the Corporation's utilities and the expectation of regulatory stability; no material capital project and financing cost overrun related to any of the Corporation's capital projects; sufficient human resources to deliver service and execute the capital program; the Board of Directors exercising its discretion to declare dividends, taking into account the business performance and financial conditions of the Corporation; risk associated with the impact of less favorable economic conditions on the Corporation's results of operations; no significant changes in laws and regulations that may materially negatively affect the Corporation and its subsidiaries; currency exchange rates and resolution of pending litigation matters. Fortis cautions readers that a number of factors could cause actual results, performance or achievements to differ materially from the results discussed or implied in the forward-looking information. These factors should be considered carefully and undue reliance should not be placed on the forward-looking information. For additional information with respect to certain of these risks or factors, reference should be made to the continuous disclosure materials filed from time to time by Fortis with Canadian securities regulatory authorities and the Securities and Exchange Commission. Fortis disclaims any intention or obligation to update or revise any forward-looking information, whether as a result of new information, future events or otherwise.

Unless otherwise specified, all financial information referenced is in Canadian dollars.

Fortis Today

- Leader in the North American regulated electric and gas utility business
- ITC provides strong platform in electric transmission sector
- Tremendous economic, geographic and regulatory diversity
- Recent regulatory outcomes provide stability for near term
- Visible growth provided by base 5-year capital program
- Pursuing several additional energy infrastructure opportunities
- Consistent dividend growth and superior long-term returns to shareholders

Our Strategic Focus Delivers Results

Strategy

Leverage the operating model, footprint of our utilities, operating expertise, reputation and financial strength to develop growth opportunities

Strategic Initiatives

- Execute Utility CAPEX Plan
- Target Additional Energy Infrastructure
- Increase Renewables
- Enhance Customer & Regulatory Relationships
- Unlock LNG Value
- Utility Acquisitions

ITC: Transformational Growth for Fortis

✓ Accretive to EPS

✓ Financing complete

✓ Integration on track
  - Minimal impact on day-to-day operations at ITC
  - ITC's new board of directors formed
  - Linda Apsey appointed President and CEO of ITC during Q4 2016
  - Joe Welch elected to Fortis' Board of Directors in 2017

ITC® A FORTIS COMPANY

Our Focused Strategy Continues to Yield Strong Results

- ✓ Focused on base growth while making prudent investments to provide safe, reliable and cost effective energy solutions to our customers
- ✓ Benefitting from the acquisition of ITC
- ✓ Maintaining constructive regulatory relationships:
  - UNS rate case settlement
- ✓ Highly executable, low risk capital plan remains on track

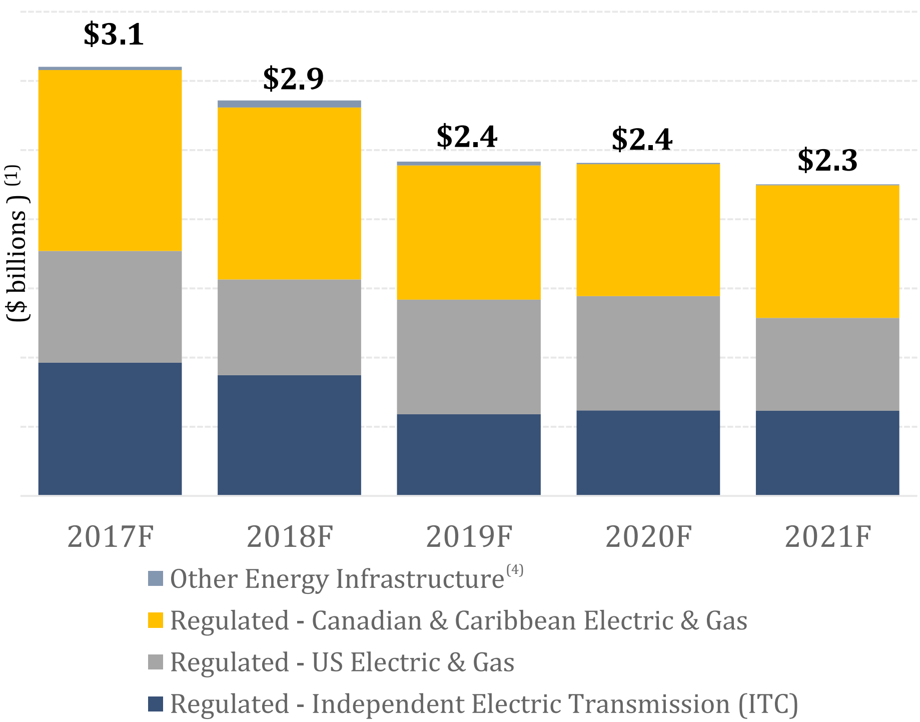
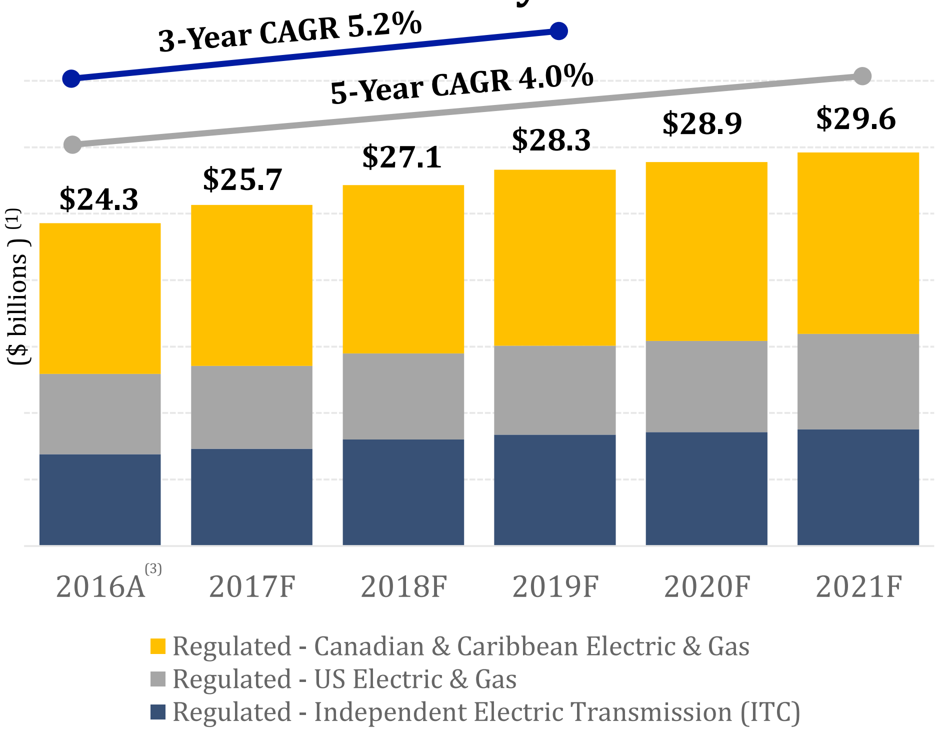
~$13B Five-Year Capital Program



2016 – 2021 Midyear Rate Base (2)



Midyear Rate Base Sensitivities	3-Year CAGR to 2019	5-Year CAGR to 2021
Capex at ~$3B for all years	+30 bps to 5.5%	+90 bps to 4.9%
Add $1 billion in rate base in the last year	+130 bps to 6.5%	+70 bps to 4.7%

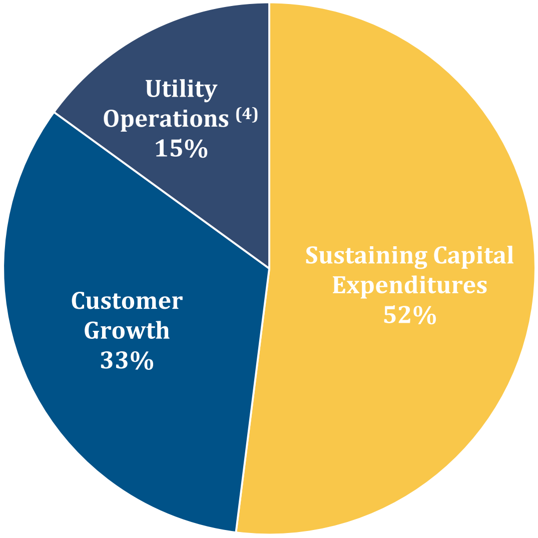
(1) US Dollar-denominated CAPEX and midyear rate base converted at a USD/CAD exchange rate of 1.30 for 2017 through 2021.
(2) Includes the impact of bonus depreciation and excludes construction work in progress.
(3) Reflects actual midyear 2016 rate base compared to the November 2016 forecast of $24.2 billion.
(4) Includes 100% of the Waneta Expansion, of which Fortis has a 51% controlling ownership interest.

Highly Executable Capital Plan

Major Capital Projects

$millions(1) (2)	Forecast 2017	Forecast 2018-2021	Total 2017-2021 Forecast
ITC Multi-Value Regional Transmission Projects (3)	305	244	549
ITC 34.5 kV to 69 kV Conversion Project	89	369	458
FortisBC Lower Mainland System Upgrade	200	182	382
Central Hudson Gas Main Replacement Program	33	169	202
FortisAlberta Pole-Management Program	43	53	96
FortisBC Tilbury LNG Facility Expansion – Tilbury 1A	65	-	65

5-Year Capital Forecast Spending



(1) Represents capital asset expenditures, including both the capitalized debt and equity components of AFUDC, where applicable.
(2) US Dollar denominated CAPEX converted at a USD/CAD exchange rate of 1.30 for 2017 through 2021.
(3) Consists of four separate multi-value projects to create a stronger connection within the Midwestern United States, improve transmission capacity and to connect wind energy.
(4) Includes facilities, equipment, vehicles, information technology and other assets.

Opportunities Beyond Base Plan

Beyond the Forecast: Development Project Update

FORTIS ONTARIO **Wataynikaneyap Power Project**	✓ Opportunity to connect remote First Nations communities in Northern Ontario to the grid ✓ In Q1 2017, the Ontario Energy Board issued its deferral account approval allowing recovery of spending that occurred since November 2010 ✓ Federal Government announced in August 2017 up to $60 million in funding to connect Pikangikum First Nation to the power grid with construction to commence in October 2017 ✓ Construction will begin following the receipt of permitting, approvals and a cost-sharing agreement between the federal and provincial governments
FORTIS BC **Woodfibre LNG**	✓ Potential pipeline expansion to the Woodfibre LNG export site ✓ Earliest expected in service date is late 2020
ITC A FORTIS COMPANY **Lake Erie Connector**	✓ Proposed 1,000 MW, bi-directional, high-voltage direct current transmission underwater line connecting the Ontario energy grid to the PJM energy market ✓ In May 2017, ITC completed the major permit process in Pennsylvania upon receipt of two required permits from the Pennsylvania Department of Environmental Protection, and in June approval was received from Canada's Governor in Council and the Certificate of Public Convenience and Necessity was issued by the National Energy Board

Poised to Deliver Quality Results

- On track to execute 2017 plan, supported by acquisition of ITC and reasonable rate case outcome at UNS
- Consistent dividend growth
  - 43 years of consecutive dividend increases
  - 6% average annual dividend growth guidance through 2021
- Highly diversified regulated utilities, focused on wires and gas businesses
- Highly executable, risk-adjusted base capital plan
- Regulatory stability
- Strong organic growth potential in existing businesses
- Track record of superior shareholder returns

Demand-Side Management Programs
2015 Annual Report

March 30, 2016

Table of Contents

List of Tables

1. REPORT OVERVIEW

FortisBC Energy Inc. (FEI or the Company)[1], is committed to delivering a broad portfolio of cost-effective Demand-Side Management[2] (DSM) measures that address the expectations of customers while meeting the requirements for public utilities to pursue cost-effective DSM[3]. In 2015, the company achieved a combined portfolio MTRC[4] of 1.2 on expenditures of $31.9 million, meeting FEI's goal of cost-effective program delivery.

This DSM Annual Report (the Report) outlines the Company's actual results and expenditures for 2015. The Report follows a similar format to the 2014 and other previous Annual Reports, relying on detailed tables to demonstrate Program results and expenditures. The Report compares 2015 activity and results to the Company's 2014-18 DSM Plan, as provided in the FEI's 2014-2018 Performance Based Ratemaking (PBR) Application and approved by the Commission in Order G-138-14. Where the details of individual programs vary substantially from the 2014-2018 Plan, explanations are provided in the applicable Program Area sections of this report.

1.1 Purpose of Report: Transparency, Accountability and Update on Progress

This Report details the Company's activities for the overall DSM portfolio and in each Program Area. Incentive and non-incentive expenditures are reported at the level of each program or measure, as well as at the program area and portfolio levels. Results for the following cost effectiveness test calculations are provided for the overall portfolio and each Program Area in Section 2, and for each program or measure in the respective Program Area sections: Total Resource Cost (TRC), Ratepayer Impact Measure (RIM), Participant Cost Test (PCT), and Utility Cost Test (UCT). In accordance with British Columbia's Demand-Side Measures Regulation, results of the modified TRC (MTRC) calculations (see Section 2.1) are also provided where appropriate.

This Report also demonstrates that the Company is meeting the accountability mechanisms directed by the Commission in Order G-36-09. One such mechanism was the requirement to file DSM Annual Reports, which states:

[1] The three BC Gas utilities formerly known as FortisBC Energy Inc. (FEI), FortisBC Energy (Vancouver Island) Inc. (FEVI) and FortisBC Energy (Whistler) Inc. (FEW) were amalgamated into a single utility - FortisBC Energy Inc. - in 2014. 2015 was the first complete year that the company operated as a single utility, which is reflected throughout this document by eliminating the breakout of separate FEI, FEVI and FEW statistics and results.

[2] Throughout this Annual Report the use of the term Demand-Side Management or "DSM" is intended to refer to demand-side measures in BC as defined in the BC Demand-Side Measures Regulation.

[3] BC Utilities Commission Act, Section 44.1 (2) and Section 44.1(8) (c), and BC Demand-Side Measures Regulation Section 3.

[4] Pursuant to the BC Demand-side Measures Regulation, the portfolio level MTRC is calculated based on costs and benefits of all programs in the portfolio as well as any program area and portfolio level administration costs, and including the benefit adders for those programs for which the MTRC is relied upon to determine cost effectiveness on an individual program basis (i.e. those programs that have been designated as being under the MTRC Cap as presented in Section 2.1 of this report).

A requirement that Terasen [now FEI] submit annually to the Commission, by the end of the first quarter following year-end, for each year of the funding period, a report on all [DSM] initiatives and activities, expenditures and results for TGI and TGVI.

1.2 Organization of the DSM Annual Report

The following describes how each section of the Report presents the results of 2015 DSM activities:

Section 1: Report Overview

- Provides a high-level background for the Report.

Section 2: Portfolio Overview

- Provides a summary and detail regarding the actual 2015 expenditures for DSM activities, along with an explanation of expenditures held in both the DSM deferral account and another deferral account set up for DSM incentive amounts provided to Alternative Energy Services ("AES") projects in which FEI is a participant.
- Section 2.5 discusses any new requirements from the Commission concerning information to be included in the 2015 DSM Annual Report.

Section 3: Funding Transfers

- Provides a discussion on funding transfers.

Section 4: Energy Efficiency and Conservation ("EEC") Advisory Group Activities

- Provides information regarding EEC Advisory Group ("EECAG") activities in 2015, including a summary of meetings and accountability considerations.

Sections 5 - 9 provide information on:

- Residential Energy Efficiency Program Area;
- Low Income Energy Efficiency Program Area;
- Commercial Energy Efficiency Program Area;
- Innovative Technologies Program Area; and
- Industrial Energy Efficiency Program Area.

Each of the above mentioned sections contain a table summarizing the planned and actual expenditures for the respective Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost-effectiveness test results. Additional tables outline the individual 2015 programs, including program and measure descriptions, program assumptions and sources for these assumptions, and a breakdown of incentive and non-incentive spending. Where applicable, details on program closures or planned programs that were not launched in 2015 are also included in these program detail sections.

Section 10: Conservation Education and Outreach Initiatives

- Provides both a summary and details regarding actual 2015 expenditures for the Conservation Education and Outreach ("CEO") Program Area.

Section 11: Enabling Activities

- Provides both summary and detail regarding actual 2015 expenditures for the Enabling Activities that support the work of the DSM portfolio as a whole.

Section 12: Evaluation

- Provides both summary and detail regarding pending and actual expenditures for 2015 program evaluation activities, as well as summary results from evaluations and studies completed in 2015.

Section 13: Data Gathering, Reporting and Internal Controls Processes

- Provides a summary of the Company's data tracking, process control and reporting for 2015 DSM activities, and a high level description of the Company's internal approval process for programs.

Section 14: 2015 DSM Programs Annual Report Summary

- Summarizes the Report and the Company's 2015 DSM activity.

2. PORTFOLIO OVERVIEW

In this Section, FEI provides its DSM energy savings, expenditures and cost-effectiveness test results at an overall portfolio level for 2015. A summary of the overall portfolio results is provided in Table 2-1, demonstrating that the Company achieved a combined portfolio MTRC of 1.2. DSM expenditures were almost $32 million and recorded natural gas savings were over 434,000 GJ.

Table 2-1: Overall DSM Portfolio Results for 2015

Annual Gas Savings (GJ/yr.)		434,550
NPV of Gas Savings (GJ)		3,238,526
Utility Expenditures, Incentives ($000s)		20,976
Utility Expenditures, Non-Incentives ($000s)		10,889
Utility Expenditures, Total ($000s)		31,865
Benefit/Cost Ratios	TRC	0.7
	MTRC	1.2
	Utility	0.9
	Participant	2.3
	RIM	0.3

Table 2-2 provides the cost-effectiveness test results by Program Area for the overall DSM portfolio.

Table 2-2: Overall DSM Portfolio Level Results by Program Area - 2015

Portfolio Level Results

Portfolio	Annual Gas Savings (GJ/yr.)		NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios

Notes:

- Portfolio Level Activities are those activities for which the costs cannot be assigned to individual DSM programs. It should be noted that these activities are distinct from the Enabling Activities specifically listed in Section 9 of the 2014-18 Plan. These distinct Portfolio Level Activities include expenditures such as EECAG activities, DSM Energy Solutions Managers, portfolio level staff labour, staff training and conferences, research and association memberships, portfolio level research studies, and regulatory work including consulting fees .

Throughout this Report, the following general notes also apply to all the program areas:

- In the above table, and in tables throughout the report, any difference in the totals between the Portfolio Overview, Program Area, and individual program tables is due to rounding. Some "zero" values are a reflection of rounding to the $000 expenditure level when expenditures were under $500.
- A "Non-Program Specific Expense" line item has been included for each program area. These expenditures represent the costs attributable to that program area but support multiple programs and, therefore, are not specific to only one program. Generally, these expenditures represent items such as training, travel, marketing collateral and consulting services that support the overall program area.

It is FEI's view that, as with prior annual reports, the savings reported herein continue to be conservative and lower than the savings experienced in the marketplace as a result of the Company's DSM activities, causing the cost-effectiveness test results reported to be lower than they would be otherwise, for the following reasons:

- <u>Net to Gross Ratio</u> - The Net-to-Gross ratio that FEI is using to report energy savings from DSM activity is highly conservative in that it includes the free ridership impact, which serves to reduce reported energy savings, but in most cases does not include the energy savings benefits of spillover[5] effect. FEI intends to continue identifying and incorporating spillover effects into reporting of energy savings impacts from DSM activity on a program-by-program basis, wherever spillover can be supported.
- <u>Attribution from Government Regulation</u> – the introduction of many municipal, provincial and federal minimum equipment and system performance standards is supported by the Company's DSM activity. Until 2014 when FEI claimed energy savings from the Residential New Home Program, the Company had not historically claimed any energy savings from the implementation of these standards. FEI will not be claiming any such energy savings in 2015. The Company continues to believe the claimed savings are conservative and do not represent all of the savings attributable to FEI's codes and standards work. FEI will continue to look for opportunities to claim energy savings from the implementation of these standards.
- <u>Conservation Education and Outreach</u> – CEO activities had expenditures of $2.8 million in 2015. These activities do result in energy savings; however, since these savings remain difficult to quantify, FEI does not currently attribute energy savings to them. Thus, these benefits are not reflected in the TRC. FEI continues to explore approaches to determining energy savings from CEO activities and may account for these energy savings in the future.

[5] Free ridership refers to individuals who participate in a program who would have participated in the absence of an incentive. Spillover refers to individuals that adopt efficiency measures because they are influenced by program-related information and marketing efforts, though they do not actually participate in the program. These can be included in the Net-to-Gross ratio employed in the cost-effectiveness analysis to capture the additive effects of spillover to balance the reductive effects of free ridership.

- Enabling Activities – Enabling Activities similarly had expenditures of $1.2 million in 2015 for work that contributes to energy savings but that cannot currently be quantified. Since these savings are not included in the portfolio TRC calculation, FEI believes the portfolio energy savings benefits are higher than reported.

FEI's DSM activities include a number of specified demand side measures. The *Demand-Side Measures Regulation* defines "specified demand-side measure" as:

a) a demand-side measure referred to in section 3 (c) or (d),
b) the funding of energy efficiency training,
c) a community engagement program,
d) a technology innovation program, or
e) financial or other resources provided
   i. to a standards-making body to support the development of standards respecting energy conservation or the efficient use of energy, or
   ii. to a government or regulatory body to support the development of or compliance with a specified standard or a measure respecting energy conservation or the efficient use of energy in the Province;

Specified demand side measures within FEI's portfolio include the Innovative Technologies programs (see Section 8), education and community engagement programs (see Section 10), and Codes and Standards related DSM activity (see Section 11). The *Demand Side Measures Regulation* defines how the Commission must consider these specified measures. Section 4(4) of the *Regulation* stipulates that the cost effectiveness of specified measures must be determined by the cost effectiveness of the portfolio as a whole. These measures are therefore not subject to the 33% 'MTRC Cap' (see Section 2.1). Additionally, these measures cannot be determined to be "not-cost effective" under the Utility Cost Test.

In summary, FEI's 2015 DSM expenditures, including specified DSM, were cost-effective under the BC *Demand-Side Measures Regulation*.

2.1 Portfolio Level MTRC Calculation and Results

In 2015, FEI met the conditions of the Province's *Demand-Side Measures Regulation*, achieving a portfolio MTRC value of 1.2 with 32 percent of the portfolio enabled by the MTRC cost-effectiveness test. While FEI strives for TRC test results that approach or exceed 1.0 within each program and across all programs, there are benefits to implementing programs that do not meet this threshold. Some of these benefits include making programs available to those customers that would otherwise be underserved (such as low income and residential customers), water savings, increased human health and comfort, and economic benefits such as job creation. These benefits were recognized in 2011 and 2014 amendments to the *Demand-Side Measures Regulation*, which enable the use of an MTRC in determining program and portfolio cost effectiveness. The MTRC uses the long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia as a proxy for the avoided cost of energy and allows for the inclusion of non-energy benefits (NEBs).[6]

Utilities can implement natural gas DSM with TRC values less than 1.0 but that meet an MTRC threshold of 1.0 as long as expenditures on these activities do not exceed 33 percent of the total portfolio expenditure. FEI refers to this 33 percent as the “MTRC Cap”. Table 2-3 shows both the TRC and MTRC of those programs with measures to which the MTRC cost effectiveness test is applied, along with the expenditures[7] related to those measures. Table 2-2 shows that the overall portfolio MTRC is 1.2 in accordance with the *Demand-Side Measures Regulation* and the Commission’s approval to assess cost effectiveness on an overall portfolio basis[8].

Table 2-3: Programs with Measures Subject to MTRC and Proportion of 2015 Portfolio Spend

Program	Program TRC	Program MTRC	Expenditure ($000s) subject to cap	% of Portfolio Spending
EnergyStar Domestic Hot Water	0.4	1.5	2,448	7.7%
Furnace Replacement	0.5	1.4	3,528	11.1%
Domestic Hot Water Conservation * Program / Low Flow Fixtures	2.2	n/a	73	0.2%
EnerGuide 80 New Construction	0.4	1.5	1,296	4.1%
Energy Efficiency Home Performance (HERO)	0.4	1.4	1,709	5.4%
Energy Conservation Assistance Program (ECAP)	0.5	1.8	1,015	3.2%
Total			**$10,069**	**31.6%**

2.2 Meeting Approved Spending Levels

The Company’s DSM expenditures were within the approved levels. FEI filed its 2014-2018 Performance Based Ratemaking (PBR) Application with the British Columbia Utilities

[6] The BC *Demand Side Measures Regulation* was amended in July, 2014 by allowing for the whole cost of the long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia to be used as a proxy for the avoided cost of natural gas in the MTRC cost-effectiveness test. As the DSM Regulation stipulates, the value that the FEI has used for the avoided cost of gas in the MTRC calculation is $100/MWh, or $27.78/GJ, as indicated in BC Hydro’s November 2013 Integrated Resource Plan, Section 9.2.12, “Long Run Marginal Cost” (pgs. 9-51 to 9-55).

[7] The expenditures listed in Table 2-3 are associated with those measures within each program that do not pass the TRC and therefore to which the MTRC avoided cost of energy and NEBs apply when calculating the MTRC portfolio cost effectiveness test. For this reason, expenditures in Table 2-3 may differ from total program expenditures listed elsewhere in this report.
* *The Energy Star Washers and Dryers that are part of the Domestic Hot Water Conservation / Low Flow Fixtures program have individual measure TRC values of 0.6 and 0.4 respectively*.

[8] The Commission approved the assessment of the cost effectiveness using an MTRC of 1 or greater on an overall portfolio basis as part of its decision on the 2012-2013 RRA Decision, Order No. G-44-12, page 174. While this approval is not explicitly stated in the PBR decision (Order No. g-139-14), FEI interprets this approval to be implicit in the approval of the 2014-2018 DSM Plan.

Commission (the Commission) on June 10, 2013. As part of the PBR Application, FEI requested acceptance, pursuant to section 44.2 of the *Utilities Commission Act* (*UCA*) of an expenditure schedule for Energy Efficiency and Conservation expenditures from 2014 to 2018. The Commission approved the PBR application on September 12, 2014 including a 2015 DSM expenditure limit of $36.5 million[9].

In the 2014-2018 PBR application, FEI proposed to maintain the 2012–2013 approved approach that only $15 million of the requested annual DSM budget be added to the DSM rate base each year of the PBR period, with any additional DSM spend being captured in an DSM non-rate base deferral account attracting AFUDC. FEI requested approval to transfer any new amounts accumulated in the non-rate base DSM deferral account to FEI rate base DSM deferral account in the following year. This included approval to transfer the balance in the non-rate base DSM incentive deferral account as of December 31, 2013 to the rate base DSM deferral account on January 1, 2014. In the 2014-2018 PBR Application, it was proposed that the amounts will be amortized over 10 years beginning in 2014 in accordance with the existing approved amortization period for the DSM rate base deferral account. In its decision, the Commission Panel approved FEI's request to (i) continue the DSM accounting treatment approved for 2012–2013 and, (ii) to transfer any new amounts accumulated in the non-rate base DSM deferral account to FEI rate base DSM deferral account in the following year. In accordance with this decision, $16.75 million was transferred to the non-rate based DSM deferral account in 2015.

FEI notes a small difference in the total DSM rate base ($15 million) plus non-rate base deferral account amount ($16.75 million) versus the total 2015 expenditures ($31.87 million) reported in Tables 2-1 and 2-2. This difference is due to some program activity that occurred in late 2015 but for which the payments were not processed prior to the 2015 year-end.

FEI has managed its 2015 DSM activity within the funding limits approved by the Commission. Section 3 discusses funding transfers between program areas in 2015 within the overall DSM funding envelope and within rules for transferring funds between program areas as set out by the Commission.

2.3 DSM Incentives for AES/TES Projects

Commission Order G-44-12 directed FEI to hold all DSM incentives that are provided for Alternative Energy Services (AES) or Thermal Energy Services (TES) technologies for projects in which the FEI is a participant in a separate deferral account. Up until 2015, FEI reported on the amounts being added to this deferral account in its DSM Annual Report. In 2015, by Order G-86-15, the Commission approved both the transfer of these amounts to the rate base deferral account and the discontinuation of the AES/TES deferral account. As such, FEI will no longer be reporting on these amounts.

[9] BCUC Order G-138-14, page 277 of the Decision.

2.4 Meeting Adequacy Requirements of the Demand-Side Measures Regulation

The *Demand-Side Measures Regulation* has the following requirements for a utility's portfolio of DSM activity to be considered adequate:

> A public utility's plan portfolio is adequate for the purposes of Section 44.1 (8) c of the Act only if the plan portfolio includes all the following:
>
> a) A demand-side measure intended specifically to assist residents of low-income households to reduce their energy consumption;
> b) If the plan portfolio is introduced on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;
> c) An education program for students enrolled in schools in the public utility's service area;
> d) If the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area.

FEI has met all the requirements for adequacy. There are a number of programs for low income customers, which are discussed in their own section (see Section 6). Although there are a number of Commercial and Low Income energy efficiency programs intended for use by owners of rental buildings, including the Energy Specialist Program (see Section 7), FEI applied and received approval for the Rental Apartment Efficiency Program (RAP) pursuant to Commission Directive 148 from the 2014-2018 PBR decision, Order G-138-14. That order required FEI to file one or more DSM programs intended specifically to address the unique market barriers to energy efficiency faced by renters. The RAP program, launched in late 2015, spans both the Residential and Commercial Program Areas. The expenditure details for RAP are presented and discussed in each of the respective Program Area sections (Sections 5 and 7) and a full program overview for RAP is presented in Section 7.2.1.

In terms of education programs, FEI's School Education Program, Commercial and Residential customer education programs and other energy efficiency and conservation outreach initiatives are presented in Section 10.

2.5 Addressing BCUC Directives from the FEI 2014-18 Performance Based Ratemaking Decision

FEI filed its 2014-18 EEC Plan and associated funding request to the BCUC with the FEI 2014-18 Performance Based Ratemaking Application. There were a number of Commission directives from that Decision that are specific to the 2014-18 EEC Plan. Many of these directives were required to be addressed in the 2014 Annual Report and as such do not need to be addressed again in this or subsequent Annual Reports. In this section, FEI addresses the BCUC directive regarding labour costs that applies to the overall 2015 DSM Portfolio. Program specific directives are addressed in the applicable program area sections of this report.

2.5.1 LABOUR COSTS

The Commission Panel directed FEI to allocate 'labour costs coded to DSM' to its DSM programs during the 2014-2018 expenditure approval period, with the exception of costs related to Evaluation, Measurement & Verification.

As with the 2014 Annual Report, FEI has included labour cost coded to each DSM program in the reported "Administration" expenditures for each program. This information is included in the specific Program tables included in each DSM Program Area section of this report (Sections 5-11). FEI Notes that while the 2014 – 2018 DSM Plan was approved by the Commission as set out in FEI's application, program and program area costs were not re-cast with labour included at the program level. This change therefore impacts the direct comparison of actual program and program area spending to planned spending. The inclusion of Labour costs at the Program level can cause program area expenditures to appear higher than the approved amounts even though non-labour costs are within approved amounts. Actual spending in the "Enabling Activities" program area will also be lower than planned since a substantial amount of labour costs planned for this program area are being reported within other program areas. This issue is also discussed in Section 3 on funding transfers.

2.6 Collaboration & Integration

FEI continues to collaborate and integrate DSM programming among BC's largest energy utilities, as well as with other entities such as governments and industry associations. The Company recognizes that doing so will maximize program efficiency and effectiveness. Collaborative activity is captured in the individual Program Area sections and program descriptions found in Sections 5 through 11.

FEI and BC Hydro continued to expand on their program and project collaborations through their voluntary Memorandum of Understanding (MOU), the purpose of which is to develop enhanced utility integration in support of government legislation, policy and direction. The two utilities agreed to extend the MOU for a further three year period covering August 2015 through August 2018. In 2015, the electric utility FortisBC Inc. (hereafter referred to as FBC) also joined the collaboration and signed the MOU.

FEI and BC Hydro again conducted a joint review of incremental cost efficiencies created as a direct result of the partnership over the April 1, 2014 to March 31, 2015 time period (BC Hydro fiscal year). This review examined the costs incurred for each program and project collaboration that was in place over that time period and determined that FEI and BC Hydro combined had total incremental cost efficiencies of approximately $5.4 million as a result of working together. FEI, FBC and BC Hydro also continue to experience additional benefits from their collaboration efforts, including streamlined application processes for customers, extended program reach and consistent and unified messaging resulting in improved energy literacy.

2.7 Summary

FEI's DSM portfolio met the goal of cost effectiveness with a MTRC value of 1.2 in 2015. The Company is of the view that both energy savings accounted for in the portfolio and the resulting TRC are conservative. Benefits from additional activities, such as CEO, play a very important role in supporting the development and delivery of programs, while creating a culture of conservation in British Columbia. FEI expects that with a more complete approach to the Net-to-Gross ratio, the incorporation of energy savings from CEO and with the recent changes to the Demand-Side Measures Regulation, the DSM portfolio will be continue to be cost effective.

3. FUNDING TRANSFERS

Two Program Areas – Residential and CEO – incurred actual program expenditures that were greater than their respective approved Program Area funding amounts[10]. In the case of CEO, exceedance of the approved Program Area funding level was the result of reporting labour expenditures at the program level as directed by the Commission[11]. The approved 2014 - 2018 EEC Plan was based on labour being reported at the portfolio level, and planned Program Area expenditure levels were not re-cast subsequent to the Commission's decision regarding the reporting of labour costs. Therefore, the approved Program Area funding limits do not include labour. Since the expenditures for CEO as shown in Table 2-2 include labour, and since the approved CEO funding level would not be exceeded if labour costs were removed, no funding transfer is required.

For the Residential Program Area, expenditures other than labour costs exceed the approved funding level by $1,241,000 as a result of the success of the residential programs. To accommodate these additional expenditures in the Residential Program area, $827,000 of available funding within the Commercial Program Area and $414,000 of available funding in the Industrial Program Area have been transferred to the Residential Program Area. None of these amounts exceed 25% of the respective program area approved funding levels[12].

[10] Order G-138-14.
[11] Directive 145, Order G-138-14
[12] According to Directive 151, Order G-138-14, funding transfers in excess of 25% of program area approved funding levels require prior approval from the Commission.

4. EEC ADVISORY GROUP ACTIVITIES

4.1 Overview

The Energy Efficiency and Conservation Advisory Group (EECAG) provides insight and feedback on FEI's portfolio of DSM activities and related issues. This includes: DSM program and portfolio performance, development and design; funding transfers; policy and regulations that may impact DSM activities; and other issues and activities as they may arise.

Members may be appointed based on their relevant subject matter expertise, representation of a common interest shared by stakeholders, or representation of a particular organization/group and/or interest. This includes, but is not limited to, governments, regions, First Nations organizations, customers, suppliers, industries, non-governmental organizations, research institutes and other groups that have historically intervened in the FEI's regulatory proceedings.

Since the formation of the EECAG in 2009, FEI has had the opportunity to gain valuable insight on DSM program design and implementation and develop positive working relationships with stakeholders. EECAG input continues to be instrumental as FEI moves forward with DSM activities, helping to ensure that efforts are aligned with the interests and suggestions of stakeholders.

4.2 Summary of the 2015 Workshop

EECAG workshops provide a forum for stakeholders to learn about DSM programs and engage in constructive dialogue with FEI. Since FEI was in the second year of an approved plan for DSM activities and because both the regulatory framework and market dynamics for DSM programming has remained stable during this time, a single workshop in 2015 was sufficient to update EECAG members and seek their input on programming issues. The EECAG workshop was held on November 4th in Vancouver and was well attended by EEGAG members or their alternate delegates. The EECAG Independent Facilitator was engaged in workshop design and facilitation of the workshop. Copies of materials and minutes for these meetings were distributed to EECAG members and other workshop attendees.

At the November workshop, FEI provided:

- Program area updates and highlights for 2015;
- An update and discussion on the Conservation Potential Review, an in-progress study being undertaken to examine available technologies and determine their conservation potential, which includes the amount of energy savings that can be achieved over the study period for each of the four largest utilities in BC (FEI, FBC, BC Hydro and Pacific Northern Gas);
- An overview of newly approved programs and an Innovative Technologies Pilot project (Condensing Make-up Air Unit Pilot);

- Plenary sessions, led by the independent facilitator, to discuss two specific issues that FEI is currently experiencing in its DSM programming and gather feedback from the group on potential solutions:

    1. Claiming and accounting for energy savings from Conservation, Education and Outreach (CEO) activities that encourage the implementation of energy efficiency measures or that change behavior to conserve energy use.

    2. The application of measurement and verification (M&V) approaches to industrial projects to address the challenge of high M&V costs and administrative burden on smaller industrial projects.

- An opportunity for EECAG members to share their own initiatives and insights on energy efficiency and conservation efforts in their own organizations or areas of influence.

With respect to the plenary sessions, the following key discussion points and feedback were raised:

CEO Activities:

FEI believes that CEO activities do result in energy savings, however, the majority of these savings are difficult to track and report since they are often behavioral in nature and involve events where energy efficiency messaging is delivered to large audiences with no way to track the subsequent energy consumption behavior of each individual. In this session, FEI presented three CEO initiatives (in-store rebates, Empower Me Energy Savings Kits and employee promotions) for which activity could be tracked and a conservative estimate of savings developed.

EECAG members were generally in favour of identifying and claiming the savings for these three initiatives where good data exists with which to determine the savings. A number of ideas for additional information sources on tracking and calculating savings on behavioral programs were offered by group members. FEI explained that they were seeking a summer student to further explore methodologies for determining behavioral energy savings. Such savings have not been claimed for 2015 but may be claimed in future annual reports.

Industrial M&V Approach:

A review of the industrial market segment and industrial programming was provided to EECAG members along with a refresher on M&V practice as it currently applies to FEI's Industrial Optimization program. FEI staff explained using examples that M&V costs are currently very similar across projects at around \$20,000 (external, 3rd party costs based on projects completed to date) and typically require a similar level of effort, regardless of the magnitude of natural gas savings or cost of the project. For smaller projects, this level of cost and effort could cause a project to fail current cost effectiveness tests and therefore be a barrier to implementing energy efficiency measures. FEI sought feedback from the EECAG on alternatives to the current M&V approach to industrial projects.

EECAG members sought clarification on the types of projects supported by industrial DSM incentives, variables contributing to the level of confidence in M&V results and savings persistence. Members also put forward ideas on how to reduce M&V costs for smaller projects. A range of approach suggestions and a few examples from industrial customers were provided by EECAG members for consideration by FEI. Scaling M&V practices based on project size, project savings and/or the level of risk inherent were common themes.

In addition to the plenary feedback sessions discussed above, FEI and EECAG members discussed the following key points throughout the workshop:

- FEI continues to maintain good relationships with the contractor community, and is now expanding industry relationships to include equipment manufacturers and distributors.
- Members would like to receive a mid-year update on annual portfolio progress.
- Members are interested in what role the utility could play on regulatory and building code compliance.
- Members would like to see more focus, if possible, on behavioral programs in the CPR study than there has been in past studies.
- It was clarified that the CPR does not make recommendations on program design such as identifying more low income programs, but rather examines available measures and their cost effectiveness which becomes an input into utility program design.
- The benefits of reaching out to renovators as well as contractors in the residential market in order to improve program awareness and energy literacy.
- The potential benefits of and barriers to deeper retrofits in the residential sector.
- The idea of developing a repository of energy efficiency technologies, housed at an educational facility.

To close the workshop, members discussed a range of initiatives and studies related to energy efficiency and conservation that are being taken by their own organizations or members. A number of follow up action items were identified and included in the workshop minutes for follow-up by various parties.

4.3 Feedback & Lessons Learned

In addition to input on specific topics presented, EECAG members are encouraged to provide general feedback on the workshops, membership or any other issues. This feedback is typically voiced during the workshops or submitted to FEI via evaluation forms distributed at each workshop. The results from these evaluation forms are compiled and all comments are considered when planning future workshops.

In an ongoing effort to improve EECAG interaction, results from feedback are considered in collaboration with the EECAG Independent Facilitator, to help design future EECAG sessions and workshops. Feedback received during the 2015 workshop indicated that adjustments made to the workshops based on prior feedback were helpful and that degree of consultation in 2015 was appropriate. FEI's efforts to share with EECAG members how their input was being used was appreciated and a good balance has been struck between providing informational sessions and facilitating sessions designed to obtain feedback on important topics.

5. RESIDENTIAL ENERGY EFFICIENCY PROGRAM AREA

5.1 Overview

The Residential Energy Efficiency Program Area was successful in reducing annual natural gas consumption by 121,000 GJ and achieving an overall TRC/MTRC of 1.5. Over $12.7 million was invested in Residential Energy Efficiency upgrades in 2015, and 82 percent of this investment was customer incentive spending.

Table 5-1 summarizes the projected and actual expenditures for the Residential Energy Efficiency Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC/MTRC and other cost-effectiveness test results.

Residential programs serve over 870,000 homes in the FEI service territories. For DSM purposes, these customers predominantly include end-use customers living in residential single-family homes, row houses, townhomes or mobile homes.[13] Some in-suite measures in Multi-unit residential buildings ("MURBS") are also included in this funding envelope. These measures may include low flow fixtures and a small number of fireplaces and water heaters in MURBS or individually metered units. Residential programs serve retrofit and new home applications. In combination with FEI's education and outreach activities, these programs play an important role in driving the culture of conservation in British Columbia.

Table 5-1: Residential Energy Efficiency Program Area Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios

[13] Programs for Multifamily Dwellings served under Rate Schedule 2 or 3 are included in the Commercial Energy Efficiency Program Area (please refer to Section 7) with a few exceptions as noted in text.

Notes:

- ∗ The Rental Apartment Efficiency Program (RAP) includes a combination of residential and commercial measures, each funded from their respective Program Areas. The *Residential Portion* details of this program included in Table 5-1 shows only those Residential Program Area expenditures. These expenditures are associated with the direct install of residential fixtures, and a portion of the communication and evaluation costs. Commercial Program Area expenditures that are part of RAP are presented in Tables 7-1 and 7-10. Cost effectiveness values for only the *Residential Portion* of RAP are not provided as they do not represent a complete program view. Please refer to Table 7-11 for a complete program view and further program details including program cost effectiveness results.

5.2 Residential TRC and MTRC Results

FEI's DSM Program Principles state that programs should be universal, offering access to programs for all residential and commercial customers. Although many Residential programs are challenged in meeting a conventional TRC test in a low gas cost environment, these programs, with their broad reach, are cost-effective when considering broader societal benefits and a greenhouse gas (GHG) emissions reduction perspective. This was recognized in the 2011 and 2014 amendments to the Demand-Side Measures Regulation that enabled the inclusion of lower TRC programs through the application of the MTRC. The overall 2015 Residential Program Area TRC was 0.5 with a blended TRC/MTRC result of 1.5.

5.3 2015 Residential Energy Efficiency Programs

Tables 5-2 through 5-9 outline the specific Residential Energy Efficiency programs undertaken in 2015, including program and measure descriptions and a breakdown of non-incentive spending.

Table 5-2: Energy Efficient Home Performance Program -Home Energy Rebate Offer (HERO)

Program Description	This collaborative program promotes energy-efficient home upgrades while educating homeowners on the value of whole home performance. Utility partners administer the program. Federal, provincial and local governments co-promote this program and other related initiatives including capacity building for the trades, home labeling and the introduction of NRCan's Home Energy Rating System in spring of 2016.						
Target Market	Residential customers						
New vs Retrofit	Retrofit						
Partners	BC Hydro, FortisBC (Electric), BC Ministry of Energy and Mines, Natural Resources Canada and local governments						
Eligible Measures	Draftproofing	Attic Insulation	Basement Insulation	Wall Insulation	$750 Bonus Offer		
Incremental Measure Cost	$989	$1,880	$1,463	$1,953	N/A		
Incentive Amount	Up to $500	Up to $600	Up to $1000	Up to $1200	$750		
Savings Per Participant	6.6 GJ	8.9 GJ	6.1 GJ	5.6 GJ	N/A		
Measure Life & Source	9 years for Draftproofing, 25 years for Insulation Consultations with BC Hydro, Habart & Hood, 2010 Conservation Potential Review and Dunsky Energy Consulting.						
Free Rider Rate & Source	20% average assumed based on past program analysis and NRCan evaluation. *Final Report: Analysis of Net-to-gross Survey Results for the ecoENERGY Retrofit for Homes Program.* Bronson Consulting Group. August, 2010						
Sources of Assumptions	Habart and Hood, Hot 2000 Energy Modeling Reports 2010, 2011 2010 Conservation Potential Review Dunsky Energy Consulting, Hot 2000 Modeling 2012, 2013, 2015 2012 Residential End Use Study, FortisBC BC Hydro PowerSmart, Evaluation of the LiveSmart BC Efficiency Incentive Program F2009-F2011						
Participants	2015	Projected	Actual				
	Total	3,276	2,010				
Expenditures ($,000s)			Non-Incentive Expenditures				
	2015	Incentives	Industry Support	Admin	Communication	Research & Evaluation	Total
	Total	1,397	51	176	45	40	1,709

Notes:

- This program is a collaboration between FEI, FBC and BC Hydro with support from BC Ministry of Energy and Mines and Natural Resources Canada
- Energy savings estimates were provided by Dunsky Energy Consulting through the evaluation of HERO participant records in comparison to LiveSmart BC measure uptake, BC Hydro Evaluation of the LiveSmart BC Efficiency Incentive Program and Hot 2000 modeling estimates.
- Measure costs were based on HERO participant records and market analysis provided by Dunsky Energy Consulting.
- Industry support includes application support fees to energy advisors and FEI's contribution to Year One establishment of the Home Performance Stakeholder Council "HPSC", The HPSC is an industry led group comprised of key industry players tasked with addressing the fragmented interests, opportunities and challenges that exist in BC's nascent home performance industry which is continuously evolving. The HPSC is supported by a three year funding agreement between FEI, FBC, BC Hydro and Ministry of Energy and Mines.

Table 5-3: Furnace Replacement Program

Program Description	The Furnace and Boiler Replacement program targets customers with functioning furnaces (standard or mid-efficiency) or boilers and, through a combination of marketing, incentives and industry outreach, encourages them to replace the equipment immediately, rather than waiting for it to fail at some point in the future.						
Target Market	Residential customers						
New vs Retrofit	Retrofit						
Partners	N/A						
Eligible Measures	Standard efficiency	Mid - Efficiency	Boilers				
Incremental Measure Cost	$2,115	$2,115	$3,560				
Incentive Amount	$800	$800	$800				
Contractor Incentive	$50	$50	$50				
Savings Per Participant	8.5 GJs	6.0 GJs	9.3 GJs				
Measure Life & Source	Furnace - 18 years and Boiler - 18 years -Navigant Consulting report, BC Hydro Power Smart QA Standard, NRCan						
Free Rider Rate & Source	Early Replacement Methodology						
Sources of Assumptions	2012 and 2013 Furnace Replacement Pilot Program Evaluation - by Habart and Associates Furnace Replacement Program - Billing Analysis of 2012 Participant Savings. Sampson Research Inc. 2012 FortisBC Residential End Use Study 2015 Analysis of Program Participants						
Participants	2015	Projected	Actual				
	Total	3,276	4,035				
Expenditures ($,000s)			Non-Incentives				
	2015	Incentives	Dealer Incentives	Admin	Communication	Research & Evaluation	Total
	Total	3,228	193	82	22	4	3,528

Notes:

- The Furnace & Boiler Replacement program continues to be run outside of heating season to reduce the incidence of emergency replacements.
- The program is successful in terms of participation targets, contractor feedback and energy savings per unit. However, cost effectiveness tests have been challenged by the following factors:
  - Over time the proportion of old standard efficiency replacements (8.5 GJs savings) to mid-efficiency replacements (6.0 GJ savings) has declined resulting in decreased energy savings overall. In 2013, standard replacements comprised 76% of total program participants while in 2015 standard replacements comprised only 66% of total participants. This is consistent with trends of the installed base of furnaces observed in the 2012 Residential End Use Study indicating that the proportion of standard efficiency furnaces has declined from 44% in 2008 to 23% in 2012.
  - The incremental cost (economic cost as developed through Early Replacement Methodology) of furnaces increased by 15% and boilers by 13% in 2015 over 2014 which adversely affects cost effectiveness. This is likely due to the declining Canadian dollar.
  - Cost effectiveness was favoured in that contractor estimates of furnace remaining life averaged 5.0 years in 2015 and 4.1 years in 2014.
- Contractor incentives of $50 per participant are allocated to the administration portion of non-incentive spend.

Table 5-4: EnerChoice Fireplace Program

Program Description	This program promotes the purchase and installation of energy-efficient EnerChoice fireplaces for zone heating. The program educates consumers and dealers about the EnerChoice label and the benefits of selecting natural gas fireplaces based on energy-efficiency and heating attributes rather than just decorative features. Program awareness and participation was promoted through a combination of customer and dealer incentives and promotional activities.						
Target Market	Residential customers						
New vs Retrofit	Both						
Partners	N/A						
Eligible Measures	EnerChoice Fireplace						
Incremental Measure Cost	EnerChoice Fireplace (Retrofit): $150, EnerChoice Fireplace (New Construction): $300						
Customer Incentive Contractor Incentive	$300 $50 (Retrofit only)						
Savings Per Participant	7.8 GJ						
Measure Life & Source	15 years- Data from prior program participants, Impact of Terasen Gas Pilot Fireplace Program (2004) by Habart and Associates, 2010 Conservation Potential Review, 2012 FortisBC Residential End Use Study						
Free Rider Rate & Source	40% - Retrofit and 15% New Construction - indicates market transformation of the EnerChoice brand						
Sources of Assumptions	Data from prior program participants Impact of Terasen Gas Pilot Fireplace Program (2004) by Habart and Associates, 2010 Conservation Potential Review 2012 FortisBC Residential End Use Study 2015 FortisBC Enerchoice Fireplace Program Impact Evaluation by Sampson Research Inc.						
Participants		Projected	Retrofit Total	New Construction Total	2015 Total		
	Total	3,468	5,113	975	6,088		
Expenditures ($,000s)			Non-Incentives				
	2015	Incentives	Dealer Incentives	Admin	Communication	Research & Evaluation	Total
	Total	1,826	253	59	42	29	2,209

Notes:

- The EnerChoice Fireplace Program Impact Evaluation and Market Effects Study demonstrated the need to redefine the EnerChoice eligible products directory to improve minimum efficiency standards. Therefore the EnerChoice program was temporarily suspended to undertake industry and government consultation for 2016 program design. The 2016 program is expected to be in market in Q2 2016.
- Contractor incentives of $50 per participant are allocated to the administration portion of non-incentive spend.

Table 5-5: Appliance Service Program

Program Description	This program will provide customer education related to the importance of regular appliance maintenance to ensure efficient operation of natural gas appliances. This program will also create opportunities for contractors to dialogue with customers about upgrading appliances to more efficient models.					
Target Market	Residential customers					
New vs Retrofit	Retrofit					
Partners	N/A					
Eligible Measures	Furnace Service (69%), Fireplace Service (31%)					
Incremental Measure Cost	N/A					
Incentive Amount	$33					
Savings Per Participant	N/A					
Measure Life & Source	N/A					
Free Rider Rate & Source	N/A					
Participants (no. of services)	2015	Projected	Actual			
	Total	0	21,380			
Expenditures ($,000s)			Non-Incentives			
	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	535	54	28	0	616

Notes:

- The incentive amount of $33 represents the average incentive awarded per participant based upon a portion of the participants having both a furnace and fireplace serviced at $25 (incentive) per service.

Table 5-6: ENERGY STAR® Water Heater Program

Program Description	This program promotes the replacement of standard efficiency water heaters with efficient ENERGY STAR® models. As part of a longer term market transformation strategy, the program introduced 0.67 EF storage tank water heaters and new technologies with energy factors (EF) greater than 0.80. The new technologies include condensing and non-condensing tankless water heaters, hybrids and condensing storage tanks. The program is available to both retrofit and new construction markets. The program supports upcoming federal and provincial Minimum Efficiency Act Standards for natural gas- and propane-fired water heaters.
Target Market	Residential customers
New vs Retrofit	Both
Partners	N/A

Eligible Measures	ESTAR 0.67 EF Storage Tank	Non-Condensing Tankless	Condensing Tankless	Hybrids	Condensing Storage Tank
Incremental Measure Cost					
Retrofit	$250	$1,510	$2,359	$2,219	$2,030
New Construction	$100	$425	$825	$1,478	$2,771
Incentive Amount	$200	$400	$500	$500	$1,000
Savings Per Participant	3.0 GJ	6.5 GJ	8.3 GJ	7.3 GJ	5.0 GJ

Measure Life & Sources	17.2 years Weighted average - Manufacturers and other utilities; ACEEE Emerging Hot Water Technologies and Practices for Energy Efficiency as of 2011. October 2011. Report Number A112. Sachs, H., Jacob Talbot and Nate Kaufman; Canadian Residential Water Heater Market Assessment. 2009. Caneta Research Inc. 2012
Free Rider Rate & Source	10%- ACEEE Emerging Hot Water Technologies and Practices for Energy Efficiency as of 2011. October 2011. Report Number A112. Sachs, H., Jacob Talbot and Nate Kaufman; Program Participant Feedback. 2012 Residential End Use Study.
Sources of Assumptions	ACEEE Emerging Hot Water Technologies and Practices for Energy Efficiency as of 2011. October 2011. Report Number A112. Sachs, H., Jacob Talbot and Nate Kaufman; 2014 and 2015 Program Participant Feedback. A Canadian high efficiency natural gas water heater pilot project. Project # 417311. Natural Gas Technologies Centre. Prepared by Adam Neale. 2012 FortisBC Residential End Use Study. 2010 Conservation Potential Review.

Participants	2015	Projected Total	Actual							
			ESTAR 0.67 EF Storage Tank		Non-Condensing Tankless		Condensing Tankless & Hybrids		Condensing Storage Tank	
			Retrofit	New Const.	Retrofit	New Const.	Retrofit	New Const.	Retrofit	New Const.
	Total	3,900	3,237	45	162	106	1,304	312	378	224

Expenditures ($,000s)	2015	Incentives	Non- Incentives				Total
			Dealer Incentives	Admin	Comm.	Research & Evaluation	
	Total	2,319	261	64	45	0	2,688

Notes:

- The Canadian high efficiency natural gas water heater pilot project conducted by Natural Gas Technologies Centre based on sub-metering analysis of 38 homes confirmed that the stated energy savings estimates are valid with overall energy savings of about 37% across new technologies over the base line 0.62 EF storage tank water heater. This study was published in 2014.
- Based on data from 2015 program participants, incremental costs for water heaters was unchanged or slightly decreased over 2014, unlike the cost increase noted for furnaces and boilers in 2015.

Table 5-7: Domestic Hot Water Conservation - Low Flow Fixtures and Washer Promotions

Program Description	The objective of this program is to reduce hot water consumption in houses, row houses and MURBS through partnerships with utilities or government. Initiatives include the installation of low-flow fixtures and ENERGY STAR washers and dryers.
Target Market	Residential customers
New vs Retrofit	Retrofit
Partners	BC Hydro, FBC, Non-Governmental Organizations (NGOs), and Municipalities
Eligible Measures	Low-Flow Fixtures; ENERGY STAR® Washers and Dryers
Low Flow Fixtures:	
Incremental Measure Cost	N/A in this direct install program
Incentive Amount	N/A in this direct install program
Savings Per Participant	Bathroom fixtures 0.8 GJ / Kitchen fixtures 0.8 GJ/ Shower 1.3 GJ
Measure Life & Source	10 years- 2010 Conservation Potential Review (ultra low-flow shower head, 1.25 GPM)
Free Rider Rate & Source	10%- City Green Report: Tap by Tap, January 10, 2012
ENERGY STAR Washers:	
Incremental Measure Cost	$102
Incentive Amount	• $50 rebate (FEU contributes $25) on qualifying ENERGY STAR® clothes washers - IMEF of 2.76 to 2.93, and WF of 3.5 to 3.3 • $100 rebate (FEU contributes $75) on qualifying ENERGY STAR clothes washers - IMEF of 2.94 or higher, WF of 3.2 or less
Savings Per Participant	1.0 GJ Natural Gas plus 0.25 GJ electric - BC Hydro
Measure Life & Source	14 years- 2010 Conservation Potential Review and Ontario Power Authority "2010 Prescriptive Measures and Assumptions: Release 1"
Free Rider Rate & Source	20%- BC Hydro based on market share of eligible washers

Participants	2015	Projected	Actual Low Flow Fixtures	Actual ENERGY STAR Washers

Expenditures ($,000s)		**Incentives**	**Non-Incentives**			**Total**
			Admin	Communication	Research & Evaluation	
	Total	99	71	18	37	226

Notes:

- The Low Flow Fixtures project in Table 5-6 summarizes 2015 activity for the Tap by Tap project on Vancouver Island and the BC Hydro MURB project for municipalities in the Lower Mainland. This pilot has been replaced in market by the Rental Apartment Program outlined in Table 5-9.
- The Washer promotion was a collaboration with BC Hydro for a spring promotion in May-June and fall promotion in September-October. In addition FEI collaborated with FBC from May 2015 through December 2015.

Table 5-8: New Home Program

Program Description	This program provides education and financial incentives to support energy-efficient building practices for the Residential sector. 2015 expenditures are related to a wrap-up of projects with 2014 building permits that qualified for the 2014 EG80 program. This program supported efficiency updates to the BC Building Code (effective Dec. 2014). In June 2015, the utilities launched ENERGY STAR® for New Homes as the new whole home performance standard. As new builds take time for completion, there are no applications to date.					
Target Market	Builders of residential properties – single family homes and townhomes and homeowner builders					
New vs Retrofit	New Construction					
Partners	BC Hydro and FBC					
Eligible Measures	EG80 Single Family Dwellings		EG80 Townhome/Rowhome		Boilers	
Incremental Measure Cost	$3,912		$1,166		$1,350	
Incentive Amount	$2,000		$200		$1,000	
Savings Per Participant	16.3 GJs		4.4 GJs		8.4 GJs	
Measure Life & Source	25 years- New Construction Costs and Savings and Life Cycle Costs, First published in 2011 and updated in 2014, Cooper and Habart, and Dunsky Energy Consulting					
Free Rider Rate & Source	15% for EnerGuide 80 and 40% for Boilers					
Participants	2015	Projected	Actual			
			EG80 SFD	EG80 Rowhome	Boiler	Total
	Total	191	407	0	295	702
Expenditures ($,000s)	2015		Non-Incentive Expenditures			
		Incentives	Admin	Communication	Research & Evaluation	Total
	Total	1,096	127	48	24	1,296

Notes:

- FEI has collaborated with BC Hydro Power Smart and FBC on this program.
- Energy savings and participant costs were derived from a 2013 study, BC Building Code (2014) & New Homes Program, by Cooper and Habart. This study was co-developed with FBC and BC Hydro.
- In 2014, the FEI's attribution for energy savings for the advancement of Codes and Standards as a direct result of the New Home Program included an estimate of 2015 program participants. The program advanced Codes and Standards by way of helping builders, developers and contractors become more knowledgeable in building more energy efficient homes and enabling the market transformation to more stringent codes. As such, this work in part enabled the introduction of the new BC Building code effective December 2014 and the 2014 Vancouver Building By-Law (VBBL) effective January 1, 2015. Both of these new building codes set a higher energy efficiency standard for residential homes that include single family homes and row homes/townhouses over the current version of the respective building codes. For more information please refer to the 2014 EEC Annual Report Section 5.3, Table 5-8 New Home Program.

Table 5-9: Rental Apartment Efficiency (RAP) – *Residential Portion* (New Program)

Program Description	There are three components to the RAP program. The first component is to provide direct install in-suite energy efficiency upgrades to building owners or property management companies of rental properties (hereinafter referred to as Participant(s)). These devices will be installed by an agent of FortisBC into each individual rental suite. The second component is to simultaneously provide those Participants with energy assessments recommending building-level energy efficiency upgrades such as condensing boilers, high efficiency water heaters and lighting upgrades. The last component is to provide the Participant with support in implementing those energy efficiency recommendations and applying for rebates. Expenditures associated with the energy assessment, implementation support, boiler/water heater rebates as well as a portion of the communication and evaluation costs are covered by the Commercial Program Area.				
Target Market	Purpose-Built Rental Apartment Buildings				
New vs Retrofit	Retrofit				
Partners	FortisBC Inc.				
Eligible Measures	1.3 GPM Showerheads, 1.3 GPM Handheld Showerheads, 0.8 GPM Bathroom Aerators, 0.8 GPM Kitchen Aerators				
Incremental Measure Cost	Varies				
Incentive Amount	Full cost				
Savings Per Participant	Varies				
Measure Life & Source	Varies				
Free Rider Rate & Source	Varies				
Participants	2015	Projected	Actual		
	Total	0	3,078		
Expenditures ($,000s)			Non-Incentives		
	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	31	24	5	6	66

Notes:

- Expenditures associated with direct install activities and a portion of the communication and evaluation costs are covered by the Residential Program Area. Expenditures associated with the energy assessment, implementation support, boiler/water heater rebates as well as the remaining portion of communication and evaluation costs are covered by the Commercial Program Area.
- Full program details including both residential and commercial activity and cost effectiveness results are available in Section 7, Table 7-11.
- Below is a list of the 2015 measure participant counts that are covered under the Residential Program Area.

Installed Measure Type	Installed #
1.5GPM Bathroom Aerators (Gas)	1023
1.5GPM Handheld Showerhead (Gas)	153
1.5GPM Kitchen Aerators (Gas)	995
1.5GPM Showerheads (Gas)	907

5.4 2015 Residential Energy Efficiency Programs Planned But Not Launched

5.4.1 CUSTOMER ENGAGEMENT TOOL

FEI developed the business case and released an RFP for vendor selection in 2014. A Customer Engagement Tool (CET) relies heavily on social norms, i.e. a customer's energy usage is compared to the average of their neighbours in order to prompt behavioural change, i.e., energy savings. The CET is being reviewed to ensure that customer data exchanged with the vendor is secure and is in compliance with the Personal Information Protection Act and corporate privacy policies. The project will be re-evaluated in 2016.

5.4.2 ON-BILL FINANCING

On-bill financing pilots were found to be expensive and administratively burdensome for utilities. Pilot implementations were unsuccessful with very low uptake rates. However, in 2014 FortisBC partnered with CIBC to offer a competitive financing package through the Trade Ally Network. Partnerships with additional financial institutions, such as VanCity, were developed in collaboration with BC Hydro and promoted through the Home Energy Rebate Offer.

5.4.3 NEW TECHNOLOGIES

FEI continues to explore New Technologies through the Innovative Technologies Program. There were no new technologies ready for deployment in 2015. Combination heat and water heating systems are currently under evaluation and a pilot was launched in early 2015. Pilot implementation learnings will be used to assess the business case, which if cost effective will be presented to BCUC for consideration for a 2017 program.

5.5 Summary

Residential Energy Efficiency Program Area activity in 2015 resulted in over 121,377 GJ/year of natural gas savings. Residential Energy Efficiency programs enabled customers to upgrade appliances and capture energy savings, supported the introduction of new provincial regulations and continued to build on relationships with the trades for education and program awareness. The combination of financial incentives, policy support, contractor outreach and effective marketing is instrumental to the ongoing success of these programs in generating natural gas savings and fostering market transformation in the residential sector.

Universality is a key guiding principle for FEI's DSM initiatives. Amendments to the Demand-Side Measures Regulations have enabled more programs to be developed, resulting in significant energy savings benefits for residential customers. The Province, in turn, benefits from the resulting GHG emissions reductions in the residential building sector.

6. LOW INCOME ENERGY EFFICIENCY PROGRAM AREA

6.1 Overview

In 2015, FEI saw continued success with the Energy Savings Kit (ESK) Program and the Energy Conservation Assistance Program (ECAP). The Company also implemented another successful Residential Energy Efficiency Works (REnEW) session, and developed three new Low Income Programs (described under 6.3 2015 Low Income Programs Planned But Not Launched).

In addition to FEI's own Low Income programs, progress continues to be made on investing the $5.2 million in funds granted to FEI by the Ministry of Energy, Mines and Natural Gas in 2009 to enable energy efficiency in low income households. In 2015, the Company invested $377 thousand of this funding primarily on retrofits in low income homes, partnership funding of the REnEW program, development of a building operator online training system, and an energy advisor position focused on the non-profit building sector. None of these investments are included in the spending amounts shown in Table 6-1. The remaining granted funds will be invested over the next 1-2 years.

Table 6-1 summarizes the planned and actual expenditures for the Low Income Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as the cost-effectiveness test results. The TRC and MTRC for low income programs uses a value of 140% of the benefits in accordance with July 2014 amendments to Section 4(2)(b) of the Demand-Side Measures Regulation. This amendment effectively increases the deemed cost effectiveness of the Low Income programs.

Table 6-1: 2015 Low Income Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

6.2 2015 Low Income Programs

Tables 6-2 through 6-4 outline the specific Low Income programs undertaken in 2015, including program and measure descriptions and a breakdown of non-incentive spending.

Table 6-2: Energy Saving Kit (ESK) Program

Program Description	The goal of this program is to reach a broad audience of low income customers and enable them to take some simple steps towards saving energy by installing a bundle of easy-to-install items that are delivered to their door. Promotional activities include bill inserts, event promotions such as food banks, targeted digital campaigns and partnerships with government ministries and non-profits that serve the low income population.					
Target Market	Low Income Residential Customers					
New vs Retrofit	Retrofit					
Partners	BC Hydro and FortisBC Inc. (FBC)					
Eligible Measures	Bundle of measures, including high efficiency water fixtures, water heater pipe wrap, draft proofing tape, outlet gaskets, window film, etc.					
Incremental Measure Cost	$ 22.44 Average based on the full cost of the gas measures included in the ESK and pro-rated by the proportion of participants that use natural gas for space or water heating.					
Incentive Amount	$ 22.44 Since the program is free to participants, the incentive equals the incremental cost.					
Savings Per Participant	2.4 GJ per year					
Measure Life & Source	10 years - Average based on the individual gas measures included in the Energy Saving Kit					
Free Rider Rate & Source	27% - Based on 2010 BC Hydro participant survey.					
Participants	2015	2015 Projected	2015 Actual			
	Total	6,379	10,538			
Expenditures ($,000s)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	236	60	67	1	364

Table 6-3: Energy Conservation Assistance Program (ECAP)

Program Description	This program enables deep energy savings in low income customer homes that have moderate to high energy consumption. Promotional activities include bill inserts, customer endorsements, outreach, promotion at events and conferences, and partnerships with government ministries, housing providers, and other organizations that serve the low income population.
Target Market	Low Income Residential Customers
New vs Retrofit	Retrofit
Partners	BC Hydro and FBC
Eligible Measures	Bundle of customized measures, which may include low-flow fixtures, water heater pipe wrap, professional draft proofing, outlet gaskets, window film, insulation, improved ventilation, CO detectors, and furnaces.
Incremental Measure Cost	$516 Based on average cost of the customized bundle of measures installed. Includes the full cost of the gas measures installed in gas heated homes.
Incentive Amount	$516 Since the program is free to participants, the incentive equals the incremental cost.
Savings Per Participant	4.5 GJ per year
Measure Life & Source	11 years - Average based on the individual gas measures installed.
Free Rider Rate & Source	4% (Source: Primarily third-party studies)
Participants	2015 Total — 2015 Projected: 1,359; 2015 Actual: 1,305
Expenditures ($,000s)	2015 Total — Incentives: 674; Admin: 160; Communication: 71; Research & Evaluation: 110; Total: 1,015

Table 6-4: Residential Energy Efficiency Works (REnEW) Program

Program Description	The goal of this program is to enhance the energy efficiency trade sector in BC in a manner that also enhances communities. This program targets individuals facing barriers to employment and provides training in energy efficiency retrofitting. The training is delivered by industry experts at no costs to participants.
Target Market	Low income individuals facing barriers to employment
New vs Retrofit	N/A
Partners	N/A
Eligible Measures	N/A
Incremental Measure Cost	N/A
Incentive Amount	N/A
Savings Per Participant	N/A
Measure Life & Source	N/A
Free Rider Rate & Source	N/A
Participants	2015 Total — 2015 Projected: 20; 2015 Actual: 13
Expenditures ($,000s)	2015 Total — Incentives: 0; Admin: 71; Communication: 1; Research & Evaluation: 0; Total: 72

6.3 2015 Low Income Programs Planned But Not Launched

In 2015 FEI developed three new Low Income Programs: Low Income Space Heat Top-Up Program, Low Income Water Heater Top-Up Program, and the Non-Profit Custom Program. These three new programs have since been approved by the BCUC and will launch in 2016.

Each are described briefly below. Results of these new programs will be reported on in the 2016 Annual Report.

Table 6-5: Low Income Space Heat Top Up

Program Description	The existing Commercial Space Heat Program offers rebates to commercial customers for the installation of high efficiency space heating equipment in commercial applications. The Low Income Space Heat Top Up Program will piggyback on the existing Commercial Space Heat Program and offer an additional incentive over and above the commercial rebate if the customer meets the eligibility criteria. Promotional activities will include partnerships with BC Housing, BC Non-Profit Housing Association (BCNPHA), and the provincial and regional BCNPHA conferences, trade shows and educational seminars.				
Target Market	The Low Income Space Heat Top Up Program is primarily focused on apartment buildings that are owned or operated by a First Nations band, a non-profit housing provider, or a housing co-operative.				
New vs Retrofit	Both				
Partners	N/A				
Eligible Measures	Condensing boilers and mid-efficiency boilers.				
Incremental Measure Cost	$7,500 per appliance (Business case assumptions. No participants in 2015.)				
Incentive Amount	$6/MBH (Business case assumptions. No participants in 2015.)				
Savings Per Participant	168 GJ/yr per appliance (Business case assumptions. No participants in 2015.)				
Measure Life & Source	20 Years				
Free Rider Rate & Source	18%				
Participants	Service Region	2015 Projected	2015 Actual		
	Total	22	0		
Expenditures ($,000s)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	3	0	0	3

Table 6-6: Low Income Water Heating Top Up

Program Description	The existing Commercial Water Heater Program was launched in 2010 and it offers rebates to commercial customers for the installation of high efficiency water heating equipment in commercial applications. The Low Income Water Heater Top Up Program will piggyback on the existing Commercial Water Heater Program and offer an additional incentive over and above the commercial rebate if the customer meets the eligibility criteria. Promotional activities will include partnerships with BC Housing, BC Non-Profit Housing Association (BCNPHA), and the provincial and regional BCNPHA conferences, trade shows and educational seminars.
Target Market	The Low Income Water Heater Top Up Program is primarily focused on apartment buildings that are owned or operated by a First Nations band, a non-profit housing provider, or a housing co-operative.
New vs Retrofit	Both
Partners	N/A
Eligible Measures	High Efficiency Storage Tanks, High Efficiency Domestic Hot Water Boilers, High Efficiency Tankless Domestic Hot Water
Incremental Measure Cost	$6,678 per appliance (Business case assumptions. No participants in 2015.)
Incentive Amount	$1.67/MBH (Business case assumptions. No participants in 2015.)
Savings Per Participant	$76 GJ/year per appliance (Business case assumptions. No participants in 2015.)
Measure Life & Source	12 Years
Free Rider Rate & Source	5%

Participants		2015 Projected	2015 Actual			
	2015 Total	20	0			
Expenditures ($,000s)	**2015**	**Incentives**	**Admin**	**Communication**	**Research & Evaluation**	**Total**
	Total	0	3	0	0	3

Table 6-7: Low Income Non-Profit Custom

Program Description	This program will encourage non-profit housing societies to replace inefficient equipment and systems with high-efficiency solutions. This program will involve an energy study and will provide incentives based on the recommendations of the study. Incentives under this program will cover all or most of the incremental cost of the cost-effective measures. The proposed program is built around three components: 1) An energy study: FEI will initially contribute up to 50% of the costs for the initial energy study for all eligible participants. Where appropriate, the Company will also provide funding so that the energy study provider can write a scope of work. 2) A capital cost incentive, equal to the incremental cost of the energy efficient measure, will be paid after the measure is installed. 3) A completion bonus: Upon implementation of at least one priority measure recommended by the energy study and deemed as eligible for incentives, the Company will contribute the remaining 50% cost of the energy study. Promotional activities will include partnerships with BC Housing, BC Non-Profit Housing Association (BCNPHA), and the provincial and regional BCNPHA conferences, trade shows and educational seminars.
Target Market	The Non-Profit Custom Program is primarily focused on apartment buildings that are owned or operated by First Nations bands, non-profit housing providers, or housing co-operatives.
New vs Retrofit	Both
Partners	N/A
Eligible Measures	Eligible measures are expected to include mechanical equipment (i.e. boilers, ventilation systems, water heat/storage, etc.) and heating controls (i.e. zone controls, temperature set back controls, etc.). In addition there will be other more customized scenarios that will be assessed for savings and incentive potential as the opporutnities arise.
Incremental Measure Cost	Energy Study: $13 thousand, Capital Incentive: $38.2 thousand (Business case assumptions. No participants in 2015.)
Incentive Amount	Energy Study: $13 thousand, Capital Incentive: $38.2 thousand (Business case assumptions. No participants in 2015.)
Savings Per Participant	831GJ/year (Business case assumptions. No participants in 2015.)
Measure Life & Source	14 Years (Business case assumptions. No participants in 2015.)
Free Rider Rate & Source	5%

Participants			
2015	2015 Projected	2015 Actual	
Total	10	0	

Expenditures ($,000s)	Incentives	Admin	Communication	Research & Evaluation	Total
2015 Total	0	3	0	0	3

6.4 Summary

The Low Income Program Area has been an important priority for the Company since the initial creation of the DSM Program Principles. The goal of creating programs that are accessible to all has been achieved through the continuation of the ESK Program, the REnEW Program and ECAP and will be further enhanced by the addition of the three new Low Income programs in 2016.

7. COMMERCIAL ENERGY EFFICIENCY PROGRAM AREA

7.1 Overview

In 2015, Commercial Energy Efficiency programs continued to encourage commercial customers to reduce their overall consumption of natural gas and their associated energy costs. The Commercial Energy Efficiency Program Area reduced annual natural gas consumption by over 270,000 GJs and achieved an overall TRC of 1.2. Nearly $11 million was invested in Commercial Energy Efficiency, of which 81% was incentive spending.

Table 7-1 summarizes the projected and actual expenditures for the Commercial Energy Efficiency Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost-effectiveness test results.

Table 7-1: 2015 Commercial Energy Efficiency Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios

Notes:

- ∗ The Rental Apartment Efficiency Program includes a combination of residential and commercial measures, each funded from their respective Program Areas. The *Commercial Portion* details of this program included in Table 7-1 and 7-10 show only those Commercial Program Area expenditures. These expenditures are associated with the commercial energy assessment, implementation support, boiler/water heater rebates as well as a portion of the communications and evaluation costs. Residential Program Area expenditures that are part of the RAP program are presented in Tables 5-1 and 5-9. Cost effectiveness values for only the *Commercial Portion* of RAP are not provided as they do not represent a complete program view. Please refer to Table 7-11 for a complete program view and further program details including program cost effectiveness results.

7.2 2015 Commercial Energy Efficiency Programs

The following tables outline the specific Commercial Energy Efficiency programs undertaken in 2015, including program and measure descriptions and a breakdown of non-incentive spending.

Table 7-2: Space Heat Program

Program Description	This program provides rebates for the installation of high efficiency space heating equipment in commercial applications. Currently only rebates for high efficiency boilers are offered. Rebates for condensing rooftop units may also be offered via the program in 2016.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
	Retrofit	New Construction				
Incremental Measure Cost	$19,279	$35,751				
Incentive Amount	$14,233	$27,669				
Savings Per Participant	418 GJ	438 GJ				
Measure Life & Source	20 years - ASHRAE Handbook and Conservation Potential Review					
Free Rider Rate & Source	18% - Efficient Boiler Program Impact Evaluation, June 12, 2003					
Participants	2015	Projected	Actual			
	Total	143	267			
Expenditures ($,000)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	4,002	222	15	11	4,249

Table 7-3: Water Heating Program

Program Description	This program provides rebates for the installation of high-efficiency commercial water heaters with thermal efficiencies greater than or equal to 84%.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
	Retrofit	New Construction				
Incremental Measure Cost	$6,235	$9,366				
Incentive Amount	$1,892	$3,493				
Savings Per Participant	115 GJ	108 GJ				
Measure Life & Source	12 years -2010 Conservation Potential Review, Navigant Consulting (16 April 2009) Measures and Assumptions for Demand Side Management Planning Appendix C: Substantiation Sheets Ontario Energy Board pp. 210-226.					
Free Rider Rate & Source	5% - Navigant Consulting (16 April 2009), Measures and Assumptions for Demand Side Management Planning, Appendix C: Substantiation Sheets, Ontario Energy Board, pp. 210-226.					
Participants	2015	Projected	Actual			
	Total	115	132			
Expenditures ($,000)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	282	89	35	14	419

Table 7-4: Commercial Food Service Program

Program Description	This program offers a suite of rebates for the installation of high-efficiency cooking appliances and it may also provide other incentives relevant to commercial food service participants such as low-flow pre-rinse spray valve or faucet aerator installs.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
		Retrofit	New Construction			
Incremental Measure Cost		$5,309	$7,270			
Incentive Amount		$2,598	$3,880			
Savings Per Participant		125 GJ	184GJ			
Measure Life & Source	12 Years - Foodservice Incentive Program Study 2012, Fisher-Nickel Inc., Marbek Conservation Potential Review (2010) and Database for Energy Efficiency Resources (DEER). San Francisco, CA, California Public Utilities Commission, 2011.					
Free Rider Rate & Source	20% - Foodservice Incentive Program Study 2012, Fisher-Nickel Inc.					
Participants	2015	Projected	Actual			
	Total	368	126			
Expenditures ($,000)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	414	114	116	0	643

Notes:

- During Q3/Q4 2014, as part of the Commercial Food Service Program, FEI in partnership with BC Hydro and the City of Vancouver participated in a program to install low-flow pre-rinse spray valves and faucet aerators in Vancouver food service establishments. All spray valves and aerators were installed in 2014, thus the participants, energy savings and incremental costs were included in the 2014 Energy Efficiency and Conservation Annual Report. The Implementation Contractor's final report and invoice were not received by FEI until 2015 however; therefore, the incentive expenditure has been included in the 2015 program incentive expenditure without associated participants, energy savings and incremental costs.

Table 7-5: Customized Equipment Upgrade Program

Program Description	This program provides eligible customers with funding towards the completion of a detailed Energy Study, to identify energy saving opportunities specific and customized to their facilities, and subsequent capital incentive funding to encourage the implementation of any cost effective measures identified therein. The program seeks to capture energy savings associated with measures that are otherwise difficult to incent as part of a prescriptive program because they are complex, and one project may include multiple measures with interactive effects. The expected energy savings, measures, capital cost, incentives etc, will necessarily vary depending on the customer, though each project is submitted to a TRC test and must be approved by the utility.					
Target Market	Commercial customers					
New vs Retrofit	Both					
Partners	BC Hydro (New Construction)					
Eligible Measures	Utility funded energy study, and utility incented Energy Saving Measures as identified in the energy study and approved by the utility. Energy Saving Measures are variable.					
Incremental Measure Cost	Variable. Dependent upon participant's proposed Energy Saving Measures.					
Incentive Amount	If TRC ≥ 1.0 then $5 / discounted GJ saved over 50% of the Energy Measure Life (EML), up to 10 yrs.					
Savings Per Participant	Variable. Dependent upon participant's proposed Energy Saving Measures.					
Measure Life & Source	Variable. Dependent upon participant's proposed Energy Saving Measures.					
Free Rider Rate & Source	Variable. Dependent upon participant's proposed Energy Saving Measures.					
	FEW	0	0			
	Total	87	56			
Expenditures ($,000s)						
	Labour	0	57	0	0	57
	Total	149	68	3	0	220
Expenditures ($,000s)						
	Labour	0	196	0	0	196
	Total	860	339	0	0	1,198

Notes:

- The Customized Equipment Upgrade Program is complex in nature and has variable measure savings, costs, incentives and/or cash flows which, unlike in prescriptive programs, occur over a period of years. Consequently, providing results for this program within an annual report format is challenging. In general, the savings in this program occur in later years after the participants have had the time to implement customized Energy Conservation Measures, while some program incentives and costs are payable at the outset. Please refer to the notes provided below for additional details.
- New Construction:
    - Participation in this program can last for approximately 5 years. This is broken down into approximately 12 months to prepare the required whole building energy simulation, followed by up to 48 months to build the proposed building. The program incurs incentive expenditures upon the successful completion of the energy simulation, as well as upon completion of the building, while natural gas savings are only obtained upon completion of the proposed building.
    - This program is in partnership with BC Hydro. Participants are recorded when the energy simulations or the new buildings are complete, and the incentive becomes payable.
    - The '2015 Actual' participants include 6 completed energy simulations, and 2 completed buildings with implemented measures. The associated natural gas savings from these 2 projects is approximately 3,875 GJ/year.

- Retrofit Program:
  - Participation in this program can last for approximately 2 years. This is broken down into approximately 6 months to prepare the required energy study, followed by 18 months to implement the proposed Energy Conservation Measures. The program incurs incentive expenditures upon the successful completion of the energy study, as well as upon installation of the approved Energy Conservation Measures, while natural gas savings are only obtained upon installation of the approved Energy Conservation Measures. As such, in years where a high number of energy studies are completed but few projects complete installation, the program's benefit/cost ratios will be impacted as incentive expenses will be incurred without obtaining natural gas savings to offset them.
  - The '2015 Actual' participants includes 41 completed energy studies, and 7 projects where Energy Conservation Measures were installed. The associated natural gas savings from these 7 projects is approximately 23,177 GJ/year.
  - The increased number of completed energy studies in 2015 versus 2014, along with the low number of completed Measure installations, has contributed to a lower TRC ratio compared to last year. Customers have continued to demonstrate interest in the program, leading to an increase in energy studies completed in 2015. However, since the majority of energy studies completed in 2014 were completed in the latter part of the year, these projects are still within their 18-month implementation stage of the program, and will not complete installation of their Measures until after the 2015 reporting year has closed. Projects that completed energy studies in 2015 and are eligible for capital incentive funding are expected to complete implementation in 2016/2017.

Table 7-6: EnerTracker Program

<table>
<tr><td>Program Description</td><td colspan="6">This pilot program is a subset of the continuous optimization (C.Op) program. It provides participants who are otherwise unable or unwilling to participate in the full C.Op program with access to an Energy Management Information System (EMIS). EMIS software provides customers with a detailed picture of their natural gas consumption in "near time". Timely access to this information is expected to speed up fault detection, thereby enabling more rapid corrective action to avoid wasted gas consumption, and to assist in the identification of additional natural gas conservation measures.</td></tr>

Notes:

- As there is currently insufficient AMR (Automated Meter Reader) infrastructure in the Vancouver Island service territory to support the rollout of this pilot, program availability is limited to the Lower Mainland and Interior service territories.
- Note that participation in the program is cumulative, meaning that a participant is enrolled for multiple years, claiming savings and incurring costs on an annual basis for the duration of the EMIS software license.
- An Evaluation of the pilot is underway but was not completed in time for this annual report. Findings will be included in the 2016 Annual Report and will be used to determine what role the EnerTracker Program will play in the Commercial Energy Efficiency Program portfolio moving forward.

Table 7-7: Continuous Optimization Program

Program Description	The Continuous Optimization Program (C.Op) is designed to help commercial building owners identify and correct energy wasting operation faults, and continuously monitor building performance to help maintain and improve energy efficiency, resulting in reduced operating costs. C.Op is offered in partnership with BC Hydro. In the FortisBC electric service territory, C.Op is offered in partnership with FortisBC Inc. as the Building Optimization Program (B.Op). The program funds re-commissioning services to study the participant's building and recommend energy efficiency improvements, as well as access to an energy management information system (EMIS) to assist in tracking the building's performance after the re-commissioning work is complete. In return, participants must implement, at their costs, measures identified by the re-commissioning study that when combined have a payback period of two years or less.					
Target Market	Commercial customers with buildings >50,000 ft^2 who consume an average of 7,500 GJ of natural gas per year or natural gas is 40% of their building's total energy consumption.					
New vs Retrofit	Retrofit					
Partners	BC Hydro					
Eligible Measures	RE/Retro-commissioning study, employee training, and "near time" energy consumption monitoring.					
Incremental Measure Cost	Average nominal program duration incremental cost (7 years): $41,275 2015 observed average implemented incremental cost: $26,096					
Incentive Amount	Average nominal program duration incentive amount (7 years): $15,915 2015 observed average implemented incentive amount: $14,213					
Savings Per Participant	Average expected annual natural gas savings: 1,465 GJ/year 2015 observed average implemented natural gas savings: 1,042 GJ/year					
Measure Life & Source	5 years - the duration of utility support for the energy management information system, plus one year.					
Free Rider Rate & Source	0% - BC Hydro					
Participants	2015	Projected	Actual	Participants Implementing in 2015	Cumulative Program Participants	
	Total	270	0	70	420	
Expenditures ($,000s)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	995	18	0	0	1,013

Notes:

- The C.Op. Program is conducted in partnership with BC Hydro and FEI. BC Hydro and FEI act as the primary administrators of program activities, with FEI providing financial and process support.
- Participation in these programs lasts for approximately 7 years for a typical participant. The 7 years are composed of approximately: 12 months of baseline data collection; 24 months of re-commissioning study work, plus the implementation of a recommended bundle of energy conservation measures; and, 48 months of monitoring and continuous improvement.
- Participants are recorded as soon as they are accepted into the program; however, natural gas savings do not occur until they have completed the implementation of a recommended bundle of energy conservation measures, approximately 36 months later. As such, the program incurs incentive expenses (for the upgrading of meter equipment, re-commissioning costs and EMIS costs) before natural gas savings are obtained.
- The average nominal program duration incremental cost represents the total incremental cost expected to be incurred when an average participant completes the full 7 year run in the program. The 2015 observed average implemented incremental cost represents the incremental costs incurred specifically in 2015 divided by the total number of participants who implemented in 2015.
- The average nominal program duration incentive amount represents the total incentive expected to be paid when an average participant completes the full 7 year run in the program. The 2015 observed average implementation incentive amount represents the incentive paid specifically in 2015 divided by the total number of participants who implemented in 2015. Due to the nature of the program, the incentive amount paid is not solely attributable to those who implemented in 2015.
- The average expected annual natural gas savings represent the expected annual natural gas savings per participant after they have completed the implementation of a recommended bundle of energy conservation measures. The 2015 observed average implemented natural gas savings represent natural gas savings attributed to customers who have completed the implementation of a recommended bundle of energy conservation measures specifically in 2015 divided by the total number of participants who implemented in 2015.

Participant count clarification:

- 2015 Actual represents the number of new participants who were approved in 2015. There were no new participants because the program has been closed to new participants since September 2013..
- Participants implementing in 2015 represents the number of participants who have successfully completed implementing the bundle of energy conservation measures in 2015.
- Cumulative Program Participants represent the total number of approved program participants from the entire multi-year duration. Program participants have the option to discontinue participation in the program during the multi-year duration. Since the 2014 Annual Report was finalized, 13 participants chose to discontinue participation, resulting in a lower cumulative participation number in 2015 versus last year.

Table 7-8: Commercial Energy Assessment Program

Program Description	This program identifies inefficiencies at the participant's facilities via an on-site walkthrough assessment by an energy-efficiency consultant. The consultant then produces a report that describes the observed inefficiencies, outlines proposed solutions, and identifies any applicable incentive programs. FortisBC then forwards the report to the participant. Simple measures, such as low-flow faucet aerators and pre-rinse spray valves, are provided to the participant at no charge.				
Target Market	Medium commercial and small industrial customers with an average annual consumption between 1,500 and 10,000 GJ.				
New vs Retrofit	Retrofit				
Partners	FortisBC Inc.				
Incremental Measure Cost	$1,550				
Incentive Amount	$1,375				
Savings Per Participant	502 GJ				
Measure Life & Source	1.07 Years - Conservative estimate based on the implementation of low-cost, simple recommendations (such as operational adjustments) from the energy assessment report, past spray valve program data and database for Energy Efficiency Resources (DEER). San Francisco, CA, California Public Utilities Commission, 2011.				
Free Rider Rate & Source	34% - 2010 Friuch Energy Assessment Evaluation				
Participants	2015	Projected	Actual		
	Total	523	49		
Expenditures ($,000s)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	67	26	0	0	93

Notes:

- At the time of writing the 2014-2018 EEC Plan, the FEI were unsure whether the Provincial Government's Business Energy Advisor ("BEA") program would continue or not. A contingency measure was planned for this program to ensure small businesses had access to energy analysis had the BEA program been discontinued. Participation from small business customers was foreseen in the 2014-2018 EEC Plan. As the BEA program was continued the scope of the Commercial Energy Assessment Program was not expanded to include small businesses and the number of participants in 2015 is significantly less than was estimated in the 2014-2018 EEC Plan. Of the 523 participants projected in the Plan, 72% were part of the small business market.

Table 7-9: Energy Specialist Program

<table>
<tr><td>Program Description</td><td colspan="6">This program funds Energy Specialist positions within customers' organizations, up to $60,000 based on an annual contract. <tr><td>Total</td><td>1,716</td><td>134</td><td>0</td><td>66</td><td>1,916</td></tr>
</table>

Notes:

- The Energy Specialist Program continues to experience success as an enabling program. In 2015, organizations with Energy Specialists were responsible for 43% of the gross natural gas savings and 43% of the incentives paid out by the Commercial DSM programs that Energy Specialists can directly participate in, not including the Energy Specialist Program itself. This is in addition to the Conservation Education and Outreach, Innovative Technologies, Low Income, and Residential programs and incentives that Energy Specialists promoted and utilized in 2015.
- Some organizations had Energy Specialists for part of the year only.
- The energy savings listed only apply to third party verified natural gas projects completed by Energy Specialists in 2015 that did not directly receive incentive funding from another DSM program.
- In 2015, FEI continued to co-fund six Business Energy Advisors (BEAs) with BC Hydro which was increased to eight part way through the year at BC Hydro's expense. FortisBC is a minority funding contributor in this arrangement, contributing $60,000 per funding year for all eight Business Energy Advisors combined. This is equivalent to the funding of one Energy Specialist. Business Energy Advisors are tasked with the same objectives as Energy Specialists but target small to medium sized businesses. As a collective they are expected to achieve FortisBC DSM program participation results similar to that of one Energy Specialist. Hence, this has been counted as one participant in the participant total for the Energy Specialist Program.

Table 7-10: Rental Apartment Efficiency (RAP) – *Commercial Portion* (New Program)

Program Description	There are three components to the RAP program. The first component is to provide direct install in-suite energy efficiency upgrades to building owners or property management companies of rental properties (hereinafter referred to as Participant(s)). These devices will be installed by an agent of FortisBC into each individual rental suite. The second component is to simultaneously provide those Participants with energy assessments recommending building-level energy efficiency upgrades such as condensing boilers, high efficiency water heaters and lighting upgrades. The last component is to provide the Participant with support in implementing those energy efficiency recommendations and applying for rebates.
Target Market	Purpose-Built Rental Apartment Buildings
New vs Retrofit	Retrofit
Partners	FortisBC Inc.
Eligible Measures	Walkthrough Energy Audits, Implementation Support, Condensing Boilers, Energy Efficiency Water Heaters
Incremental Measure Cost	Varies
Incentive Amount	Varies
Savings Per Participant	Varies
Measure Life & Source	Varies
Free Rider Rate & Source	Varies
Participants	2015 / Projected / Actual Total / 0 / 26
Expenditures ($,000s)	2015 / Incentives / Admin / Communication / Research & Evaluation / Total Total / 34 / 29 / 7 / 5 / 76

Notes:

- The Participant number listed under Table 7-10 represents the number of Energy Assessments conducted. Incentives for implementation support and building-level upgrades such as condensing boilers and high efficiency water heaters were not realized in 2015 due to the program's entry into the market late in the year and the time required for the Participants to make building-level upgrade decisions.

7.2.1 2015 PROGRAMS WITH JOINT PROGRAM AREA BUDGETS – FULL PROGRAM OVERVIEW

Table 7-11: Rental Apartment Efficiency (RAP)

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending						
	2014-2018 EEC Plan	2015 Actual		2014-2018 EEC Plan	2015 Actual	2014-2018 EEC Plan	2015 Actual	2014-2018 EEC Plan	2015 Actual	TRC	MTRC	Utility	Participant	RIM
Rental Apt Efficiency (RAP) - Commercial Portion														
Total	0	3,363	3,363	0	34	0	41	0	76	0.3	n/a	0.3	3.4	0.2
Rental Apt Efficiency (RAP) - Residential Portion														
Total	0	2,992	21,017	0	31	0	35	0	66	2.6	n/a	2.6	8.8	0.6
Overall Program														
Total	**0**	**6,356**	**24,380**	**0**	**65**	**0**	**77**	**0**	**142**	**1.5**	**n/a**	**1.4**	**6.5**	**0.5**

Notes:

- The Rental Apartment Efficiency Program was launched in October 2015 in response to Commission directive 148 of Order G-138-14 and Commission approval of Order G-138-14. This Table provides a complete Program View of expenditures and savings for both the Residential and Commercial Program Areas. Please refer to Table 5-9 and Table 7-10 for more details regarding the Rental Apartment Efficiency Program specific to each Program Area. Expenditures associated with the direct install activities and a portion of the communication and evaluation costs are covered by the Residential Program Area. Expenditures associated with the energy assessment, implementation support, boiler/water heater rebates as well as a portion of the communication and evaluation costs are covered by the Commercial Program Area. The higher non-incentive expenditures for the Commercial activities relative to the energy savings result in a TRC of 0.3 while the TRC for the Residential activities is 2.6. The TRC for the Rental Apartment Efficiency Program (Overall) which includes both the Commercial and Residential activity expenditures is 1.5.

7.3 2015 Commercial Energy Efficiency Programs Planned But Not Launched

7.3.1 MECHANICAL INSULATION PILOT PROGRAM

This pilot program had originally been set to launch in 2013 but was subsequently cancelled as FEI was unable to conclude a satisfactory agreement with a 3rd party contractor to deliver the project. FEI is not presently pursuing this pilot further.

7.4 Summary

Commercial Energy Efficiency Program Area activity in 2015 successfully achieved 270,933 GJ of annual natural gas savings and a positive TRC of 1.2. The Space Heat program continues act as the corner stone program as it invests more in natural gas efficiency projects than the other commercial programs. However all programs continue to experience growth in participation, incentive spend and natural gas savings. The Commercial Food Service Program in particular experienced significant growth in 2015, helping food service establishments in British Columbia reduce natural gas consumption and costs. Moving forward, the programs will continue to generate natural gas savings and foster market transformation in the commercial sector.

8. INNOVATIVE TECHNOLOGIES PROGRAM AREA

8.1 Overview

A primary objective of the Innovative Technologies Program Area is to identify market-ready technologies that are not yet widely adopted in British Columbia, and which are suitable for the development of or inclusion in the portfolio of ongoing DSM programs in other Program Areas. This is accomplished through pilot and demonstration projects, pre-feasibility studies and the use of Industry Standard Evaluation, Measurement and Verification (EM&V) protocols to validate manufacturers' claims related to equipment and system performance. Results from Innovative Technologies activities are used in making future DSM programming decisions and technology inclusions.

Just as important as identifying new technologies that should be incorporated into the DSM portfolio are findings that indicate which technologies should not. Section 8.3 summarizes how the activities and processes for the Innovative Technologies Program Area were successful in identifying proposed projects that should not proceed to full pilot phase or further.

All 2015 activities undertaken in this Program Area meet the definition of technology innovation programs as set out in the *Demand-Side Measures Regulation*. It should be noted that Innovative Technologies are considered a "specified demand-side measure,"[14] meaning that the Program Area or the measures therein are not subject to a cost-effectiveness test. Instead the cost-effectiveness of these expenditures will be evaluated as part of the DSM portfolio as a whole.[15] Innovative Technologies expenditures are also not subject to the 33 percent cap on programs for which the MTRC is utilized as a cost-effectiveness measure according to Section 4 (4) of the *Demand-Side Measures Regulation*.[16]

Table 8-1 summarizes the projected and actual expenditures for the Innovative Technologies Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost-effectiveness test results where applicable.

Table 8-1: 2015 Innovative Technologies Program Area Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

15 Subsection 4(4) of the Demand-Side Measures Regulation, and the Decision on the 2012 – 2013 Revenue Requirements Application and Natural Gas Rates Application, page 175.

16 BCUC Log No. 36730, Request for Further Clarification of Order G-44-12 and Decision on the 2012 – 2013 Revenue Requirements Application and Natural Gas Rates Application and the Commission's May 11, 2012 letter.

Notes:

- Innovative Technologies are considered a "specified demand-side measure," meaning that the Program Area or the measures therein are not subject to a cost-effectiveness test. Instead the cost-effectiveness of these expenditures will be evaluated as part of the DSM portfolio as a whole.

8.2 2015 Innovative Technologies Activities

Tables 8-2 to 8-3 outline the specific Innovative Technologies activities undertaken in 2015, including program and measure descriptions and a breakdown of non-incentive spending[17].

Table 8-2: Pilots

Program Description	The Pilot Program focused on evaluating market-ready technologies and conducting small scale pilots to gather data to validate manufacturers' claims about measure system performance and energy savings. The data from pilots can also be used to help improve the quality and installation of future systems, and to understand and reduce market barriers. Technologies that successfully emerge from the Innovative Technologies Program will be considered for inclusion in the various program areas within the larger EEC portfolio.					
Target Market	Variable					
New vs Retrofit	Retrofit					
Pilots						
Condensing Make-up Air Unit (CMUA) Pilot	Objectives of the program are to validate energy savings claims, assess customer acceptance rates, and identify technical issues associated with the installation and operation of condensing gas-fired ventilation units in British Columbia commercial buildings. These results were completed in Q3 2015 and handed off to the Commercial Program Area.					
	2015 Total	Participants 0				
Apartment Fireplace Efficiency Retrofit (AFER) Pilot	Objectives of the pilot are to verify energy savings from replacing older decorative style "B" vented fireplaces with Direct Vent EnerChoice level heating style fireplaces in Multi Unit Residential Buildings (MURB'S). The results will be used to determine the feasibility of launching a rebate program for high efficient EnerChoice direct vent fireplaces in MURB's or to extend the existing fireplace rebate offers to MURB'S. Results are expected Q2 2016.					
	2015 Total	Participants 33				
Combination Space and Water Heating System (CURP) Pilot	Objectives of the pilot are to identify field-validated energy performance of each combination system type, technical issues, field-validated incremental costs, customer acceptance and the effective marketing channels for promoting a combination system retrofit rebate. The results will provide insight into a cost-effective rebate program for residential customers to upgrade their existing space and water heating equipment to combination systems. Results are expected Q2 2016.					
	2015 Total	Participants 78				
Participants	2015 Total	Projected n/a	2015 Actual 111			
Expenditures ($,000s)	2015	Incentives	Non-Incentive Expenditures: Admin	Non-Incentive Expenditures: Communication	Non-Incentive Expenditures: Research & Evaluation	Total
	Total	217	68	14	113	411

[17] As Innovative Technologies activities are considered pilots rather than EEC programs, they were not presented in individual program tables as in other Program Area sections in this report.

Table 8-3: Studies

Description	Studies are used to assess the market opportunity, technical characteristics and projected energy savings of commercially available DSM technologies. The results can be used to determine the feasibility of launching a pilot or to make future program area inclusion decisions.					
Target Market	Variable					
New vs Retrofit	N/A					
Studies						
Combination Unit Space and Water Heating Performance Assessment	Study facilitated through the Canadian Gas Association and in partnership with Natural Resources Canada to assess the Combo performance in a lab controlled environment, identifying the different sources of energy loss followed by a comparison of the performance to the base-case system. The final report is expected to be completed for Q2 of 2016.					
Expenditures ($,000s)			Non-Incentive Expenditures			
	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	15	0	0	15

8.3 Summary

Innovative Technologies represent a key component of FEI's overall commitment to DSM activities by identifying viable technologies and projects that have the potential to support the development of new programs within the larger DSM portfolio.

In 2015, the Company received outcomes from the .67 EF Water Heater pilot that were used to inform program decisions for the ENERGY STAR water heater program and internal statistics of relative DHW loads. The Measurement and Verification study (M&V) was conducted over a 2 year period from November 2012 to December 2014. Based on the M&V results, the 0.67 EF Energy Star water heater resulted an average of 6 GJ or 15% of energy savings in residential use across the nine M&V participants. The M&V results confirmed that it's more cost-effective to upgrade from a standard efficiency water heater to a 0.67 EF Energy Star water heater if the rate of the Domestic Hot Water use per day is very high.

Additionally, in 2015 FEI received outcomes from the Condensing Make-up air unit ("CMUA") pilot that resulted in those technologies being included as eligible measures within the Commercial Program Area. Condensing Make up air units extract a portion of the latent heat available in the combustion products through condensation of the flue gas, boosting the nameplate efficiency from 80% to 90% or greater. The M&V was conducted over a 2 year period from January 2013 to July 2015. Based on the M&V results, the CMUA's indicated natural gas savings of 28% relative to pre-existing make up air units and 17% relative to new 80% efficient make up air units.

Furthermore, the Innovative Technologies Program Area were successful in identifying technologies that should not proceed to full pilots at the time of writing or not to be included as an eligible measure within an existing program. In 2015, FEI received outcomes from the Coil Cleaning Pilot that resulted in excluding it as an eligible measure within the Commercial Program Area. The intake air of an air handling unit (AHU) is filtered and conditioned through the heating and cooling coil before entering the occupant space for space heating and ventilation. The intake filters are only effective to a certain degree in cleaning the intake air which causes the downstream heating and cooling coils to plug up. Cleaning of the heating and cooling coil was expected to save natural gas due to increased heat transfer on the heating coil. The analysis of the measurement data shows that the average normalized energy consumption at the heating coils (BTU/°C/cfm) are marginally different between the two systems. The marginal difference in heating coil effectiveness, expressed as units of BTU to raise one cfm by one °C, between the two systems does not provide a conclusive natural gas energy savings result.

Overall, the Innovative Technologies initiatives successfully achieved results in evaluating the feasibility of new technologies and providing insights used towards the design of future DSM programs. The Innovative Technologies Program Area continues to use consistent criteria to ensure the greatest potential for screening technologies for further development as full programs in other areas of the DSM portfolio.

9. INDUSTRIAL ENERGY EFFICIENCY PROGRAM AREA

9.1 Overview

In 2015, the Industrial Energy Efficiency Program Area continued to encourage industrial customers to consume natural gas more efficiently and achieved an overall TRC of 1.0, with a combined net natural gas savings of 16,575 GJ/yr.

2015 Industrial Optimization Program activities resulted in seven new Technology Implementation funding agreements being executed and five projects being commissioned. In addition, eight energy audit reports were completed and identified energy conservation measures with the potential to provide natural gas savings of over 200,000 GJ/yr.

Table 9-1 summarizes the projected and actual expenditures for the Industrial Energy Efficiency Program Area in 2015, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost-effectiveness test results.

Table 9-1: 2015 Industrial Energy Efficiency Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending						
	2014-2018 EEC Plan	2015 Actual		2014-2018 EEC Plan	2015 Actual	2014-2018 EEC Plan	2015 Actual	2014-2018 EEC Plan	2015 Actual	TRC	MTRC	Utility	Participant	RIM
Non Program Specific Expenses

Specialized Industrial Process Technology Program														
Total	38,246	0	0	318	0	81	0	399	0	No Direct Savings				
ALL PROGRAMS														
Total	**142,349**	**16,575**	**132,597**	**1,686**	**578**	**671**	**412**	**2,357**	**989**	**1.0**	**n/a**	**1.1**	**2.2**	**0.6**

Notes:

- For the purpose of cost-effectiveness tests, 16,575 GJ in savings have been claimed for 2015. As a project's total incentive can be made across multiple years, the annual natural gas savings reported for each project are pro-rated based on the proportion of the project's total incentive that is made in any given year. Please refer to the Industrial Optimization Program description below for further details on this methodology and 2015 application.
- Please refer to section 9.3.1 below for Specialized Industrial Process Technology Program details.

9.2 2015 Industrial Energy Efficiency Programs

The following table outlines the Industrial Energy Efficiency Program Area activity undertaken in 2015, including program and measure descriptions and a breakdown of non-incentive spending.

Table 9-2: Industrial Optimization Program

Program Description	The program includes measures that allow customers to identify, assess, and implement customized cost-effective energy efficiency projects for industrial processes using natural gas as process heat or an energy source.					
Target Market	Medium and large industrial facilities					
New vs Retrofit	Both					
Eligible Measures	Variable. Natural gas measures with a TRC ≥ 1.0					
Incremental Measure Cost	Dependent upon participant's proposed energy conservation measures					
Incentive Amount	Varies by measure. If TRC ≥ 1.0 then approximately $5 / GJ saved over 3 years					
Savings Per Participant	Variable					
Measure Life & Source	Variable. Dependent upon participant's proposed energy conservation measures					
Free Rider Rate & Source	10% Technology Implementation; 20% Industrial Energy Audit, Plant Wide Audit, Feasibility Study. Source: Best estimate.					
Participants	2015	Projected	Actual			
	Total	26	13			
Expenditures ($,000s)	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	578	206	8	68	860

Notes:

- The Industrial Optimization Program includes measures that allow industrial customers to identify, investigate, and implement natural gas energy efficiency projects. Measures include Plant Wide Audit, Feasibility Study, Industrial Energy Audit and Technology Implementation. The Plant Wide Audit and Feasibility Study measures were introduced in 2015 and are designed as a high level, facility wide audit and a detailed system or process specific study respectively. These two new measures replace the Industrial Energy Audit measure. As such, Industrial Energy Audit applications are no longer being accepted and it is expected that the last participant will complete their energy audit in 2016.
- The Industrial Energy Audit, Plant Wide Audit and Feasibility Study measures do not include direct savings as the incentives are aimed only at identifying energy saving opportunities and the participant is not bound to implement energy conservation measures identified in the audit process. The Industrial Optimization Program claims 16,575 GJ of net natural gas savings in 2015 which are attributable to Technology Implementation projects.
- Depending on the size of the incentive, Technology Implementation project incentive payments are either paid fully on project commissioning or are paid across the first three years after commissioning and based on the natural gas saving performance in each year. Hence, for larger incentives, only a portion of the incentive is paid on project commissioning. For consistency in performing cost benefit analyses, only a prorated portion of the natural gas savings and project costs are included in the determination of the cost benefit ratios (e.g. if 25% of the incentives were paid in 2015, only 25% of the project cost and only the NPV of 25% of the project's savings would be used as inputs). This approach was adopted in 2013.
- In the 2012 EEC Annual Report, the cost-effectiveness ratios for the only project commissioned under the Technology Retrofit Program were calculated using the NPV of the total estimated natural gas savings, the total estimated project cost, but only twenty five percent of the calculated incentive. As such, the incentive paid in 2015 towards this project was necessarily included as an input to the 2015 cost-effectiveness ratios, though any energy savings, project costs, and participant count were not, as these had been recorded in full in 2012. Any subsequent incentives paid for this project will be included in future reports, without any corresponding costs,

benefits, and participant counts until such time as the full value of the incentive commitment has been accounted for.

- The time between Technology Implementation funding agreement execution and project commissioning can span across multiple annual reporting periods due to the lead times associated with energy conservation measure procurement and the often limited and predetermined maintenance shutdown windows in industrial facilities. To provide greater insight into program activity, seven funding agreements were executed under the Technology Implementation measure in 2015 and are estimated to result in 80,438 GJ/yr of net natural gas savings. Five projects were commissioned in 2015.

9.3 2015 Industrial Energy Efficiency Programs Planned But Not Launched

9.3.1 SPECIALIZED INDUSTRIAL PROCESS TECHNOLOGY PROGRAM

The Commission's Decision to FEI's Multi-Year Performance Based Ratemaking Plan for 2014-2018 requested that detailed plans for the program were to be approved by the Commission prior to incurring expenditures. FEI developed plans associated with the Specialized Industrial Process Technology Program more fulsomely in 2015. Detailed plans of this program were submitted to and approved by the Commission in early 2016.

9.4 2015 Industrial Energy Efficiency Program Closures

There were no program closures for the Industrial Energy Efficiency Program Area in 2015.

9.5 Summary

The Industrial Energy Efficiency Program Area activity in 2015 resulted in 16,575 GJ/yr of net natural gas savings and a TRC of 1.0. The Industrial Optimization Program was enhanced by introducing the Plant Wide Audit and Feasibility Study measures and participation in the program continued to grow. The conversion rate from the energy study component to the implementation component of the program increased in 2015 and is demonstrated by the number of projects initiated and commissioned throughout the year. These projects will lead to significant additional natural gas savings in the years to come.

In 2016, FEI will look to further refine and enhance the Industrial Optimization Program to encourage continued growth in participation and implementation of natural gas energy efficiency projects. In addition, FEI has recently received the Commission's approval of the Specialized Industrial Process Technology Program business case and will be launching this program into market.

10. CONSERVATION EDUCATION AND OUTREACH INITIATIVES

10.1 Overview

The CEO portfolio continues to support the DSM portfolio goals of energy conservation in a variety of ways. In order to foster a culture of conservation, several programs and campaigns were undertaken in 2015, giving the team new learnings and new insights into behaviour change and customer attitudes on efficiency. Educating all types of customers including residential, commercial and students – remains a strong priority and we are continuing to ensure steps are taken to make the information relevant and timely for these customers.

Continued collaboration with the FBC was executed in an effort to maximize efficiencies across both teams. In 2015 costs were shared on school outreach, community outreach, retail campaigns, communications pieces and various event materials. Steps were also taken to further partner with BC Hydro in the CEO portfolio in 2015, leading to a new collaboration with the Workplace Conservation Awareness (WCA) Program focusing on post-secondary institutions. Our ethnic outreach program, Empower Me continued to reach out to our Punjabi and Chinese communities through a community based social marketing approach. BC Hydro and FortisBC worked closely together in that development and continued to support the program expansion into new regions and new audiences. New retail and point-of-sale opportunities were also explored in partnership with BC Hydro in 2015.

CEO continued to provide information to customers and the general public on natural gas conservation and energy literacy and sought out new opportunities to reach customers, both face-to-face and online. FortisBC won Chartwell's 2015 Best Practices Bronze Award in Program Marketing for our behavior change digital tool The Conserver Club. FortisBC also continues to support various training seminars and educational workshops in collaboration with such organizations as the Greater Vancouver Home Builders Association and other industry associations. In addition, our first annual Efficiency in Action awards were held to recognize those commercial organizations that have most effectively utilized FEI's DSM programs.

As these are not incentive-based programs, FEI has not attributed direct savings to them in 2015. The following tables do not contain information about eligible measures, incentive amounts, savings levels, free-ridership, spillover or participation levels. CEO costs are included at the portfolio level and incorporated into the overall DSM portfolio cost-effectiveness results. Although there were no energy savings attributed to the CEO Program Area in 2015, it should be noted that the FEI continues to explore ways to identify and confirm energy savings from CEO activities.

Table 10-1 summarizes the projected and actual expenditures for the CEO Program Area in 2015. The approved spending for 2015 was $2.4 million and actual spending in 2015 was $2.8 million.

Table 10-1: 2015 CEO Initiative Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

10.2 2015 CEO Programs

Tables 10-2 through 10-4 outline the CEO initiatives undertaken in 2015. This includes program descriptions as well as a breakdown of spending, all of which is classified as "non-incentive spending".

Table 10-2: Residential Education Program

Program Description	This program provides information to Residential customers and the general public on natural gas conservation and energy literacy by seeking opportunities to engage with customers directly (either face-to-face or through online programs). This audience also included low income and ethnic customers. Promotional activities in 2015 included print and online communications and engagement campaigns as well as educational seminars, development of online tools and participation in home shows and community events. The Program also included the cost of production of materials for events and prizing for audience engagement that are utilized at events targeting Residential customers and children. In addition, continuing partnerships with the regional Canadian Home Builders' Associations and local sports organizations expanded outreach opportunities to engage with Residential customers. Furthermore, FEI continued to focus on behavioural change opportunities that resulted in energy savings.
Target Market	Residential customers and general public
New vs Retrofit	Both
Expenditures ($,000s)	see below

Expenditures ($,000s)			Non-Incentive Expenditures			
	2015	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	1,092	659	44	1,795

Table 10-3: Commercial Education Program

Program Description	This program provides ongoing communication and education about energy conservation initiatives as well as encourages behavioural changes that help Commercial customers reduce their organization's energy consumption. The Commercial sector is made up of small and large businesses in a variety of sub sectors such as retail, offices, multi-family residences, schools, hospitals, hospitality services and municipal/institutions. Promotional activities for 2015 included print and online communications, event support of industry trade shows, industry association meetings, award events, and development of tools to assist with education and engagement. In addition, the Companies furthered partnerships with organizations such as the Business Improvement Associations of BC (BIABC) and Climate Smart, who all work with small to medium-sized businesses. This program area continued to guide and support behaviour education campaigns delivered by energy specialists (or an energy manager) in their respective organizations. Collaborations between internal departments, as well as with other utilities, were pursued to achieve cost efficiencies in the budget, in particular on advertising and outreach events.
Target Market	Commercial customers, multi-family, energy specialists, energy management staff
New vs Retrofit	Retrofit
Expenditures ($,000s)	

		Non-Incentive Expenditures			
2015	Incentives	Admin	Communication	Research & Evaluation	Total
Total	0	227	50	5	282

Table 10-4: School Education Program

Program Description	This program responds to section 44.1 (8) (c) of the Utilities Commission Act, R.S.B.C 1996, c.473, s.125.1 (4) (e), where a public utility's plan portfolio is adequate if it includes an education program for students enrolled in [K-12] schools and post-secondary schools in the Company's service area. Activities included building partnerships and funding support for a variety of in-class and online programs related to conserving energy for K-12 students, delivered both internally and externally by third parties such as non-profit organizations or local sports teams. Some of the activities included were: Energy is Awesome, Green Bricks, Energy Champion assembly presentations and Beyond Recycling. Some of these activities also included distribution or education of low-flow fixtures, colouring books, mood pencils, and educational playing cards as part of the program. Partnerships and funding support for post-secondary activities included in-residence and on-campus education campaigns.
Target Market	Students
New vs Retrofit	Retrofit
Expenditures ($,000s)	

		Non-Incentive Expenditures			
2015	Incentives	Admin	Communication	Research & Evaluation	Total
Total	0	523	6	79	609

10.3 Summary

All of the Conservation Education and Outreach initiatives described above are designed to foster a culture of energy conservation in BC. This portfolio is immensely important to FEI's overall DSM effort and helps to keep the program information and energy conservation message top-of-mind with all of our customers. By changing attitudes and behaviours, the Company will help communities reach their goals, help customers save energy and money, increase participation in DSM programs and ultimately support the shared goals of FEI and the Provincial Government. This portfolio will continue to explore new ways and seek out new opportunities and channels to connect with our customers to ultimately grow that culture of energy conservation.

11. ENABLING ACTIVITIES

11.1 Overview

In 2015, Enabling Activities continued to support and supplement FEI's DSM program development and delivery, advancing energy efficiency in British Columbia. This included:

- the ongoing Trade Ally Network program;
- work completed in advancing national and provincial building codes, appliance/ equipment standards, and regulations;
- maintenance on the Company's DSM program tracking system;
- work on a new Conservation Potential Review; and,
- continued funding to support post-secondary energy management programs.

While these activities play a very important role in FEI's portfolio of DSM activities by advancing the delivery of all Program Areas, the Company has not claimed any energy savings in 2015 for work completed in this area.

While no energy savings will be claimed for Enabling Activities in 2015, FEI developed an acceptable methodology for measuring and attributing energy efficiency savings from Codes and Standards work for the 2014 Residential New Home program (see Table 5-8, page 32 of the 2014 Annual Report). Attribution savings were not available to be claimed in 2015 as there were no changes to energy efficiency regulation in the BC Building code energy efficiency that came into effect in 2015. FEI will continue to examine and, where appropriate, adopt methodologies for claiming energy savings from Codes and Standards for future programs.

Table 11-1 summarizes the projected and actual expenditures for the Enabling Activities in 2015.

Table 11-1: 2015 Enabling Activities Results

11.2 2015 Enabling Activities by Program

The following tables outline the specific Enabling Activities undertaken in 2015 by activity, including activity descriptions along with a breakdown of spending. Note that all spending under Enabling Activities is considered non-incentive spending.

Table 11-2: Trade Ally Network

Program Description	This program develops and manages a contractor network to promote DSM programs and energy-efficiency messaging. FEI identifies trade allies as equipment manufacturers, service contractors, distributors and retailers, and recognizes the influence these industry groups have with the end-use Residential, Commercial and Industrial customers who make energy-efficiency decisions. This program also supports funding energy efficiency training as outlined in the DSM Regulation.				
Expenditures ($,000s)	2015	Admin	Communication	Research & Evaluation	Total
	Total	265	378	0	643

Table 11-3: Codes and Standards

<table>
<tr><td>Program Description</td><td colspan="5">Utilities have a unique understanding of energy supply and customer demand cycles, which can be of assistance in the development of codes and standards. The content and timing of code implementation directly affects market transformation in all program areas. FEI’s level of regulatory involvement typically includes one of three involvement classifications: monitoring, stakeholder engagement and developing regulations. The Codes & Standards area “supports the development of or compliance with specified standard or a measure respecting energy conservation or the efficient use of energy” as referred to in the definition of “specified demand-side measures” in the DSM Regulation.</td></tr>
<tr><td>Policy Initiatives consultation process</td><td colspan="5">Evaluation, analysis and review of national, provincial and municipal initiatives for energy efficiency.</td></tr>
<tr><td>Industry consultation process</td><td colspan="5">Collaboration with entities like BC Hydro and the Home Owner Protection Office (HPO) for the development of industry training and guidelines on implementation of new energy efficiency measures. Participation with the BC Safety Authority Gas Technology Committee industry stakeholder group.</td></tr>
<tr><td>Involvement with supporting projects</td><td colspan="5">Active participation for supporting projects like: the Natural Resources Canada new EnerGuide rating system and Leadership in Energy Efficiency Partnerships (LEEP).</td></tr>
<tr><td>Codes and Standards Strategy</td><td colspan="5">Active participation on the Canadian Standards Association (CSA) Strategic Steering Committee on Fuel Burning Equipment. This committee is the highest level committee in the fuel sector at CSA and oversees all committees and sub-committees in the fuel burning sector. Consultation with the Canadian Gas Association (CGA), Canadian Institute of Plumbing and Heating (CIPH), Heating Refrigeration and Air-conditioning Institute (HRAI) and the Canadian Home Builders Association (CHBA) on codes and regulations that are common to our industries.</td></tr>
<tr><td>Codes and Standards Maintenance</td><td colspan="5">Active participation on the CSA Technical Committee on Energy Efficiency and Related Performance of Fuel-Burning Appliances and Equipment. This committee oversees all of the eleven existing performance standards for gas-fired equipment and is looking to develop new needed standards for equipment. Participation in the Standards Council of Canada, committee on Domestic gas cooking appliances ISO/TC 291.</td></tr>
<tr><td>Internal awareness of Code and Regulatory changes</td><td colspan="5">Development of internal documents and updates for relevant program areas and personnel.</td></tr>

Table 11-4: TrakSmart Maintenance

Program Description	Ongoing IT license and maintenance costs related to the portfolio DSM tracking system.				
Expenditures ($,000s)	2015	Admin	Communication	Research & Evaluation	Total
	Total	126	0	0	126

Notes:

- Spending on TrakSmart maintenance was higher than Plan (see Table 11-1 for Plan amount) as a result of enhancements completed to improve incentive application processing time. These enhancements were not anticipated when the 2014-2018 Plan was prepared.

Table 11-5: Conservation Potential Review

Program Description	FEI considers the CPR to be an important tool for use in developing, supporting, and assessing current and future DSM expenditure applications, as well as for directional input into program development. The purpose of a CPR study is to examine available technologies and determine their conservation potential, which includes the amount of energy savings that can be achieved through energy-efficiency and conservation programs over the study period. This project is being worked on in collaboration with BC Hydro, Pacific Northern Gas and FortisBC Electric. Core work on the CPR began 2015. As of end-2015 the CPR project was approximately one third complete.

	Total	101	0	0	101

11.3 2015 Enabling Activities Planned But Not Launched

11.3.1 Home Energy Efficiency Web Portal

This project concept was to develop a home energy-efficiency web portal with content, energy saving tips, online calculators, and a “one-stop rebate shop” for the entire Province of BC.

Partners were to include the provincial government, BC Hydro and FBC. The budget was to cover building the site communications to launch the site, and ongoing support. This project has been delayed while utilities address branding issues and customer information privacy concerns associated with a joint web portal. These funds may be accessed in 2016 as utility partners assess options for online forms and administrative functionality of the Home Energy Rebate Offer.

11.4 Summary

Enabling Activities are critical initiatives that support and supplement DSM program development and delivery. The success of the Residential Furnace Replacement program (see Section 5, Table 5-3), which was promoted through the contractor network, demonstrates the value of the Trade Ally Network program. Communications were immediate and responsive through the network and at the end of the program, 73% per cent of the program's participants used contractors who were members of the Trade Ally Network.

FEI's involvement in codes and standards work in 2015 continued to encompass varying degrees of activities including monitoring, reviewing and responding to existing and proposed regulatory changes and direct participation in various working groups that explore the development of future targets, codes and standards. For the first time, BC Hydro, Pacific Northern Gas, FEI and FBC began collaboration on a Conservation Potential Review study. The Conservation Potential Review project contract was awarded in 2015 and was well underway by the end of the year.

12. EVALUATION

FEI continued to advance their evaluation activities in 2015 by conducting evaluation studies[18] on a program by program basis. In alignment with the Company's Evaluation Measurement & Verification (EM&V) Framework and industry standard practice, program evaluation activities are assessed at different stages of each program's lifecycle. Based on this ongoing assessment, all programs are evaluated when appropriate. The 2015 evaluation activities presented here reflect the number of programs in market, the different stages of their lifecycle, and the type of evaluation activities required to provide program feedback. The evaluation activities conducted in 2015 are in accordance with the evaluation principles presented in the Company's EM&V Framework.

12.1 2015 Program Evaluation and Evaluation Research Activities

In 2015, FEI's various evaluation activities included quantifying energy savings, assessing participant awareness and satisfaction, identifying barriers to participation, assessing the effectiveness of education initiatives, and conducting industry research. Measurement and Verification (M&V) activities were focused on identifying and verifying project and measure level savings assumptions and understanding any issues associated with equipment installation in the field.

Table 12-1 presents an inventory of all program evaluation and evaluation research related activities undertaken in 2015. Expenditures for these activities have been accounted for within the applicable program or Program Area, non-incentive costs included in previous sections, but are also reported here in order to provide a concise, easy-to-view summary of evaluation activities. Included in the table are: a list of all the 2015 evaluation activities; the Program Area each activity occurred in; the general type of evaluation activity undertaken; the Company's actual 2015 evaluation expenditures; and, a status update on each activity. The total expenditure for program evaluation and research activities in 2015 was $459,000.

[18] Types of evaluation activities include: Communication evaluations, which focus on advertising and media outreach; Evaluation studies, where quality assurance or inspection is conducted to gain more insight on the incented measure; Process evaluations, where surveys and interviews are used to assess customer satisfaction and program success; Impact evaluations, to measure the achieved energy savings attributable from the program; and, Measurement & Verification, to monitor real time energy savings associated with energy conservation measures.

Table 12-1: Inventory of DSM Program Evaluation and Evaluation Research Activities Conducted in 2015[19]

Evaluation Name	Program Area	Type of Evaluation	Years the program has been running [20]	Evaluation Partnership	Actual Evaluation Expenditure (000's)	Evaluation Status [21]
FortisBC Communications Tracking: Energy Efficiency and Conservation	C&EM Portfolio	Communication	ongoing	none	$10	Customer engagement and awareness of C&EM activities. **Completed December 2015 by TNS**
Residential Outreach Program - Empower Me	Conservation Education and Outreach	Process	2	FortisBC Inc. and BC Hydro	$20	Mentor and Champion survey conducted for the program evaluation. **Expected completion by Q3 2016**
Furnace Replacement Pilot Program - Contractor Survey (2014 Contractors)	Residential	Process	3	none	$3	Contractor Survey for 2014 program year. **Completed January 2015 by TNS**
EnerChoice Fireplace Evaluation - Participant Survey & Billing Analysis	Residential	Process & Impact	3	none	$5	Customer survey and billing analysis conducted for program evaluation. **Completed April 2015 by Samspon Research Inc.**
EnerChoice Fireplace Evaluation - Market Study	Residential	Market Analysis	3	none	$24	Analysis of the program's influence on the fireplace market. **Expected completion by Q2 2016**
Home Energy Rebate Offer (HERO) - Participant Survey	Residential	Process	1	FortisBC Inc. and BC Hydro	$15	Customer survey conducted for the program evaluation. **Expected completion by Q3 2016**
Home Energy Rebate Offer (HERO) - Quality Study of Insulation	Residential	Evaluation Study	1	FortisBC Inc. and BC Hydro	$13	On-site visit of homes with insulation and draft proofing measures **Expected completion by Q3 2016**
Home Energy Rebate Offer (HERO) - Quantitative Analysis	Residential	Evaluation Study	1	FortisBC Inc. and BC Hydro	$12	HERO participant analysis to determine inputs for cost effectiveness tests and feedback on 2016 program design. **Completed December 2015 by Dunsky Energy Consulting**
Rental Apartment Efficiency Program (RAP)	Residential / Commercial	Evaluation Study	new	none	$1	Ongoing performance testing for RAP participants. This test uses a flow meter bag measuring device to measure the flow timed to one minute of pressure/flow per suite before and after the installation of the in-suite water-efficient devices. Flow testing will be conducted on 5 units within each participating building location.
Rental Apartment Efficiency Program (RAP)	Residential / Commercial	Process	new	none	$10	Building owner and Tenant survey for program evaluation. **Expected completion by Q4 2016**
Energy Conservation Assistance Program (ECAP)	Conservation for Affordable Housing	Evaluation Study	5	BC Hydro	$45	Ongoing Quality Assurance to ensure all products are installed according to vetted installation policies and procedures.
Energy Savings Kit (ESK)	Conservation for Affordable Housing	Process	5	BC Hydro	$1	Ongoing BC Hydro participant survey to assess customer satisfaction and program awareness.

[19] Table 12-1 does not include Prefeasibility Studies. Please refer to the Innovative Technologies section (Section 8) for details.
[20] Measurement & Verification studies require time to conduct the M&V activities which include but not limited to project commissioning and coordination, installing and removal of monitoring equipment, data collection and, data analysis and reporting. The column 'Years the program has been running' will refer to the time required to conduct the M&V activities. M&V activities align with the International Performance Measurement and Verification Protocol (IPMVP). Concepts and Options for Determining Energy and Water Savings. Prepared by the Efficiency Valuation Organization. www.evo-world.org. January 2012.
[21] M&V completion refers to the time period where the actual monitoring and data collection ends. Analysis and reporting will require additional time

Table 12-1: Inventory of DSM Program Evaluation and Evaluation Research Activities Conducted in 2015[19] (continued)

Evaluation Name	Program Area	Type of Evaluation	Years the program has been running [20]	Evaluation Partnership	Actual Evaluation Expenditure (000's)	Evaluation Status [21]
Energy Specialist Program Energy Savings Audit (Update for 2015)	Commercial	Impact	6	none	$40	The study is an update to the Energy Savings Audit to verify energy savings for projects completed in 2014. **Completed June 2015 by Prism Engineering Ltd and ClearLead Consulting Ltd.**
Energy Specialist Program Energy Savings Audit (Update for 2016)	Commercial	Impact	6	none	$25	The study is an update to the Energy Savings Audit to verify energy savings for projects completed in 2015. **Expected completion by Q2 2016**
EnerTracker Pilot Program - Impact Evaluation	Commercial	Impact	3	none	$43	Billing analysis of the program participants' energy usage. **Expected completion by Q2 2016**
Commercial Water Heating Program	Commercial	Impact	5	none	$13	Customer survey and billing analysis conducted for program evaluation. **Expected completion by Q2 2016**
Condensing Gas-Fired Ventilation Units (CMUA)	Innovative Technologies	Measurement & Verification	2	none	$44	M&V and Final report completed - **November 2015 by Fresco Building Efficiency and SES Consulting**
Apartment Fireplace Efficiency Pilot (AFER)	Innovative Technologies	Measurement & Verification	1	none	$57	Completion of M&V Plan, purchase and installation of monitoring equipment, and baseline monitoring started December 2014. **Expected completion of M&V + Final Report by Q3 2016**
Combination Space/Water Heating Units Pilot	Innovative Technologies	Evaluation Study & Measurement & Verification	1	none	$11	Implementation of a participant survey. **Expected completion of M&V + Final Report by Q1 2017**
Industrial Optimization Program	Industrial	Measurement & Verification	4	none	$68	There were 12 projects requiring M&V activity in 2015. The M&V activities include the completion of an M&V plan, commissioning validation site visits, and M&V reports. Expected M&V completion dates by project: 2016 - 2 projects 2017 - 2 projects 2018 - 4 projects 2019 - 4 projects

1 Table 12-2 contains a summary of all program evaluation studies and pilot program reports completed in 2015 and includes a brief
2 description of the methodologies and key findings.

3 **Table 12-2: Summary of Key Findings and Methodology for 2015 Completed DSM Program Evaluation Studies and Pilot Program**
4 **Reports**

Evaluation Name	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
FortisBC Communications Tracking: Energy Efficiency and Conservation	C&EM Portfolio	Communication	Online interviews conducted over two waves with 1,200 (600 per wave) British Columbia adults living within the FortisBC service territory.	**Results**: The percentage of participants had aided awareness of at least one of the three main energy efficiency activities undertaken by FortisBC improved from 53% in 2014 to 64% in 2015. Overall, half of the participants surveyed were classified as being at least somewhat engaged with energy efficiency. The level of engagement improved significantly during the second wave. **Outcome of Key Findings:** Continue to emphasize the overarching energy efficiency activities rather than individual programs to build awareness.
Furnace Replacement Pilot Program - Contractor Survey (2014 Contractors)	Residential	Process	102 telephone interviews were conducted between November 24 and November 30, 2015 with Contractors who participated in the program.	**Results:** The key findings are: 1) 54% of contractors stated that over 80% of all furnaces sold / installed during the 2014 program period received a rebate from the program which increased from 23% in the 2013 program. 2) Contractors are very satisfied with the amount of the rebates and the selection of furnaces that qualify for the program. They also noted that the information made available regarding the program has improved. 3) Contractors suggest FortisBC could provide more program promotion, maintain the program for a longer duration or a different seasonal timing. **Outcome from Key Findings:** Continue to work closely with industry on program design and communication efforts.

5

Table 12-2: Summary of Key Findings and Methodology for 2015 Completed DSM Program Evaluation Studies and Pilot Program Reports (continued)

Evaluation Name	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
EnerChoice Fireplace Evaluation - Participant Survey & Billing Analysis	Residential	Process & Impact	A combination of an online participant survey (n=1,559), estimation of net-to gross factors including free ridership and participant spillover, and a fixed effects billing analysis (n=591) were used to evaluated the 2011 to 2013 program years.	**Results:** 1) 93% of participants were satisfied with the overall program and 89% satisfied with the selection of program qualifying fireplaces. 2) 45% of participants surveyed replaced an inefficient gas fireplace and the remaining replaced either a wood or electric fireplace, or a new install. 3) The average increase in annual gas consumption for wood-to-gas, electric-to-gas, and new installations was estimated at 13.1 GJ. 4) The average increase in annual gas consumption for retrofits was estimated at 8.6 GJ which is attributed to the increase hours of use in the post-program period. **Outcome from Key Findings:** Internal decision was made to put the program on hold while we collaborated with industry stakeholders on program design to continue to raise the minimum efficiency standards for fireplaces. Further analysis and research are to be conducted to provide support for program design.
Home Energy Rebate Offer (HERO) - Quantitative and Qualitative Analysis	Residential	Evaluation Study	Quantitative and qualitative analysis of the overall program. Analysis included a review of the following: n=3,110 program participants (54% natural gas, 46% electric), contractor survey n= 68, stakeholder interviews, comparison to LiveSmart BC for energy savings, overall program performance and program design recommendations.	**Results:** Assumptions for cost effectiveness tests are provided in Section 5.3. Contractor feedback is favorable overall. Program design recommendations include increasing wall and basement insulation amounts and raising insulation maximum payouts as a means of increasing multi-measure uptake. **Outcome from Key Findings:** Updated program offer will be introduced into market in 2016 Q2 or Q3. Contractor engagement is key to reduce application declines and improve quality of workmanship.

Table 12-2: Summary of Key Findings and Methodology for 2015 Completed DSM Program Evaluation Studies and Pilot Program Reports (continued)

Evaluation Name	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
Energy Specialist Program Energy Savings Audit (Update for 2016)	Commercial	Impact	The methodology remains consistent with the Energy Savings Audit -2015 Update. A total of 28 completed projects were reviewed by Prism Engineering Ltd. Each Energy Specialist was required to complete a project-specific questionnaire and provide detailed project calculations and information for review. Project savings were verified on a project by project basis. Energy Specialist gas savings projects verified were those that did not take advantage of an existing FortisBC incentive program.	**Results:** A total of 28 completed projects for 2015 were reviewed to represent savings in 2015. The total verified savings of these 28 projects is 9,414 GJ/year. NPV gas savings equate to 58,394 GJ which is calculated using a methodology to account for the potential that projects may not persist over the anticipated measure life. **Outcome of Key Findings:** Continue to provide the Energy Specialists with support where required to properly document estimated energy savings.
Condensing Gas-Fired Ventilation Units (CMUA)	Innovative Technologies	Measurement & Verification	**The M&V Plan:** Complies with the International Performance Measurement & Verification Protocol. The selected IPMVP option and measurement boundary was Option B[22] **M&V:** M&V was conducted on 8 commercial sites within the Lower Mainland and Victoria regions. Baseline data was collected and measured for 3 months during the heating season and for 12 month post-retrofit of the CMUA.	**Results:** The M&V results indicated natural gas savings of; 28% relative to pre-existing make up air units, 17% relative to new 80% efficient make up air units. **Outcome from Key Findings:** Data to be used to justify inclusion of CMUA as an eligible measure in the Commercial Custom Design Program. Will also be used for inclusion as a prescriptive measure under the Commercial Space Heat program.
ENERGY STAR© 0.67 Storage Tank Water Heater Pilot	Innovative Technologies	Measurement & Verification	**The M&V Plan:** Complies with the International Performance Measurement & Verification Protocol. The selected IPMVP option and measurement boundary was Option B[22] **M&V:** M&V was conducted and monitored for hot water usage, and natural gas and electricity consumption by the water heaters for 9 residential homes within a 15 month period.	**Results:** Based on the M&V results, the 0.67 EF Energy Star water heater resulted an average of 6 GJ or 15% of energy savings in residential use across the nine M&V participants. The M&V results confirmed that it's more cost-effective to upgrade from a standard efficiency water heater to a 0.67 EF Energy Star water heater if the rate of the Domestic Hot Water use per day is very high. **Outcome from Key Findings:** Transitioned 0.67 Water Heater Pilot results to Residential Program Team. Data to be used to inform program decisions and internal statistics on relative Domestic Hot Water loads.

[22] IPMVP Option A - Measurement of key parameters governing energy use to assess consumption. www.evo-world.org

12.2 Evaluation Collaboration

The FEI have continued to seek opportunities to increase collaboration activities with FBC, BC Hydro, and other entities to conduct program evaluation for DSM programs. The number of collaboration activities depends on the timing of the activity, program participants, legal and privacy concerns and, available budget to conduct the study. Tables 12-1 and 12-2 provide information on program evaluation activities conducted in partnership with other organizations. Three jointly funded evaluation projects were initiated in 2015 as a result of the collaboration efforts between FEI and BC Hydro; Residential Outreach Program – Empower Me Participant Survey, Home Energy Rebate Offer (HERO) – Participant Survey, and Home Energy Rebate Offer (HERO) – Quality Study of Insulation. In addition, BC Hydro and FEI continue to collaborate in the evaluation projects for the Energy Conservation Assistance Program (ECAP) and the Energy Savings Kit Program (ESK).

Collaboration efforts on evaluation have been further enhanced by the Memorandum of Understanding (MOU) on collaboration discussed in Section 2.6. The FEU and BC Hydro evaluation staff held update meetings to review the evaluation plans and discuss future evaluation activities. Evaluation staff from FEI, FBC and BC Hydro continue to hold update meetings and explore opportunities for future collaboration on program evaluations.

13. DATA GATHERING, REPORTING AND INTERNAL CONTROLS PROCESSES

13.1 Overview

The following section demonstrates that FEI has business practices in place to ensure DSM activities and associated spending are in compliance with Commission Orders and the Company's internal control processes. In its 2009 Decision, the Commission directed the FEI to include a discussion in the DSM Annual Report of the Company's internal data gathering, monitoring and reporting control practices. FEI continues to provide this information. This section addresses that directive by providing general information on data gathering and on FEI's business practices related to program development and application processing.

13.2 Program Tracking, Evaluation and Reporting Functions

FEI staff responsible for tracking, evaluation and reporting of DSM activities continue to report to a different Director than staff responsible for program development and implementation in order to:

- conduct independent evaluation activities;
- maintain an independent library of inputs into cost effectiveness calculations; and
- centralize reporting processes.

13.3 Robust Business Case Process Applied to All Programs

Before a new DSM pilot or program can be implemented, a business case must first be developed. FEI is committed to putting each pilot or program through the appropriate level of internal scrutiny before moving ahead, and believe doing so ensures an increased chance of pilot or program effectiveness.

Business cases include information about program rationale and purpose, as well as a description of the target audience, assumptions, cost-benefit tests and proposed evaluation methods. Cost effectiveness analysis is performed using the California Standard Tests (CST) as outlined in the California Standard Practice Manual. FEI uses an in-house cost-benefit modeling tool developed in partnership with expert industry consultants[23] to apply the program costs and benefits in each of the four standard cost-effectiveness tests based on the California Standard Practice Manual (Rate Impact Measure [RIM], Utility, Participant, and TRC) and the MTRC in accordance with British Columbia Demand-Side Measures Regulation.

The results from this modelling are used as inputs for the business cases, which are approved in accordance with FEI's policy on financial authorization levels.

In addition to the internal business case process, the Commission, in its' 2014-2018 PBR decision, has directed FEI to submit a written request and business plan for any new programs

[23] Willis Energy Services Ltd. and The Cadmus Group Inc. provided input into this in-house cost-benefit modelling.

they want to implement that have not previously been identified within the approved DSM Plan. Such requests must demonstrate the new program results in a net improvement to the Portfolio effectiveness or is needed to ensure balanced access to DSM programming among different customer groups. In 2015, business plans were submitted to the Commission for the new RAP program, the Low Income Top-up Programs and the Specialized Industrial Process Technology Program. Each program submission received Commission approval and is discussed in each of the relevant Program Area sections above.

13.4 Incentive Applications Vetted for Compliance with Program Requirements

Ensuring that all customer applications are compliant with program eligibility requirements as laid out in program terms and conditions is also part of the internal control process. FEI has a number of mechanisms in place to ensure DSM incentive funding applications are in compliance with program requirements. The verification process is specific to each program and is dependent on the type of program, its complexity, the financial value of the incentive and other parameters. The general principles applied are as follows:

- Each application is reviewed for completeness and accuracy;
- Applications must meet the criteria outlined in the terms and conditions of the program put forward through the approval process;
- Once approved, incentives are distributed to participants; and
- Copies of application and supporting documents are filed and stored for seven years in case of an audit.

13.5 Internal Audit Services

FEI regularly engages the Company's own Internal Audit Services (IAS) group to review the internal controls associated with the DSM activities. The IAS utilize the most recently completed year of operation on which to conduct their audit (In this case, the 2014 Audit covers the 2013 year. This is consistent with past reports). This audit has been conducted annually up until 2015. In 2015, the IAS group determined that since each of its previous audits determined that FEI's DSM activities were satisfactorily in compliance, the frequency of the audits would be reduced. Therefore, this internal audit was not conducted in 2015. FEI expects the next audit to be completed in late 2016 or early 2017.

13.6 Summary

FEI is committed to strong internal controls in all aspects of the DSM programs. As demonstrated in this section, the Company's business practices related to program development, application processing and ongoing monitoring are all sound and subject to continuous improvement.

14. 2015 DSM PROGRAMS ANNUAL REPORT SUMMARY

In 2015, FEI's DSM portfolio expenditures reached 87% of Plan with 66% of actual DSM program spending going toward customer incentives. With more than 434,000 GJ of annual savings, DSM programming continued to contribute options for customers to reduce their energy use. The FEI cost-effectively delivered these programs within the spending limits approved by the Commission, and in accordance with the BC Demand-Side Measures Regulation. FEI believes that they have made every reasonable effort to ensure DSM programs are operating in compliance with the Company's own DSM Guiding Principles and are meeting provincial requirements for adequacy. FEI also continues to implement good internal data gathering, monitoring and reporting control practices.

2016 Annual Report

March 31, 2017

Table of Contents

List of Tables

1. REPORT OVERVIEW

FortisBC Energy Inc. (FEI or the Company),[1] is committed to delivering a broad portfolio of cost effective Demand-Side Management[2] (DSM) measures that address the expectations of customers while meeting the requirements for public utilities to pursue cost effective DSM. In 2016, the company achieved a combined portfolio MTRC[3] of 1.2 on expenditures of $32.165 million, meeting FEI's goal of cost effective program delivery.

This DSM Annual Report (the Report) outlines the Company's actual results and expenditures for 2016. The Report follows a similar format to the 2015 and other previous Annual Reports, relying on detailed tables to demonstrate Program results and expenditures. The Report compares 2016 activity and results to the Company's 2014-2018 DSM Plan, as provided in the FEI's 2014-2018 Performance Based Ratemaking (PBR) Application and approved by the Commission in Order G-138-14. Where the details of individual programs vary substantially from the 2014-2018 DSM Plan, explanations are provided in the applicable Program Area Sections of this report.

1.1 PURPOSE OF REPORT: TRANSPARENCY, ACCOUNTABILITY AND UPDATE ON PROGRESS

This Report details the Company's activities for the overall DSM portfolio and in each Program Area. Incentive and non-incentive expenditures are reported at the level of each program or measure, as well as at the program area and portfolio levels. Results for the following cost effectiveness test calculations are provided for the overall portfolio and each Program Area in Section 2, and for each program or measure in the respective Program Area sections: Total Resource Cost (TRC) Ratepayer Impact Measure (RIM), Participant Cost Test (PCT), and Utility Cost Test (UCT). In accordance with British Columbia's *Demand-Side Measures Regulation* (DSM Regulation), results of the modified TRC (MTRC) calculations (see Section 2.1) are also provided where appropriate.

This Report also demonstrates that the Company is meeting the accountability mechanisms directed by the British Columbia Utilities Commission (BCUC or the Commission) in Order G-36-09. One such mechanism was the requirement to file DSM Annual Reports, which states:

---

1 The three BC Gas utilities formerly known as FortisBC Energy Inc. (FEI), FortisBC Energy (Vancouver Island) Inc. (FEVI) and FortisBC Energy (Whistler) Inc. (FEW) were amalgamated into a single utility - FortisBC Energy Inc. - in 2014. 2015 was the first complete year that the company operated as a single utility, which is reflected throughout this document by eliminating the breakout of separate FEI, FEVI and FEW statistics and results.

2 Throughout this Annual Report the use of the term Demand-Side Management or "DSM" is intended to refer to demand-side measures in B.C. as defined in the B.C. *Demand-side Measures Regulation* (DSM Regulation).

3 Pursuant to the DSM Regulation, the portfolio level MTRC is calculated based on costs and benefits of all programs in the portfolio as well as any program area and portfolio level administration costs, and including the benefit adders for those programs for which the MTRC is relied upon to determine cost effectiveness on an individual program basis (i.e. those programs that have been designated as being under the MTRC Cap as presented in Section 2.1 of this report).

> A requirement that Terasen [now FEI] submit annually to the Commission, by the end of the first quarter following year-end, for each year of the funding period, a report on all [DSM] initiatives and activities, expenditures and results for TGI and TGVI.

Use of Report:

The energy savings and cost effectiveness results presented in this report are strictly those resulting from FEI's annual DSM activities as calculated according to industry accepted methods. This information should not be interpreted as the total energy savings from all natural gas conservation initiatives in the FEI service territory, nor the total savings an individual customer may experience. Examples of energy savings not reported here because they are achieved through mechanisms other than FEI's DSM activity include natural conservation through ongoing advancements in equipment efficiency and building envelope construction and initiatives funded by individuals or entities other than FEI.

1.2 *ORGANIZATION OF REPORT*

The following describes how each section of the Report presents the results of 2016 DSM activities:

Section 1: Report Overview

- Provides a high-level background for the Report.

Section 2: Portfolio Overview

- Provides a summary and detail regarding the actual 2016 expenditures for DSM activities.
- Section 2.5 discusses any new requirements from the Commission concerning information to be included in the 2016 DSM Annual Report.

Section 3: Funding Transfers

- Provides a discussion on funding transfers between program areas.

Section 4: Energy Efficiency and Conservation ("EEC") Advisory Group Activities

- Provides information regarding EEC Advisory Group ("EECAG") activities in 2016, including a summary of meetings and accountability considerations.

Sections 5 - 9 provide information on:

- Residential Energy Efficiency Program Area;
- Low Income Energy Efficiency Program Area;
- Commercial Energy Efficiency Program Area;
- Innovative Technologies Program Area; and

- Industrial Energy Efficiency Program Area.

Each of the above mentioned sections contain a table summarizing the planned and actual expenditures for the respective Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost effectiveness test results. Additional tables outline the individual 2016 programs, including program and measure descriptions, program assumptions and sources for these assumptions, and a breakdown of incentive and non-incentive spending. Where applicable, details on program closures or planned programs that were not launched in 2016 are also included in these program detail sections.

Section 10: Conservation Education and Outreach Initiatives

- Provides both a summary and details regarding actual 2016 expenditures for the Conservation Education and Outreach (CEO) Program Area.

Section 11: Enabling Activities

- Provides both summary and detail regarding actual 2016 expenditures for the Enabling Activities that support the work of the DSM portfolio as a whole.

Section 12: Evaluation

- Provides both summary and detail regarding pending and actual expenditures for 2016 program evaluation activities, as well as summary results from evaluations and studies completed in 2016.

Section 13: Data Gathering, Reporting and Internal Control Processes

- Provides a summary of the Company's data tracking, process control and reporting for 2016 DSM activities, and a high level description of the Company's internal approval process for programs.

Section 14: 2016 DSM Annual Report Summary

- Summarizes the Report and the Company's 2016 DSM activity.

2. PORTFOLIO OVERVIEW

In this Section, FEI provides its DSM energy savings, expenditures and cost effectiveness test results at an overall portfolio level for 2016. A summary of the overall portfolio results is provided in Table 2-1, demonstrating that the Company achieved a combined portfolio MTRC of 1.2. DSM expenditures were almost $32.2 million and recorded natural gas savings were over 438,827 GJ.

Table 2-1: Overall DSM Portfolio Results for 2016

Indicator - 2016 Results		Total
Annual Gas Savings (GJ/yr.)		438,827
NPV of Gas Savings (GJ)		3,682,160
Utility Expenditures, Incentives ($000s)		21,045
Utility Expenditures, Non-Incentives ($000s)		11,120
Utility Expenditures, Total ($000s)		32,165
Benefit/Cost Ratios	TRC	0.7
	MTRC	1.2
	Utility	1.0
	Participant	1.5
	RIM	0.5

Table 2-2 provides the cost effectiveness test results by Program Area for the overall DSM portfolio.

Table 2-2: Overall DSM Portfolio Level Results by Program Area 2016

Portfolio	Annual Gas Savings (GJ/yr.)		NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending						
	2014-2018 EEC Plan	2016 Actual		2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	TRC	MTRC	Utility	Participant	RIM

Notes:

- Portfolio Level Activities are those activities for which the costs cannot be assigned to individual DSM programs. It should be noted that these activities are distinct from the Enabling Activities specifically listed in Section 9 of the 2014-18 Plan. These distinct Portfolio Level Activities include expenditures such as EECAG activities, DSM Energy Solutions Managers, portfolio level staff labour, some staff training and conferences, research and association memberships, and portfolio level research studies.

Throughout this Report, the following general notes also apply to all the program areas:

- In the above table, and in tables throughout the report, any difference in the totals between tables in the Portfolio Overview or Program Area Sections, and individual program tables is due to rounding. Some "zero" values are a reflection of rounding to the $000 expenditure level when expenditures were under $500.
- A "Non-Program Specific Expense" line item has been included for each program area. These expenditures represent the costs attributable to that program area but support multiple programs and, therefore, are not specific to only one program. Generally, these expenditures represent items such as training, travel, marketing collateral and consulting services that support the overall program area.

It is FEI's view that, as with prior annual reports, the savings reported herein continue to be conservative and lower than the savings experienced in the marketplace as a result of the Company's DSM activities, causing the cost effectiveness test results reported to be lower than they would be otherwise, for the following reasons:

- Net-to-Gross-Ratio - The Net-to-Gross ratio that FEI is using to report energy savings from DSM activity is highly conservative in that it includes the free ridership impact, which serves to reduce reported energy savings, but in most cases does not include the energy savings benefits of spillover[4] effect, which serves to increase energy savings.
- Attribution from Government Regulation –The Company continues to believe the claimed savings reported in this report do not represent all of the savings attributable to FEI's codes and standards work, due to limitations in the rules for reporting these savings.
- Conservation Education and Outreach – CEO activities had expenditures of $2.4 million in 2016. These activities do result in energy savings; however, since these savings remain difficult to quantify, FEI does not currently attribute energy savings to them.
- Enabling Activities – Enabling Activities similarly had expenditures of $1.4 million in 2016 for work that contributes to energy savings but that cannot currently be quantified. Since these savings are not included in the portfolio TRC calculation, the Company believes the portfolio energy savings benefits are higher than reported.

FEI's DSM activities include a number of specified demand side measures. The DSM Regulation stipulates that the cost effectiveness of specified measures must be determined by the cost effectiveness of the portfolio as a whole. These measures are therefore not subject to the 33 percent 'MTRC Cap' (see Section 2.1). Additionally, these measures cannot be determined to be not-cost effective under the UCT.

[4] Free ridership refers to individuals who participate in a program who would have participated in the absence of an incentive. Spillover refers to individuals that adopt efficiency measures because they are influenced by program-related information and marketing efforts, though they do not actually participate in the program. These can be included in the Net-to-Gross ratio employed in the cost effectiveness analysis to capture the additive effects of spillover to balance the reductive effects of free ridership.

In summary, FEI's 2016 DSM expenditures, including specified DSM, were cost effective under the BC DSM Regulation.

2.1 PORTFOLIO LEVEL MTRC CALCULATION AND RESULTS

In 2016, FEI met the conditions of the Province's DSM Regulation, achieving a portfolio MTRC value of 1.2 (see Table 2-2). While FEI strives for TRC test results that approach or exceed 1.0 within each program and across all programs, there are benefits to implementing programs that do not meet this threshold. Some of these benefits include making programs available to those customers that would otherwise be underserved (such as low income and residential customers), water savings, increased human health and comfort, and economic benefits such as job creation. These benefits are recognized in the DSM Regulation, which enable the use of an MTRC in determining program and portfolio cost effectiveness. The MTRC uses the long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia as a proxy for the avoided cost of natural gas and allows for the inclusion of non-energy benefits (NEBs).[5]

Utilities can implement DSM with TRC values less than 1.0 but that meet an MTRC threshold of 1.0[6] as long as expenditures on these activities do not exceed 33 percent of the total portfolio expenditure. FEI refers to this 33 percent as the "MTRC Cap". Table 2-3 shows both the TRC and MTRC of those programs to which the MTRC cost effectiveness test is applied and confirms that these programs make up 30.7 percent of FEI's 2016 DSM portfolio spending.

Table 2-3: Programs Subject to MTRC and the Relative Proportion of 2016 Portfolio Spending

Program	Program TRC	Program MTRC	Expenditure ($000s) subject to cap	% of Portfolio Spending
Energy Star Domestic Hot Water	0.3	1.5	2,685	8.3%
Furnace Replacement	0.4	1.3	3,294	10.2%
EnerGuide 80 New Construction	0.3	1.1	50	0.2%
Energy Efficiency Home Performance (HERO)	0.4	1.6	2,282	7.1%
Domestic Hot Water Conservation Program/Low Flow fixtures	0.5	1.2	2	0.0%
Energy Conservation Assistance Program (ECAP)	0.5	1.9	1,553	4.8%
Total			**$9,864**	**30.7%**

5 The DSM Regulation was amended in July, 2014 by allowing for the whole cost of the long-run marginal cost of acquiring electricity generated from clean or renewable resources in British Columbia to be used as a proxy for the avoided cost of natural gas in the MTRC cost effectiveness test. As the DSM Regulation stipulates, the value that the FEI has used for the avoided cost of gas in the MTRC calculation is $100/MWh, or $27.78/GJ, as indicated in BC Hydro's November 2013 Integrated Resource Plan, Section 9.2.12, "Long Run Marginal Cost" (pgs. 9-51 to 9-55).

6 The Commission approved the assessment of the cost effectiveness using an MTRC of 1 or greater on an overall portfolio basis as part its decision on the 2012-2013 RRA, page 174. While this approval was not explicitly stated in the most recent 2014-2018 PBR application decision, FEI interprets this approval to be implicit in the approval of the 2014-2018 DSM Plan.

2.2 *MEETING APPROVED SPENDING LEVELS*

FEI's 2016 DSM expenditure limit of $35.8 million was approved on September 12, 2014, as part of the Commission's decision on the Company's 2014-2018 PBR Application[7], pursuant to section 44.2 of the *Utilities Commission Act*. The Company's DSM expenditures were within the approved levels and have increased from 2015 spending of just under $32 million. As part of the Commission's decision, FEI was granted approval to add $15 million of the requested annual DSM budget to rate base each year of the PBR period, with any additional DSM spend being captured in a DSM non-rate base deferral account attracting AFUDC. Any new amounts accumulated in the non-rate base DSM deferral account are then transferred to the FEI rate base DSM deferral account in the following year. The Commission also approved the amortization of these amounts over 10 years. In accordance with the Commission's decision $16.4 million was placed in the non-rate based DSM deferral account in 2016.

FEI notes a difference in the total DSM rate base ($15 million) plus non-rate base deferral account amount ($16.4 million) versus the total 2016 expenditures ($32.2 million) reported in Tables 2-1 and 2-2. This difference is due to funding from the Provincial government in support of residential and low income programs in partnership with the Utility and on a few cases of amounts being reported in the annual report in one year and processed in the FEI accounting system in the next at year-end.

FEI has managed its 2016 DSM activity within the funding limits approved by the Commission. Section 3 discusses funding transfers between program areas in 2016 within the overall DSM funding envelope and within rules for transferring funds between program areas as set out by the Commission.

2.3 *MEETING ADEQUACY REQUIREMENTS OF THE DEMAND-SIDE MEASURES REGULATION*

The DSM Regulation has the following requirements for a utility's portfolio of DSM activity to be considered adequate:

> A public utility's plan portfolio is adequate for the purposes of Section 44.1 (8) c of the Act only if the plan portfolio includes all the following:
>
> a) A demand-side measure intended specifically to assist residents of low-income households to reduce their energy consumption;
> b) If the plan portfolio is introduced on or after June 1, 2009, a demand-side measure intended specifically to improve the energy efficiency of rental accommodations;
> c) An education program for students enrolled in schools in the public utility's service area;

[7] BCUC Order G-138-14, page 277 of the Decision.

d) If the plan portfolio is submitted on or after June 1, 2009, an education program for students enrolled in post-secondary institutions in the public utility's service area.

The Company has met all the requirements for adequacy. There are a number of programs for low income customers, which are discussed in Section 6. FEI operates a Rental Apartment Efficiency Program specifically to address the unique market barriers to energy efficiency faced by renters in addition to a number of Commercial and Low Income energy efficiency programs intended for use by owners of rental buildings. In 2016, the Rental Apartment Efficiency Program ("RAP") program has been expanded to include incentives as part of the Low Income Program Area.

In terms of education programs, FEI's School Education Program, Commercial and Residential customer education programs and other energy efficiency and conservation outreach initiatives are presented in Section 10.

2.4 ADDRESSING BCUC DIRECTIVES FROM THE FEI 2014-2018 PERFORMANCE BASED RATEMAKING DECISION

The Company filed their 2014-2018 DSM Plan and associated funding request to the BCUC with the FEI 2014-2018 PBR Application. There were a number of Commission Directives from that Decision that are specific to the 2014-2018 DSM Plan. In this section, FEI addresses Directives relevant to the overall 2016 DSM Portfolio. Program specific directives are addressed in the applicable program area sections of this report.

2.4.1 Labour Costs

As with the 2015 Annual Report, FEI has included labour cost coded to each DSM program in the reported "Administration" expenditures for each program as directed by the Commission in the FEI PBR[8] approval. This information is included in the specific Program tables included in each DSM Program Area section of this Report (Sections 5-11). FEI notes that while the 2014–2018 DSM Plan was approved by the Commission as set out in FEI's application, program and program area costs were not re-cast with labour included at the program level. This change therefore impacts the direct comparison of actual program and program area spending to plan. The inclusion of Labour costs at the Program level can cause program area expenditures to appear higher than the approved amounts even though non-labour costs are within approved amounts. Actual spending in the "Enabling Activities" program area will also be lower than planned since a substantial amount of labour costs planned for this program area are being reported within other program areas. This issue is also discussed in Section 3 on funding transfers.

[8] Order G-138-14.

2.5 *COLLABORATION & INTEGRATION*

The Company continues to collaborate and integrate DSM programming among B.C.'s largest energy utilities - FEI, FortisBC Inc. (FBC) and BC Hydro and Power Authority (BC Hydro), or together the "BC Utilities" - as well as with other entities such as governments and industry associations. The Company recognizes that doing so will maximize program efficiency and effectiveness. Collaborative activity is captured in the individual Program Area sections and program descriptions found in Sections 5 through 11.

The BC Utilities continued collaborating on a wide range of programs and projects in 2016 through their voluntary Memorandum of Understanding ("MOU"), the purpose of which is to develop enhanced utility integration in support of government legislation, policy and direction. The BC Utilities are currently working under a collaborative MOU covering August 2015 through August 2018.

2.6 *SUMMARY*

The Company's DSM portfolio met the goal of cost effectiveness with a MTRC value of 1.2 in 2016. The Company is of the view that both energy savings accounted for in the portfolio and the resulting TRC remain conservative. Benefits from additional activities, such as CEO, play a very important role in supporting the development and delivery of programs, while creating a culture of conservation in British Columbia.

3. FUNDING TRANSFERS

Two program areas – Residential and CEO – incurred actual program expenditures that were greater than their respective approved Program Area funding amounts. In the case of CEO, exceedance of the approved Program Area funding level was the result of reporting labour expenditures at the program level as directed by the Commission[9]. The approved 2014-2018 DSM Plan was based on labour being reported at the portfolio level, and planned Program Area expenditure levels were not re-cast subsequent to the Commission's decision regarding the reporting of labour costs. Therefore, the approved Program Area funding limits do not include labour. Since the expenditures for CEO as shown in Table 2-2 include labour, and since the approved CEO funding level would not be exceeded if labour costs were removed, no funding transfer is required.

For the Residential Program Area, expenditures including labour and other costs exceed the approved funding level by $1,421,000 as a result of the success of the residential programs. This amount can be drawn from a combination of funds remaining in other program areas without exceeding 25 percent of the respective program areas' approved funding levels[10], notwithstanding the inclusion of labour in actual program area expenditures, but not in approved plan expenditures for those program areas.

[9] Order G-138-14, Directive 145

[10] According to Order G-128-14, Directive 151, funding transfers in excess of 25 percent of program area approved funding levels require prior approval from the Commission.

4. EEC ADVISORY GROUP ACTIVITIES

4.1 *OVERVIEW*

The Energy Efficiency and Conservation Advisory Group (EECAG) provide insight and feedback on FEI's portfolio of DSM activities and related issues. This includes: DSM program and portfolio performance, development and design; funding transfers; policy and regulations that may impact DSM activities; and other issues and activities as they may arise.

Members may be appointed based on their relevant subject matter expertise, representation of a common interest shared by stakeholders, or representation of a particular organization/group and/or interest. This includes, but is not limited to, governments, regions, First Nations organizations, customers, suppliers, industries, non-governmental organizations, research institutes and other groups that have historically intervened in FEI's regulatory proceedings.

Since the formation of the EECAG in 2009, FEI has had the opportunity to gain valuable insight on DSM program design and implementation and develop positive working relationships with stakeholders. EECAG input continues to be instrumental as FEI moves forward with DSM activities, helping to ensure that efforts are aligned with the interests and suggestions of stakeholders.

4.2 *SUMMARY OF THE 2016 WORKSHOP*

EECAG workshops provide a forum for stakeholders to learn about DSM programs and engage in constructive dialogue with FEI. Since FEI was in the third year of an approved plan for DSM activities and both the regulatory framework and market dynamics for DSM programming has remained stable during this time, a single workshop in 2016 was sufficient to update EECAG members and seek their input on programming issues. The EECAG workshop was held on November 23, 2016 in Vancouver and was well attended by EEGAG members or their alternate delegates. The EECAG Independent Facilitator was engaged in workshop design and facilitation of the workshop. Copies of materials and minutes for these meetings were distributed to EECAG members and other workshop attendees.

The design and outcomes of the November EECAG workshop recognized that FEI is currently operating its portfolio of DSM activities in a stable period of programming and DSM funding. This stability offered an opportunity for the EECAG to reflect on milestones achieved and lessons learned over the past several years of DSM program implementation. The group also examined what future trends and issues might impact the Company's DSM programming going forward as FEI begins planning the preparation of its next DSM Plan for submission to the BCUC. At the workshop, EECAG Members:

- Updated the rest of the group on initiatives related to energy efficiency that they have been either following or directly involved with;
- Identified concerns around implementing upcoming step code changes, including a potential shortage of trades people and contractors to implement changes;

- Identified challenges in reaching target audiences with key messages and resources needed to implement energy efficiency;
- Presented considerations and ideas for working with indigenous communities to improve and implement energy efficiency programs;
- Suggested potential new partnerships and areas to strengthen existing partnerships;
- Identified opportunities to improve communications with customers and other industry players;
- Suggested alternatives for resourcing initiatives and communication efforts;
- Provided alternate view points on how customers might respond to various energy efficiency initiatives;
- Provided comparisons with other initiatives (recycling programs, for example) from which to draw ideas,
- Suggested alternative incentive approaches for consideration, and
- Identified a number of trends / opportunities to watch / explore.

The purpose of these discussions was to identify potential ways that FEI DSM programs might help to overcome barriers and challenges to implementing energy efficiency, as well as identify potential opportunities for future DSM programming so that this information can be considered as FEI prepares its next DSM Plan for 2019 and beyond.

5. RESIDENTIAL ENERGY EFFICIENCY PROGRAM AREA

5.1 *OVERVIEW*

The Residential Energy Efficiency Program Area was successful in reducing annual natural gas consumption by 121,860 GJ and achieving an overall blended TRC/MTRC of 1.5. Over $12.5 million was invested in Residential Energy Efficiency programs in 2016, and 82 percent of this investment was customer incentive spending.

Table 5-1 summarizes the projected and actual expenditures for the Residential Energy Efficiency Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC/MTRC and other cost effectiveness test results.

Residential programs serve over 890,000 customers in the FEI service territories. For DSM purposes, these customers predominantly include those living in single-family homes, row houses, townhomes or mobile homes.[11] Some in-suite measures, such as low flow fixtures and a small number of fireplaces and water heaters in multi-unit residential buildings are also included in this funding envelope. Residential programs serve retrofit and new home applications. In combination with the Company's education and outreach activities, these programs play an important role in driving the culture of conservation in British Columbia.

Table 5-1: 2016 Residential Energy Efficiency Program Area Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

[11] Programs for Multifamily Dwellings served under Rate Schedule 2 or 3 are included in the Commercial Energy Efficiency Program Area (please refer to Section 7) with a few exceptions as noted in text.

Notes:

- RAP includes a combination of residential and commercial measures for both low income qualified and the able to pay rental apartment market, each funded from their respective program areas. RAP expenditures shown here are related only to the residential portion of RAP. Full RAP details are provided in Section 7.3.1 Table 7-10.
- Cost effectiveness values for the *Residential Portion* of RAP are not provided as they do not represent a complete program view. Please refer to Table 7-10 for the programs cost effectiveness results.

5.2 RESIDENTIAL TRC AND MTRC RESULTS

FEI's DSM Program Principles state that programs should be universal, offering access to programs for all residential and commercial customers. Although many Residential programs are challenged in meeting a conventional TRC test where gas costs are relatively low, these programs, with their broad reach, are cost effective when considering broader societal benefits, including greenhouse gas (GHG) emissions reductions. This is recognized in the DSM Regulation which enables the inclusion of lower TRC programs through the application of the MTRC. The overall 2016 Residential Program Area TRC was 0.5 with a blended TRC/MTRC result of 1.5.

5.3 2016 RESIDENTIAL ENERGY EFFICIENCY PROGRAMS

Tables 5-2 through 5-8 outline the specific Residential Energy Efficiency programs undertaken in 2016, including program and measure descriptions and a breakdown of non-incentive spending.

Table 5-2: Energy Efficient Home Performance Program -Home Renovation Rebate (formerly known as Home Energy Rebate Offer "HERO")

Program Description	This collaborative program promotes energy-efficient home upgrades while educating homeowners on the value of whole home performance. Utility partners administer the program. Federal, provincial and local governments co-promote this program and other related initiatives, including capacity building for the trades, home labeling and the introduction of NRCan's updated Home Energy Rating System in the spring of 2016.						
Target Market	Residential customers						
New vs Retrofit	Retrofit						
Partners	BC Hydro, FortisBC (Electric), BC Ministry of Energy and Mines, Natural Resources Canada and local governments						
Eligible Measures	Draftproofing	Attic Insulation	Basement Insulation	Wall Insulation	$750 Bonus Offer		
Incremental Measure Cost	$100	$1,147	$1,463	$1,953	N/A		
Incentive Amount	Up to $500	Up to $600	Up to $1,000	Up to $1,200	$750		
Savings Per Participant	2.4 GJ	8.9 GJ	6.1 GJ	5.6 GJ	N/A		
Measure Life	6 years for Draftproofing, 25 years for Insulation Consultations with BC Hydro, Habart & Hood, 2010 Conservation Potential Review and Dunsky Energy Consulting.						
Free Rider Rate	20% average assumed based on past program analysis and NRCan evaluation. *Final Report: Analysis of Net-to-gross Survey Results for the ecoENERGY Retrofit for Homes Program.* Bronson Consulting Group. August, 2010						
Sources of Assumptions	2010 Conservation Potential Review Dunsky Energy Consulting, Hot 2000 Modeling 2012, 2013, 2015 2012 Residential End Use Study, FortisBC BC Hydro PowerSmart, Evaluation of the LiveSmart BC Efficiency Incentive Program F2009-F2011 BC Hydro, DSM Standard - Effective Measure Life and Persistence - Revision 10 (June 2016) Analysis of program participants and data						
Participants	2016	Projected	Actual				
	Total	3,360	2,251				
Expenditures ($,000s)			Non-Incentives				
	2016	Incentives	Industry Support	Admin	Communication	Research & Evaluation	Total
	Total	2,231	65	252	67	49	2,663

Notes:

- In 2016, the Home Energy Rebate Offer was renamed Home Renovation Rebate Program as this title more accurately describes the program for customers.
- This program is a collaboration between FEI, FBC and BC Hydro with support from BC Ministry of Energy and Mines and Natural Resources Canada
- Industry support includes application support fees to energy advisors and FEI's contribution to Year-two support of the Home Performance Stakeholder Council "HPSC". The HPSC is an industry led group comprised of key industry players tasked with addressing the fragmented interests, opportunities and challenges that exist in B.C.'s nascent home performance industry which is continuously evolving.

Table 5-3: Furnace and Boiler Replacement Program

Program Description	The Furnace and Boiler Replacement program targets customers with functioning furnaces (standard or mid-efficiency) or boilers. Through a combination of marketing, incentives and industry outreach, the program encourages customers to replace the equipment immediately, rather than waiting for it to fail at some point in the future.						
Target Market	Residential customers						
New vs Retrofit	Retrofit						
Partners	N/A						
Eligible Measures	Standard efficiency	Mid - efficiency	Boilers				
Incremental Measure Cost	$1,899	$1,899	$3,756				
Incentive Amount	$800	$800	$800				
Contractor Incentive	$50	$50	$50				
Savings Per Participant	7.0 GJs	5.1 GJs	9.0 GJs				
Measure Life	Furnace & boilers - 18 years						
Free Rider Rate	Early Replacement Methodology						
Sources of Assumptions	2012 and 2013 Furnace Replacement Pilot Program Evaluation - Habart and Associates Furnace Replacement Program - Billing Analysis of 2012 Participant Savings - Sampson Research Inc. 2012 FortisBC Residential End Use Study Navigant Consulting report BC Hydro Power Smart QA Standard NRCan Analysis of program participants and data						
Participants	2016	Projected	Actual				
	Total	3,730	4,117				
Expenditures ($,000s)			Non-Incentive Expenditures				
	2016	Incentives	Dealer Incentives	Admin	Communication	Research & Evaluation	Total
	Total	3,294	211	72	66	0	3,642

Notes:

- As in previous years, the Furnace & Boiler Replacement program pre-qualification period was run outside of heating season to reduce the incidence of emergency replacements.
- Contractor incentives of $50 per participant are allocated to the administration portion of non-incentive spend.
- Based on industry feedback received during 2016, FEI is considering some program design updates.

Table 5-4: EnerChoice Fireplace Program

Program Description	This program promotes the purchase and installation of energy-efficient EnerChoice fireplaces for zone heating. The program educates consumers and dealers about the EnerChoice label and the benefits of selecting natural gas fireplaces based on energy-efficiency and heating attributes, rather than just decorative features. Program awareness and participation was promoted through a combination of customer and dealer incentives and promotional activities. The program was out of market from January 1 to April 30, 2016, to re-evaluate the eligible models directory and reintroduced May 1, 2016.
Target Market	Residential customers
New vs Retrofit	Both
Partners	N/A
Eligible Measures	EnerChoice Fireplace
Incremental Measure Cost	$132
Customer Incentive	$300
Contractor Incentive	$50 (Retrofit only)
Savings Per Participant	EnerChoice Fireplace (Retrofit): 7.8GJ EnerChoice Fireplace (New Construction): 5.0GJ
Measure Life	15 years
Free Rider Rate	2015 program participants - 30% based upon participant questionnaire responses 2016 program participants - 38% based upon participant questionnaire responses
Sources of Assumptions	Impact of Terasen Gas Pilot Fireplace Program (2004) by Habart and Associates 2010 Conservation Potential Review 2012 FortisBC Residential End Use Study 2013 FortisBC Fireplace Upgrades Pre-Feasibility Study 2015 FortisBC EnerChoice Fireplace Program Impact Evaluation 2016 FortisBC EnerChoice Market Effects Study 2016 FortisBC Apartment Fireplace Efficiency Pilot Gas Fireplace Regulatory Proposal - BC Ministry of Energy and Mines, Energy Efficiency Branch (September 2016) Analysis of program participants and data

Participants	2016	Projected Total		Retrofit	New Construction	Total
			2015 Program	2,832	0	2,832
			2016 Program	1,270	1017	2,287
	Total	3,285		4,102	1,017	5,119

Expenditures ($,000s)			Non-Incentives				
	2016	Incentives	Dealer Incentives	Admin	Communication	Research & Evaluation	Total
	Total	1,536	203	82	75	0	1,896

Notes:

- 2016 EnerChoice fireplace program was out of market from Jan through April, while FEI developed a new eligible products directory.
- The EnerChoice Fireplace Program evaluation suggested the need to update the EnerChoice eligible products directory to improve minimum efficiency standards. Therefore the EnerChoice retrofit program was temporarily suspended to undertake industry and government consultation for 2016 program design. The 2016 program was launched May 1, 2016 with a new eligible products directory as the key program enhancement.
- Models included in the FEI eligible EnerChoice fireplace directory must be direct-vented and not have a standing pilot. These requirements support the B.C. Building Code and provincial policy. In addition, the models must be modulating as reported in the Natural Resources Canada fireplace models directory.
- Contractor incentives of $50 per participant are allocated to the administration portion of non-incentive spend.

- In 2016, the Energy Efficiency Branch of the B.C. Government introduced a regulatory proposal to increase the standard of efficiency for fireplaces sold in B.C. that will take effect in 2018. This announcement presents an opportunity for FEI to claim savings, pursuant to the DSM Regulation, as a result of advancing a standard. FEI is assessing the benefits of this advancement for inclusion in the 2017 portfolio results.

Table 5-5: Appliance Service Program

Program Description	This program provides customer education related to the importance of regular appliance maintenance to ensure efficient operation of natural gas appliances. This program also creates opportunities for contractors to dialogue with customers about upgrading appliances to more efficient models.					
Target Market	Residential customers					
New vs Retrofit	Retrofit					
Partners	N/A					
Eligible Measures	Furnace Service (62%), Fireplace Service (33%), Boiler (5%)

Table 5-6: ENERGY STAR® Water Heater Program

Program Description	This program promotes the replacement of standard efficiency water heaters with efficient ENERGY STAR® models. As part of a longer term market transformation strategy, the program introduced 0.67 EF storage tank water heaters and new technologies with energy factors (EF) greater than 0.80. The new technologies include condensing and non-condensing tankless water heaters, hybrids and condensing storage tanks. The program is available to both retrofit and new construction markets. The program supports upcoming federal and provincial Minimum Efficiency Act Standards for natural gas- and propane-fired water heaters.

	Total	50	8	0	0	57

Table 5-8: New Home Program

Program Description	This program provides education and financial incentives to support energy-efficient building practices for the Residential sector. This program supports efficiency updates to the BC Building Code (effective Dec. 2014). In June 2015, the utilities launched ENERGY STAR® for New Homes as the new whole home performance standard.					
Target Market	Builders of residential properties – single family homes and townhomes and homeowner builders					
New vs Retrofit	New Construction					
Partners	BC Hydro and FBC					
Eligible Measures	**ENERGY STAR Single Family Dwellings**				**ENERGY STAR Townhome/Rowhome**	
Incremental Measure Cost	$3,007				*No applicants to date	
Incentive Amount	$2,000					
Savings Per Participant	20.1 GJs					
Measure Life	25 years					
Free Rider Rate	15% for ENERGY STAR					
Sources of Assumptions	New Construction Costs and Savings and Life Cycle Costs, First published in 2011 and updated in 2014, Cooper and Habart, and Dunsky Energy Consulting Analysis of program participants and data					
Participants	2016	Projected	Actual			
				ENERGY STAR SFD		Total
	Total	1,520		25		25
Expenditures ($,000s)	2016		Non-Incentives			
		Incentives	Program Administration	Communication	Research & Evaluation	Total
	Total	50	40	57	2	149

Notes:

- FEI has collaborated with BC Hydro Power Smart and FBC on this program in past years. As of January 2016, BC Hydro removed their incentives although they continue to collaborate with FEI in providing education to builders and energy advisors and support policy regarding High Performance Homes in the province.
- The participant counts in this table are for the ENERGY STAR whole home component of the program. Incentives for natural gas water heaters and fireplaces installed in new home construction are noted under their respective program tables.

5.4 *2016 RESIDENTIAL ENERGY EFFICIENCY PROGRAMS PLANNED BUT NOT LAUNCHED*

5.4.1 Customer Engagement Tool

The Customer Engagement Tool pilot, being developed in partnership with FBC, was postponed to ensure that customer data exchanged with the service provider is secure and in compliance with the *Personal Information Protection Act* (PIPA) and corporate privacy policies. Work is currently underway to further develop and move forward with this pilot.

5.4.2 On-Bill Financing

On-bill financing pilots were found to be expensive and administratively burdensome for utilities. Pilot implementations were unsuccessful with very low uptake rates. However, in 2016 FEI continued to partner with CIBC to offer a competitive financing package through the Trade Ally Network. Partnerships with additional financial institutions, such as Vancity, also continued through 2016 in collaboration with BC Hydro and marketed through the Home Renovation Rebate Program.

5.4.3 New Technologies

FEI continues to explore New Technologies through the Innovative Technologies Program. There were no new technologies introduced in 2016. A combination space and water heating system program is under consideration based on results from the combination space and water heating system pilot (refer to Table 8-2).

5.5 SUMMARY

Residential Energy Efficiency Program Area activity in 2016 resulted in over 120,000 GJs/year of natural gas savings. These programs enabled customers to upgrade appliances and capture energy savings, and continued to build on relationships with the trades for education and program awareness. The combination of financial incentives, policy support, contractor outreach and effective marketing in these programs is instrumental to their ongoing success in generating natural gas savings and fostering market transformation in the residential sector.

6. LOW INCOME ENERGY EFFICIENCY PROGRAM AREA

6.1 *OVERVIEW*

Investments in Low Income DSM programs increased by more than 46 percent in 2016 over 2015. FEI saw the highest participation in Energy Saving Kit (ESK) since 2011, the highest participation in Energy Conservation Assistance Program (ECAP) since the program inception, maintained the Residential Energy Efficiency Works (REnEW) session, and launched three new programs: Low Income Space Heat Top Up, Low Income Water Heating Top Up and the Non-Profit Custom Program.

In addition to FEI's own Low Income programs, progress continues to be made on investing the $5.155 million in funds granted to FEI by the Ministry of Energy, Mines and Natural Gas in 2009 to enable energy efficiency in low income households. In 2016, the Company invested $499 thousand of this funding primarily on retrofits in First Nations bands, Low Income households, outreach focused on the ECAP program, partnership funding of the REnEW program, development of a building operator online training system, and an energy advisor position focused on the non-profit building sector. None of these investments are included in the spending amounts shown in Table 6-1. The remaining granted funds, $867 thousand, will be invested in 2017.

Table 6-1 summarizes the planned and actual expenditures for the Low Income Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as the cost effectiveness test results. The TRC and MTRC for low income programs use a value of 140 percent of the benefits in accordance with July 2014 amendments to Section 4(2)(b) of the DSM Regulation. This amendment effectively increases the deemed cost effectiveness of the Low Income programs.

Table 6-1: 2016 Low Income Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios

Total	**27,747**	**36,918**	**270,705**	**1,654**	**1,597**	**1,387**	**679**	**3,042**	**2,277**	**1.2**	**2.3**	**1.4**	**3.0**	**0.7**

Notes:

- The Space-Heat Top Up, Water-Heating Top Up and Non-Profit Custom Programs are new programs launched in 2016, following BCUC approval.
- During implementation of the Non-Profit Custom Program, FEI determined that some program objectives could be more easily met by extending RAP eligibility to low-income customers. Hence the introduction of the Low-Income RAP line item in Table 6-1.
- RAP includes a combination of residential and commercial measures for both low income-qualified and the able-to-pay rental apartment market, each funded from their respective program areas. RAP expenditures shown here are related only to the Low Income portion of RAP. Full RAP details are provided in Section 7.3.1, Table 7-10
- Cost effectiveness values for *the Low Income Portion* of RAP are not provided as they do not represent a complete program view. Please refer to Table 7-10 for the program's cost effectiveness results.

6.2 *2016 LOW INCOME PROGRAMS*

Tables 6-2 through 6-7 outline the specific Low Income programs undertaken in 2016, including program and measure descriptions and a breakdown of non-incentive spending.

Table 6-2: Energy Saving Kit (ESK) Program

Program Description	The goal of this program is to reach a broad audience of Low Income customers and enable them to take some simple steps towards saving energy by installing a bundle of easy-to-install items that are delivered to their door. Promotional activities include bill inserts, event promotions such as food banks, targeted digital campaigns and partnerships with government ministries and non-profits that serve the low income population.
Target Market	Low Income Residential Customers
New vs Retrofit	Retrofit
Partners	BC Hydro and FortisBC Inc. (FBC)
Eligible Measures	Bundle of measures including high efficiency water fixtures, draft proofing tape, outlet gaskets, window film, etc.
Incremental Measure Cost	$ 20.10 Average based on the full cost of the gas measures included in the ESK.
Incentive Amount	$ 20.10 Since the program is free to participants, the incentive equals the incremental cost.
Savings Per Participant	2.7 GJ per year
Measure Life & Source	10 years - Average based on the individual gas measures included in the Energy Saving Kit
Free Rider Rate & Source	27% - Based on 2010 BC Hydro participant survey.
Participants	2016 / Projected / Actual Total / 5,740 / 12,640
Expenditures ($,000s)	2016 / Incentives / Admin / Communication / Research & Evaluation / Total Total / 254 / 53 / 62 / 0 / 369

Table 6-3: Energy Conservation Assistance Program (ECAP)

Program Description	This program enables deep energy savings in low income customer homes that have moderate to high energy consumption. Promotional activities include bill inserts, customer endorsements, outreach, promotion at events and conferences, and partnerships with government ministries, housing providers, and other organizations that serve the low income population.
Target Market	Low Income Residential Customers
New vs Retrofit	Retrofit
Partners	BC Hydro and FortisBC Inc. (FBC)
Eligible Measures	Bundle of customized measures, which may include low-flow fixtures, water heater pipe wrap, professional draft proofing, outlet gaskets, window film, insulation, improved ventilation, CO detectors, and furnaces.
Incremental Measure Cost	$627 Based on average cost of the customized bundle of measures installed. Includes the full cost of the gas measures installed in gas heated homes.
Incentive Amount	$627 Since the program is free to participants, the incentive equals the incremental cost.
Savings Per Participant	4.4 GJ per year
Measure Life & Source	12 years - Average based on the individual gas measures installed.
Free Rider Rate & Source	4% (Source: Primarily third-party studies)
Participants	2016 / Projected / Actual Total / 1,495 / 1,941
Expenditures ($,000s)	2016 / Incentives / Admin / Communication / Research & Evaluation / Total Total / 1,216 / 191 / 63 / 82 / 1,553

Table 6-4: Residential Energy Efficiency Works (REnEW) Program

Program Description	The goal of this program is to enhance the energy efficiency trade sector in BC in a manner that also enhances communities. This program targets individuals facing barriers to employment and provides training in energy efficiency retrofitting. The training is delivered by industry experts at no cost to participants.				
Target Market	Low income individuals facing barriers to employment				
New vs Retrofit	N/A				
Partners	Ministry of Energy and Mines, FortisBC Inc. (FBC)				
Eligible Measures	N/A				
Incremental Measure Cost	N/A				
Incentive Amount	N/A				
Savings Per Participant	N/A				
Measure Life & Source	N/A				
Free Rider Rate & Source	N/A				
Participants	2016	Projected	Actual		
	Total	20	13		
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	72	2	0	74

Table 6-5: Low Income Space Heat Top Up

Program Description	The existing Commercial Space Heat Program offers rebates to commercial customers for the installation of high efficiency space heating equipment in commercial applications. The Low Income Space Heat Top Up Program is an add-on to the existing Commercial Space Heat Program and offers an additional rebate over and above the commercial rebate if the customer meets the eligibility criteria. Promotional activities include partnerships with BC Housing, BC Non-Profit Housing Association (BCNPHA), and the provincial and regional BCNPHA conferences, trade shows and educational seminars.					
Target Market	The Low Income Space Heat Top Up Program is primarily focused on apartment buildings that are owned or operated by a First Nations band, a non-profit housing provider, or a housing co-operative.					
New vs Retrofit	Both					
Partners	N/A					
Eligible Measures	Condensing boilers and mid-efficiency boilers.					
Incremental Measure Cost	$7,683 per appliance					
Incentive Amount	Condensing: $6/MBH Mid-efficiency: $3/MBH					
Savings Per Participant	129 GJ/yr					
Measure Life & Source	20 years - ASHRAE Handbook and Conservation Potential Review					
Free Rider Rate & Source	18% - Efficient Boiler Program Impact Evaluation, June 12, 2003					
Participants	2016	Projected	Actual			
	Total	27	11			
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	62	2	0	0	64

Note:

- The Low Income Space Heat Top Up program was launched mid-year which led to fewer participants than planned. It's expected that participation will grow in 2017.

Table 6-6: Low Income Water Heating Top Up

</table>

Note:

- The Low Income Water Heating Top Up program was launched mid-year which lead to fewer participants than planned. It’s expected that participation will grow in 2017.

Table 6-7: Non-Profit Custom Program

Program Description	This program is designed to encourage social housing apartment buildings to replace inefficient equipment and systems with high-efficiency solutions. The program is built around three components: 1) An energy study: Currently there are two avenues available to non-profit housing providers to receive a free energy audit and study. Most participants are having their energy study performed by BC Non-Profit Housing Association (BCNPHA). Some participants are opting to go through the RAP Low Income program for these services. 2) Implementation support: Currently the implementation support is available through the RAP Low Income program. There is additional work still under development for this component of the program. Future implementation support could be offered to housing providers that have used BCNPHA for their energy study. 3) Incentives for Measures: At this point, it is only the Space Heat Top Up and the Water Heater Top Up measures that are available. Analysis is currently being performed on additional measures to offer additional incentives for.					
Target Market	The Non-Profit Custom Program is primarily focused on apartment buildings that are owned or operated by First Nations bands, non-profit housing providers, or housing co-operatives.					
New vs Retrofit	Both					
Partners	N/A					
Eligible Measures	Eligible measures include boilers and water heaters. Additional measures may in the future include items such as heating controls (i.e. zone controls, temperature set back controls, etc.) and potentially building envelope measures.					
Incremental Measure Cost	N/A					
Incentive Amount	N/A					
Savings Per Participant	N/A					
Measure Life & Source	N/A					
Free Rider Rate & Source	N/A					
Participants	2016	Projected	Actual			
	Total	11	0			
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	23	0	8	31

Notes:

- Before FEI could bring this program to market several things changed that caused FEI to consider a modified path to achieving the program objectives. These changes include:
  - a desire to ensure that there is no confusion between existing FEI programs (e.g..RAP) and the Non-Profit Custom Program
  - the energy audits that were envisioned to be included in the Non-Profit Custom Program are now being performed by staff at BCNPHA (two of which are FEI-funded Energy Specialists); and
  - RAP is open to low income buildings and thus there are some low income buildings that have participated in RAP Low Income. Please refer to Table 7-10 for the cost effectiveness results for the RAP Low Income Portion and Table 7-11 for program details.
- FEI believes that it is on a path to achieving many of the objectives outlined in the Non-Profit Custom Program through a phased approach that began in 2016 by allowing Low Income Non-Profit Housing Providers to be eligible for RAP.

6.3 *SUMMARY*

The Low Income Program Area has been an important priority for the Company since the initial creation of the DSM Program Principles. In 2016 all historical Low Income programs were operating at their highest levels to date and three new programs were introduced.

7. COMMERCIAL ENERGY EFFICIENCY PROGRAM AREA

7.1 OVERVIEW

In 2016, Commercial Energy Efficiency programs continued to encourage commercial customers to reduce their overall consumption of natural gas and their associated energy costs. The Commercial Energy Efficiency Program Area reduced annual natural gas consumption by approximately 255,400 GJs and achieved an overall TRC of 1.1. $10.637 million was invested in Commercial Energy Efficiency, of which 80 percent was incentive spending.

Table 7-1 summarizes the projected and actual expenditures for the Commercial Energy Efficiency Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost effectiveness test results.

Table 7-1: 2016 Commercial Energy Efficiency Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

Notes:

- RAP includes a combination of residential and commercial measures for both low income-qualified and the able to pay rental apartment market, each funded from their respective program areas. RAP expenditures shown here are related only to the commercial portion of RAP. Full RAP details are provided in Section Table 7-10.
- Cost effectiveness values for the *Commercial Portion* of RAP are not provided as they do not represent a complete program view. Please refer to Section 7.3.1, Table 7-10 for the program's cost effectiveness results.

7.2 2016 COMMERCIAL ENERGY EFFICIENCY PROGRAMS

The following tables outline the specific Commercial Energy Efficiency programs undertaken in 2016, including program and measure descriptions and a breakdown of non-incentive spending.

Table 7-2: Space Heat Program

Program Description	This program provides rebates for the installation of high efficiency space heating equipment in commercial applications. Currently only rebates for high efficiency boilers are offered. Rebates for condensing rooftop units may also be offered via the program in 2017.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
	Retrofit	New Construction				
Incremental Measure Cost	$21,777	$24,436				
Incentive Amount	$13,111	$20,142				
Savings Per Participant	402 GJ	757 GJ				
Measure Life & Source	20 years - ASHRAE Handbook and Conservation Potential Review					
Free Rider Rate & Source	18% - Efficient Boiler Program Impact Evaluation, June 12, 2003					
Participants	2016	Projected	Actual			
	Total	204	234			
Expenditures ($,000)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	3,208	232	33	0	3,473

Table 7-3: Water Heating Program

Program Description	This program provides rebates for the installation of high-efficiency commercial water heaters with thermal efficiencies greater than or equal to 84%.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
	Retrofit	New Construction				
Incremental Measure Cost	$9,274	$13,199				
Incentive Amount	$2,028	$4,222				
Savings Per Participant	119 GJ	188 GJ				
Measure Life & Source	12 years -2010 Conservation Potential Review, Navigant Consulting (16 April 2009) Measures and Assumptions for Demand Side Management Planning Appendix C: Substantiation Sheets Ontario Energy Board pp. 210-226.					
Free Rider Rate & Source	38% - Efficient Commercial Water Heater Evaluation 2016, Prism Engineering					
Participants	2016	Projected	Actual			
	Total	128	128			
Expenditures ($,000)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	319	117	22	52	510

Table 7-4: Commercial Food Service Program

Program Description	This program offers a suite of rebates for the installation of high-efficiency cooking appliances and it may also provide other incentives relevant to commercial food service participants such as low-flow pre-rinse spray valve or faucet aerator installations.					
Target Market	Commercial					
New vs Retrofit	Both					
Partners	N/A					
	Retrofit	New Construction				
Incremental Measure Cost	$1,968	$6,793				
Incentive Amount	$1,050	$3,224				
Savings Per Participant	47 GJ	160 GJ				
Measure Life & Source	13 Years - Foodservice Incentive Program Study 2012, Fisher-Nickel Inc., Marbek Conservation Potential Review (2010) and Database for Energy Efficiency Resources (DEER). San Francisco, CA, California Public Utilities Commission, 2011.					
Free Rider Rate & Source	20% - Foodservice Incentive Program Study 2012, Fisher-Nickel Inc. and Database for Energy Efficiency Resources (DEER). San Francisco, CA, California Public Utilities Commission, 2011.					
Participants	2016	Projected	Actual			
	Total	398	307			
Expenditures ($,000)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	385	122	104	10	622

Notes:

- In 2016 as part of the Commercial Food Service Program, FEI in partnership with The City of Richmond and The City of Victoria offered a program to install low-flow pre-rinse spray valves and faucet aerators in food service establishments.
- The savings, participation and incremental costs for these measures are included in the average values for the retrofit market. The low cost and savings of these measures has resulted in comparatively low average incentives, savings and incremental costs for retrofit participants.

Table 7-5: Customized Equipment Upgrade Program

Program Description	This program provides eligible customers with funding towards the completion of a detailed Energy Study, to identify energy saving opportunities specific and customized to their facilities, and subsequent capital incentive funding to encourage the implementation of any cost effective measures identified therein. The program seeks to capture energy savings associated with measures that are otherwise difficult to incent as part of a prescriptive program because they are complex, and one project may include multiple measures with interactive effects. The expected energy savings, measures, capital cost, incentives etc., will necessarily vary depending on the customer, though each project is submitted to a TRC test and must be approved by the utility.				
Target Market	Commercial customers				
New vs Retrofit	Both				
Partners	BC Hydro (New Construction) FortisBC (New Construction and Retrofit programs - Program development/testing stage)				
Eligible Measures	Utility funded energy study, and utility incented Energy Saving Measures as identified in the energy study and approved by the utility. Energy Saving Measures are variable.				
Incremental Measure Cost	Variable. Dependent upon participant's proposed Energy Saving Measures.				
Incentive Amount	If TRC ≥ 1.0 then $5 / discounted GJ saved over 50% of the Energy Measure Life (EML), up to 10 yrs.				
Savings Per Participant	Variable. Dependent upon participant's proposed Energy Saving Measures.				
Measure Life & Source	Variable. Dependent upon participant's proposed Energy Saving Measures.				
Free Rider Rate & Source	Variable. Dependent upon participant's proposed Energy Saving Measures.				
Participants	2016	Projected	Actual		
	Total	78	64		
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	2,017	432	17	17	2,483

Notes:

- The Customized Equipment Upgrade Program is complex in nature and has variable measure savings, costs, incentives and/or cash flows which, unlike in prescriptive programs, occur over a period of years. Consequently, providing results for this program within an annual report format is challenging. In general, the savings in this program occur in later years after the participants have had the time to implement customized Energy Conservation Measures, while some program incentives and costs are payable at the outset. Please refer to the notes provided below for additional details.
- New Construction Program:
  - Participation in this program can last for approximately 5 years. This is broken down into approximately 12 months to prepare the required whole building energy simulation, followed by up to 48 months to build the proposed building. The program incurs incentive expenditures upon the successful completion of the energy simulation, as well as upon completion of the building, while natural gas savings are only obtained upon completion of the proposed building.
  - Participants are recorded when the energy simulations or the new buildings are complete, and the incentive becomes payable.
  - The 2016 Actual participants include 14 completed energy simulations, and 3 completed buildings with implemented measures. The associated gross natural gas savings from these 3 projects is approximately 25,269 GJ/year.

- Retrofit Program:
  - Participation in this program can last for approximately 2 years. This is broken down into approximately 6 months to prepare the required energy study, followed by 18 months to implement the proposed Energy Conservation Measures. The program incurs incentive expenditures upon the successful completion of the energy study, as well as upon installation of the approved Energy Conservation Measures, while natural gas savings are only obtained upon installation of the approved Energy Conservation Measures.
  - The '2016 Actual' participants included 23 completed energy studies, and 24 projects where Energy Conservation Measures were installed. The associated gross natural gas savings from these 24 projects is approximately 56,756 GJ/year.

Table 7-6: EnerTracker Program

Program Description	This pilot program is a subset of the continuous optimization (C.Op) program. It provides participants who are otherwise unable or unwilling to participate in the full C.Op program with access to an Energy Management Information System (EMIS). EMIS software provides customers with a detailed picture of their natural gas consumption in "near time". Timely access to this information is expected to speed up fault detection, thereby enabling more rapid corrective action to avoid wasted gas consumption, and to assist in the identification of additional natural gas conservation measures.					
Target Market	Commercial customers with existing AMR devices (FEI only)					
New vs Retrofit	Retrofit					
Partners	N/A					
Eligible Measures	Energy Management Information System					
Incremental Measure Cost	$799/yr (Average)					
Incentive Amount	$799/yr (Average)					
Savings Per Participant	2% of annual natural gas consumption -- Proof of concept study					
Measure Life & Source	1 year -- Measure Life is based on annual EMIS software subscription					
Free Rider Rate & Source	65% - EnerTracker Pilot Program Evaluation 2016, Prism Engineeering					
Participants	2016	Projected	Actual			
	Total	0	255			
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	204	14	7	5	230

Notes:

- An Evaluation of the pilot was completed in 2016. As described therein the program was not found to be particularly effective, and is thus discontinued after 2016.
- As there is currently insufficient AMR (Automated Meter Reader) infrastructure in the Vancouver Island service territory to support the rollout of this pilot, program availability was limited to the Lower Mainland and Interior service territories.
- Note that participation in the program is cumulative, meaning that a participant is enrolled for multiple years, claiming savings and incurring costs on an annual basis for the duration of the EMIS software license.

Table 7-7: Continuous Optimization Program

Program Description	The Continuous Optimization Program (C.Op) is designed to help commercial building owners identify and correct energy wasting operation faults, and continuously monitor building performance to help maintain and improve energy efficiency, resulting in reduced operating costs. C.Op is offered in partnership with BC Hydro. In the FortisBC electric service territory, C.Op is offered in partnership with FortisBC Inc. as the Building Optimization Program (B.Op). The program funds re-commissioning services to study the participant's building and recommend energy efficiency improvements, as well as access to an energy management information system (EMIS) to assist in tracking the building's performance after the re-commissioning work is complete. In return, participants must implement, at their costs, measures identified by the re-commissioning study that when combined have a payback period of two years or less.					
Target Market	Commercial customers with buildings >50,000 ft^2 who consume an average of 7,500 GJ of natural gas per year or natural gas is 40% of their building's total energy consumption.					
New vs Retrofit	Retrofit					
Partners	BC Hydro FortisBC					
Eligible Measures	RE/Retro-commissioning study, employee training, and "near time" energy consumption monitoring.					
Incremental Measure Cost	Average nominal program duration incremental cost (7 years): $41,275 2016 observed average implemented incremental cost: $28,435					
Incentive Amount	Average nominal program duration incentive amount (7 years): $15,915 2016 observed average implemented incentive amount: $10,834					
Savings Per Participant	Average expected annual natural gas savings: 1,465 GJ/year 2016 observed average implemented natural gas savings: 1,033 GJ/year					
Measure Life & Source	5 years - the duration of utility support for the energy management information system, plus one year.					
Free Rider Rate & Source	0% - BC Hydro					
Participants	2016	Projected	Participants Implementing in 2016	Cumulative Program Participants		
	Total	467	36	395		
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	390	10	19	0	418

Notes:

- The C.Op Program is conducted in partnership with BC Hydro and FBC. BC Hydro and FBC Inc. act as the primary administrators of program activities, with CEM providing financial and process support.
- Participation in this program lasts for approximately 7 years for a typical participant. The 7 years are composed of approximately: 12 months of baseline data collection; 24 months of re-commissioning study work, plus the implementation of a recommended bundle of energy conservation measures; and, 48 months of monitoring and continuous improvement.
- Participants are recorded as soon as they are accepted into the program; however, natural gas savings do not occur until they have completed the implementation of a recommended bundle of energy conservation measures, approximately 36 months later. As such, the program incurs incentive expenses (for the upgrading of meter equipment, re-commissioning costs and EMIS costs) before natural gas savings are obtained.

- The average nominal program duration incremental cost represents the total incremental cost expected to be incurred when an average participant completes the full 7 year run in the program. The 2016 observed average implemented incremental cost represents the incremental costs incurred specifically in 2016 divided by the total number of participants who implemented in 2016.
- The average nominal program duration incentive amount represents the total incentive expected to be paid when an average participant completes the full 7 year run in the program. The 2016 observed average implementation incentive amount represents the incentive paid specifically in 2016 divided by the total number of participants who implemented in 2016. Due to the nature of the program, the incentive amount paid is not solely attributable to those who implemented in 2016.
- The average expected annual natural gas savings represent the expected annual natural gas savings per participant after they have completed the implementation of a recommended bundle of energy conservation measures. The 2016 observed average implemented natural gas savings represent natural gas savings attributed to customers who have completed the implementation of a recommended bundle of energy conservation measures specifically in 2016 divided by the total number of participants who implemented in 2016.

Participant count clarification:

- "2016 Actual" represents the number of new participants who were approved in 2016. There were no new participants because the program is currently closed to new participants.
- “Participants Implementing in 2016" represents the number of participants who have successfully completed implementing the bundle of energy conservation measures in 2016.
- “Cumulative Program Participants" represent the total number of approved program participants from the entire multi-year duration. Program participants have the option to discontinue participation in the program during the multi-year duration. A number of program participants chose to discontinue participation in 2016 which, combined with the program being closed to new participants, resulted in a lower cumulative participation number than the previous year.

Table 7-8: Commercial Energy Assessment Program

Program Description	This program identifies inefficiencies at the participant's facilities via an on-site walkthrough assessment by an energy-efficiency consultant. The consultant then produces a report that describes the observed inefficiencies, outlines proposed solutions, and identifies any applicable incentive programs. FortisBC then forwards the report to the participant. Simple measures, such as low-flow faucet aerators and pre-rinse spray valves, are provided to the participant at no charge.					
Target Market	Medium commercial and small industrial customers with an average annual consumption between 1,500 and 10,000 GJ.					
New vs Retrofit	Retrofit					
Partners	FortisBC Inc.					
Incremental Measure Cost	$1,548					
Incentive Amount	$1,347					
Savings Per Participant	495.3 GJ					
Measure Life & Source	1.17 Years - Conservative estimate based on the implementation of low-cost, simple recommendations (such as operational adjustments) from the energy assessment report, past spray valve program data and database for Energy Efficiency Resources (DEER). San Francisco, CA, California Public Utilities Commission, 2011.					
Free Rider Rate & Source	35% - 2010 Friuch Energy Assessment Evaluation, past spray valve program data					
Participants	2016	Projected	Actual			
	Total	524	27			
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	36	26	3	0	65

Notes:

- At the time of writing the 2014-2018 DSM Plan, the FEI were unsure whether the Provincial Government's Business Energy Advisor ("BEA") program would continue or not. A contingency measure was planned for this program to ensure small businesses had access to energy analysis had the BEA program been discontinued. Participation from small business customers was foreseen in the 2014-2018 DSM Plan. As the BEA program was continued the scope of the Commercial Energy Assessment Program was not expanded to include small businesses and the number of participants in 2016 is significantly less than was estimated in the 2014-2018 DSM Plan. In addition, a significant number of multi-family apartment customers now receive their energy assessments through RAP.

Table 7-9: Energy Specialist Program

Program Description	This program funds Energy Specialist positions within customers' organizations, up to $60,000 based on an annual contract. Funded Energy Specialists' key priority is to identify and implement opportunities for their organization to participate in FortisBC's DSM programs, while also identifying and implementing non-program specific opportunities to use natural gas more efficiently. This program is funded as an enabling program.					
Target Market	Large Commercial and Institutional Customers					
New vs Retrofit	Retrofit					
Partners	BC Hydro					
Eligible Measures	Energy Specialist position					
Incremental Measure Cost	$60,000					
Incentive Amount	$60,000					
Savings Per Participant	Total 2016 verified (non-C&M program) annual natural gas savings = 6,257 GJs/ year					
Measure Life & Source	N/A					
Free Rider Rate	0% - Internal Engineering review					
Participants	2016	Projected	Actual			
	Total	36	27			
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	1,634	122	0	25	1,780

Notes:

- The Energy Specialist Program continues to experience success as an enabling program. In 2016, organizations with Energy Specialists were responsible for 28 percent of the natural gas savings and 33 percent of the incentives paid out by Commercial C&EM programs. This is in addition to the Conservation Education and Outreach, Innovative Technologies, Low Income, and Residential programs and incentives that Energy Specialists promoted and utilized in 2016.
- Some organizations had Energy Specialists for part of the year only.
- The energy savings listed only apply to natural gas projects completed by Energy Specialists in 2016 that did not directly receive incentive funding from another C&EM program. These energy savings are only reported and have not been included in the calculations for the benefit/cost tests, as the required inputs are not available.
- In July 2016, BC Hydro discontinued funding for the Business Energy Advisors (BEAs). Prior to this FEI had been co-funding eight BEAs with BC Hydro. FEI was a minority funding contributor in this arrangement, contributing $60,000 per funding year for all eight BEAs combined. This is equivalent to the funding of one Energy Specialist. BEAs were tasked with the same objectives as Energy Specialists but targeted small to medium sized businesses. As a collective they were expected to achieve FEI C&EM program participation results similar to that of one Energy Specialist. Hence, this has been counted as one participant in the participant total for the Energy Specialist Program.

7.3 *2016 PROGRAMS WITH JOINT PROGRAM AREA BUDGETS*

7.3.1 Rental Apartment Efficiency Program (RAP)

RAP includes a combination of residential and commercial measures for both the low income and the able to pay rental apartment market, each funded from their respective program areas. This program is specifically designed to overcome barriers to adopting energy efficiency measures otherwise experienced by rental building owners and their tenants, and includes expenditures from each of the residential, low income and commercial program areas. The expenditures and related savings for this program attributable to each program area are provided in Table 7-10 and correspond to the RAP expenditures shown in the Program Area Summary Tables for each of the three program areas.

Table 7-10: Rental Apartment Efficiency (RAP) – Full Program Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending

Notes:

- RAP was launched in October 2015 and addresses Commission directive 148 of Order G-138-14.

Table 7-11: Rental Apartment Efficiency (RAP)

Program Description	There are three components to the RAP program. The first component is to provide direct install in-suite energy efficiency upgrades to building owners or property management companies of rental properties (hereinafter referred to as Participant(s)). These devices will be installed by an agent of FortisBC into each individual rental suite. The second component is to simultaneously provide those Participants with energy assessments recommending building-level energy efficiency upgrades such as condensing boilers, high efficiency water heaters and lighting upgrades. The last component is to provide the Participant with support in implementing those energy efficiency recommendations and applying for rebates. Expenditures for RAP are covered by 3 program areas based on the in-suite versus the common area expenses and the able-to-pay versus the low income rental apartment customer. For the able-to-pay rental customer, all the in-suite related expenses associated with the direct install activities are covered by the Residential Program Area, while the common area related expenses are covered by the Commercial Program Area. This includes expenditures associated with the energy assessment, implementation support, and boiler/water heater rebates. For the low income rental customer all expenditures related to both the in-suite and common area expenses are covered by the Low Income Program Area.
Target Market	Purpose-Built Rental Apartment Buildings
New vs Retrofit	Retrofit
Partners	FortisBC Inc.
Eligible Measures	1.5 GPM Showerheads, 1.5 GPM Handheld Showerheads, 0.8 GPM Bathroom Aerators, 0.8 GPM Kitchen Aerators Walkthrough Energy Audits, Implementation Support, Condensing Boilers, Energy Efficiency Water Heaters

7.4 2016 COMMERCIAL ENERGY EFFICIENCY PROGRAM CLOSURES

7.4.1 EnerTracker Program

Since inception the EnerTracker pilot has not achieved a TRC 1.0 or better, nor is it expected to do so moving forward. Further, the evaluation revealed that although some participants utilized the EMIS tool consistently, a significant portion of participants (25 percent) had not logged into the provided software since starting the program. Moreover, program participants who actively used the provided EMIS tool were found to have reduced natural gas consumption by no more than those participants who did not use the provided EMIS or indeed any energy management software. This program was closed as of December 31, 2016.

7.5 *Summary*

Commercial Energy Efficiency Program Area activity in 2016 successfully achieved approximately 255,400 GJ of annual natural gas savings and a positive TRC of 1.0. The Space Heat program continues to act as the cornerstone program as it invests more in natural gas efficiency projects than the other commercial programs. On the other hand all programs continue to experience growth in participation, incentive spend and natural gas savings. The Commercial Custom Design Program in particular experienced significant growth in 2016, investing over $2 million in energy saving measures that would not otherwise be able to obtain incentives via a prescriptive rebate program. Moving forward, the programs will continue to focus on generating natural gas savings and fostering market transformation in the commercial sector.

8. INNOVATIVE TECHNOLOGIES PROGRAM AREA

8.1 *OVERVIEW*

A primary objective of the Innovative Technologies Program Area is to identify market-ready technologies that are not yet widely adopted in British Columbia, and which are suitable for the development of or inclusion in the portfolio of ongoing DSM programs in other program areas. This is accomplished through pilot and demonstration projects, pre-feasibility studies and the use of Industry Standard Evaluation, Measurement and Verification (EM&V) protocols to validate manufacturers' claims related to equipment and system performance. Results from Innovative Technologies activities are used in making future DSM programming decisions.

Just as important as identifying new technologies to be incorporated into the DSM portfolio are findings that indicate which technologies to not include. Section 8.3 summarizes how the activities and processes for the Innovative Technologies Program Area were successful in identifying proposed projects that should not proceed to full pilot phase or further.

All 2016 activities undertaken in this Program Area meet the definition of technology innovation programs as set out in the DSM Regulation. It should be noted that Innovative Technologies are considered a "specified demand-side measure,"[12] meaning that the Program Area or the measures therein are not subject to a cost effectiveness test. Instead the cost effectiveness of these expenditures will be evaluated as part of the DSM portfolio as a whole.[13] Innovative Technologies expenditures are also not subject to the 33 percent cap on programs for which the MTRC is utilized as a cost effectiveness measure according to Section 4 (4) of the DSM Regulation.[14]

Table 8-1 summarizes the projected and actual expenditures for the Innovative Technologies Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost effectiveness test results where applicable.

Table 8-1: 2016 Innovative Technologies Program Area Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending						
	2014-2018 EEC Plan	2016 Actual		2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	TRC	MTRC	Utility	Participant	RIM

[12] BCUC Letter Log No. 36730, Request for Clarification of Order G-44-12 and Decision on the 2012 – 2013 Revenue Requirements Application and Natural Gas Rates Application

[13] Subsection 4(4) of the DSM Regulation, and the Decision on the 2012 – 2013 Revenue Requirements Application and Natural Gas Rates Application, page 175.

[14] BCUC Letter Log No. 36730, Request for Further Clarification of Order G-44-12 and Decision on the 2012 – 2013 Revenue Requirements Application and Natural Gas Rates Application and the Commission's May 11, 2012 letter.

Notes:

- Innovative Technologies are considered a "specified demand-side measure," meaning that the Program Area or the measures therein are not subject to a cost effectiveness test. Instead the cost effectiveness of these expenditures will be evaluated as part of the DSM/C&EM portfolio as a whole.

8.2 *2016 INNOVATIVE TECHNOLOGIES ACTIVITIES*

Tables 8-2 to 8-3 outline the specific Innovative Technologies activities undertaken in 2016, including program and measure descriptions and a breakdown of non-incentive spending[15].

[15] Innovative Technologies activities are distinct from C&EM programs and are not presented in individual program tables as in other Program Area sections in this report.

Table 8-2: Pilots

Program Description	The Pilot Program focused on evaluating market-ready technologies and conducting small scale pilots to gather data to validate manufacturers' claims about measure system performance and energy savings. The data from pilots can also be used to help improve the quality and installation of future systems, and to understand and reduce market barriers. Technologies that successfully emerge from the Innovative Technologies Program will be considered for inclusion in the various program areas within the larger C&EM portfolio.
Target Market	Variable
New vs Retrofit	Retrofit
Heat Reflector (HRP) Pilot	To assess energy savings, costing and customer acceptance data related to the installation of a Reflector Panel behind a perimeter heating system in rental MURBs. Energy saving details will be achieved through analysis of billing consumption data on a building level, costing data from the completion of 30 installations and customer acceptance from surveying all building managers at the end of the heating season. Results are expected Q2 2017. 2016 — Participants Total — 30
Apartment Fireplace Efficiency Retrofit (AFER) Pilot	Objectives of the pilot are to verify energy savings from replacing older decorative style "B" vented fireplaces with Direct Vent EnerChoice level heating style fireplaces in Multi Unit Residential Buildings (MURB'S). The results will be used to determine the feasibility of launching a rebate program for high efficient EnerChoice direct vent fireplaces in MURB's or to extend the existing fireplace rebate offers to MURB'S. Results were handed off to the Residential program team in Q4 2016. 2016 — Participants Total — 32
Combination Space and Water Heating System (CURP) Pilot	Objectives of the pilot are to identify field-validated energy performance of each combination system type, technical issues, field-validated incremental costs, customer acceptance and the effective marketing channels for promoting a combination system retrofit rebate. The results will provide insight into a cost-effective rebate program for residential customers to upgrade their existing space and water heating equipment to combination systems. Results are expected Q1 2017. 2016 — Participants Total — 19
Participants	2016 — Projected — Actual Total — n/a — 81

Expenditures ($,000s)			Non-Incentive Expenditures			
2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	67	104	0	125	296

Notes:

- Final results from the Apartment Fireplace Efficiency Pilot (AFER) were received in 2016, the findings of which will inform future program design for the Residential Program area. The primary purpose of the study was to compare sub metered gas consumption and run-time on existing natural gas B-vent style fireplaces with EnerChoice natural gas vertical direct-vent fireplaces in apartments. Please refer to Section 12 Evaluation, Table 12-2 for more information on the AFER pilot.

Table 8-3: Studies

Description	Studies are used to assess the market opportunity, technical characteristics and projected energy savings of commercially available DSM technologies. The results can be used to determine the feasibility of launching a pilot or to make future program area inclusion decisions.
Target Market	Variable
New vs Retrofit	N/A
Drain Water Heat Recovery Prefeasibility Study	Drain Water Heat Recovery (DWHR) systems recover part of the energy from the warm drain water to preheat the cold mains water that enters the domestic hot water heating system. DWHR units usually consist of copper piping that is tightly wrapped around a vertical section of a copper drainpipe. The objective of the study is to assess the technical characteristics, market opportunity, and projected energy savings of installing DWHR systems in both new construction and retrofit applications for all suitable residential building types. The study is expected to be completed by Q1 2017.
LEEP BC Climate Zone 5 Study	BC Housing and its BC Partners have defined the target for selection of innovative technologies for new homes to be at 25% reduction in annual space heating energy use from applicable building code, bylaw or green rezoning policy requirements for Climate Zone 5 (Southern Interior and Island North) and Climate Zone 6-8 (Central and Northern BC). NRCan, through the Innovative and Energy Technology Sector (IETS) will lead a series of Local Energy Efficiency Partnership (LEEP) builder group meetings to assess, screen and report on technologies based on their suitability and marketability. The project is expected to be completed by Q4 2017.
LEEP Low Use Homes Study	The objective of this project is to support the home building industry's ability to find and apply new and existing gas based mechanical systems for the growing market share of homes with design heating loads of up to 30,000 BTUs. A companion guide will be developed to support builders and their mechanical designers as they make decisions together on the type of natural gas fuelled mechanical system they want to use in homes with low space heating loads. Some of the technologies considered are drain water heat recovery systems, combined space and water heating units and direct vent wall furnaces. Workshops for the first 2 markets are expected to be conducted by Q4 2017 and workshops for the remaining 6 markets by Q2 2018.
Residential HVAC Zoning Prefeasibility Study	Forced-air zoning systems allow central heating ventilation and air conditioning (HVAC) equipment to be controlled by multiple thermostats or sensors, each serving specific zones of the home. This strategy allows for programmed or occupancy-based temperature set-back or set-forward by zone. The objective of the study is to conduct a technology, market and energy savings assessment of Residential HVAC zone controls for force aired systems. The scope of the study is limited to residential HVAC zoning controls and equipment in single family homes/duplexes, and row/townhouses for all applicable building vintages. The study is expected to be completed in Q1 2017.
Steam Trap Market Characterization Study	Steam traps are installed inline in steam distribution pipe systems, and are used to remove steam condensate from pipes. Improving steam trap maintenance practices provides an opportunity for natural gas energy savings, as failed steam traps are a source of steam losses. The objective of the Steam Trap Market Characterization study was to identify the process of steam trap system surveys and the process of maintaining the steam traps in an attempt to understand why steam traps are not being replaced at the point of failure in the Industrial sector. The study was concluded in Q3 2016.

Table 8-3: Studies Continued

Direct Vent Wall Furnace Study Prefeasibility Study	Direct Vent Wall Furnaces are compact self-contained combustion units that are installed on exterior walls so that combustion by-products are discharged outside through a vent. Direct Vent Wall Furnaces can be a good alternative to central heating systems, especially if a home does not have existing ducting or is built on a concrete slab. The objective of the study is to investigate Direct Vent Wall Furnaces that can be installed to replace lower efficiency space heating systems and lower efficiency fireplaces in both new construction and retrofit applications for all suitable residential building types. The study is expected to be completed in Q2 2017.
Net Zero Homes study	A recent significant research project done through Natural Resources Canada and with builders across Canada has demonstrated the feasibility of net zero energy homes in five Canadian cities. The main objective of this project is to identify the barriers and opportunities for the natural gas industry in a net zero energy home context. The report aims to define a net zero energy home case and to provide sufficient information for the selection of an all-electric scenario and a natural gas and electric combination scenario. The project is expected to be completed in Q3 2017.
Gas fired Heat Pump Prefeasibility Study	Gas heat pumps extract heat from air, ground, or water sources using thermally-driven cycles (engines or absorption), and can achieve high efficiencies in low temperature operation. The objective of the study is to conduct a technology, market and energy savings assessment of all relevant Gas Heat Pump technologies for space and water heating being installed in both Commercial and Residential buildings for all applicable vintages. The study is expected to be completed in Q2 2017.

Expenditures ($,000s)			Non-Incentive Expenditures			
	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	0	252	0	0	252

Notes:

- Outcomes from the Steam Trap Market Assessment study were received in 2016, resulting in steam trap replacements and audits to be considered as future eligible measures under the Industrial Program Area. The goal of the study was to better understand the operator decision making process and whether certain elements that prevent replacement can be mitigated through utility programming intervention. Insights gained from steam trap market characterization enhanced FEI's understanding of steam trap use and maintenance practices within industrial facilities.

8.3 SUMMARY

Innovative Technologies represent a key component of FEI's overall commitment to DSM activities by identifying viable technologies and projects that have the potential to support the development of new programs within the larger DSM portfolio. Overall, the Innovative Technologies initiatives successfully achieved results in evaluating the feasibility of new technologies and providing insights used towards the design of future DSM programs. The Innovative Technologies Program Area continues to use consistent criteria to ensure the greatest potential for screening technologies for further development as full programs in other areas of the DSM portfolio.

9. INDUSTRIAL ENERGY EFFICIENCY PROGRAM AREA

9.1 OVERVIEW

In 2016, the Industrial Energy Efficiency Program Area continued to encourage industrial customers to consume natural gas more efficiently and achieved an overall TRC of 1.0, with a combined net natural gas savings of 18,349 GJ per year.

Table 9-1 summarizes the projected and actual expenditures for the Industrial Energy Efficiency Program Area in 2016, including incentive and non-incentive spending, annual and NPV gas savings, as well as TRC and other cost effectiveness test results.

Table 9-1: 2016 Industrial Energy Efficiency Program Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios				
				Incentives		Non-Incentives		All Spending						
	2014-2018 EEC Plan	2016 Actual		2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	2014-2018 EEC Plan	2016 Actual	TRC	MTRC	Utility	Participant	RIM
Non Program Specific Expenses														
Total	No Direct Savings			0	0	262	75	262	75	No Direct Savings				
Industrial Optimization Program

Specialized Industrial Process Technology Program														
Total	50,597	608	7,059	380	18	81	44	461	62	0.8	n/a	1.1	1.0	0.9
ALL PROGRAMS														
Total	**168,173**	**18,349**	**157,454**	**1,925**	**529**	**737**	**474**	**2,662**	**1,003**	**1.0**	**n/a**	**1.4**	**1.9**	**0.7**

Notes:

- For the purpose of cost effectiveness tests, 18,349 GJ in savings have been claimed for 2016. As a project's total incentive can be made across multiple years, the annual natural gas savings are pro-rated based on the proportion of the project's incremental cost that is reported in that year. Please refer to the Industrial Optimization Program description below for further details on this methodology.

9.2 2016 INDUSTRIAL ENERGY EFFICIENCY PROGRAMS

The following tables outline the Industrial Energy Efficiency Program Area activity undertaken in 2016, including program and measure descriptions and a breakdown of non-incentive spending.

Table 9-2: Industrial Optimization Program

Program Description	The program includes measures that allow customers to identify, assess, and implement customized cost-effective energy efficiency projects for industrial processes using natural gas as process heat or an energy source.				
Target Market	Medium and large industrial facilities				
New vs Retrofit	Both				
Eligible Measures	Variable. Natural gas measures with a TRC ≥ 1.0				
Incremental Measure Cost	Dependent upon participant's proposed energy conservation measures.				
Incentive Amount	Variable. Dependent on project characteristics.				
Savings Per Participant	Variable. Dependent on project characteristics.				
Measure Life & Source	Variable. Dependent upon participant's proposed energy conservation measures				
Free Rider Rate & Source	10% Technology Implementation; 20% Industrial Energy Audit, Plant Wide Audit, Feasibility Study. Source: Best estimate.				
Participants	2016	Projected	Actual		
	Total	29	14		
Expenditures ($,000s)	2016	Incentives	Admin	Communication	Research & Evaluation	Total
	Total	511	279	18	59	867

Notes:

- The Industrial Optimization Program includes measures that allow industrial customers to identify, investigate, and implement natural gas energy efficiency projects. Participation in the program can span multiple years due to the timescales associated with completing an energy study, procuring and installing an energy conservation measure, and multi-year measurement and verification analysis.
- Measures include Industrial Energy Audit, Plant Wide Audit, Feasibility Study, and Technology Implementation. FEI is no longer accepting applications for the Energy Audit measure as this was replaced by the Plant Wide Audit and Feasibility Study measures in 2015. Energy Audit participants that completed energy studies and received incentives in 2016 are reported herein.
- The net natural gas savings reported in 2016 are solely attributable to projects implemented through the Technology Implementation measure. The other measures are aimed only at identifying energy saving opportunities and the participant is not bound to implement energy conservation measures identified in the energy study process.
- In 2016, three energy audits, one plant wide audit and four feasibility studies were completed. Five projects progressed to Technology Implementation measure and are expected to save 75,802 GJ per year of natural gas once installed.
- Depending on the size of the incentive, Technology Implementation project incentive payments are either paid fully on project commissioning or are paid across several years after commissioning and based on the natural gas saving performance. Hence, for larger incentives, only a portion of the incentive is paid on project commissioning. For consistency in performing cost benefit analyses, only a prorated portion of the natural gas savings and project costs are included in the determination of the cost benefit ratios. In 2016, FEI reviewed and revised the proration methodology adopted in 2013. The revised methodology results in a more accurate reflection of program cost effectiveness by mitigating the risk of not fully reporting a project's incremental cost and more accurately presenting natural gas savings in a given year. The revised approach has been adopted for the 2016 reporting period.

- In the 2012 DSM Annual Report, the cost effectiveness ratios for the project commissioned under the Technology Retrofit Program were calculated using the NPV of the total estimated natural gas savings, the total estimated project cost, but only twenty five percent of the calculated incentive. As such, the incentive paid in 2016 towards this project was necessarily included as an input to the 2016 cost effectiveness ratios, though any energy savings, project costs, and participant count were not, as these had been recorded in full in 2012. Any subsequent incentives paid for this project will be included in future reports, without any corresponding costs, benefits, and participant counts until such time as the full value of the incentive commitment has been accounted for.

Table 9-3: Specialized Industrial Process Technology Program

</table>

Notes:

- The Commission approved FEI's detailed plans for the Specialized Industrial Process Technology Program under Order G-11-16 in January 2016.
- FEI launched the hot water process boiler measure in Q2 2016. Applications for this measure are administered through the Commercial Program Area's Space Heating Program for efficiency, however, incentives, non-incentives, participation counts, incremental costs, and natural gas savings are reported under the Specialized Industrial Process Technology Program.
- Incentive structure, natural gas savings methodology, and free ridership rates used for the hot water process boiler measure are sourced from the Commercial Program Area's Space Heating Program.
- Development of the steam trap audit and replacement, steam boiler upgrades, and pipe insulation measures continued in 2016 but were not released to market.

9.3 *SUMMARY*

The Industrial Energy Efficiency Program Area activity in 2016 resulted in 18,349 GJ per year of net natural gas savings and a TRC of 1.0. Enhancements to the Industrial Optimization Program have resulted in increased participation and greater natural gas savings in 2016 relative to 2015. Launching the Specialized Industrial Process Technology Program into market is a significant milestone as it represents the first time FEI has been able to support a customer consuming less than 10,000 GJ per year to implement high efficiency equipment for their industrial processes. This showcases FEI's commitment to supporting energy efficiency in the province regardless of sector or size.

FEI looks forward to continuing its support of industrial sector energy efficiency in British Columbia in 2017 and expects growth in program participation and implementation of natural gas energy efficiency projects.

10. CONSERVATION EDUCATION AND OUTREACH INITIATIVES

10.1 *Overview*

The CEO portfolio continues to support the DSM portfolio goals of energy conservation in a variety of ways. In order to foster a culture of conservation, several programs and campaigns were undertaken in 2016, giving the team new information and new insights into behaviour change and customer attitudes on efficiency. Educating all types of customers including residential, commercial and students – remains a strong priority and FEI continues to ensure steps are taken to make the information relevant and timely for these customers.

Collaboration with FBC continued in an effort to maximize efficiencies across both teams. Costs continue to be shared on school, residential and commercial outreach as applicable. The second annual Efficiency in Action awards were held recognizing both electric and gas commercial organizations that have most effectively utilized C&EM programs. FEI's partnership with BC Hydro continued in 2016. This included collaboration on the Energy Wise Network Program for commercial customers (formerly known as the Workplace Conservation Awareness Program) which led to 40 natural gas behavior change projects being submitted by participating commercial customers in 2016. The ethnic outreach program, Empower Me continued to reach new Canadians in 8 languages through a community based social marketing approach. BC Hydro and FEI worked closely together in that development and continued to support the program expansion into new audiences. Empower Me received an honourable mention for its public sector collaboration at the 2016 Community Energy Association Climate & Energy Action Awards.

CEO continued to provide information to customers and the general public on natural gas conservation and energy literacy and sought out new opportunities to reach customers, both face-to-face and online. FEI launched its curriculum-connected online resource program called Energy Leaders for B.C. elementary and secondary school teachers. Currently in the pilot phase, teachers can download bias-balanced lesson plans to assist them with the energy related sections of the curriculum. FEI also continues to support various training seminars and educational workshops in collaboration with such organizations as the Greater Vancouver Home Builders Association and other industry associations.

As these are not incentive-based programs, FEI has not attributed direct savings to them in 2016. The following tables do not contain information about eligible measures, incentive amounts, savings levels, free-ridership, spillover or participation levels. CEO costs are included at the portfolio level and incorporated into the overall DSM portfolio cost effectiveness results. Although there were no energy savings attributed to the CEO Program Area in 2016, it should be noted that FEI continues to explore ways to identify and confirm energy savings from CEO activities. In late 2016 through the Clean Energy Research Centre a University of British Columbia student completed a research paper on FEI's behalf to further examine energy savings attributed to the CEO Program Area. The results from this paper will be reviewed and considered in 2017.

Table 10-1 summarizes the projected and actual expenditures for the CEO Program Area in 2016. The approved spending for 2016 was $2.400 million and actual spending in 2016 was $2.415 million.

Table 10-1: 2016 CEO Initiative Results Summary

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s) Incentives		Non-Incentives		All Spending		Benefit/Cost Ratios

10.2 *2016 CEO PROGRAMS*

Tables 10-2 through 10-4 outline the CEO initiatives undertaken in 2016. This includes program descriptions as well as a breakdown of spending, all of which is classified as "non-incentive spending".

Table 10-2: Residential Education Program

Program Description	This program provides information to Residential customers and the general public on natural gas conservation and energy literacy by seeking opportunities to engage with customers directly (either face-to-face or through online programs). This audience also included low income and ethnic customers. Promotional activities in 2016 included print and online communications and engagement campaigns as well as educational seminars and participation in home shows and community events. The Program also included the cost of production of materials for events and prizing for audience engagement that are utilized at events targeting Residential customers and children. In addition, continuing partnerships with the regional Canadian Home Builders' Associations and local sports organizations expanded outreach opportunities to engage with Residential customers. Furthermore, FEI continued to focus on behavioural change opportunities that resulted in energy savings.
Target Market	Residential customers and general public
New vs Retrofit	Both
Expenditures ($,000s)	

2016	Incentives	Non-Incentive Expenditures Admin	Communication	Research & Evaluation	Total
Total	0	1,036	460	0	1,495

Table 10-3: Commercial Education Program

Program Description	This program provides ongoing communication and education about energy conservation initiatives as well as encourages behavioural changes that help Commercial customers reduce their organization's energy consumption. The Commercial sector is made up of small and large businesses in a variety of sub sectors such as retail, offices, multi-family residences, schools, hospitals, hospitality services and municipal/institutions. Promotional activities for 2016 included print and online communications, event support of industry trade shows, industry association meetings, award events, and development of tools to assist with education and engagement. In addition, the Companies furthered partnerships with organizations such as the Business Improvement Associations of BC (BIABC) and Climate Smart, who all work with small to medium-sized businesses. This program area continued to guide and support behaviour education campaigns delivered by energy specialists (or an energy manager) in their respective organizations. Collaborations between internal departments, as well as with other utilities, were pursued to achieve cost efficiencies in the budget, in particular on advertising and outreach events.
Target Market	Commercial customers, multi-family, energy specialists, energy management staff
New vs Retrofit	Retrofit
Expenditures ($,000s)	

		Non-Incentive Expenditures			
2016	Incentives	Admin	Communication	Research & Evaluation	Total
Total	0	134	143	0	277

Table 10-4: School Education Program

Program Description	This program responds to section 44.1 (8) (c) of the Utilities Commission Act, R.S.B.C 1996, c.473, s.125.1 (4) (e), where a public utility's plan portfolio is adequate if it includes an education program for students enrolled in [K-12] schools and post-secondary schools in the Company's service area. The program area now has an online resource for teachers directly linking to the K-9 curriculum. Other activities included building partnerships and funding support for a variety of in-class and online programs related to conserving energy for K-12 students, delivered both internally and externally by third parties such as non-profit organizations or local sports teams. Some of the activities included were: Energy is Awesome, Green Bricks, Energy Champion assembly presentations and Beyond Recycling. Some of these activities also included distribution or education of energy-efficient fixtures, colouring books, mood pencils, and educational playing cards as part of the program. Partnerships and funding support for post-secondary activities included in-residence and on-campus education campaigns.
Target Market	This program responds to section 44.1 (8) (c) of the Utilities Commission Act, R.S.B.C 1996, c.473, s.125.1 (4) (e), where a public utility's plan portfolio is adequate if it includes an education program for students enrolled in [K-12] schools and post-secondary schools in the Company's service area.

		Non-Incentive Expenditures			
2016	Incentives	Admin	Communication	Research & Evaluation	Total
Total	0	141	70	330	541

10.3 *Summary*

All of the initiatives described in CEO outreach are designed to foster a culture of energy conservation in B.C. This portfolio is immensely important to the overall C&EM message and helps to keep the program information and energy conservation message top-of-mind with all customers. By changing attitudes and behaviours, the Company will help communities reach their goals, help customers save energy and money, increase participation in DSM programs and ultimately support the shared goals of FEI and the Provincial Government. This portfolio will continue to explore new ways and seek out new opportunities and channels to connect with customers and grow the culture of energy conservation.

11. ENABLING ACTIVITIES

11.1 OVERVIEW

In 2016, Enabling Activities continued to support and supplement FEI's DSM program development and delivery, advancing energy efficiency in British Columbia. This included:

- the ongoing Trade Ally Network program;
- work completed in advancing national and provincial building codes, appliance/equipment standards, and regulations;
- maintenance on the Company's DSM program tracking system;
- work on a new Conservation Potential Review; and
- continued funding to support post-secondary energy management programs.

While these activities play a very important role in FEI's portfolio of DSM activities by advancing the delivery of all program areas, the Company has not claimed any energy savings in 2016 for work completed in this area.

FEI has developed an acceptable method for measuring and attributing energy efficiency savings from Codes and Standards work for the 2014 Residential New Home program (see Table 5-8, page 32 of the 2014 Annual Report). FEI used the same method to examine potential for attributing efficiency standards advancement in the Residential Fireplace Program (See Notes to Table 5-4) and will continue to examine and, where appropriate, claim energy savings from Codes and Standards advancement.

Table 11-1 summarizes the projected and actual expenditures for the Enabling Activities in 2016.

Table 11-1: 2016 Enabling Activities Results

Program	Annual Gas Savings (GJ/yr.)		Actual NPV Gas Savings (GJ)	Utility Expenditures ($000s)						Benefit/Cost Ratios

Note:

- The 2014-2018 DSM Plan had budgeted a one-time cost of $500,000 for the CPR and anticipated that this would take place in the year 2015. The CPR was started in 2015 but the majority of the expenditures for the project were incurred in 2016.

11.2 2016 ENABLING ACTIVITIES BY PROGRAM

The following tables outline the specific Enabling Activities undertaken in 2016 by activity, including activity descriptions along with a breakdown of spending. Note that all spending under Enabling Activities is considered non-incentive spending.

Table 11-2: Trade Ally Network

Program Description	This program develops and manages a contractor network to promote DSM programs and energy-efficiency messaging. FEI identifies trade allies as equipment manufacturers, service contractors, and distributors, and recognizes the influence these industry groups have with the end-use Residential and Commercial customers who make energy-efficiency decisions. This program also supports funding energy efficiency training as outlined in the DSM Regulation.				
Expenditures ($,000s)	2016	Admin	Communication	Research & Evaluation	Total
	Total	263	461	0	723

Table 11-3: Codes and Standards

Program Description	Utilities have a unique understanding of energy supply and customer demand cycles, which can be of assistance in the development of codes and standards. The content and timing of code implementation directly affects market transformation in all program areas. FEI's level of regulatory involvement typically includes one of three involvement classifications: monitoring, stakeholder engagement and developing regulations. The Codes & Standards area "supports the development of or compliance with specified standard or a measure respecting energy conservation or the efficient use of energy" as referred to in the definition of "specified demand-side measures" in the DSM Regulation.
Policy Initiatives consultation process	Evaluation, analysis and review of national, provincial and municipal initiatives for energy efficiency.
Industry consultation process	Collaboration with entities like BC Hydro and the Home Owner Protection Office (HPO) for the development of industry training and guidelines on implementation of new energy efficiency measures. Participation with the BC Safety Authority Gas Technology Committee industry stakeholder group.
Involvement with supporting projects	Active participation for supporting projects like: the Natural Resources Canada new EnerGuide rating system and Leadership in Energy Efficiency Partnerships (LEEP).
Codes and Standards Strategy	Active participation on the Canadian Standards Association (CSA) Strategic Steering Committee on Fuel Burning Equipment. This committee is the highest level committee in the fuel sector at CSA and oversees all committees and sub-committees in the fuel burning sector. Consultation with the Canadian Gas Association (CGA), Canadian Institute of Plumbing and Heating (CIPH), Heating Refrigeration and Air-conditioning Institute (HRAI) and the Canadian Home Builders Association (CHBA) on codes and regulations that are common to our industries.
Codes and Standards Maintenance	Active participation on the CSA Technical Committee on Energy Efficiency and Related Performance of Fuel-Burning Appliances and Equipment. This committee oversees all of the eleven existing performance standards for gas-fired equipment and is looking to develop new needed standards for equipment. Participation in the Standards Council of Canada, committee on Domestic gas cooking appliances ISO/TC 291.
Internal awareness of Code and Regulatory changes	Development of internal documents and updates for relevant program areas and personnel.
Standards library	Purchase of up to date standards for reference.
Expenditures ($,000s)

Table 11-5: Conservation Potential Review

Program Description	FEI considers the CPR to be an important tool for use in developing, supporting, and assessing current and future DSM expenditure applications, as well as for directional input into program development. The purpose of a CPR study is to examine available technologies and determine their conservation potential, which includes the amount of energy savings that can be achieved through energy-efficiency and conservation programs over the study period. This project is being worked on in collaboration with BC Hydro, Pacific Northern Gas and FortisBC Electric. Core work on the CPR began in 2015. As of end-2016 the CPR project was close to being completed.

11.3 *2016 ENABLING ACTIVITIES PLANNED BUT NOT LAUNCHED*

11.3.1 Home Energy Efficiency Web Portal

Funds allocated to the Home Energy Efficiency Web Portal were not accessed in 2016 as the main focus of the Home Renovation Rebate Program (formerly known as Home Energy Rebate Offer) was customer experience, contractor engagement, and municipal home energy coaching pilots. In 2017, utility partners will continue to assess options for online resources and tools to support enhanced customer, contractor and administrative services.

11.3.2 Residential End Use Study (REUS)

The REUS provides a snapshot of the FEI Residential customer base. It provides information about the building characteristics, the fuel choice for heating, cooling and cooking, the types and ages of appliances installed, energy-use behaviours, and customer attitudes towards energy issues. The REUS also includes a billing analysis to determine natural gas consumption by appliance type. This study is shared with other FEI departments. Initial scoping for the study was started in 2016 but no expenditures will be incurred until 2017.

11.4 *SUMMARY*

Enabling Activities are critical initiatives that support and supplement DSM program development and delivery. The success of the Residential Furnace and Boiler Replacement Program (see Section 5.3, Table 5-3), which was promoted through the contractor network, demonstrates the value of the Trade Ally Network program. Communications were immediate and responsive through the network and at the end of the program, 71 per cent of the program's participants used contractors who were members of the Trade Ally Network.

FEI's involvement in codes and standards work in 2016 continued to encompass varying degrees of activities including monitoring, reviewing and responding to existing and proposed regulatory changes and direct participation in various working groups that explore the development of future targets, codes and standards. Work also continued on the Conservation Potential Review study which is a collaboration between BC Hydro, Pacific Northern Gas and both FEI and FBC. The Technical and Economic Potential portions of the Conservation Potential Review project were nearing conclusion.

12. EVALUATION

FEI continued to advance their evaluation activities in 2016 by conducting evaluation studies[16] on a program by program basis. In alignment with the Company's Evaluation Measurement & Verification (EM&V) Framework and industry standard practice, program evaluation activities are assessed at different stages of each program's lifecycle. Based on this ongoing assessment, all programs are evaluated when appropriate. The 2016 evaluation activities presented here reflect the number of programs in market, the different stages of their lifecycle, and the type of evaluation activities required to provide program feedback. The evaluation activities conducted in 2016 are in accordance with the evaluation principles presented in the Company's EM&V Framework.

12.1 *2016 PROGRAM EVALUATION AND EVALUATION RESEARCH ACTIVITIES*

In 2016, FEI's various evaluation activities included quantifying energy savings, assessing participant awareness and satisfaction, identifying barriers to participation, assessing customer usability and engagement with various FEI DSM outreach activities, and conducting industry research. Measurement and Verification (M&V) activities were focused on identifying and verifying project and measure level savings assumptions and understanding any issues associated with equipment installation in the field.

Table 12-1 presents an inventory of all program evaluation and evaluation research related activities undertaken in 2016. Expenditures for these activities have been accounted for within the applicable program or Program Area as part of the non-incentive costs, but are also reported here in order to provide a concise, easy-to-view summary of evaluation activities. Included in the table are: a list of all the 2016 evaluation activities; the Program Area each activity occurred in; the general type of evaluation activity undertaken; the Company's actual 2016 evaluation expenditures; and, a status update on each activity. The total expenditure for program evaluation and research activities in 2016 is $518,000 which is an increase from 2015.

[16] Types of evaluation activities include: Communications evaluations, which focus on advertising and media outreach; Evaluation studies, where quality assurance or inspection is conducted to gain more insight on the incented measure; Process evaluations, where surveys and interviews are used to assess customer satisfaction and program success; Impact evaluations, to measure the achieved energy savings attributable from the program; Market Analysis, to characterized the industry and the program's effect on market penetration and, Measurement & Verification, to monitor real time energy savings associated with energy conservation measures.

Table 12-1: Inventory of DSM Program Evaluation and Evaluation Research Activities Conducted in 2016[17]

Evaluation Name	Program Area	Type of Evaluation	Years the program has been running [18]	Evaluation Partnership	Actual Evaluation Expenditure (000's)	Evaluation Status [19]

C&EM Rebates UX Testing - Phase I and II	C&EM Portfolio	Communication	ongoing	none	$2	Usability testing of the rebates section of FortisBC.com website. **Completed July and December 2016 by Participant Research**
Home Energy Rebate Offer (HERO) - Participant Survey	Residential	Process	2	FortisBC Inc. and BC Hydro	-$2	Customer survey conducted for the program evaluation. Partnership funding received in 2016 which resulted in a negative expenditure for 2016. **Completed April 2016 by Sentis Research**
Home Energy Rebate Offer (HERO) - Quality Study of Insulation	Residential	Evaluation Study	2	FortisBC Inc. and BC Hydro	$15	On-site visit of homes with insulation and draft proofing measures **Completed May 2016 by RDH Building Science Inc.**
Home Energy Rebate Offer (HERO) - Quantitative Analysis	Residential	Evaluation Study	2	FortisBC Inc. and BC Hydro	$6	HERO participant analysis to determine inputs for cost effectiveness tests and feedback on 2016 program design.
Home Energy Rebate Offer (HERO) - Insulation Home Visit	Residential	Evaluation Study	2	FortisBC Inc.	$9	On-site visit of homes with insulation and draft proofing measures. **Expected completion by Q2 2017.**
BC Fenestration Market Study	Residential	Market Analysis	2	FortisBC Inc., FortisBC Energy Inc., BC Hydro and MEM	$10	Study to characterize market conditions for fenestration products manufactured, sold, and/or installed in British Columbia . **Completed October 2016 by RDH Building Science Inc.**
Evaluation & Contractor Outreach	Residential	Evaluation Study	ongoing	none	$9	Ongoing studies and workshops to gather contractor feedback and awareness.
Rental Apartment Efficiency Program (RAP)	Residential / Commercial	Evaluation Study	1	none	$3	Ongoing performance testing for RAP participants.
Rental Apartment Efficiency Program (RAP)	Residential / Commercial	Process	1	none	$11	Building owner and Tenant survey for program evaluation. **Completed December 2016 by Cohesium Research**
Energy Conservation Assistance Program (ECAP)	Low Income	Evaluation Study	5	BC Hydro	$82	Ongoing Quality Assurance to ensure all products are installed according to program installation policies and procedures.

[17] Table 12.1 does not include Prefeasibility Studies. Please refer to the Innovative Technologies section (Section 8) for details.

[18] Measurement & Verification studies require time to conduct activities which include, but are not limited to, project commissioning, installing and removal of monitoring equipment, data collection and, data analysis and reporting. The column 'Years the program has been running' will refer to the time required to conduct the M&V activities. M&V activities align with the International Performance Measurement and Verification Protocol (IPMVP). Concepts and Options for Determining Energy and Water Savings. Prepared by the Efficiency Valuation Organization: www.evo-world.org. January 2012.

[19] M&V completion refers to the time period where the actual monitoring and data collection ends. Analysis and reporting will require additional time

Table 12-1: Inventory of DSM Program Evaluation and Evaluation Research Activities Conducted in 2016[17] (continued)

Evaluation Name	Program Area	Type of Evaluation	Years the program has been running [18]	Evaluation Partnership	Actual Evaluation Expenditure (000's)	Evaluation Status [19]
Energy Specialist Program Energy Savings Audit (Update for 2016)	Commercial	Impact	7	none	$25	The study is an update to the Energy Savings Audit to verify energy savings for projects completed in 2015. **Completed May 2016 by Prism Engineering. Preliminary results reported in 2015 Annual Report.**
EnerTracker Pilot Program - Impact Evaluation	Commercial	Impact	4	none	$5	Billing analysis of the program participants' energy usage. **Completed April 2016 by Prism Engineering**
Commercial Water Heating Program	Commercial	Process/Impact	6	none	$52	Customer survey and billing analysis conducted for program evaluation. **Completed October 2016 by Prism Engineering**
Commercial Food Service Incentive Program	Commercial	Process & Impact	5	none	$10	Participant Survey and billing analysis conducted for program evaluation. **Expected completion by Q3 2017**
Apartment Fireplace Efficiency Pilot (AFER)	Innovative Technologies	Measurement & Verification	2	none	$119	High efficiency gas fireplace M&V study. **Completed M&V October 2016 by Building Energy Solutions Ltd**
Combination Space/Water Heating Units Pilot	Innovative Technologies	Process Evaluation	2	none	$11	Results from the completed participant survey will be incorporated in the 2017 billing analysis summary report. **Expected completion by Q3 2017**
Combination Space/Water Heating Units Pilot	Innovative Technologies	Measurement & Verification	2	none	$71	Boiler testing to assess the DHW energy factor. **Completed M&V July 2016 by Natural Gas Technologies Centre (NGTC)**
Heat Reflector Pilot (HRP)	Innovative Technologies	Evaluation Study & Measurement & Verification	1	none	$6	Thermal Imaging completed through RDH in 2016. **Expected completion of Final Report by Q1 2018**
Industrial Optimization Program	Industrial	Measurement & Verification	5	none	$59	M&V was conducted on 15 projects in 2016 of which one completed its M&V requirements. The M&V activities include the completion of an M&V plan, commissioning validation site visits, and M&V reports.

Table 12-2 contains a summary of all program evaluation studies and pilot program reports completed in 2016 and includes a brief description of the methodologies and key findings.

Table 12-2: Summary of Key Findings and Methodology for 2016 Completed DSM Program Evaluation Studies and Pilot Program Reports

	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
FortisBC Communications Tracking: Energy Efficiency and Conservation	C&EM Portfolio	Communication	Online interviews conducted over three waves with 2,400 (800 per wave) British Columbia adults living within the FortisBC service territory.	**Results**: The percentage of participants had aided awareness of at least one of the three main energy efficiency activities undertaken by FortisBC trended upward from 64% in 2015 to an average over the 3 waves of 66% in 2016. Overall, half of the participants surveyed were classified as being at least somewhat engaged with energy efficiency. **Outcome of Key Findings:** Continue to emphasize the overarching energy efficiency activities rather than individual programs to build awareness.
C&EM Rebates UX Testing - Phase I and II	C&EM Portfolio	Communication	One-on-one user testing sessions	**Results:** Improvements identified in both Phase I and II for the rebates web page. **Outcome of Key Findings:** As a result of the study, improvements were made to the rebates section of corporate website.
Home Energy Rebate Offer (HERO) - Participant Survey	Residential	Process	Online survey completed for 435 program participants between March 3 to March 18, 2016.	**Results:** 87% of participants were satisfied with the overall program and 94% were satisfied with the home upgrades. The factor most likely to have motivated participants to sign up for the program is reduced energy bills, with 78% of participants indicating that 'saving money on energy bills' is their main reason for undertaking the home upgrades. **Outcome of Key Findings:** Feedback from customers was taken into account as new program offer, application form and messaging was introduced September 1.

Table 12-2: Summary of Key Findings and Methodology for 2016 Completed DSM Program Evaluation Studies and Pilot Program Reports (continued)

	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
Home Energy Rebate Offer (HERO) - Quality Study of Insulation	Residential	Evaluation Study	Site visits for 42 houses with HERO improvements were completed in February and March of 2016 to identify compliant installation practices in the installed upgrades.	**Results:** The results of the site visits revealed good installation practices such as including insulation baffles for soffit vents, insulating and air-sealing attic hatches in many houses, and two-thirds of installs providing sufficient insulation in a uniform and consistent manner, aligned with the rebate applications. **Outcome of Key Findings:** The study suggested that overall insulation and air sealing met minimum standards although variability across contractors suggested that there was need for contractor education about best practices. Also noted some non-compliance that was further addressed through contractor education and face to face meetings.
BC Fenestration Market Study	Residential	Market Analysis	Market surveys (interviews) were conducted with industry entities, including fenestration manufacturers and their suppliers, and builders. Analysis and review of public data sources and literature, and government and utility data from related programs.	**Results:** The report summarizes three key findings pertaining to three research questions. 1) U-value ranges for new and replacement windows. -New construction and replacement (U-values that comply with or exceed the USI-1.80 BCBC. 2) Expected energy savings if U-values are lowered below current regulated levels. - Natural gas heated home in Vancouver can range from 2.0GJ for USI-1.8 windows to 9.8 GJ for USI-1.0 windows 3) Market readiness for manufactures with the introduction of higher-performance, lower U-value products requires a shift away from double-pane windows frames. **Outcome of Key Findings:** Update on current market conditions to inform policy and program development.
Rental Apartment Efficiency Program (RAP)	Residential / Commercial	Process	Two separate surveys were conducted; a building owners survey and tenant survey. A telephone survey was completed for 56 owners/managers and 2 onsite contractors and an online survey was completed for 193 tenants.	**Results**: 91% of the building owners and 71% of the tenants surveyed were "very" or "somewhat satisfied" with the overall program. Assessment of the program communications were positive, with approximately 9 in 10 owners/managers "very" or "somewhat satisfied" with the accessibility of the program information, the ease of understanding the information and knowing how/who to contact regarding the program. **Outcome of Key Findings**: Continue to conduct ongoing tenant and building owner surveys to provide feedback to program design.

Table 12-2: Summary of Key Findings and Methodology for 2016 Completed DSM Program Evaluation Studies and Pilot Program Reports (continued)

	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
EnerTracker Pilot Program - Impact Evaluation	Commercial	Impact	The evaluation was carried out for 145 sites which had a minimum of 12 months post implementation data available. In addition to analyzing the consumption data, interviews with program participants were conducted to gain a better understanding of site specific behaviors and to determine if gas savings actions were triggered as a result of utilizing the EnerTracker sponsored EMIS software.	**Results:** The evaluation revealed that although some participants utilized the EMIS tool consistently, a significant portion of participants (25%) had not logged into the provided software since starting the program. Moreover, program participants who actively used the provided EMIS tool were found to have reduced natural gas consumption by no more than those participants who did not use the provided EMIS or indeed any energy management software. **Outcome of Key Findings:** Net-to-Gross values were updated for 2016 and the pilot program period ended in 2016.
Commercial Water Heating Program	Commercial	Process/Impact	Online survey for 115 program participants was conducted between May 2 to May 16. 240 participant sites were included in the energy savings analysis which included 12 months post consumption usage.	**Results:** 84% of participants were satisfied with the program and 73% were satisfied with the equipment selection. 23% of participants were not satisfied with the process of completing the application forms or with the program requirements. The overall program average savings is 0.23 GJ/yr/MBH for On-Demand, Boilers and Storage heater types. **Outcome of Key Finding:** Net-to-Gross values updated for 2016 program. Deemed savings for water heaters will be developed in 2018 based in large part on the findings of the Evaluation Study.
Apartment Fireplace Efficiency Pilot (AFER)	Innovative Technologies	Measurement & Verification	**M&V Plan:** Complies with the International Performance Measurement & Verification Protocol. The selected IPMVP option and measurement boundary was Option A[20] **M&V:** M&V was conducted on 4 Multi Unit Residential Buildings in the Lower Mainland area representing 27 participants across the four sites. Baseline data was collected and measured for 3 months (Jan to Mar) and 2 months post retrofit of the direct-vent fireplace.	**Results**: The M&V results indicated an overall change in energy use across all Baseline fireplace types over a normalized Winter Heating Season; average natural gas consumption reduction per hour of runtime of 49 - 52% where high BTU/h units were replaced and a reduction of 25 - 27% where low BTU/h units were replaced. **Outcome of Key Findings**: Results presented to the Residential Program Team. Data to be used to inform program decisions.

[20] IPMVP Option A - Measurement of key parameters governing energy use to assess consumption. www.evo-world.org

Table 12-2: Summary of Key Findings and Methodology for 2016 Completed DSM Program Evaluation Studies and Pilot Program Reports (continued)

	Program Area	Type of Evaluation	Methodology	Outcome from Key Findings
Combination Space/Water Heating Units Pilot	Innovative Technologies	Measurement & Verification	Three models of combi-boilers (CB) and three models of boilers with indirect tanks (IT) were tested to determine the DHW energy factor (EF). The energy factor testing used was the CAN/CSA P.7 testing method which targets residential instantaneous natural gas water heaters .	**Results:** The test results indicated in general, the energy factors for combi-boilers were roughly equal to the recovery efficiency of the corresponding boiler. Average EF varied between 0.80 and 0.84 depending on the model. For the indirect tanks, the energy factors were much lower than the recovery efficiencies. Average EF varied between 0.63 and 0.67. **Outcome of Key Findings:** Continue to gather information from participant survey and energy savings analysis.
Industrial Optimization Program	Industrial	Measurement & Verification	**M&V Plan:** Complies with the International Performance Measurement & Verification Protocol. The selected IPMVP option and measurement boundary was Option B[21] **M&V:** M&V was conducted on (Project reference ITRP003) for a lime kiln upgrade project in a pulp and paper mill.	**Results:** Three year M&V completed with a total verified natural gas savings of 132,000 GJ. The mill reduced their natural gas consumption by 132,000 GJ by upgrading a key mechanical component of their lime kiln. The achieved savings were well above the minimum savings to achieve cost effectiveness of the project and provided the plant valuable feedback on the performance of the energy efficiency upgrade. **Outcome of Key Findings:** M&V project completed with the full incentive payment issued to the participant as the natural gas savings exceeded pre-installation estimates.

12.2 *EVALUATION COLLABORATION*

FEI has continued to seek opportunities to increase collaborative activities with FBC, BC Hydro, and other entities to conduct program evaluation for DSM programs. The number of collaborative activities depends on the timing of the activity, program participants, legal and privacy concerns, and available budget to conduct the study. Tables 12-1 and 12-2 provide information on program evaluation activities conducted in partnership with other organizations. One jointly funded evaluation project was initiated in 2016 as a result of the collaboration efforts between FEI, BC Hydro and the BC Ministry of Energy and Mines; Home Energy Rebate Offer (HERO) – Fenestration Market Study. In addition, BC Hydro and FEI continue to collaborate in the evaluation projects for HERO – Participant Survey, HERO – Quality Study of Insulation, and the Energy Conservation Assistance Program (ECAP).

Collaboration efforts on evaluation have been further enhanced by the MOU on collaboration discussed in Section 2.5. The BC Utilities evaluation staff held update meetings to review the evaluation plans and discuss future evaluation activities. Evaluation staff from the BC Utilities continue to hold update meetings and explore opportunities for future collaboration on program evaluations.

13. DATA GATHERING, REPORTING AND INTERNAL CONTROLS PROCESSES

13.1 *Overview*

The following section demonstrates that FEI has business practices in place to ensure DSM activities and associated spending are in compliance with Commission Orders and the Company's internal control processes. In its 2009 Decision[21], the Commission directed the Company to include a discussion in the DSM Annual Report of the Company's internal data gathering, monitoring and reporting control practices. FEI continues to provide this information.

13.2 *Program Tracking, Evaluation and Reporting Functions*

FEI staff responsible for tracking, evaluation and reporting of DSM activities continue to report to a different director than staff responsible for program development and implementation in order to:

- conduct independent evaluation activities,
- maintain an independent library of inputs into cost effectiveness calculations; and
- centralize reporting processes.

13.3 *Robust Business Case Process Applied to All Programs*

Before a new DSM pilot or program can be implemented, a business case must first be developed. FEI is committed to putting each pilot or program through the appropriate level of internal scrutiny before moving ahead, and believes doing so increases pilot or program effectiveness.

Business cases include information about program rationale and purpose, as well as a description of the target audience, assumptions, cost-benefit tests and proposed evaluation methods. Cost effectiveness analysis is performed using the California Standard Tests (CST) as outlined in the California Standard Practice Manual. FEI uses an in-house cost-benefit modeling tool developed in partnership with expert industry consultants[22] to apply the program costs and benefits in each of the four standard cost effectiveness tests based on the California Standard Practice Manual (Rate Impact Measure [RIM], Utility, Participant, and TRC) and the MTRC in accordance with British Columbia DSM Regulation. The results from this modelling are used as inputs for the business cases, which are approved in accordance with FEI's policy on financial authorization levels.

In addition to the internal business case process, the Commission, in its 2014-2018 PBR Application Decision, directed FEI to submit a written request and business plan for any new

[21] BCUC Order G-36-09 dated April 16, 2009
[22] Willis Energy Services Ltd. and The Cadmus Group Inc. provided input into this in-house cost-benefit modelling.

programs they want to implement that have not previously been identified within the approved DSM Plan. Such requests must demonstrate the new program results in a net improvement to the Portfolio effectiveness or is needed to ensure balanced access to DSM programming among different customer groups. Four such business cases were submitted to, reviewed and accepted by the BCUC in 2016. Three of these were in the Low Income Programs: Space Heat Top up, Water Heating Top Up and the Non-Profit Custom Program. Each of these programs is described in Section 6.2. The fourth business case was for the Specialized Industrial Process Technology Program described in Section 9.2.

13.4 *INCENTIVE APPLICATIONS VETTED FOR COMPLIANCE WITH PROGRAM REQUIREMENTS*

Ensuring that all customer applications are compliant with program eligibility requirements as laid out in program terms and conditions is also part of the internal control process. The Company has a number of mechanisms in place to ensure DSM incentive funding applications are in compliance with program requirements. The verification process is specific to each program and is dependent on the type of program, its complexity, the financial value of the incentive and other parameters. The general principles applied are as follows:

- Each application is reviewed for completeness and accuracy;
- Applications must meet the criteria outlined in the terms and conditions of the program put forward through the approval process;
- Once approved, incentives are distributed to participants; and
- Copies of application and supporting documents are filed and stored for seven years in case of an audit.

13.5 *INTERNAL AUDIT SERVICES*

FEI regularly engages the Company's own Internal Audit Services (IAS) group to review the internal controls associated with DSM activities. The IAS utilizes the most recently completed year of operation on which to conduct their audit (in this case, the 2017 Audit will cover the 2016 DSM operations consistent with past reports). At the time of writing this report, the 2017 Audit of 2016 activity has been initiated but not yet completed. FEI will therefore make the results available in the next annual report or upon request from the Commission, once complete.

13.6 *SUMMARY*

FEI is committed to strong internal controls in all aspects of the DSM programs. As demonstrated in this section, the Company's business practices related to program development, application processing and ongoing monitoring are all sound and subject to continuous improvement.

14. 2016 DSM PROGRAMS ANNUAL REPORT SUMMARY

In 2016, FEI's DSM portfolio expenditures reached 90 percent of Plan with 65 percent of actual DSM program spending going toward customer incentives. With almost 438,000 GJ of annual savings, DSM programming continued to contribute valuable options for customers to reduce their energy use. FEI cost effectively delivered these programs within the spending limits approved by the Commission, and in accordance with the B.C. DSM Regulation. FEI works to ensure DSM programs are operating in compliance with the Company's DSM Guiding Principles and are meeting Provincial requirements for adequacy. FEI also continues to implement good internal data gathering, monitoring and reporting control practices.

Statement of Aboriginal Principles

FortisBC is committed to building effective Aboriginal relationships and to ensure we have the structure, resources and skills necessary to maintain these relationships.

In order to meet this commitment, the actions of the company and its employees will be guided by the following principles:

- FortisBC companies' acknowledge, respect and understand that Aboriginal Peoples have unique histories, cultures, protocols, values, beliefs and governments.
- FortisBC supports fair and equal access to employment and business opportunities within FortisBC companies for Aboriginal Peoples.
- FortisBC will develop fair, accessible employment practices and plans that ensure Aboriginal Peoples are considered fairly for employment opportunities within FortisBC.
- FortisBC will strive to attract Aboriginal employees, consultants and contractors and business partnerships.
- FortisBC is committed to dialogue through clear and open communication with Aboriginal communities on an ongoing and timely basis for the mutual interest and benefit of both parties.
- FortisBC encourages awareness and understanding of Aboriginal issues within its work force, industry and communities where it operates.
- To achieve better understanding and appreciation of Aboriginal culture, values and beliefs, FortisBC is committed to educating its employees regarding Aboriginal issues, interests and goals.
- FortisBC will ensure that when interacting with Aboriginal Peoples, its employees, consultants and contractors demonstrate respect, and understanding of Aboriginal Peoples' culture, values and beliefs.
- To give effect to these principles, each of FortisBC's business units will develop, in dialogue with Aboriginal communities, plans specific to their circumstances.

TABLE OF CONTENTS

FOREWORD

The National Energy Board (NEB, or the Board) is an independent, federal, quasi-judicial regulator established to promote safety and security, environmental protection and economic efficiency in the Canadian public interest within the mandate set by Parliament for the regulation of pipelines, energy development and trade. The Board's main responsibilities include regulating:

- the construction, operation and abandonment of pipelines that cross international borders or provincial/territorial boundaries, as well as the associated pipeline tolls and tariffs;
- the construction and operation of international power lines, and designated interprovincial power lines; and
- imports of natural gas and exports of crude oil, natural gas liquids (NGLs), natural gas, refined petroleum products and electricity.

For oil and gas exports, the Board's role is to evaluate whether the oil and natural gas proposed to be exported is surplus to reasonably foreseeable Canadian requirements, having regard to the trends in the discovery of oil or gas in Canada.

If a party wishes to rely on material from this report in any regulatory proceeding before the Board, it may submit the material, just as it may submit any public document. Under these circumstances, the submitting party in effect adopts the material and could be required to answer questions pertaining to its content.

While preparing this report, in addition to conducting its own quantitative analysis, the NEB held a series of informal meetings and discussions with various industry and government stakeholders. The NEB appreciates the information and comments provided and would like to thank all participants for their time and expertise.

This report does not provide an indication about whether any application will be approved or not. The Board will decide on specific applications based on the material in evidence before it at that time.

Overview and Summary

This report provides an outlook of Canadian natural gas deliverability[1] from the beginning of 2016 to the end of 2018. The outlook presents three distinct cases, a Higher Price Case, Mid-Range Price Case, and a Lower Price Case, each of which are based on a set of assumptions.

Since mid-2014, lower commodity prices have effected Canadian producers via reduced revenues, constrained cash flows and significantly reduced gas-targeted drilling. Major cuts to capital expenditures were made in 2015. Producers are wrestling with spending within cash flows and having to remain within bank-imposed debt limits, while continuing drilling operations to help minimize declines in reserves and production. Canadian natural gas deliverability is expected to decline in the near-term as reduced drilling activity and continued U.S. competition further challenge Canadian output. The lower Canadian dollar has resulted in additional complications, although providing a modest boost to revenues because exports to U.S. markets are paid in U.S. currency, it also creates challenges because some equipment and required supplies are purchased from the U.S., and paid for in U.S. dollars. Despite this challenging environment North American producers may continue to find deliverability gains on a per-well basis through high-grading[2].

It is expected that gas prices and Canadian drilling activity in 2016 will remain suppressed because the warmer-than-average winter softened demand and left ample storage volumes that require less production to refill. Multiple pipeline projects flowing gas out of the U.S. Appalachian Basin are scheduled to be operational by 2017-2018 and are expected to further challenge western Canadian gas in key markets. The Canadian liquefied natural gas (LNG) picture remains ambiguous. A 2016-2017 final investment decision (FID) for one or more Canadian LNG export projects could accelerate pre-positioning by producers and result in additional Canadian deliverability over the projection period.

In the Mid-Range Price Case, the Henry Hub price of natural gas would initially fall from $2.70/MMBtu[3] in 2015 to $2.50/MMBtu in 2016, climbing thereafter to $3.00/MMBtu by 2018, while Canadian natural gas deliverability declines slightly from 427 $10^6m^3/d$ (15.1 Bcf/d) in 2015 to 412 $10^6m^3/d$ (14.5 Bcf/d) in 2018. The Higher Price Case would see natural gas prices at $4.00/MMBtu by 2018, resulting in more drilling and Canadian deliverability increasing to 434 $10^6m^3/d$ (15.3 Bcf/d) by 2018. In a Lower Price Case, prices would remain at, or below $2.50/MMBtu, and deliverability would decline to 393 $10^6m^3/d$ (13.9 Bcf/d) by 2018. A comparison of the price assumptions for each case can be found in Figure 1.1.

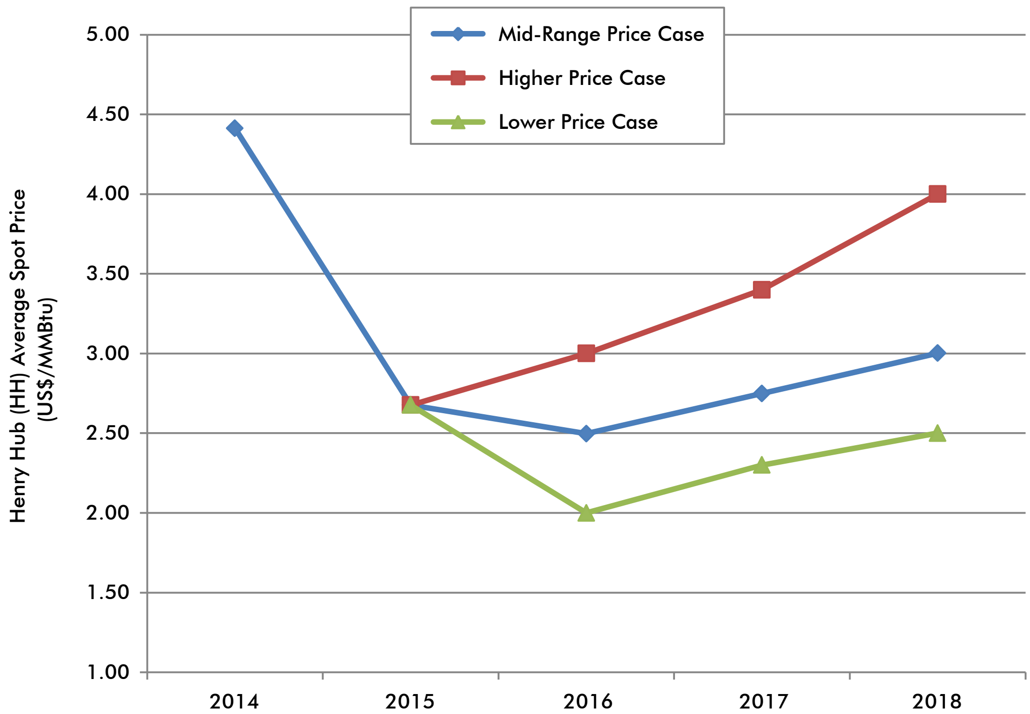
1 Deliverability is the estimated amount of gas supply available from a given area based on historical production and individual well declines, as well as projected activity. Gas production may be less than deliverability due to a number of factors, such as weather-related supply interruptions, and shut-in production due to economic or strategic considerations or insufficient demand.

2 When the amount of investment capital available to industry tightens, producers and service companies attempt to reduce costs while focusing their drilling efforts on the most economic prospects–commonly referred to as 'high-grading'.

3 Unless otherwise specified, North American natural gas prices are quoted at Henry Hub, given in $US/MMBtu and rounded to the nearest $0.05. Canadian natural gas prices are quoted as the Alberta Gas Reference Price and are listed in $C/GJ.

FIGURE 1.1

Historical and Projected Henry Hub Natural Gas Spot Price



The Analysis and Outlook section of this report contain key assumptions for each price case.
The Appendices contain a detailed description of the input assumptions used in projecting deliverability.

Background

The North American Natural Gas Market

North American producers continue to struggle with lower commodity prices. This is resulting in reduced revenues, constrained cash flows, less gas-targeted drilling, and a reduction of oil-derived natural gas production. Reserve write-downs[4] and reduced credit ratings have made it more difficult for some producers to access capital. Consequently, producers are decreasing drilling activity, reducing staff, seeking price concessions from suppliers and pursuing efficiency improvements in order to reduce cost. While the devaluation of the Canadian dollar relative to the U.S. dollar benefits Canadian producers when export sales are paid in U.S. currency, it also disadvantages Canadian producers when purchasing equipment and supplies in U.S. dollars.

Canada

- Canada produced an average of 427 $10^6m^3/d$ (15.1 Bcf/d) of marketable[5] natural gas in 2015, up 2.6 per cent from 2014, remaining well below the 482 $10^6m^3/d$ (17 Bcf/d) peak in 2005.
    - Western Canada is the primary natural gas producing region, contributing 99 per cent of total Canadian natural gas production in 2015. The remainder of Canadian natural gas production is supplied by Nova Scotia, Ontario, and New Brunswick.
- Overall natural gas demand in Canada was up slightly in 2015 at about 269 $10^6m^3/d$ (9.5 Bcf/d) and is expected to see ongoing modest growth as lower gas prices encourage industrial consumption. Rising oil sands production is fueled by natural gas and including gas consumed for cogeneration is now over 88 $10^6m^3/d$ (3.1 Bcf/d). Gradual growth in Canadian electricity demand is being met by a combination of increases in renewable generating capacity (wind, solar and hydro) and from natural gas. Imports of U.S. Marcellus and Utica gas will continue to challenge Canadian gas for markets in central Canada.
- Canada's natural gas exports to the U.S. remained flat in 2015 at about 211 $10^6m^3/d$ (7.4 Bcf/d). Imports of U.S. gas declined moderately in 2015 due to an increase in firm service contracting on Canadian pipelines resulting in Canadian net exports of 158 $10^6m^3/d$ (5.6 Bcf/d) in 2015. This represented about a five percent increase in net exports in 2015, but remained well below the 2007 peak in Canadian exports of 294 $10^6m^3/d$ (10.4 Bcf/d).
- Canadian natural gas exports to the U.S. Midwest continued to decline in 2015 as pipeline reversals and expansions flow more U.S. Marcellus and Utica gas into that market. Part of this decline was made up by increased Canadian gas exports to the western U.S. as higher temperatures increased demand for gas-fired power generation to meet air conditioning demand.

4 A write-down is a reduction in the estimated or nominal value of an asset.

5 Marketable (sales) gas is gas that has been processed to remove impurities and NGLs and meets specifications for use as an industrial, commercial, or domestic fuel.

United States

- U.S. natural gas production has increased steadily since 2005 and averaged 2 103 $10^6m^3/d$ (74.2 Bcf/d)[6] in 2015. This represents an increase of 5.3 per cent year-over-year and a 50 per cent increase over production of 1 401 $10^6m^3/d$ (49.5 Bcf/d) in 2005.
    - Natural gas produced in the U.S. is increasingly derived from tight and shale formations and is serving a growing share of U.S. demand, in turn reducing the need for Canadian natural gas imports.
- The U.S. expects only modest growth in natural gas demand. Only the power generation sector has shown robust demand as lower gas prices have allowed gas-fired power plants to maintain higher utilization rates beyond the typical summer period of air-conditioning loads. In addition, a number of coal plant retirements and increases in requirements for gas-fired generation as a backup for intermittent wind and solar capacity are adding to gas demand. In 2015, U.S. natural gas demand was 2 129 $10^6m^3/d$ (75.2 Bcf/d), an increase of three per cent over the prior year.
- The U.S. shipped its first LNG cargo export in February 2016. By the end of 2018, the U.S. is expected to have operational[7] liquefaction capacity of 241 $10^6m^3/d$ (8.5 Bcf/d) which is equivalent to about 11 per cent of 2015 U.S. natural gas production.
- Mexico is becoming an increasingly important outlet for excess U.S. natural gas supply. The amount of gas moving southward to meet growing Mexican demand represents volumes not available to compete with Canadian gas in other regions of the U.S. and Canadian market.

Mexico

- Mexican natural gas production decreased slightly between 2006 and 2015 to about 114 $10^6m^3/d$ (4 Bcf/d)[8]. Although Mexico may turn out to have sizeable resources of shale gas, its development lags behind the U.S. and Canada. Shale gas production is unlikely to expand rapidly in the short-term.
- Mexican demand for natural gas is expected to increase significantly in the mid to long term due to the planned construction of dozens of natural gas-fired power plants. In 2015 Mexico imported 82 $10^6m^3/d$ (2.9 Bcf/d) of natural gas from the U.S.[9]. It is expected that Mexico will continue to rely on imports to meet incremental demand for natural gas.
- As additional pipeline infrastructure is added, imports from the U.S. are expected to satisfy an increasing portion of Mexican demand and potentially displace some imports of higher cost LNG from other countries. Mexican natural gas imports from the U.S. are expected to increase to 142 $10^6m^3/d$ (5 Bcf/d) by 2020[10].

Current Trends in Supply and Demand

The North American natural gas market continues to be oversupplied. Storage inventories in the U.S. began 2016 above historical averages due to a warmer than usual winter. Strong U.S. gas production, ample inventories and reduced heating demand are expected to keep the market amply supplied and could keep price soft for most of 2016.

- Cyclical imbalances of supply and demand are typical of the North American natural gas market. Demand often varies because of weather, changes to economic growth, and infrastructure constraints.
    - A typical cycle occurs as follows: during periods of increased demand, prices increase to ration supply and direct it toward the markets that value it most. Higher prices also provide incentives to develop and produce the next most costly natural gas resources which can cause deliverability to exceed demand, subsequently depressing prices. Lower prices discourage production of high cost supply sources but at the same time also foster demand. As demand grows, prices begin to rise again and the cycle repeats itself.
- Natural gas prices have been on a downward trend since early 2014 and oil prices dropped sharply in mid-2014 which subsequently reduced demand for drilling rigs and well-servicing equipment across the oil and gas sector. Producers and service companies have since lowered costs, improved operational efficiencies, and achieved higher levels of production per-well by high-grading.
    - Producers significantly reduced costs in 2015, some reporting cost reductions between 25 and 50 per cent.
    - Although producers will continue to look for further savings in 2016, it is unlikely future cost reductions will be of the same magnitude as those achieved in prior years as the majority of cost savings have likely already been obtained.
- Modern drilling technologies, such as multi-stage hydraulic fracturing and multi-well pads, are now used extensively, improving the size and economics of the Canadian and U.S. natural gas resource base while boosting deliverability.
- It may take years for new major markets to develop for natural gas. Natural gas has largely displaced competing fuels in traditional space-heating markets in Canada and the U.S. already.
    - Proposed LNG export facilities represent a large potential increase in gas demand. Long lead times to obtain approvals, establishing overseas markets, and the construction of facilities are factors that slow down the development of these projects. Currently, none of the proposed Canadian LNG projects with approved export licenses have announced a FID, although one project has issued a conditional FID.
    - Other potential sources of major demand growth could require years or decades to develop to meaningful scale. Examples include growth of the North American petrochemical industry, additional upgrading of bitumen in Alberta, and widespread use of compressed natural gas or LNG for transportation.
- The U.S. has a large inventory of wells that have been drilled but not completed. This allows producers to avoid selling into the market at lower prices, while taking advantage of lower drilling and service costs available because of reduced activity. These wells can be completed later when prices rise, which could rapidly increase supply, stifling large price increases.

Future Uncertainties

Trends in future Canadian and U.S. deliverability will likely follow a pattern similar to previous cycles, but several factors make it difficult to anticipate the duration and extent of the current cycle:

- Many small and mid-sized Canadian oil and gas producers could have difficulty accessing capital, which not only challenges drilling operations, but also increases the chance of bankruptcy or acquisition of smaller producers by larger, more financially stable companies.
    - In lieu of debt financing, producers and service companies in the U.S. and Canada are utilizing private equity[11] investment. This may provide the capital required by smaller and mid-sized producers to continue operations. Currently, there is more private equity investment activity in the U.S. than in Canada.
    - As commodity prices remain depressed, an increase in merger and acquisitions (M&A) is expected. In order to obtain the best deal possible, investors typically wait to see evidence of prices bottoming out before investing. Anticipation of even lower prices partially explains why Canada has yet to see an increase in M&A activity. In 2015, year-over-year M&A activity in the Canadian oil and gas sector fell by almost half, from $41 billion in 2014 to $21 billion[12].
    - The extraction of NGLs[13] (which are priced in relation to crude oil) from natural gas production represents an additional source of producer revenue. As natural gas prices declined after 2008 and crude oil prices continued to rise, the increasing value of the NGLs from some natural gas wells could exceed the value of the natural gas produced. This promoted NGL-targeted drilling and resulted in additional natural gas deliverability based on the value of the NGLs rather than the natural gas. Eventually rising NGL deliverability began creating excess supplies of ethane, propane, and butane in Canada and the U.S. Excess NGL volumes coupled with declining crude oil prices since 2014 have decreased the supplemental revenues generated from NGL-targeted activity and slowed the development of this source of natural gas deliverability.
    - Heavier NGLs such as condensate have higher value in western Canada because they are used to dilute bitumen for pipeline transport. It is possible that condensate-rich gas plays could see sustained drilling activity in western Canada.
- Shale gas resources such as the Marcellus and Utica are close to markets in central Canada, the U.S. northeast, and the U.S. Midwest. Gas from this area has significantly displaced Canadian exports to the North East U.S. market because proximity presents a cost advantage relative to shipping in Western Canada Sedimentary Basin (WCSB) gas.
    - By 2018, newly constructed pipelines in the Marcellus and Utica region could add additional 88 $10^6m^3/d$ (3.1 Bcf/d) import capacity into Canadian markets and 156 $10^6m^3/d$ (5.5 Bcf/d) into the U.S. Midwest. This additional capacity could displace some of the supply provided by the WCSB in these markets.
    - Since July 2015 production from the Marcellus shale has been slowly declining as companies wait for higher prices and new pipeline infrastructure. Production from the Utica however, is increasing and has largely offset Marcellus production declines, continuing to challenge Canadian market share.

---

11 Private equity investment generally refers to capital invested by individuals or funds into private (non-publically traded) companies, or into publically traded companies with the intention of taking them private.

12 Evaluate Energy – CanOils M&A database.

13 NGLs are liquid hydrocarbons including ethane, propane, butanes, and pentanes plus. Natural gas containing commercial amounts of NGLs is known as NGL-rich, liquids-rich or wet gas. Dry natural gas contains little or no NGLs.

- Producers are testing gas resources in western Canada that could support proposed LNG exports, potentially increasing drilling in the area. A FID to proceed with a Canadian LNG export project in 2016-2018 could accelerate this activity within the time period assessed in this report.
- The Nova Scotia Deep Panuke project was expected to offset declining output from the Sable Offshore Energy Project. Deep Panuke is now operating seasonally, producing in winter when demand is greater. Increasing amounts of water are being produced with natural gas at Deep Panuke, and this could shorten the project's lifetime.
- The Alberta Government recently reviewed and updated its oil and gas royalties program. The new royalty framework, which comes into effect for wells drilled in 2017, favors efficiency and may create benefits for some producers. The new royalty framework recommends that existing royalties remain in effect for 10 years on investments already made, and royalty changes should only be implemented on new wells[14].
- The lower price of natural gas alongside a change in environmental regulations is encouraging the switch from coal to gas for power generation in the U.S. Coal-to-gas switching for power generation would create additional demand for natural gas. To date, the majority of coal plant retirements have been aging units, not heavily utilized. In the U.S., the extent to which the displacement of modern efficient coal plants equipped with emissions controls by gas plants would depend on the price competitiveness of gas compared to coal. The timing of further displacement in power generation will depend on mandated timelines in government legislation, demand for power generation, and relative prices of gas and coal.

14 Alberta At A Crossroads: Royalty Review Advisory Panel Report – January 2016.

Analysis and Outlook

Canadian natural gas drilling activity decreased significantly in 2015 (Table 3.1) due to lower prices, major slashes to capital expenditures, and a difficult economic environment. Drilling costs are expected to continue declining slightly throughout 2016, as producers find remaining efficiencies. Increased deliverability from the U.S. continues to depress gas prices, rendering some western Canadian natural gas prospects uneconomic to pursue.

Three price cases for Canadian natural gas deliverability are examined in this report. These cases differ primarily in terms of Canadian and U.S. natural gas prices and the rate at which Canadian gas is backed out of key markets by lower cost U.S. supply. The Appendices contain a detailed description of the assumptions used for projecting deliverability.

A summary of the key assumptions used in the cases and their respective deliverability results are shown in Table 3.1.

TABLE 3.1

Pricing Overview and Deliverability Results

		Mid-Range Price Case			Higher Price Case			Lower Price Case		
	2015	**2016**	**2017**	**2018**	**2016**	**2017**	**2018**	**2016**	**2017**	**2018**

[b] GLJ Publications.

For this analysis, the Board divides natural gas production in western Canada into conventional, coalbed methane (CBM), and shale gas, with tight gas included as a sub-category of conventional production. Due to large regional differences in geological and production characteristics, the Board further subdivides these categories into smaller geographic areas, or regions, which have similar characteristics for production decline analysis. Within each region, groupings of the producing formations are made on a geological basis. Details on the characterization of the resources are available in Appendix B. Canadian natural gas production outside of western Canada includes:

- Onshore production from New Brunswick and Ontario, which is declining as minimal future drilling activity is expected over the projection period.
- Nova Scotia production from the offshore Sable Island project and Deep Panuke.

Shale gas potential exists in Quebec, New Brunswick, and Nova Scotia, however, provincial policies currently prohibit hydraulic fracturing which is required for shale gas development. It is assumed these policies do not change over the projection period. Natural gas production from the Mackenzie Delta and elsewhere along the Mackenzie Corridor in the Northwest Territories ceased in 2015 on account of lower prices rendering production uneconomic.

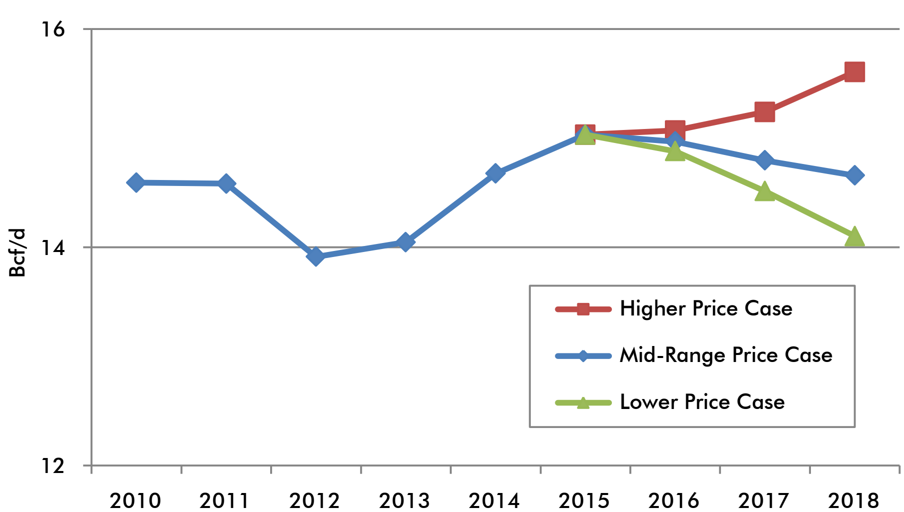
Deliverability Outlooks

- The three price cases cover a range of market conditions: In the Mid-Range Price Case, Canadian gas struggles to maintain market share as low cost U.S. natural gas sources back Canadian supply out of central Canada and the U.S. Midwest market. Deliverability remains relatively flat in 2016 and declines through 2018. By the end of 2018 deliverability declines as newly drilled wells are unable to replace declining production from older wells.
- In the Higher Price Case, U.S. production from the Marcellus and Utica region is needed to support increasing Mexican exports, increasing U.S. LNG exports, additional gas-fired power generation and petrochemical industry requirements, and to offset declines in U.S. natural gas produced from oil wells. These factors increase the opportunity for Canadian gas to flow into key markets. Strong economic growth and U.S. LNG projects finishing ahead of schedule contribute to increased demand over the period. As a result, Canadian deliverability rises throughout the projection period.
- In the Lower Price Case, lower cost Marcellus and Utica shale gas resources further increase their market share in central Canada and the U.S. Midwest, facilitated by new pipeline capacity. Displaced U.S. Rockies supply creates challenges for Canadian gas to access markets on the U.S. West Coast. U.S. LNG exports increase more gradually resulting in increased U.S. gas surplus. Consequently, western Canadian natural gas is further challenged and squeezed out of key markets. Lower prices and reduced market opportunities result in steadily decreasing deliverability over the projection period.

A comparison of the three Canadian natural gas deliverability outlooks to 2018 is shown in Figure 3.1.

FIGURE 3.1

Historical and Projected Natural Gas Deliverability



The levels of drilling activity that support these deliverability estimates are the result of capital investment assumptions and estimated drilling costs. Comparisons of natural gas drilling activity in the three cases in terms of drill days and gas-intent wells drilled are shown in Figure 3.2 and Figure 3.3, respectively.

FIGURE 3.2

Natural Gas-Intent Drilling Days

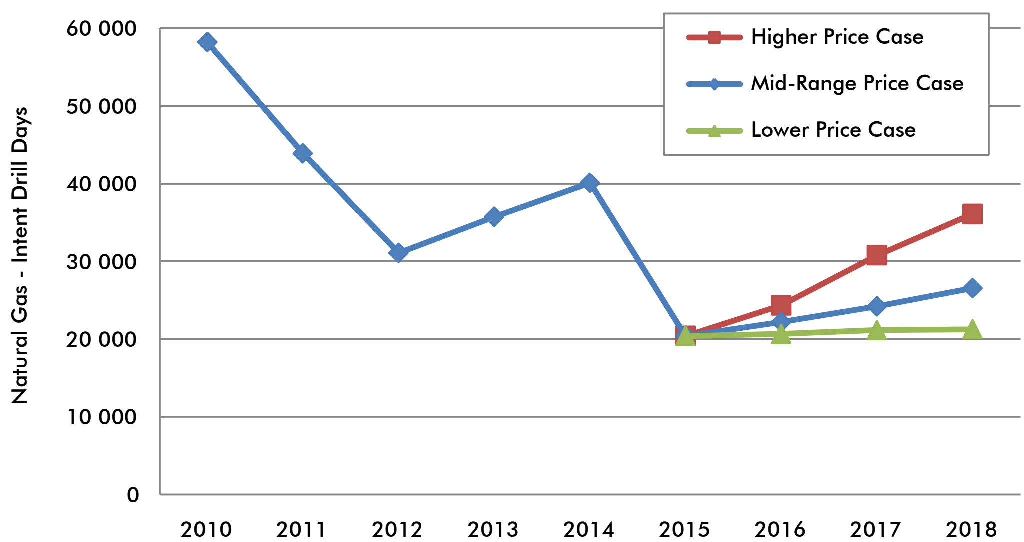


FIGURE 3.3

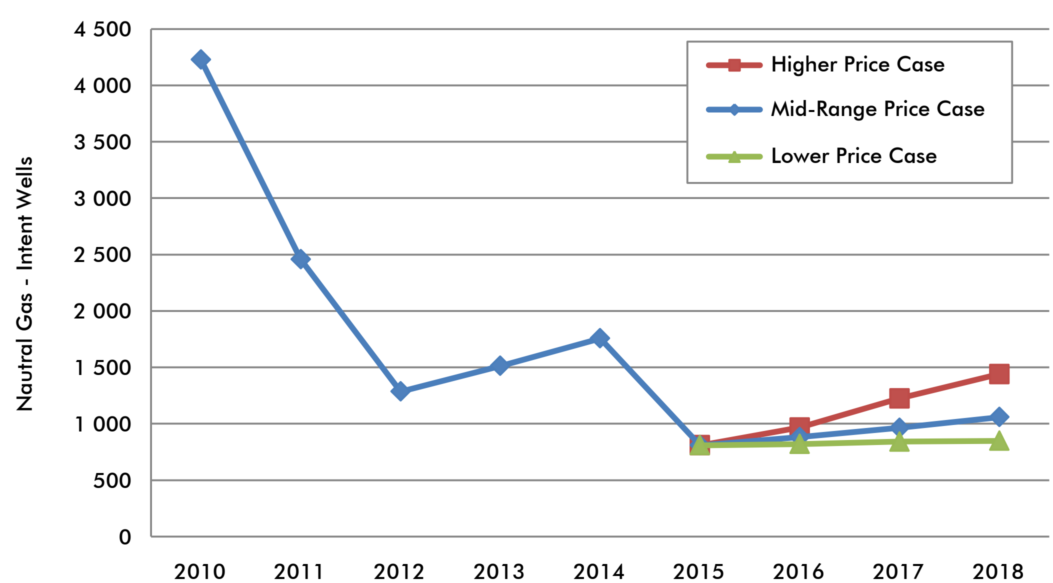
Natural Gas-Intent Wells



Mid-Range Price Case

Throughout the projection period the Mid-Range Price Case assumes moderate economic growth, weather conditions in line with seasonal averages, continued modest growth in Canadian and U.S. natural gas demand, and on-time completions of U.S. LNG facilities and pipeline infrastructure. Following the warmer-than-average winter of 2015-2016 the North American market remains oversupplied in 2016, both in terms of NGLs and marketable natural gas, resulting in slimmer margins for producers. Following major cuts in 2015, capital expenditures increase slightly over the projection period as pricing conditions improve; however, U.S. natural gas continues to back Canadian supplies out of markets in central Canada and the U.S. Midwest. The outlook for Canadian LNG remains ambiguous with no FID's made before 2017. In spite of additional drilling, Canadian deliverability declines over the projection, as newly drilled wells are unable to fully replace declining production from older wells.

Deliverability Results

In the Mid-Range Price Case, Canadian natural gas deliverability continues to be well above Canadian demand.[15] Canadian deliverability remains relatively flat in 2016 and falls throughout 2017 and 2018 as declines from older wells outpace drilling and production from new wells. Tight gas activity increases over the projection with 700 tight gas wells drilled in western Canada in 2018, including 411 in the Montney tight gas play. The Duvernay Shale play continues to see the most Canadian shale gas activity with 35 wells drilled in 2018. A summary of the Mid-Range Price Case is available in Table 3.2.

TABLE 3.2

Mid-Range Price Case Summary and Results

	Alberta Gas Reference Price	Gas Intent Drill Days	Gas Intent Wells	Average Deliverability	
	C$/GJ			$10^6 m^3/d$	Bcf/d
2015	$2.57[a]	20 412	814	427 [b]	15.1
2016	$2.69	21 249	848	425	15.0
2017	$2.97	22 965	919	418	14.8
2018	$3.25	24 234	971	412	14.5

[a] GLJ Publications.
[b] Annual average of NEB reported provincial production, where available.

Implications

Canadian and U.S. gas markets have been well supplied at historically moderate prices for the past few years. A warmer-than-average winter and elevated storage levels going into 2016 keep prices depressed in the short term. Markets could tighten from reduced capital expenditures, drilling reductions, rising natural gas demand from improved integration of the Mexican market or U.S. LNG projects coming online ahead of schedule.

15 Projections of Canadian demand for natural gas are available in Appendix E.

Higher Price Case

The Higher Price Case assumes a larger recovery for Canadian natural gas deliverability because of higher gas demand from a combination of various factors including: stronger economic growth in the U.S. and Canada, weather that is cooler in the winter and warmer in the summer than average to increase space heating and cooling demand, increased Mexican demand that draws more U.S. gas southward, and U.S. LNG facilities being completed ahead of schedule and heavily utilized. Increased demand boosts prices and results in less displacement of Canadian gas by U.S. supplies. Despite rising natural gas prices, it is assumed that power generators prefer natural gas over coal in specific markets, potentially to meet stricter environmental regulations or to better match variations in the electricity demand profile. It is also assumed that the U.S. petrochemical industry completes a major expansion and increases its use of natural gas and NGLs. Accordingly, Canadian producers are able to obtain capital more easily while continuing to focus drilling efforts on highly productive prospects. A FID in 2016-2017 to proceed with a Canadian LNG export project would accelerate pre-positioning by producers and result in additional Canadian deliverability over the projection period.

Deliverability Results

Canadian natural gas deliverability grows continuously over the projection in the Higher Price Case, increasing from 427 $10^6 m^3$/d (15.1 Bcf/d) in 2015 to 434 $10^6 m^3$/d (15.3 Bcf/d) by 2018. Tight gas production is still the primary source of new production growing from 221 $10^6 m^3$/d (7.8 Bcf/d) in 2015 to 253 $10^6 m^3$/d (8.9 Bcf/d) in 2018. A summary of the Higher Price Case is available in Table 3.3.

TABLE 3.3

Higher Price Case Summary and Results

	Alberta Gas Reference Price	Gas Intent Drill Days	Gas Intent Wells	Average Deliverability	
	C$/GJ			$10^6 m^3$/d	Bcf/d
2015	$2.57 [a]	20,412	814	427 [b]	15.1
2016	$3.24	23,614	943	428	15.1
2017	$3.67	27,875	1,115	430	15.2
2018	$4.13	31,366	1,257	434	15.3

[a] GLJ Publications.

[b] Annual average of NEB reported provincial production, where available.

Implications

Higher prices, increased demand, and improved competitiveness of Canadian gas relative to the U.S. keep deliverability increasing over the projection period. Capital expenditures increase steadily and the supply overhang experienced in the North American market over the past few years diminishes slightly, as harsh weather and U.S. LNG facilities finishing ahead of schedule increase demand and drilling takes place to meet it.

Lower Price Case

In the Lower Price Case, demand for Canadian and U.S. natural gas is assumed to decrease because of warmer winters and cooler summers than average to decrease space heating and cooling demand coupled with more modest economic growth. Other factors include less growth in U.S. exports to Mexico due to slower Mexican demand growth and higher Mexican LNG imports, U.S. LNG facilities not being utilized to maximum capacity, and strong production growth out of the Marcellus and Utica which further displaces Canadian supply. Lower prices reduce revenues, resulting in less capital dedicated to drilling. Canadian producers continue to experience difficulty obtaining debt financing, while private equity investment would occur almost exclusively in the U.S. Canadian natural gas deliverability would remain more than adequate to meet domestic demand. The Lower Price case would also assume no FIDs for Canadian LNG projects are made during the 2016-2018 period.

Deliverability Results

Canadian natural gas deliverability declines in 2016 to 420 $10^6m^3/d$ (14.8 Bcf/d) and falls significantly thereafter reaching 393 $10^6m^3/d$ (13.9 Bcf/d) by 2018. Lower natural gas prices further reduce investment in the sector. A summary of the Lower Price Case is available in Table 3.4.

TABLE 3.4

Lower Price Case Summary and Results

	Alberta Gas Reference Price	Gas Intent Drill Days	Gas Intent Wells	Average Deliverability	
	C$/GJ			$10^6m^3/d$	Bcf/d
2015	$2.57 [a]	20 412	814	427 [b]	15.1
2016	$2.16	17 424	696	420	14.8
2017	$2.42	18 817	753	406	14.3
2018	$2.58	19 847	795	393	13.9

[a] GLJ Publications.
[b] Annual average of NEB reported provincial production, where available.

Implications

Canadian natural gas consumers would benefit from lower natural gas prices in the short term. This case shows the greatest decline in natural gas deliverability which results in intensified competition from U.S. sources of natural gas, as well as a significant reduction in drilling and other gas-related service activities.

Key Differences from Previous Projection

The key difference from the previous deliverability projection, *Short-term Canadian Natural Gas Deliverability Outlook 2015-2017*[16], has been the announcement of major cuts to capital expenditures because of sustained lower commodity prices. Drilling activity in 2015 was significantly lower than the previous year as a result. The warmer-than-average winter of 2015-2016 also reduced natural gas heating demand, keeping storage levels above average going into spring and keeping prices soft.

Commodity prices have been lower for longer than was assumed in the 2015-2017 projection. Producers are adjusting by slashing capital expenditures and operating within available cash flows. In addition to tighter capital constraints, reduced producer creditworthiness has increased the difficulty of obtaining capital. Lower NGL prices due to oversupply are expected to reduce the amount of drilling for liquids-rich natural gas, while low oil prices are expected to reduce oil drilling. Altogether, this has significantly reduced demand in the service sector. Throughout 2015 producers worked with service companies to lower service costs and improve capital efficiency on a per-well basis. Although further improvements are possible, it is unlikely they will be of the same magnitude as in 2014-2015.

The Alberta Reference Price in 2015 was $2.57/GJ, below the $2.85/GJ projected in the 2015-2017 Mid-range Price Case and well below the $3.00/GJ projected in the 2015-2017 Higher Price Case. However, actual production averaged 427 10^6m^3/d (15.1 Bcf/d) in 2015, which was near the Higher Price Case projection of 429 10^6m^3/d (15.1 Bcf/d). Actual production was higher than anticipated in the 2015-17 Mid-range Price Case projection due to improved drilling efficiency and improved initial production from some newly drilled wells.

16 Short-term Canadian Natural Gas Deliverability Outlook 2015-2017.

Recent Issues and Current Trends

Factors that will influence future Canadian natural gas deliverability include:

- The development of a Canadian LNG export market. Canada's LNG future remains uncertain. A FID could increase Canadian natural gas deliverability though the construction of facilities would only occur beyond the projection period. It is likely that a significant portion of natural gas exported as LNG will be produced from corporate reserves devoted to the project. Prior to LNG export project completion, these gas resources will need to be proven by additional drilling and testing, and the resultant production would be sold into the North American market.
- The price spreads between natural gas, oil and NGL. The developing NGL glut and subsequent decrease in NGL prices, along with lower oil prices, may result in reduced NGL and oil-targeted drilling, which produces natural gas as a byproduct. It is possible that reduced gas production from these sources would help to balance markets.
- Coordinated production efforts as a result of acquisitions and the consolidation of smaller North American producers by major companies. Moreover, economies of scale could be achieved by integrating supply chains of major companies, further reducing costs.
- The rate at which Canadian natural gas is displaced from markets in central Canada and the U.S. Additional pipeline capacity from the Marcellus and Utica to the U.S. Midwest will be a key factor affecting markets which have been past supporters of Canadian natural gas.
- The potential for increased future deliverability from the Montney despite lower gas prices. NGL-rich gas from the Montney is some of the lowest cost gas in North America and can be competitive with Marcellus gas in certain markets depending on relative transportation costs and foreign exchange rates.
- Improved economics of North American natural gas production. Technological advancements, efficiency gains, and improved data analytics in drilling and hydraulic fracturing operations have improved production capacity of North American natural gas. Inputs including labour and materials have seen cost rollbacks in response to lower activity levels. Depending on the individual producer, improvements in these economic factors may contribute to increased deliverability.
- The development of oil sands. Natural gas is used as a major fuel source to provide energy for Canadian oil sands projects. Oil sands projects under construction and scheduled to begin production between 2016 and 2018 are generally considered sufficiently advanced to be completed despite lower oil prices. Projects in early stages of planning or development may be postponed until global oil markets become more supportive.
- The pace of coal to gas switching for electricity generation in key markets of Canada and the U.S. This has the potential to increase demand for WCSB natural gas and subsequently increase Canadian deliverability.

LIST OF ACRONYMS

Electrical Efficiency of Electrolytic Hydrogen Production

Kaveh Mazloomi[1,*], *Nasri b. Sulaiman*[1], *Hossein Moayedi*[2]

[1] Department of Electrical and Electronic Engineering, Faculty of Engineering, University Putra Malaysia

Received: 12 January 2012 / *Accepted:* 6 March 2012 / *Published:* 1 April 2012

Common industrial electrolyzers have a nominal hydrogen production efficiency of around 70%. High power dissipation value is the most important drawback of such systems since electric power expense has the largest share in the price of electrolytic hydrogen. The electrical impedance of an electrolysis cell causes a fraction of the applied energy to be wasted as heat while the electric current passes through it. As the prior publications show, many efforts are made to reduce this effect. According to the available literature, several internal and external variables are pointed out to have an influence on the electrical behavior of such cells. This paper provides an insight to these factors in regards to minimize the energy loss of the process of water electrolysis.

Keywords: Water electrolysis, Hydrogen production, Electrical power, Efficiency, power dissipation

1. INTRODUCTION

Electrolytic hydrogen production has been scientifically studied for more than a century [1, 2]. According to the literature, hydrogen has been used by for military, industrial and commercial purposes since late 19th century [3]. Nowadays, electrolytic hydrogen has a share of only 4% [4, 5] in the global production of the most abundant element of the universe [6, 7]. Electricity expense constitutes the largest fraction of hydrogen production costs [9]. High hydrogen production expenses count as the main deficiency of commercial and industrial electrolyzers. Hence electrolytic methods are usually outperformed by other approaches such as steam methane reformation. An electrolyzer is usually subjected to massive current values in order to break the water molecules into oxygen and hydrogen. The reaction equation is noted as below:

$$2H_2O \rightarrow 2H_2 + O_2 \qquad (1)$$

Electrochemical decomposition energy of water is relatively high since water molecules have a stable structure at ambient temperature [8]. Approximately, a minimum voltage of 1.23V is required to be applied to a water molecule at laboratory conditions to break the bonds between hydrogen and oxygen atoms. This voltage is also known as the equilibrium voltage of water. However, much higher voltage levels are used in industrial electrolysis cells. The excess voltage is referred to as the "overpotential" of the process reaction [10]. The overpotential value is affected by different factors, which are going to be discussed in the following sections of this paper.

In addition, by following the Ohm's law (equation 2) the electric power can be calculated as in equation 3.

$$U=RI \qquad (2)$$

$$P=UI \qquad (3)$$

Where U is the electrical potential in volts, I is the electric current in Amperes, R is the electrical resistance in Ohms and P is the electric power in Watts. Obviously, for very large current levels, any slight increase of the cell voltage can cause a drastic raise in the power demand. Moreover, technical data show electrolyzers to usually perform their process under low voltage and high current level conditions.

Massive current densities cause a noticeable value of unwanted ohmic voltage drop between the electrodes. As a result, formation of unwanted electrical power loss and less process efficiency values are inevitable. Many efforts are made in order to force an electrolysis cell to reach a certain current level by applying lower voltage levels to it. Major causes of the overvoltage requirement are introduced and discussed in the following sections of this paper. Moreover, possible modifications are pointed out in order to minimize the unwanted negative effects of each parameter.

2. FACTORS WITH AN INFLUENCE ON ELECTRICAL EFFICIENCY

2.1. Electrolyte quality

Bases and acids are known to change the nonconductive nature of pure water. These compounds have a great reducing effect on the overvoltage value of an electrolyzer [11, 12] due they improve the ionic conductivity aqueous electrolyte compounds. However, the concentration level of acidic and alkali solutions are limited in practice due to the highly corrosive behavior of such materials. A 25% to 30% KOH aqueous solution is reported to have a wide use in electrolyzers [13].

On the other hand, the electrocatalytic performance of water electrolysis cell is known to be limited [14, 15]. This limitation is mainly cause the overall electrical resistance of a cell to rise and will cause the efficiency to fall. Therefore, substitute electrolytes such as ionic liquids have been introduced to improve the conductivity and stability factors of electrolytic baths [16, 17]. de Souza et al. [18] performed a series of experiments on the use of the ionic liquid of 1-butyl-3-methyl–

imidazolium-tetrafluoroborate (BMI.BF4) [19] in water at ambient temperature. The electrode plates of these cases were selected from a number of easily found metals such as carbon steel (CS), Nickel (Ni), Nickel-Molybdenum (Ni-Mo) alloy and Molybdenum (Mo). A maximum efficiency value of 96% was reported for the case of low carbon steel electrodes [20] in 10 vol.% aqueous solution of MBI.MF4. All tests took place at the current density value of 44mA cm^{-2}. The reported efficiency levels of this research are much higher than the average 73% efficiency of common commercial and industrial electrolyzers [21]. However, it should be considered that such electrolyzers usually function at much higher current densities than the mentioned experimental value.

Moreover, any existence of impurities may cause unwanted side reactions in an electrolysis cell [22]. Magnesium, chloride and calcium ions can be named as a few common examples of these impurities. In addition, contaminations can block and passivate the electrode plates and/or separator surfaces [11, 23] and sabotage the inter-electrode mass and electron transfer. The latter-mentioned is another formation cause for the excess ohmic resistance of the electric current path.

2.2. Temperature

Temperature is known to be one of the most effective variables on the electric power demand of an electrolysis cell. Electrolysis process is much more efficient at raised temperatures [20]. The reasons of this behavior can be discussed according to the thermodynamic characteristics of a water molecule, as its splitting reaction potential is known to reduce as the temperature increases. Moreover, ionic conductivity and surface reaction of an electrolyte rise directly with temperature [24]. High temperature water electrolysis requires less energy to reach any given current density in analogy with a low temperature process [25, 26]. As a practical example of the latter, Bailleux [27] tracked the operation of a test hydrogen production plant for two years. Implemented plant technology of this case was much simpler back in early 1980's in contrast with current most recent electrolyzers. The case study plant of this report used a 40%wt potassium hydroxide alkaline solution as an electrolyte to be decomposed under the pressure, current density and temperature range conditions of 20bar, 10kA m^{-2} and 120°C to 160 °C respectively. Data scanners were used to monitor the mentioned parameters as well as the purity of the output gasses in order to determine the unwanted contents of oxygen and hydrogen outlets. The report shows a voltage reduction of 120mV as the temperature was raised from 120°C to 150°C. However, the increased temperature and pressure were mentioned to cause some "stability problems" such as container cracks and gasket leaks.

In more recent experiments, high temperature electrolysis is referred to cases with much higher temperature ranges. As an example of such, we can mention a work of Mingyi et al. [28]. Their tests were conducted for the analysis of the electrochemical behavior and thermodynamic characteristics of a high temperature steam electrolyzer (HTSE). They expressed high temperature water electrolysis to need less energy than conventional low temperature electrolysis processes. More efficient process was observed as a result.

Moreover, they divided the total electrolysis efficiency to three separate and individual factors of: electrical efficiency, electrolysis efficiency and thermal efficiency. They calculated the share of each parameter to be 70%, 22% and 8% respectively from the total efficiency. According to their discussion, increased cell temperature leads to a higher thermal and lower electrical efficiency values where the electrolysis efficiency remains without any significant changes. The authors also reported the possibility of coupling the HTSE device with a high temperature gas cooled reactor (HTGR). When the electrolysis temperature was increased to 1000°C, an overall efficiency of the process of 59% was recorded which was remarkably higher than the 33% initial value. The process efficiency was stated to be more than twice of those of the conventional low temperature electrolyzers of the time.

In addition, Ganley [29] studied the process efficiency of high temperature/ high pressure electrolyte solutions (steam state). The experiments were carried out in a chemical resistant container since the sample electrolyte was a highly concentrated KOH solution heated up to 400 °C. During the studies, the electrolyte was subjected to different values of compression during the experimental work. The electrolyte concentration was set at 19 M at the starting phase of each experiment which is highly corrosive to many metals and alloys. Another varying condition of the experimental work was the electrodes material which is the subject of discussion in following sections. Lower voltage level was required to reach any given current density for temperatures between 200 °C and 400 °C. The results show that a voltage level of 1.8 V was enough to cause a current density of 200 mA cm^{-2} at 200 °C. This value was only 1.5V when the electrolyte was heated up to 400 °C at the same pressure and current density.

As Nagai et al. [30] expressed, heat can reduce the "reversible" potential of water (also known as the equilibrium voltage). This parameter also enlarges the size of the gas bubbles and reduces their rising velocity. The latter-mentioned causes a larger void fraction in the electrolyte and decreases the efficiency as a result. The void fraction is the subject of discussion in section *2.3*.

In another case, Ulleberg [14] developed models for the process. Their thermodynamic and electrochemical models show noticeable cut downs in both over voltage and reversible potential of the heated cells. This expression is also supported by comparing the voltage versus current curves for both cases of low and high temperature electrolysis. They reported remarkably improved efficiency levels to be a resultant of conducting the electrolysis process in high temperatures.

Conducting such processes in drastically high temperature levels on gas state electrolyte is expressed to be more efficient than the low temperature processes although, mechanical, stability and physical properties of such systems are still a concern for manufacturers and designers of industrial and commercial electrolyzers.

2.3. Pressure

Appleby et al. [31] tried to lower the costs of hydrogen production by creating higher current density conditions in conventional electrolyzers According to their research, high pressure electrolytes will consume less power in the process of electrolytic decomposition. The main reason was stated to be the shrinking effect of pressure on the gas bubbles which cause the ohmic voltage drop and power dissipation to reduce. Moreover, high pressure electrolysis has less power demand for the phase of product compression. These experiments were conducted in a typical three compartment electrolyzer with a varying temperature between 25°C and 90°C. Cell current density was kept at 1 mA cm^{-2} with an electrolyte of either a 34%wt or 25%wt KOH solution in distilled water. The electrodes were chosen from pure platinum (99.99%) and smooth nickel (Ni 200) plates with a 1 cm^2 surface area. Authors noted an overall voltage drop of up to 100mV when the conversion process was conducted at a pressure level of under 30 atm. No significant further voltage drop was recorded at higher pressure values (up to 40 atm). The cell voltage vs pressure graph has its highest reduction slope when the pressure was raised from 1atm to 10atm despite of the process temperature.

Referring to a similar work, Onda et al. [32] calculated the energy consumption of compressing a liquid electrolyte to be much less than those of gas state hydrogen compression. These calculations were based on the results of an earlier research of LeRoy et al. [33]. They estimated the ideal temperature and pressure conditions for electrolytic hydrogen production to be around 70 MPa and 250 °C relatively. High temperature and intense pressure will change both Gibbs energy and enthalpy levels of an electrolysis process. Hence, lower voltage level will be required as the temperature rises in high pressures and vice versa. However, in pressure levels higher than 20MPa, they found the voltage rise to be negligible. This behavior became more sensible at lower temperatures. Finally, an electrolysis efficiency enhancement of 5% was observed. Another 50% of energy was saved at the compression phase of high pressure electrolytic hydrogen production.

2.4. Electrical resistance of the electrolyte

Electrical resistance of an object is an evaluation of its opposition to the passage of electric current. The level of this force is proportional to the cross section area and the length of the current path and the material resistivity of the conducting material. The relationship between the mentioned variables is shown in equation 4 as bellow.

$$R = \frac{\rho\, l}{A} \qquad (4)$$

Where A is the cross section area, ρ is the material resistivity, R is the electrical resistance, and l is the length of the current path. Inside and electrolysis cell, electrons start their travel from the surface of an electrode, move through the electrolyte and end their journey at the surface of the other electrode. We can assume the path as an object with the same length as the distance between electrodes, the cross section of the area of electrodes overlap and an equivalent resistivity value. The equivalent resistivity consists of different variables such as the electrodes resistivity, electrical admittance of the electrolyte and the reaction between electrodes surfaces and electrolyte. Hence, the equivalent resistivity is a function of the following variables:

2.4.1. Space between the electrodes

According to equation 4, by reducing the distance between electrodes, lower electrical resistance can be obtained. However, the question may occur that how much proximity of electrode plates is practically possible?

Nagai et al. [30] carried out a series of experiments to find the optimum space between electrodes. They examined the effects of the void fracture between electrodes which is caused by the formation of gas bubbles.

These experiments were conducted at ambient pressure with Ni-Cr-Fe alloy electrodes in a 10%wt potassium hydroxide aqueous solution. They varied the current density, system temperature and the distance between electrodes, their size, wettability and inclination. The results clearly depict that placing the electrodes too close to each other will increase the value of the void fracture and will lead to a less efficient process. This phenomenon became more sensible at high current density levels. By placing the electrodes at different distances and comparing the result values of cell voltage and current, the authors concluded that positioning the electrodes too close to each other will decrease the process efficiency. LeRoy et al. [34] also reported the same effect. They expressed larger electrical resistance of an electrolyte is a result of gas bubbles accumulation in the inter-electrode area. Therefore, this accumulation will cause the process to be less efficient.

2.4.2. Size and alignment of the electrodes

Another variable of equation 4 is the cross section area of an object. Less resistive current path is known to be a result of using electrodes with larger surface areas. Again, in this case, it would be useful to define the term "larger surface area" in more details. This definition will help us to know the practical dimension limits of an electrode plate?

A series of experiments have been conducted in order to test the effects of using electrodes of different sizes on the process efficiency [30]. As the results show, at the same electrode width, larger electrode height will cause additional power dissipation in a cell. The reason was expressed to be the formation of a larger volume of void fraction. The models of gas bubbles movement [35] clearly depict larger amounts of bubble accumulation in higher parts of the electrodes.

These experiments also show that higher efficiency levels can be obtained by placing the electrodes in a vertical position. The latter is caused by reduced ohmic resistance due to the "optimum bubble departure rate".

2.4.3. Forcing the bubbles to leave

Ohmic resistance in an electrolysis bath is related to the bubble coverage of all surfaces since gas bubble accumulation on each surface will reduce its conductivity. Hence, it causes a higher level of ohmic voltage drop [36]. On the other hand, bubbles diameter depends on the current density, temperature and pressure. Pressure value has an inverse correlation with the bubbles size where current density and temperature have an opposite affect it [37]. Moreover, the disengagement rate of gas bubbles from the surfaces and their departure velocity play a significant rule in the value of the electrical resistance of an electrolytic bath. Figure 1 justifies this subject. In this figure, the distance between electrodes *"l"* is broken into *n* smaller segments *"l_i"*. Equation 4 can be used to calculate the resistance for each partial length of l_i. The presence of gas bubbles significantly reduces the efficient cross section area for each l_i. Therefore, it increases the total value of *R*.

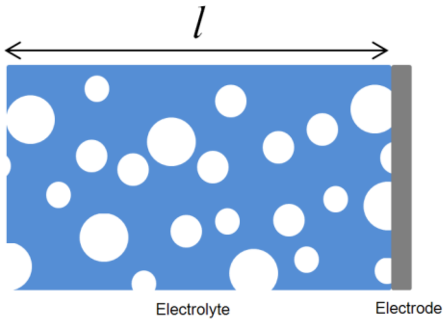

Figure1. The formation of void fraction

Hence, equation 4 could be re-written as bellow:

$$R=\frac{\rho}{A}\left(\sum l_i\right) \qquad (5)$$

Equation 5 and figure 1 depict the effect of void fracture which has been discusses earlier. Many efforts are made to force the bubbles leave the cell environment. As an instance, De Li et al. [38] exposed their experimental electrolysis apparatus to an ultrasonic field in this regard. System efficiency and energy consumption were recorded in both cases of presence and absence of such field. Subjecting the electrolyzer to such fields caused a remarkable cell voltage reduction. The latter was more obvious in the cases of high current density and low electrolyte concentration. An improvement rate of 15% to 18% was observed in high current density experiments. Hence, the authors were able to achieve a maximum energy saving rate of 10% to 25%. Forcing the bubbles to Disengage from electrodes, membrane and electrolyte surface is known to improve the local mass and heat transfer as well as the process efficiency. Power consumption of the ultrasonic generator is expressed to be negligible in contrast with the power demand of the cell itself. A 0.05kW ultrasonic generator provided a field strong enough for a 100kA electrolysis cell. In this case, the field was able to deduct up to 30 kW from the total power demand of the system.

Wang et al. [39] conducted another set of experiments to force the adsorbed gas bubbles on the electrodes and membrane surfaces to detach. They exposed the cell to a super gravity field in this regard. Super gravity condition was simulated by placing the cell in a centrifugal (rotating) installation. In this experiment cell temperature was maintained at 333 °K throughout the process. High gravity acceleration environment is known to increases both velocities of convection flow and inter-phase slip [40]. Therefore, better multiphase separation in gas-liquid and gas-solid phases [41] is a result of subjecting an electrolysis cell to a super-gravity field. Such improved separation leads to easier gas bubble disengagement and faster departure from the electrolyte surface. Lower ohmic loss and over potential are the predicted result of this approach. Wang et al. [39] measured the required level of cell voltage to reach a given current density for different gravity conditions. The results show remarkably lower voltage levels for the cases with higher gravity values. The difference became more significant for increased current densities. Authors reported improved levels of efficiency for the cells which are performing under super gravity conditions. According to this report, a centrifuge installation with a nominal power of 3 kW was able to deduct up to 51 kW from the power demand of a 100 kA industrial electrolyzer.

2.5. Electrode material

A wide range of materials are being used as electrodes. Each metal has a different level of activity, electrical resistance and corrosion resistivity. Platinum and gold are known to be two of the best choices for being used as electrodes. However, high prices limit their usage in industrial and commercial electrolyzers. Aluminum, Nickel, Raney nickel and cobalt are the most common electrode materials for being used in alkaline electrolytic baths. This popularity is the result of their satisfactory price range, corrosion resistance and chemical stability [21].

Appleby et al. [31] conducted a set of experiments by utilizing different electrodes such as 99.99% pure Ni, Pt, Ir and Rh as well as Ni cloth, Ni sinter, Ni-Cd and low impregnation Nickel and cobalt molybdate catalyst on nickel sinter. Each electrode was pre-anodized in order to obtain stable potential characteristics. The results express nickel to show more desirable potential characteristics among the mentioned materials. In addition, authors found woven or porous sintered electrodes to be 30 times more active those with a smooth surface. Larger electrode surface area causes an “Apparent exchange current density”. The latter is known to be the main reason of the excess observed activity.

There is a wide range of variations in the value of electrode-electrolyte activity for different materials. For example, platinum electrodes show higher activity levels in contact with KOH aqueous solutions in comparison with molybdenum plates. Literature show utilization of 1-butyl-3-methylimidazole tetrafluoroborate (BMI.BF4) ionic liquid will lead to exceptional efficiency levels for almost all electrode plates [18].

2.6. Separator material

Placing a separator plate in a cell, blocks the free movement of mass and ions to some extent. Moreover, the presence of such barrier increases the void fracture by further accumulating of gas bubbles in the electrolyte [30]. In addition, the effective electrical resistance of a separator plate is frequently calculated to be as large as three to five times of those of the electrolyte solutions [42].

Electrical resistance of a separator depends on different variables such as corrosion, temperature and pressure [43]. Back in middle 1990’s many scientists named asbestos to be the best choice for being used as a diaphragm due to its highly wettable and porous structure. These features cause a plate to show electrical resistance in practice [44] . However, asbestos is known to be a toxic and hazardous material [44-47]. These characteristics caused the researchers to start looking for substitute materials. Nowadays there are different materials and technologies available to reduce the negative electrical effect of separators [45, 46, 48-50].

2.7. Applied voltage waveform

It is almost common for electrolysis systems to use a steady (Figure 2a) or smooth (Figure 2b) DC voltage to decompose an electrolyte.

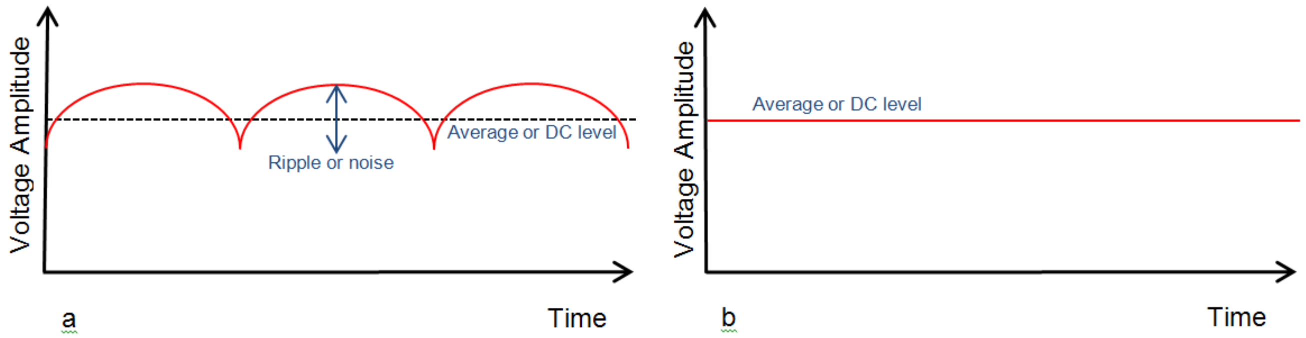

Figure 2. (a) Steady DC voltage waveform. (b) Smooth DC voltage waveforms

Accoring to the Ohm's law, applied DC voltage *U* causes the current *I* to pass through the electrolyte with the resistance of *R* (refer equation 2). Hence, the common method of current or current density regulation is by the application of a certain voltage to a cell. Shimizu et al. [51] conducted their experiment to test the behavior of a cell while the voltage was applied in the form of ultra short pulses. Their goal was to reach higher cell power (increase the gas production rate) without reducing the efficiency. They placed platinum electrode plates 3 cm apart from each other in a 1M KOH aqueous solution. Electrolyte temperature was maintained to 293 ± 2 °K throughout the experiment. The results were compared for the cases of using a conventional DC, and an ultra-short pulse power supply with an output pulse width of about 300 ns. Output frequency and peak voltage of this power supply were adjustable from 2 kHz to 25 kHz and 7.9 V to 140 V respectively.

In the case of applying ultra-short pulses to an electrolysis cell, there will not be enough time for formation of stable double-layers or diffusion-layers. A formation period of 3 µs is known to be required by the authors for diffusion-layers. Moreover, a pulse width of 3 ns is also much less than the time requirement of formation of a stable double-layer which is known to be not larger than several hundred milliseconds. A sample waveform of applied ultra short pulse is illustrated in figure 3.

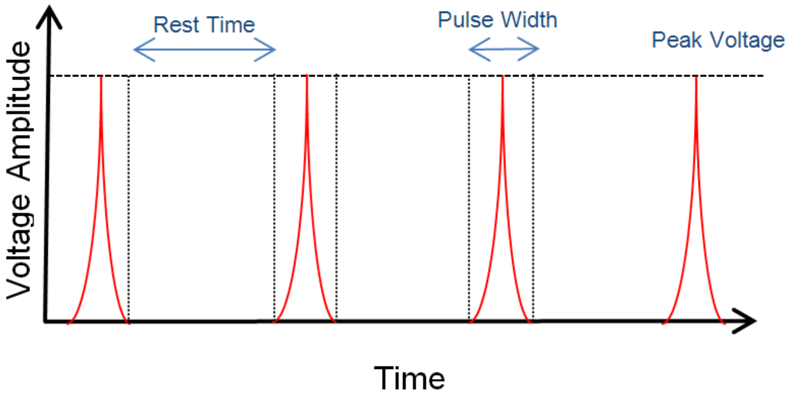

Figure 3. Ultra short pulse waveform

The production rate versus input power graph deviated more from the ideal graph as the input power was increased when the cell was subjected to a pure DC voltage. In addition, the efficiency was reduced significantly. As the authors mentioned, applying 0.25 Watts of power to the cell caused the process to be five times more efficient than the case with a consumption level of 250 Watts.

Regarding to the literature, the utilization of an ultra-short pulse generator provided the possibility of subjecting the cell to higher power levels without causing any further energy loss. The latter is achievable if the power is regulated by adjusting the peak pulse voltage levels. Moreover, raised pulse frequency can deliver extra power to the cell without causing any significant effect on the efficiency. The authors mentioned a lower electron energy level caused by sharper pulse waveforms to be the reason of this behavior.

However, the authors did not provide much information about any possible relation between the peak voltage and frequency regarding the process efficiency. Hence, we believe conducting further researches in this regard might lead to very interesting results.

In another related research, Ursua et al. [52] characterized a commercial electrolyzer unit. The apparatus was able to handle the maximum electrical current and temperature values of up to 120 A and 65 °C respectively. Two different types of voltage regulators were used to deliver the required energy to the system. Their objective was to analyze the behavior, efficiency and power consumption of the system with each power supply.

The first voltage regulator was thyristor based. These regulators adjust their output voltage level by the means of controlling the switching times of a semiconductor device. The semiconductor switch is connected to the AC power line in series. This topology works at the same frequency of the input power line which is either 50Hz or 60Hz (varies by regional standards). Results show the cell to have a non-continues voltage and current waveform. Furthermore, an undesirable distribution of current harmonics was detected in the output waveform. A maximum efficiency of 70.9% could be achieved for this case.

The tests were repeated with a transistor based power supply. This topology works at a much higher frequency (up to 100 kHz). In this case, the time ratio of "conducting" to "cut-off ratio" of a rapidly switching power transistor determines the amount of energy passing through the power supply unit. The load voltage or current is regulated as a result of this action where they usually have an almost pure DC wave form. In addition, the output harmonics of such units are negligible in contrast with those of thyristor based devices. A maximum efficiency rate of 77.6% was observed for the case of using the latter-described power supply. The results of this experimental work show a 10% more efficient conversion process by using a transistor based power regulator.

Unfortunately, experiments on the pure electrical characteristic of electrolysis process are very rare to find. Electrical variables are very common for measuring the electrochemical characteristics of electrolytic baths. However, we believe more study is required to analyze the behavior of such cells as a pure electrical load in order to develop more reliable equivalent circuits.

We should mention that the available equivalent circuits for electrochemical systems usually contain a few non-electrical components such as faradic impedances which are not easily analyzed by electrical approaches. Brad [53], and Armstrong and Henderson [54] Introduced very similar equivalent circuits for an electrolysis cell. These circuits consider the electrical impedance of the electrolysis system to be in a non-linear form. Existence of capacitive and faradic elements is the reason of such consideration. Moreover, it is more common to conduct the electrolysis process by applying a pure DC waveform to the cell which is suitable to test linear impedances and ohmic loads. Therefore, according to the mentioned equivalent circuits, the effect of applying other forms of voltage might lead to interesting and important findings.

3. CONCLUSION

This study provides information about the physical, chemical and electrical propertied of water electrolysis cells with a view on their effects on the efficiency of the process. The possible modifications can be done on a cell in order to minimize its electrical power dissipation.

a. High temperature and pressure processes are more efficient. These parameters can be raised as much as the physical strength of the apparatus allows.

b. Utilization of highly concentrated electrolytes will lead to less impedance values. On the other hand, the use contaminated solutions cause side reactions to take place in the cell and will reduce the lifespan of the apparatus.

c. Placing the electrodes in an absolutely vertical position at a certain distance from each other will reduce the ohmic resistance between them. Moreover, the utilization of metals with high degrees of activity and porous materials will enhance electric and ionic conductivity of the system.

d. Forcing gas bubbles to detach from the electrode and separator surfaces and to leave the system will decrease the void fraction. Lower impedance and higher efficiency levels will be achieved as a result.

e. Selecting the electrodes of larger sizes is an important factor for to enlarge their overlap surface area and therefor the current path. However, since gas bubbles will accumulate in higher altitudes of the cell, certain considerations are recommended to limit the height of the electrode plates.

f. Since the equivalent circuit of a water electrolysis cell contains non-linear elements, more research is required to study the best method of power application to a cell.

Executive Summary

Hydrogen is being pursued as a sustainable energy carrier for fuel cell electric vehicles (FCEVs) and as a means of storing renewable energy at utility scale. Hydrogen can also be used as a fuel in stationary fuel cell systems for buildings, backup power, or distributed generation. Blending hydrogen into the existing natural gas pipeline network has been proposed as a means of increasing the output of renewable energy systems such as large wind farms. If implemented with relatively low concentrations, less than 5%–15% hydrogen by volume, this strategy of storing and delivering renewable energy to markets appears to be viable without significantly increasing risks associated with utilization of the gas blend in end-use devices (such as household appliances), overall public safety, or the durability and integrity of the existing natural gas pipeline network. However, the appropriate blend concentration may vary significantly between pipeline network systems and natural gas compositions and must therefore be assessed on a case-by-case basis. Any introduction of a hydrogen blend concentration would require extensive study, testing, and modifications to existing pipeline monitoring and maintenance practices (e.g., integrity management systems). Additional cost would be incurred as a result, and this cost must be weighed against the benefit of providing a more sustainable and low-carbon gas product to consumers.

Blending hydrogen into natural gas pipeline networks has also been proposed as a means of delivering pure hydrogen to markets, using separation and purification technologies downstream to extract hydrogen from the natural gas blend close to the point of end use. As a hydrogen delivery method, blending can defray the cost of building dedicated hydrogen pipelines or other costly delivery infrastructure during the early market development phase. This hydrogen delivery strategy also incurs additional costs, associated with blending and extraction, as well as modifications to existing pipeline integrity management systems, and these must be weighed against alternative means of bringing more sustainable and low-carbon energy to consumers.

Though the concept of blending hydrogen with natural gas is not new (IGT 1972), the rapid growth in installed wind power capacity and interest in the near-term market readiness of FCEVs has made blending a more tangible consideration within several stakeholder activities (Florisson 2012; GM 2010), including recent agreements on “Power-to-Gas” initiatives with Hydrogenics (2012a; 2012b). Delivering blends of hydrogen and methane (the primary component of natural gas) by pipeline also has a long history, dating back to the origins of today’s natural gas system when manufactured gas produced from coal was first piped during the Gaslight era to streetlamps, commercial buildings, and households in the early and mid-1800s. The manufactured gas products of the time, also referred to as town gas or water gas, typically contained 30%–50% hydrogen, and could be produced from pitch, whale oil, coal or petroleum products (Castaneda 1999; Tarr 2004; Melaina 2012). The use of manufactured gas persisted in the United States into the early 1950s, when the last manufactured gas plant in New York was shut down and natural gas had displaced all major U.S. manufactured gas production facilities. In some urban areas, such as Honolulu, Hawaii, manufactured gas continues to be delivered with significant hydrogen blends and is used in heating and lighting applications as an economic alternative to natural gas (TGC 2012; GM 2010).

This report reviews seven key issues related to blending hydrogen into natural gas pipeline networks, which are described briefly in the following sections. Though these issues are interrelated, they are presented separately for the sake of clarifying explanation:

1. Benefits of blending
2. Extent of the U.S. natural gas pipeline network
3. Impact on end-use systems
4. Safety
5. Material durability and integrity management
6. Leakage
7. Downstream extraction

The review material presented in this report relies heavily on a study from the Gas Technology Institute (GTI), which is included as Appendix A. While conventional means of producing and delivering hydrogen are relatively well understood, blending as a means of storing or delivering hydrogen is very dependent on specific characteristics of the natural gas pipeline system. The GTI assessment therefore details the implications of hydrogen blending in relation to the distinct characteristics of the U.S. natural gas pipeline system. This report also relies on the extensive studies conducted within the *NaturalHy* project, associated with the Sixth Framework Programme of the European Commission (Florisson 2012), as well as information from a Greenhouse Gas R&D Programme study sponsored by the International Energy Agency (IEA) (Haines et al. 2003).

Benefits of Blending

Adding hydrogen to natural gas can significantly reduce greenhouse gas emissions if the hydrogen is produced from low-carbon energy sources such as biomass, solar, wind, nuclear, or fossil resources with carbon capture and storage (CCS). Any social or environmental benefits associated with sustainable hydrogen pathways could arguably be attributed to natural gas with a hydrogen blend component in proportion to the hydrogen concentration. In the downstream extraction pathway, use of hydrogen in FCEVs improves air quality by reducing sulfur dioxide, oxides of nitrogen, and particulate emissions and displacing conventional gasoline or diesel fuels. The blending benefit would be similar, in some respects, to the introduction of biogas into the natural gas pipeline as a means of providing a renewable natural gas product to consumers. Conceivably, a credit trading system could apply to natural gas with a specified blend content of renewable hydrogen, paralleling the renewable energy credit system used in the electricity sector. If properly crafted, this credit system could provide an economic incentive for converting otherwise curtailed renewable energy to hydrogen, increasing the energy provided from existing renewable energy production facilities, and enhancing the sustainability of the natural gas supply system. Understanding the techno-economic potential and spatial logistics associated with this type of energy storage and hydrogen delivery system would require additional analysis. Recent efforts to develop such a system in Germany will provide useful empirical data to understand better the potential to apply renewable credits to hydrogen and natural gas blends (Wilson 2012; E.ON 2011).

Extent of the U.S. Natural Gas Pipeline Network

The U.S. natural gas pipeline system has evolved from local manufactured gas networks serving municipalities in the mid-1800s to a vast network of interconnected pipeline systems comprising 2.44 million miles of pipe, 400 underground storage facilities, and 1,400 compressor stations. Natural gas accounted for 24.6 quads of U.S. energy consumption in 2010, roughly 25% of total energy consumed. Moreover, recent increased domestic production rates suggest that the existing natural gas system will continue to provide relatively clean and domestic energy for some time, especially with increased adoption of energy efficiency measures (EIA 2012). Given these characteristics, hydrogen blending could become a widespread, long-term, and integral practice to supplement a critical domestic energy infrastructure.

Impact on End-Use Systems

Several studies have discussed the issue of maximum hydrogen blend levels at which no or minor modifications would be needed for end-use systems, including appliances such as household boilers or stoves and industrial or power generation (Florisson 2010; De Vries 2009; Haeseldonckx 2007; De Vries 2007; Schumra and Klingenberg 2005; Kelly and Hagler 1980). The conditions determining a maximum hydrogen blend level that does not adversely influence appliance operation or safety vary significantly and include the composition of the natural gas, the type of appliance (or engine), and the age of the appliance. The impact of hydrogen blends on industrial facilities must be addressed on a case-by-case basis, and stationary gas engines likely will require changes to control systems (Florisson 2010). Ranges noted as being acceptable generally for end-use systems fall within 5%–20% hydrogen, and most discussions note types of changes, precautions, or costs associated with higher blends. For example, Haines et al. (2003) estimate the cost of upgrades in the United Kingdom, Netherlands, and France with respect to modifications required for 3%, 12%, and 25% hydrogen blends. Given the inertia behind any required changes to end-user appliances or industrial facilities, hydrogen blending likely would begin at very low concentrations and then increase gradually over time (if warranted) as required modifications for higher concentrations are addressed. As noted by Florisson (2009), end-use requirements are generally the most restrictive conditions on increasing hydrogen blend levels in natural gas. The natural gas composition in a given pipeline is an important consideration (Zachariah-Wolff et al. 2007). Meeting these requirements would often preclude risks posed by safety and material integrity concerns.

Safety

Multiple factors must be taken into consideration to assess the safety concerns associated with blending hydrogen into the existing U.S. natural gas pipeline system. It is difficult to make general claims about safety due to the large number of factors involved; detailed risk assessment results likely will vary from location to location. Because hydrogen has a broader range of conditions under which it will ignite, a main concern is the potential for increased probability of ignition and resulting damage compared to the risk posed by natural gas without a hydrogen blend component. The probability of an incident and the consequence of the incident are combined into an overall risk factor. In the literature reviewed, these risk factors have been assessed for hydrogen blends of various concentrations (e.g., 20%, 25%, and 50%), for different sections of the existing natural gas pipeline system (e.g., distribution mains and service lines), and for different conditions (e.g., contained or uncontained releases). The context for describing safety concerns is therefore the degree to which different types of hazards may increase or decrease risks for different hydrogen concentrations, pipeline types, and failure mode conditions. The risk assessment results described here would not apply to new, dedicated hydrogen pipelines carrying pure hydrogen, and blending risks will vary between natural gas pipeline systems of different types, materials, and ages across the United States.

It is important to place energy-related risks into perspective. All large-scale energy systems—including nuclear, fossil fuel and renewable energy systems—present different types of risks to human health and the environment (Schneider 1979; Holdren et al. 1979). The overall risks posed by the existing natural gas pipeline system can be quantified, and these results are used as a baseline for comparing risks associated with hydrogen blends. However, in general, natural gas systems pose a lower risk of severe accidents than do other large-scale energy systems such as coal, petroleum, nuclear, and hydropower (the latter two involving less frequent but higher impact accidents), although they appear to pose greater risk than non-hydro renewables such as wind and solar (Hirschberg et al. 2004; Bergherr and Hirschberg 2008; Bergherr et al. 2012; PSI 2012).

The present study reviews new analysis conducted by GTI of various safety hazards with reference to a numerical risk assessment scale with rankings that range from zero (no significant hazard) to 50 (severe hazard). Within this numerical system, a hazard significance ranking of 10 is described as "minor," 30 is "moderate," and 50 is "severe" (see Appendix A). Though actual rankings may vary based on multiple factors, the general conclusion of the research findings presented here is that adding low concentrations of hydrogen to existing natural gas pipeline systems, at volumes of 20% or less, results in a minor increase in the risk of ignition. Moreover, in instances where natural gas leaks result in explosions, inclusion of 20% or less hydrogen would result in minor increases in the severity of the explosion. Higher concentrations of hydrogen may be acceptable from a safety perspective in transmission lines upstream from distribution lines and city gate metering and pressure regulation stations.

As in any risk assessment, it is important to understand the conditions under which risks are being assessed. The GTI assessment presented here is based upon data specific to the U.S. natural gas supply system. Findings suggest that higher concentrations of hydrogen in distribution mains, up to 50%, present a minor increase in overall risk (including probability and severity). Risks associated with service lines are different because service lines are often found in confined spaces where leaked gas would be more likely to accumulate. If hydrogen concentrations exceed 20% in service lines, the increase in overall risk is more significant than for distribution mains. For both distribution mains and service lines, proper risk management practices, such as the installation of monitoring devices, reduces overall risk. However, adding more than 50% hydrogen to either distribution mains or service lines results in a significant increase in overall risk. Again, these risk results are associated with introducing hydrogen blends into the existing U.S. natural gas pipeline system and do not apply to new, dedicated hydrogen pipelines carrying pure hydrogen, which would be designed and managed differently than the existing natural gas pipeline system.

Material Durability and Integrity Management

The durability of some metal pipes can degrade when they are exposed to hydrogen over long periods, particularly with hydrogen in high concentrations and at high pressures. This effect may be of concern for cases where hydrogen is injected at high concentrations into existing high-pressure natural gas transmission lines. The effect is highly dependent on the type of steel and must be assessed on a case-by-case basis. However, metallic pipes in U.S. distribution systems are primarily made of low-strength steel, typically API 5L A, B, X42, and X46, and these are generally not susceptible to hydrogen-induced embrittlement under normal operating conditions. At the pressures and stress levels occurring in the natural gas distribution system, hydrogen-induced failures are not major integrity concerns for steel pipes. For the other metallic pipes—including ductile iron, cast and wrought iron, and copper pipes—there is no concern of hydrogen damage under general operating conditions in natural gas distribution systems. There is also no major concern about the hydrogen aging effect on polyethylene (PE) or polyvinylchloride (PVC) pipe materials. Most of the elastomeric materials used in distribution systems are also compatible with hydrogen. These topics are reviewed in Appendix A.

Hydrogen blends can influence the accuracy of existing gas meters. The deviation of a gas meter with hydrogen blends varies with the meter design. This deviation was found to be acceptable based on the requirement for recalibration (less than 4%) when a gas mixture containing less than 50% hydrogen is being measured. It is anticipated that meters would not need to be tuned under low hydrogen blend levels (less than 50%) in natural gas (Appendix A). One of the remaining gaps in durability research is the need to study the potential impact of contaminants in hydrogen gas that might be introduced into the network. This would be an issue in cases where the hydrogen production system does not produce pure hydrogen.

In most research programs, the focus of integrity management has been on transmission pipelines because of concerns at high operating pressures, up to 2,000 psi (139 bar), and the pipeline steels that are subject to hydrogen-induced cracking. Hydrogen can be carried by existing natural gas transmission pipelines with only minor adaptations to the current Integrity Management Program (IMP) (Appendix A). The adaptations needed depend on hydrogen concentration and operating conditions of the individual pipelines. These are generally insignificant with concentrations up to 50% hydrogen, but a detailed investigation for every case is mandatory and could result in the upper limitation on hydrogen concentration being reduced (Appendix A).

Natural gas distribution systems are very different from transmission pipelines, and the integrity program for transmission pipelines does not apply to distribution systems. One important difference between distribution systems and transmission pipelines is location with respect to populated areas. The level of hydrogen that is acceptable for transmission pipelines may need to be reassessed for distribution systems in terms of the frequency and severity of fire or explosion in a highly populated area. In addition, the hazards arising from gas leakage in a distribution system may be more severe than in transmission pipelines, especially in a confined service area. The integrity management for distribution systems under hydrogen services may require a leak detector or a monitoring device or sensor. The maintenance costs for distribution systems under hydrogen service likely will increase because these systems will need to be inspected more frequently and likely will require additional leak detection systems. Florisson et al. (2010) outline general conclusions of detailed studies of both durability and integrity issues, and they estimate that modifications to existing integrity management practices may incur an additional 10% cost increase due to hydrogen blends.

Leakage

Hydrogen is more mobile than methane in many polymer materials, including the plastic pipes and elastomeric seals used in natural gas distribution systems. The permeation coefficient of hydrogen is higher through most elastomeric sealing materials than through plastic pipe materials. However, pipes have much larger surface areas than seals, so leaks through plastic pipe walls would account for the majority of gas losses (Appendix A). Permeation rates for hydrogen are about 4 to 5 times faster than for methane in typical polymer pipes used in the U.S. natural gas distribution system. Leakage in steel and ductile iron systems mainly occurs through threads or mechanical joints. Leakage measurements from GTI for steel and ductile iron gas distribution systems (including seals and joints) suggest that the volume leakage rate for hydrogen is about a factor of 3 higher than that for natural gas (Appendix A).

A calculation based on literature data for the permeation coefficient of hydrogen and methane in polyethylene (PE) pipes suggests that most gas loss would occur through the pipe wall, rather than through joints, in distribution mains smaller than 2 in. and operating at 60 psig (5 bar) or higher. Extending this calculation to the larger pipeline network suggests that use of a 20% hydrogen blend within the approximately 415,000 miles of PE pipes in the United States would result in a gas loss of about 43 million ft^3/yr, with about 60% of the losses being hydrogen and 40% being natural gas (Appendix A). Though this estimate of gas loss is almost twice the total gas loss for systems delivering natural gas only, it is still considered economically insignificant. As reference, this theoretical distribution main leakage rate (43 million ft^3/yr) would be 0.0002% of the 24.13 trillion cubic feet of natural gas consumed in 2010 (EIA 2011). Furthermore, this calculation likely overestimates actual gas loss because the permeation coefficient taken from the literature is considered larger than those observed in experiments using pipe under actual operating pressures, especially at lower pressures. In general, hydrogen blends would slightly reduce natural gas leakage due to the higher mobility of hydrogen molecules, resulting in a net reduction in the greenhouse gas impact due to leakage. A calculation for the Dutch pipeline system, based upon experimentally derived permeation coefficients, predicts a gas leakage rate of 0.00005% with a 17% hydrogen blend (Haines at al. 2003). Further investigation and additional empirical data would be necessary to provide more accurate gas loss estimates associated with hydrogen blends.

Though gas loss from service lines is economically negligible, leakage into confined spaces may pose a safety risk. Gas leakage from elastomeric seals at joints in service lines may also increase the risk in confined spaces, and this topic warrants additional risk assessment. Further investigation into specific pipe and seal materials and systems can provide a basis to estimate gas leakage more accurately. This basis can be used to determine whether leakage in confined spaces might present a safety risk over time and the degree to which detection and monitoring devices may be required to manage risks.

Downstream Extraction

Three gas-separation technologies that could be used to extract hydrogen from mixtures in natural gas pipelines have been reviewed: pressure swing adsorption (PSA), membrane separation, and electrochemical hydrogen separation (EHS, or hydrogen pumping). PSA units operating on low hydrogen concentrations, such as 20% mixtures, are feasible. However, these units are sized for the impurities in the gas, so with low hydrogen concentrations, the PSA units become very large. PSA units appear to be economically practical only at pipeline pressure reduction stations (i.e., pressure regulation stations) where the pressure drop is synergistic with hydrogen separation. Without this drop in pressure, uneconomically large amounts of compression energy and compressor capital would be needed to reinject hydrogen-depleted gas back into a pipeline.

Membrane separation technologies work very efficiently with relatively high concentrations of hydrogen, and the purity of the hydrogen product gas can be very high with certain membrane technologies, as they can be designed for high selectivity. Most membrane technology applications recover bulk hydrogen from industrial facilities and do not require high purity levels. Some membrane technologies, however, can realize near 100% pure hydrogen. Dilute hydrogen poses a significant challenge for membrane technology. Recovery of hydrogen with lower concentrations requires a higher pressure differential across the membrane. This means that significant volumes of non-hydrogen gas need to be compressed to high pressures in order for the hydrogen to pass through the membrane. This type of technology may be best suited for high-pressure pipelines (transmission pipelines), where the gas in the pipeline is sufficiently pressurized to allow significant recovery of hydrogen.

Electrochemical separation (also known as hydrogen pumping) is a more elaborate method for bulk hydrogen recovery. Two technologies are currently used: a Nafion-based membrane system and a polybenzimidazole (PBI) system. Nafion-based pumps have been in development longer and are considered more technologically mature, but PBI is more desirable for several reasons. One is the lower compression requirement. For a 1,000-psi pipeline, both the product gas and hydrogen would come out at essentially 1,000 psi (minus specific process pressure drop). However, while pressurization requirements are reduced, system complexity can be higher, and the technology is not as mature as PSA or some membrane technologies. Electrochemical pumping requires water to function, and addition of water involves a humidification system. On the other hand, pipeline gases have to be dry, so a water-removal system is required downstream.

Of the three separation technologies considered, PSA is the most commercially ready. Because PSA is mature and cost information is available, NREL staff estimated the cost of PSA hydrogen extraction assuming conditions for a hydrogen mixture in a distribution natural gas pipeline. Capital cost estimates for the PSA unit are based on quotes and with reference to an N^{th} plant concept, which reflects a mature system that is functionally reliable in the field and has been produced in sufficiently high annual and cumulative quantities to have a capital (and unit) cost approaching the technology's asymptotic lower cost limit. The cost estimate represents a future technology that may be available when hydrogen mixtures can be carried through natural gas pipelines, rather than current PSA technology. This report assesses only the cost of hydrogen extraction. The other costs (injection cost, hydrogen losses along the pipeline, underutilization during lag-in-demand seasons, analytical costs, etc.) are not accounted for here.

For a 10% concentration and 80% recovery factor, the estimated cost of hydrogen extraction by PSA from a 300 psi pipeline is \$3.3–\$8.3/kg hydrogen extracted, for a range of recovery rates of 1,000–100 kg/day. For a 20% concentration and 80% recovery factor, the extraction cost is \$2.0–\$7.4/kg hydrogen extracted, for the same range of recovery rates. These additional supply chain costs are high relative to a competitive hydrogen cost goal of \$2–\$4/kg for FCEV markets (Ruth and Joseck 2011). However, if hydrogen is extracted at a pressure-reduction facility, the high cost of recompressing the natural gas to the original natural gas pipeline pressure can be avoided. The resulting estimated extraction cost for a 10% concentration and 80% recovery factor is \$0.3–\$1.3/kg, with the range resulting from economies of scale for a system size or recovery rate of 1,000–100 kg/day (see Figure 18). These costs per kilogram are reduced by approximately 10% if the hydrogen concentration is increased to 20%. PSA extraction could therefore become a relatively small cost component of the total delivered cost of hydrogen if the extraction is done at a pressure-reduction facility. With major pressure reduction stations often located near large urban areas, downstream extraction could prove to be an economical delivery option. It has been estimated that there are 11,200–14,800 metering and pressure regulating stations with inlet pressures greater than 300 psig in the United States (see section 3.1), and 34,600–56,700 stations with inlet pressures between 100 and 300 psig. Approximately 23%–25% of the stations with inlet pressures greater than 300 psig are contained within vaults, which is typical for stations located near urban or suburban areas. Therefore, it is likely that several thousand high-pressure city gate stations are located in close proximity to large U.S. urban areas where natural gas is transferred from transmission lines to distribution lines, and many of these may be candidates for hydrogen extraction.

List of Figures

Introduction

Hydrogen can play an important role as an energy carrier in a sustainable, reliable, and cost-effective energy future. This report reviews key issues related to the concept of blending hydrogen into natural gas pipeline networks. Under appropriate conditions and at relatively low hydrogen concentrations, blending may require only minor modifications to the operation and maintenance of the pipeline network. The hydrogen blend component may be carried through to end-user systems, or the hydrogen could be extracted downstream and used in applications such as automotive or stationary fuel cells. In general, based on research to date, only minor issues arise with blends of less than 5%–15% hydrogen (by volume), depending on site-specific conditions and particular natural gas compositions. More significant issues must be addressed for higher blends in the range of 15%–50%, such as conversion of household appliances or an increase in compression capacity along distribution mains serving industrial users. Blends above 50% face more challenging issues across multiple areas, including pipeline materials, safety, and modifications required for end-use appliances or other uses.

Hydrogen blending may prove to be a viable means of increasing the output of renewable energy facilities, such as wind farms, by providing a hydrogen storage and delivery pathway across a broad range of geographic locations. Given the large geographic scope and scale of the existing natural gas infrastructure, even very low blend levels (less than 3%–5%) could absorb very large quantities of otherwise curtailed or uneconomical wind or solar power. Blending renewable hydrogen with natural gas can improve the carbon intensity and sustainability of the final natural gas product delivered to consumers. Though this pathway requires additional analysis and research, and may be limited by site-specific conditions, it appears to be viable in the near term.

Blending may also prove to be a viable means of delivering hydrogen produced in remote locations and extracting the hydrogen downstream near end-use applications, such as FCEVs or stationary fuel cells. Hydrogen pipeline delivery is considered a cost-effective way to move hydrogen from its production location to end users, but only at large volumes and long distances. Moreover, the cost to construct a large-scale, dedicated hydrogen pipeline system is very high, and completion could take decades. Alternative delivery pathways will be employed during the early market growth phase. Some early market pathways, such as tank trucks or onsite production, may endure alongside pipeline delivery in a mature hydrogen infrastructure. If hydrogen blending in natural gas with downstream extraction proves to be economically viable during the early market growth phase, it could prove to be viable in the long term as an additional mode of delivery.

This report reviews seven key and interrelated issues related to hydrogen blending:

1. Benefits of blending
2. Extent of the U.S. natural gas pipeline network
3. Impact on end-use systems
4. Safety
5. Material durability and integrity management
6. Leakage
7. Downstream extraction.

The benefits of hydrogen blending and the extent of the U.S. natural gas pipeline network provide context for the concept of blending and are reviewed in Sections 2 and 3. The next three issues limit the blend fraction that might be found acceptable, in the general order of stringency indicated in Figure 1; actual blend levels that might be found acceptable will be very location and system specific and will depend on a number of factors (Florisson 2009). The impact on existing end-use systems limits the hydrogen blend factor the most and is discussed first (Section 4). Safety is the next most limiting condition (Section 5). Pipeline material durability imposes fewer limitations than end uses or safety but is still an important consideration, especially for high-pressure transmission lines (Section 6). The issue of leakage is addressed in Section 7, and Section 8 discussed methods of extracting hydrogen. A simple cost analysis suggests that extraction at pressure reduction stations is likely to prove more economical than extraction along transmission lines. Though these issues are interrelated, they are presented separately for the sake of clarifying explanation. Section 9 provides a summary and recommendations.

Summary of GTI Subcontract Report to NREL

The Gas Technology Institute (GTI) performed a literature review for NREL and assessed some aspects of blending hydrogen into the existing U.S. natural gas pipeline system. The full GTI report is included here as Appendix A. This review covers the major aspects of blending addressed by the European NaturalHy project (Florisson 2012).[1] GTI also included additional literature sources on material performance in hydrogen environments and provided a scientific basis for assessing the durability and integrity of the existing pipeline infrastructure and potential gas leakage under hydrogen service.

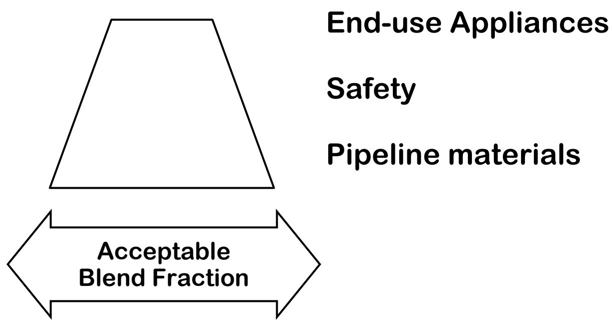

Figure 1. General order of stringency conditions on hydrogen blends for appliances, safety, and material durability (Florisson 2009).

[1] The goal of the NaturalHy Project is to determine the feasible conditions under which hydrogen produced from a centralized production site can be injected into high-pressure transmission pipelines and delivered to end users through distribution networks. The NaturalHy project, which was co-financed by the European Commission through the Sixth Framework Program for research, technology development and demonstration. spanned from 2004 to 2009, (http://www.naturalhy.net/).

Benefits of Blending

Lifecycle Assessment – Literature Review by GTI and NaturalHy

The potential benefits of adding hydrogen to natural gas have been addressed in the "NaturalHy Project-Work Package 1" through life cycle and socio-economic assessment. This study was led by Loughborough University (UK), and participants included COGEN Europe (Belgium)**,** The Energy Research Centre (Netherlands), Instituto de Soldadura e Qualidade (ISQ) (Portugal), Planungsgruppe Energie und Technik GbR (Germany), SAVIKO Consultants Ltd. (Denmark), and Technische Universität Berlin (Germany). The details of this review can be found in Appendix A, Task 4.

In summary, the following are benefits of adding hydrogen to the natural gas network:

- Overall benefits: significant reduction of greenhouse gas emissions if hydrogen is produced from renewable sources.
- Hydrogen in automotive applications: potential benefits from reducing petroleum consumption and improving air quality by reducing sulfur dioxide, oxides of nitrogen, and particulate emissions.
- Greening natural gas: when a hydrogen/natural gas mixture is used in existing appliances for heat and electricity generation. This benefit is similar to increasing the mix of renewable generation on the electricity grid in that it does not require significant changes in end-use equipment.

A better understanding of the cost-benefit tradeoffs for blending in the U.S. natural gas pipeline system, as compared to the European assessment, would require significant additional analysis and investigation.

Renewable Gas Credit Trading Considerations

Renewable natural gas is a very desirable feedstock. In California alone, state incentives for power generation offer $4,500/kW and $2,500/kW for fuel cell systems running on biogas and natural gas, respectively (self-generation incentive program – SGIP). However, California does not require the biogas to be directly used in a fuel cell system, but instead allows credit trading. For example, a water treatment plant that generates methane can choose to clean the methane and inject it in the gas pipeline system, generating certificates for producing renewable natural gas. These certificates can, in turn, be sold to a geographically remote entity that can apply the credits to classifying fossil natural gas as renewable. This entity can then use the gas in a fuel cell and claim credits as if the fuel cell were operating on renewable gas. Renewable methane in such trading is commonly valued at $12–$14/MMBtu (GSE 2011). For example, renewable gas can be purchased by this means from Pacific Gas & Electric. A similar credit trading system is conceivable for renewable hydrogen blended into the natural gas system.

Extent of the U.S. Natural Gas Pipeline Network

This section reviews general characteristics of the U.S. natural gas pipeline network to provide context for the concept of blending hydrogen into natural gas pipelines. Additional analysis would be needed to draw more concrete and detailed conclusions about the technical and economic potential for hydrogen blending with respect to the large amount of information available on pipeline system materials, performance, operation, and regional markets. Advantages of the existing natural gas pipeline network include the following:

- Broad geographic extent
- Interconnectivity
- High capacity
- Well-developed maintenance and control structure
- Well-established safety procedures
- Well-established grid management
- Well-established operational strategies
- Broad public acceptance.

Pipeline Type, Capacity, Miles, Size, and Materials

Four general types of transmission lines are indicated in the supply chain schematic in Figure 2. Gathering lines bring natural gas from various sources to processing plants, typically high-volume and long-distance transmission lines deliver gas to the city gate, and two types of distribution lines—mains and service lines—deliver it to local consumers. Underground storage facilities, typically depleted natural gas caverns or salt domes, and large industrial consumers are connected directly to transmission lines. In terms of supply capacity, the U.S. transmission line system is supplemented by natural gas storage capacity to meet peak demand during the winter heating season, and the distribution pipeline system is sized for this peak demand (EIA 2012).

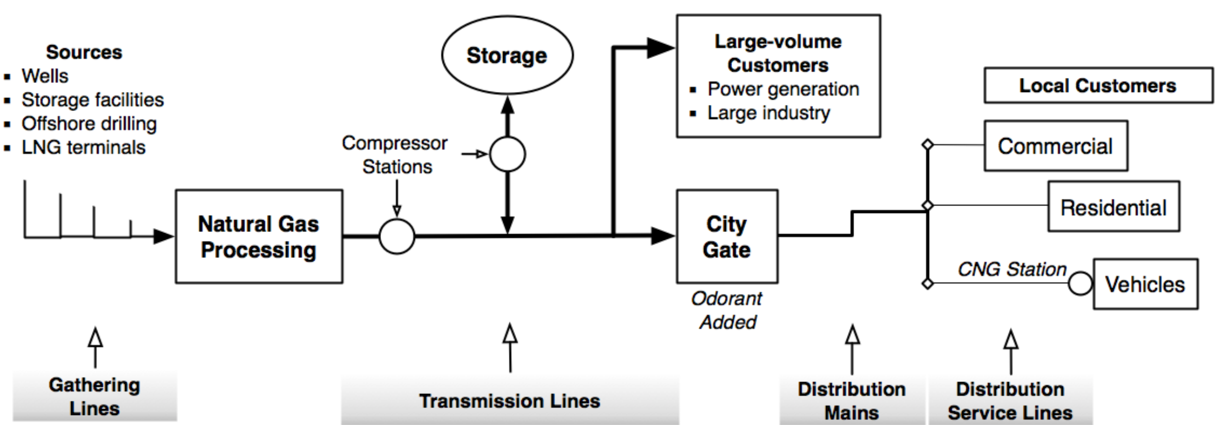

Figure 2. Natural gas supply chain consisting of gathering lines, transmission lines, distribution mains, and distribution service lines.

The annual mileage for each of these pipeline types is shown in Figure 3, with gathering lines and transmission lines changing only slightly and both types of distribution lines experiencing relatively steady growth since 1980. For 2011, the U.S. Department of Transportation reports 1.23 million miles of distribution mains and 0.88 million miles of distribution services lines. In 2011, there were 19,662 and 304,087 miles of gathering and transmission lines, respectively (PHMSA 2012). The network also includes 1,400 compressor stations and 400 underground natural gas storage facilities, most of which are depleted natural gas fields, oil fields, aquifers, and salt caverns (EIA 2012). These elements are indicated in the maps shown in Figures 6, 7, and 8. In 2010, natural gas provided 25% of all energy consumed in the United States (EIA 2011). This extensive infrastructure is a critical component of the U.S. energy system, comparable in scale to electricity and petroleum-based liquid fuels.

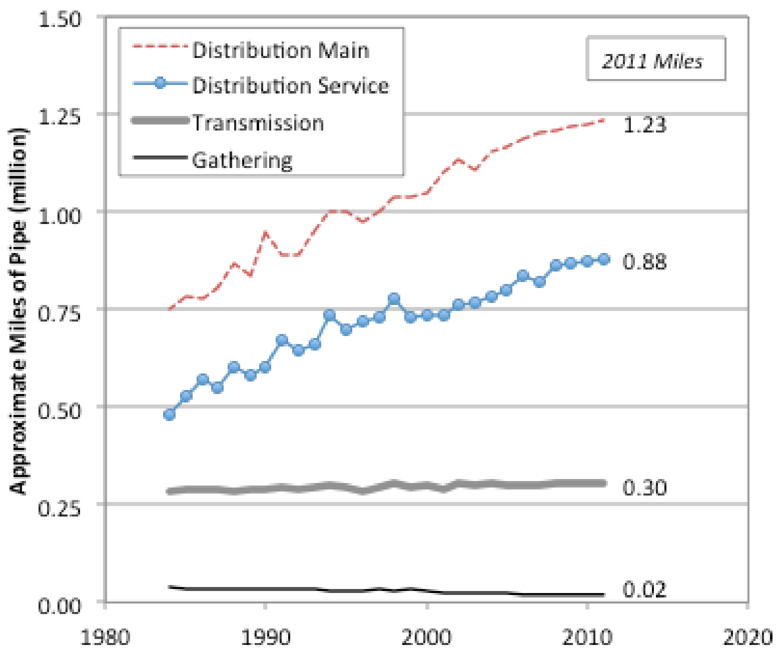

Figure 3. Annual mileage of pipe for four natural gas pipeline types (PHMSA 2012).

City gate stations with metering and pressure regulating equipment are relevant to the concept of blending hydrogen into natural gas pipelines. These stations are located where high-pressure transmission lines transfer gas to distribution systems (also called transmission-to-distribution custody transfer stations) and are therefore candidates for downstream hydrogen extraction. A study conducted by Radian International LLC for the U.S. Environmental Protection Agency and the Gas Research Institute estimated the number of metering and pressure regulating stations, as well as the number of stations with only pressure regulating equipment, in the United States in 1992 based upon data collected from eleven natural gas distribution companies (Campbell and Stapper 1996). The stations were categorized into four types according the inlet pressure (psig): >300, 100–300, 40–100, and <40. Gas pressures in the distribution lines were not specified, but it was noted that stations with inlet pressures less than 300 psig were more typical of stations located downstream from gate stations. This study estimated the total number of U.S. stations using a ratio of the number of stations of each type to the total miles of main distribution lines. Applying these same ratios to the total number of main distribution miles in 2011 results in an estimate of 14,800 stations with inlet pressures greater than 300 psig, and 56,700 stations with inlet pressures between 100 and 300 psig. However, the 2010 Greenhouse Gas Inventory (EPA 2012) estimates the number of stations based upon the ratio of total gas consumption in 2010 and 1992, rather than the station per mile ratios. This approach (Weitz 2012) provides an estimate of 11,200 and 34,600 stations at >300 psig and 100–300 psig, respectively. These estimates may be considered a high and low range on the total number of stations within these pressure inlet categories. Stations with lower inlet pressures, less than 100 psig, are more numerous, ranging from 102,000 to 134,300 stations based upon these two estimation approaches.

Nearly 100% of U.S. transmission pipelines are steel with diameters of 4–48 in. They typically operate at pressures of 600–1,200 psig (42–84 bar) and in some cases up to 2,000 psig (139 bar). Approximately 96% of all onshore and offshore transmission pipelines are steel, wrapped/coated and cathodically protected against corrosion. Details about transmission pipelines can be found in Appendix A. The major U.S. natural gas transportation routes include 11 distinct corridors (Figure 9). The volume of gas delivered is proportional to the width of the routes. Five of them originate in the Southwest (1–5), four deliver natural gas to the United States from Canada (6–9), and the remaining two extend from the Rocky Mountain area (10–11).

Material use in pipelines is indicated by pipeline type in Figure 4. Steel and polyethylene (PE) are the dominant materials (47% and 48%, respectively) in the natural gas distribution system. Main distribution pipes are typically 1.5–8 in. wide and made of either PE (48%) or steel (47%). Distribution service line sizes are typically 0.5–2 in. wide and made of either PE (63%) or steel (33%). Other materials include cast iron and various plastics (see Appendix A). The fraction of miles for all U.S. pipelines (gathering, transmission, and distribution) by material type is indicated in Figure 5. Distribution pipeline pressures are 0.25–60 psig (1.03–5.15 bar) and sometimes up to 100 psig (8 bar). A few distribution pipelines operate at pressures as high as 400 psig (29 bar). Distribution facilities are primarily located in populated areas. Distribution lines do not follow class locations, but most lines fall into Class 3 and Class 4 locations under transmission class location definitions.[2] Distribution piping is frequently located in congested urban areas, typically under paved streets, highways, and other public right-of-ways or utility easements. Additional details about the U.S. natural gas distribution pipelines can be found in Appendix A.

[2] The following are class location definitions from the Code of Federal Regulations (GPO 2011). A "class location unit" is an onshore area that extends 220 yards (200 meters) on either side of the centerline of any continuous 1-mile (1.6 kilometers) length of pipeline. A Class 1 location is: (i) An offshore area; or (ii) Any class location unit that has 10 or fewer buildings intended for human occupancy. A Class 2 location is any class location unit that has more than 10 but fewer than 46 buildings intended for human occupancy. A Class 3 location is: (i) Any class location unit that has 46 or more buildings intended for human occupancy; or (ii) An area where the pipeline lies within 100 yards (91 meters) of either a building or a small, well-defined outside area (such as a playground, recreation area, outdoor theater, or other place of public assembly) that is occupied by 20 or more persons on at least 5 days a week for 10 weeks in any 12-month period. (The days and weeks need not be consecutive.) A Class 4 location is any class location unit where buildings with four or more stories above ground are prevalent.

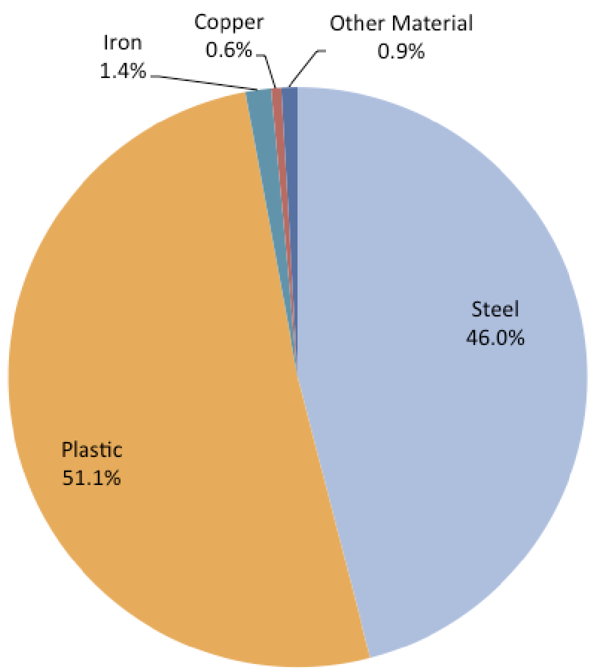

Figure 5. Pipeline material as a percentage of miles of all pipeline types (PHMSA 2012).

Major U.S. Pipeline Corridors

The interstate pipeline grid consists of wide-diameter (20–42 in.), high-capacity pipelines. In 2007, more than 36 trillion ft^3 of natural gas were transported by the interstate pipeline system. Figure 10 shows interstate natural gas supply dependency, particularly designating states that are more than 85% dependent on the interstate pipeline network for their supply. Intrastate natural gas pipelines operate within state borders and link natural gas producers to local markets and to the interstate grid. Intrastate pipelines constitute about 29% of the total miles. Texas and California have the largest intrastate pipeline systems in the nation. Intrastate and interstate pipelines are color coded in Figure 6.

Natural Gas Pipeline Capacity and Utilization

Even though natural gas companies prefer to operate their systems as close to full capacity as possible, the average utilization rate seldom reaches 100% (EIA 2012). Figure 11 shows the interregional natural gas transmission pipeline capacity (2008 data). Utilization rates below 100% do not necessarily entail additional capacity availability, as some companies serve seasonal markets. Exceeding 100% capacity, while remaining within safety limits, is a technique used to temporarily raise pipeline throughput. This is achieved by secondary compression, line packing, or both. Average daily utilization rates also can be increased by integrating storage capacity into natural gas pipeline networks.

Impact on End-Use Systems

Adaptation of end-use systems is required at higher hydrogen blend levels. NREL reviewed NaturalHy studies on the impacts for the end user that might be caused by adding hydrogen to natural gas pipelines (De Vries 2009). The study included an assessment of maximal hydrogen concentrations that required no or minor appliance adjustments. The study concluded that hydrogen concentrations up to 28% may safely be used with properly serviced existing domestic appliances. Long-term (more than 15 years from now) material compatibility of domestic appliances with hydrogen and natural gas mixtures is uncertain. For poorly adjusted appliances, no hydrogen blends would be acceptable (Florisson 2010). The natural gas composition in a given pipeline is an important consideration (Zachariah-Wolff et al. 2007).

Haines et al. (2003) estimate the cost of upgrades—in the United Kingdom, the Netherlands, and France—with respect to sensor modifications required for a 3% blend ($430,000 to $470,000 for each country) and then the cost of modifying engine controls ($5.6 million in the United Kingdom, $30 million in the Netherlands, and no cost in France), medium-pressure transmission lines ($500–$850 million for each country), and domestic appliances ($170–$470 million for each country) for introduction of a 12% blend.

NaturalHy recommended that the consequences of mixing hydrogen with natural gas for industrial combustion applications be considered case by case. Several restrictions might apply for stationary natural gas engines and modern gas turbines. The preferable operating regime of stationary gas engines does not favor hydrogen concentration variations. These devices will need to be modified or adjusted based on manufacturer specifications. Modern gas turbines have strict fuel specifications. Operation outside of these specifications will require modification or readjustment of control systems with manufacturer permission. Also, unexpected hydrogen concentration variations are unacceptable for gas turbines (Florisson 2010).

Safety

The safety review included publications of the NaturalHy Project (Florisson 2010) and the Greenhouse Gas R&D Programme (Haines at al. 2003) sponsored by the International Energy Agency (IEA). Also, GTI performed a quantitative risk assessment of conveying hydrogen via the current U.S. natural gas distribution system. The details of the review and risk assessment can be found in Appendix A, Task 4.2.

NaturalHy Safety Assessment

The potential risks of transporting hydrogen using the existing natural gas pipeline network have been investigated by "NaturalHy Project in Work Package 2." This work was led by Loughborough University (UK); Leeds University (UK); Commissriat a' l'Energie Atomique (France); Shell Hydrogen; Health and Safety Executive (UK); and National Grid (UK). The NaturalHy Project assessed (through modeling and experimentation) three risks of adding hydrogen to natural gas, which are summarized in the following sections (Lowesmith 2009):

- Gas buildup
- Explosions in enclosures
- Risk from transmission pipelines.

Gas Buildup

The NaturalHy study examined gas buildup behavior in two experimental releases, one in a smaller household room and another in a larger room more typical of a commercial or industrial building. It was found that gas buildup behavior of blends was similar to that of pure natural gas. No separation of hydrogen from the mixture was observed. Increased flow rate resulted in higher gas concentrations, but to a lesser extent than anticipated due to buoyancy-driven ventilation generated by the release. In general, the steady-state concentration following a release is only slightly higher for blends of up to 50% hydrogen, but concentration increases become more significant for hydrogen blends greater than 70% (Florisson 2010; Lowesmith 2009).

Explosions in Enclosures

Compared with explosions of pure natural gas in confined areas, the relative increase in the severity of confined vented explosions was modest for blends with less than 20% hydrogen. A more significant increase in overpressure, and therefore risk or damage, was observed for blends with more than 50% hydrogen. Vapor cloud explosion overpressure can be significantly reduced for higher hydrogen concentrations if ventilation is used or if the structural congestion causing confinement is reduced (Florisson 2010; Lowesmith 2009).

Risk from Transmission Pipelines

Risk here is determined using the following general equation:

> Risk = Frequency of Pipeline Failure × Probability of Ignition × Consequences of the Fire

This risk can be estimated on an individual or societal basis. When defined as an individual risk, the result is the likelihood of a person becoming a fatality in a year. NaturalHy used a risk evaluation model to determine these values. For transmission pipelines, the risk factor was dominated by the rupture of the pipeline (Florisson 2009, p. 24).

Compared to natural gas transmission pipeline explosions, there is a consistent tendency for the severity of the risk with hydrogen mixtures to shift spatially, increasing closer to the point of explosion and decreasing further from the point of explosion. This shift in the spatial extent of risk is increased for higher concentrations of hydrogen, as shown in Figure 12. For the large, high-pressure pipeline represented by results in Figure 12 (914 mm and 70 bar [1,000 psig]), the magnitude of risk to an individual per year declines for hydrogen blends at a distance of 265–400 m and increases closer to the pipeline (0–275 m). The risk associated with explosion of a natural gas pipeline drops to zero at just over 400 m from the pipeline (Figure 12). However, adding 25% hydrogen decreases this distance by about 25 m while slightly increasing risk closer to the pipeline. The important causal factor here is the more rapid dispersion of hydrogen mixtures, which results in lower concentrations at shorter distances and therefore reduced risk at the far edge of the hazard distance. For 50% and 75% mixtures, the hazardous distance is reduced by about 75 m and 100 m, respectively, and the increase in risk closer to the pipeline is more significant. Given this generic risk result for a transmission pipeline, site-specific risks would vary depending on the population density and distribution near the pipeline. As a reference, the area contained within a radius of 280 meters is roughly equal to the area contained between the radii of 280 and 400 meters, which is where the probability of risk is reduced for higher hydrogen blends.

This shift in the spatial extent of risk has been examined for multiple pipeline sizes (Figure 13). The figure compares the risk of explosion for various pipeline diameters with 100% natural gas and a blend of 75% natural gas and 25% hydrogen. The 508-mm pipeline is apparently at a lower pressure than the other pipelines and therefore follows a different trend (Lowesmith 2009). The smaller-diameter pipelines have shorter hazardous distances, and the addition of 25% hydrogen reduces the hazardous distance while slightly increasing risk near the pipeline. This shift is quite small for a 25% blend. As mentioned above, for higher blends and specific pipeline segments, it would become more important to consider population density across the hazard distance to properly interpret the significance of this spatial shift in risk.

Greenhouse Gas Programme Safety Assessment (IEA)

A review of the IEA report on hydrogen blending is provided by Haines et al. (2003). The study focuses on a blend of 25% hydrogen in natural gas and provides a general assessment of hazards associated with a matrix of six causes and six consequences. Notably, compared to the use of natural gas without a hydrogen component, hazards are increased in cases of fire resulting from unburned gas in the air and in the case of burns resulting from the use of gas and open fire in a device or heating appliance. Hazardous phenomena are reduced by blends in four other cases: explosion resulting from unburned gas in air, suffocation due to unburned gas in air, suffocation due to flue gas system (malfunction), and poisoning due to heated media (Haines et al. 2003). Ten other hazards are identified as being unchanged in terms of risk when adding hydrogen to natural gas. Note that the general claim of a reduction in risk posed by explosion due to unburned gas in air is somewhat at odds with the more specific claim of slightly increased overpressure resulting from confined vented explosions with 20% hydrogen blends reported by Lowesmith et al. (2011). This emphasizes the condition-specific nature of risk assessments and the limited degree to which general statements can be used to simplify a complex topic.

Gas Technology Institute Safety Assessment of Distribution Pipelines

Distribution pipeline incidents typically result in a leak instead of a rupture because of their relatively low operating pressures (see Appendix A). According to 2007 data from the U.S. Department of Transportation (PHMSA 13), the following are eight major distribution pipeline failure modes caused by leakage:

- Corrosion
- Material defect
- Natural force
- Excavation damage
- Other outside force
- Equipment malfunction
- Operation
- Other.

GTI assessed the risk aggravation of adding hydrogen at various levels for these failure modes for distribution mains and service pipes. Detailed results are provided in Tables 13 and 14 in Appendix A. In summary, the GTI analysis suggests that adding hydrogen to the natural gas pipeline network increases risk posed by leakage. However, this increase is small for service lines at concentrations of less than 20% hydrogen, and the increase is moderate for distribution mains at less than 50% hydrogen (Appendix A). Again, many different factors influence risk estimates, and actual risks can vary widely from location to location.

Material Durability and Integrity Management

This section briefly notes reviews of pipeline material durability and integrity with the use of hydrogen and natural gas blends. Appendix A provides additional detail. Durability refers to the potential physical and chemical impact of hydrogen on pipeline materials, especially embrittlement of steel, and integrity management refers to the various practices conducted by pipeline operators to inspect, maintain and assess pipeline systems. These topics are discussed in the Executive Summary, and the sections below notes previously conducted reviews.

NaturalHy Studies Review of Durability

Durability was studied in "NaturalHy Project-Work Package 3." This investigation was led by GDF SUEZ (France), with participation by Commissariat à l'Energie Atomique (France), CMI, CSM, DBI Gas (Germany), DEPA, Ecole Nationale des Ingénieurs de Metz (France), Gasunie Technology & Assests (Netherlands), Institut Français du Pétrole, Istanbul Gas Distribution Co. Inc. (Turkey), Instituto de Soldadura e Qualidade (Portugal), StatoilHydro (Norway), TNO Science and Technology (Netherlands), TOTAL (France), and Turkish Scientific and Technical Research Council. The details of this review can be found in Appendix A (Task 4.4).

In addition, the GTI report includes literature sources related to the effect of hydrogen mixtures on pipeline materials and equipment. The details of this review can be found in Appendix A (Task 4.4).

NaturalHy Studies Review of Integrity

The need to upgrade the current IMP for transporting hydrogen and natural gas mixtures was investigated in "NaturalHy Project-Work Package 4." The aim of this project was to provide a specification for an Integrity Management Tool (IMT) that allows the operator to modify the existing IMP for hydrogen service. The cost of the new IMP was also evaluated in this study. This work was led by DBI Gas (Germany), with participation by TNO Science & Industry (Netherlands), Computational Mechanics BEASY (UK), GDF SUEZ (France), PII Ltd. (UK), Istanbul Gas Distribution Co. Inc. (IGDAS), N.V. Nederlandse Gasunie (Netherlands), Instituto de Soldadura e Qualidade (Portugal), Turkish Scientific and Technical Research Council, StatoilHydro (Norway), and TOTAL (France). The details of this review can be found in Appendix A (Task 4.5). Florisson et al. (2010) outline general conclusions of detailed studies of both durability and integrity issues, and they estimate that modifications to existing integrity management practices may incur an additional 10% cost increase due to hydrogen blends.

In the United States, the Pipeline and Hazardous Materials Safety Administration (PHMSA) has implemented integrity management requirements for hazardous liquid and gas transmission pipelines, but no similar requirements currently exist for non-hazardous gas distribution pipelines. In 2009, PHMSA published the final rule effective on February 12, 2010, to establish integrity management requirements for gas distribution pipeline systems. Operators are given until August 2, 2011, to write and implement the integrity program for distribution pipeline systems.

GTI reviewed the natural gas distribution systems and the 14 potential threats to the distribution systems identified by the American Gas Foundation through a survey of utility operators. GTI reevaluated each threat for the conditions under which the systems transport hydrogen and natural gas mixtures. The details of this study can be found in Appendix A (Task 4.5).

Leakage

Hydrogen is a much smaller molecule than methane, so its leakage rate through pipe walls and joints may be greater; it also causes economic and safety concerns because of the total gas loss. Leakage assessments include publications from the NaturalHy Project (Florisson 2012), which focuses on the permeability of plastic pipe materials, including PE and PVC; a report from the IEA Greenhouse Gas R&D Programme (Haines et al. 2003); and other relevant information for gas leakage in the natural gas distribution pipeline under hydrogen services. The details of this review can be found in Appendix A. The following sections summarize the findings.

NaturalHy Pipeline Leakage Assessment

The NaturalHy Project investigated permeation gas loss from plastic pipes in Work Package 3. This work was performed by Gaz de France.

PE80 Pipeline (10% Hydrogen)

The pressures tested were 58, 116, and 174 psig (5, 9, and 13 bar). Table 14 of Appendix A shows the permeation coefficients and gas losses for hydrogen and methane in a mixture of 90% methane and 10% hydrogen. The following are the findings:

- The hydrogen permeation coefficient is four or five times higher than that of methane.
- The permeation rate of methane and hydrogen increases with pressure.
- The aging of pipelines has no apparent significant effect on permeation coefficients.

Polyethylene Disk Samples (20% Hydrogen)

A 20% hydrogen mixture at 58 psig (5 bar) was investigated for leakage (Haines et al. 2003). The leakage rates for methane and hydrogen from this blend under these conditions are 1.1 and 2.3 L/km/day, respectively. For comparison, the permeability of pure methane under similar conditions is 1.4 L/km/day.

Greenhouse Gas Programme Pipeline Leakage Assessment

The IEA Programme performed experimental measurements of the hydrogen permeation coefficient in plastic pipes at 68°F (20°C) (see Table 15 of Appendix A). The hydrogen loss for the Dutch natural gas distribution grid after 17% hydrogen was added is estimated at 0.0005% of the hydrogen transported and therefore was considered insignificant (Haines et al. 2003).

GTI Steel and Ductile Iron Pipe Leakage Assessment

Hydrogen and natural gas leakage in steel or iron pipes primarily occurs through the threads or mechanical joints. The GTI study indicates that the volume leakage rate of hydrogen is three times higher than that of natural gas.

GTI Estimate of Gas Loss in U.S.-Grade Plastic Distribution Pipelines

GTI reviewed U.S. studies on gas loss in plastic distribution pipelines (see Appendix A). The permeation coefficients of hydrogen and methane for the various plastic materials are shown in Table 16 of Appendix A. The hydrogen permeation coefficient in U.S.-grade plastic pipes is five or six times higher than that of methane. GTI performed calculations on gas loss in U.S.-grade plastic pipes for pressures of 60, 3, and 0.25 psig (5.15, 1.22, and 1.03 bar). Results are shown in Table 17 of Appendix A.

Distribution Mains (60 psig [5.15 bar])

Adding 20% hydrogen to natural gas in plastic pipes doubles the total gas loss (77 ft^3/mi/yr). Higher concentrations aggravate this effect.

Service Lines

Service pipelines operate at much lower pressure than distribution mains, so the gas loss is much less significant. For pure natural gas, the gas losses are 2.5 and 0.2 ft^3/mi/yr at 3 and 0.25 psig (1.22 and 1.03 bar), respectively. Even though a 20% hydrogen mixture doubles the gas loss in the service pipeline, it is still economically insignificant.

Downstream Extraction

This section briefly notes the NaturalHy Project's review of using membranes to separate hydrogen from hydrogen and natural gas mixtures. This is followed by a description of technologies used to extract hydrogen from hydrogen and natural gas mixtures and an estimate of the cost of hydrogen extraction.

NaturalHy Membrane Studies Review

The NaturalHy Project focused on developing advanced hydrogen selective membranes for the separation of hydrogen from natural gas/hydrogen mixtures in Work Package 5 (Task 5.3–5.7). This work was led by the University of Oxford, with participation by the Norwegian University of Science and Technology and Compagnie Europeenne des Technologies del'Hydrogene. For details, see the GTI review of the NaturalHy membrane studies in Appendix A (Task 4.6).

Technologies for Extracting Dilute Hydrogen from a Pipeline

The following sections describe hydrogen extraction technologies for hydrogen and natural gas mixtures of 5%–20%. While we are considering the extraction of hydrogen in high purity for transportation, we have to consider that this differs from traditional separations. Most hydrogen today is produced via steam methane reforming (SMR), where natural gas and steam are used to produce a hydrogen-rich stream via the following reaction:

$$\begin{array}{lllllll} CH_4 & + & H_2O & \rightarrow & CO & + & 3H_2 \quad \text{(reforming)} \\ \underline{CO} & \underline{+} & \underline{H_2O} & \underline{\rightarrow} & \underline{CO_2} & \underline{+} & \underline{H_2 \quad \text{(shift)}} \\ CH_4 & + & 2H_2O & \rightarrow & CO_2 & + & 4H_2 \quad \text{(overall)} \end{array} \qquad (1)$$

Pressure Swing Adsorption (PSA)

PSA is a well-established technology. The systems are typically produced in sizes of 50 Nm^3/h–200,000 Nm^3/h. In the above reactions, excess water is used to push the equilibrium to higher hydrogen conversion and discourage side reactions such as coking. The resulting gas mixture is dried by condensing excess steam prior to hydrogen extraction. The dry gas entering the PSA unit has the following approximate composition:

H_2	=	75%
CO_2	=	19%
CO	=	3%
CH_4	=	3%

PSA operates on the adsorption isotherm principle. Every material has a characteristic correlation of surface adsorption of gases versus gas partial pressure. As gas pressure increases, the concentration of adsorbed (immobilized) species on the surface increases. For example, doubling the gas pressure may double the surface concentration of species. In PSA, highly porous packing materials are used. The materials are carefully chosen to adsorb non-hydrogen compounds at elevated pressure (150–300 psig). Multiple materials and layers of packing are typically used, which are tailored to the specific gas composition entering the bed. As reformate gas flows through the packed bed, CO_2, CO, CH_4, and other impurities are retained, while hydrogen passes through the bed. Once the packed bed is saturated, reformate flow is directed to a freshly regenerated bed, and the saturated bed is slated for regeneration. In the regeneration phase, the pressure in the vessel is reduced, thus allowing surface-adsorbed gases to go back in the gas phase. High-purity applications may also utilize hydrogen as a sweep gas to backflow any impurities from the bed. Figure 14 provides a simplified graphical layout of a PSA system.

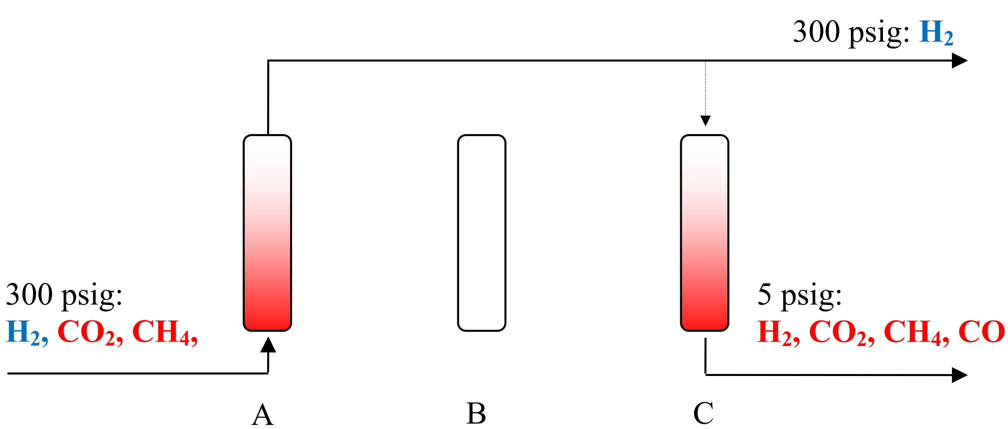

Figure 14. Simplified PSA arrangement.

Notes: Bed A is being actively exposed to reformate. In this bed, all species but H_2 are adsorbed (filtered), and H_2 flows through at high pressure. Once this bed saturates with impurities, flow is directed to a fresh bed (B). Beds are regenerated by reducing the pressure to near-ambient levels and flowing small quantities of product gas to flush impurities.

The cost of PSA units falls into four areas:

- Valving and flow controls
- Vessels
- Packing materials
- Compressors.

PSA technology is the industry standard and works best for high concentrations of hydrogen such as gas streams from conventional SMR production plants, which can be on the order of 75% hydrogen. Many design factors impact a PSA bed embodiment. One important factor to consider is its size vs. level of impurities. The PSA packing layers have two general operating regimes. The upstream portion of the bed is typically saturated with gas during operation and does the bulk of the extraction. The downstream portion of the bed is the fine polishing section of the bed and reduces the concentration of impurities that break through with hydrogen. Thus, the size of the PSA bed is strongly impacted by the concentration of non-hydrogen species entering the bed. For example, if we double the concentration of impurities, a PSA bed would require nearly double the size of the saturation portion of the bed (bulk extraction). The impact is not quite double, as the material saturation point increases for many materials with higher impurity concentration. Additionally, more beds may be required for high concentration impurities. This is due to a higher regeneration period as well as higher temperature swings.

As previously described, PSA units operate by pressure reduction. Gas is provided at high pressure, and impurities are removed at low pressure. In this technology, pressurization of impurities is strictly parasitic as the pressure is not recovered in the regeneration of the bed. As we consider lower concentrations of hydrogen, the concentration of non-hydrogen gas species increases. This means that we would compress larger quantities of gas to recover smaller quantities of hydrogen. For example, in the case of SMR, we would compress approximately 1.3 parts of total gas per 1 part of hydrogen. However, if we consider purification of 10% hydrogen, we would compress 10 parts impurities per 1 part hydrogen. Thus, for equivalent inputs and outputs, our compression work would increase by seven times.

It is notable that typical SMR systems often operate under pressure to avoid bulk gas compression. In such systems, natural gas is taken at pressure from a pipeline, and water is pressurized via liquid pumps (very low auxiliary power). Steam and methane are reacted at pressure to provide high-pressure gas to the PSA units. Hence, the PSA units operate using the pressure of the natural gas pipe and the low pressure of the burner of the SMR unit. This is analogous to conditions found at pressure reduction stations in a natural gas distribution network. In such locations, high pressure gas with potential hydrogen content is present. This gas is taken from transmission pressures as high as 1,000 psig, and pressure is reduced to lower distribution pressures. Gas can be introduced into PSA units at this point for hydrogen extraction, and the beds can be regenerated into the low-pressure distribution lines.

For production of ultra-high-purity hydrogen, the PSA unit can be operated with more frequent cycling of the beds. In such a case, the recovery rate decreases in favor of higher purity product. High-purity hydrogen can also be obtained by a second-stage PSA, which recycles its waste gas to the bulk PSA extraction of via other purification processes such as membrane purification for gas polishing.

Membrane Separation

Membrane technology is another industry-practiced technology for hydrogen extraction and purification. This technology operates on the principle of selective permeation, by which random motion of molecules across a permeable membrane will equilibrate to equivalent partial pressures on each side of the membrane. For example, if one side of a membrane has 50% hydrogen at 1 atm of absolute pressure, and the opposing side has pure hydrogen, the pressure of the opposing side would be 0.5 atm. The equation for this equilibration would thus be:

$$\text{(2)} \quad \begin{array}{c}\text{Side A:}\\ \text{(Total pressure)*(mol fraction)}\end{array} = \begin{array}{c}\text{Side B:}\\ \text{(Total pressure)*(mol fraction)}\end{array}$$

The above equation is for an idealized system, in which the concentrations are equal on both sides. In such a system, the flux is zero, as there is no driving force for gases in either direction across the membrane. To support an appreciable flux, a differential partial pressure of hydrogen would be necessary. For example, the gas pressure of the pure hydrogen side may need to be 0.2 atm, as this would give a driving force of 0.3 atm.

Membrane separation technologies work very efficiently with relatively high hydrogen concentrations. The purity of product gas can be high at very low fractional recovery but monotonically decreases as recovery increases, as the relatively slower co-permeation of impurities proceeds to a greater degree. Most applications using membrane technology industrially recover the bulk hydrogen at 95%–99% purity.

Palladium (Pd) membrane technologies can achieve hydrogen at 99.9999999% purity. At temperatures of approximately 752°F (400°C), Pd efficiently causes hydrogen molecules to dissociate on contact. The resulting protons dissolve into the metal. If the Pd is in the form of a thin membrane and a differential partial pressure is maintained across the membrane, the protons will migrate from the high-pressure side to the low-pressure side, where the protons recombine to form hydrogen atoms. As only hydrogen molecules exhibit this property, extremely pure hydrogen can be obtained from Pd membrane devices.

This technology is employed in the electronics industry to supply hydrogen with a total impurity load in sub-ppb range, and it is being increasingly used in the mobile power market and in renewable fuels research to provide fuel-cell-ready hydrogen from streams of reformate gas.

In practice, the Pd metal is alloyed with another metal to enhance the mechanical strength of the membranes. When copper is included, the resulting membrane can resist degradation by sulfur-bearing compounds at concentrations in the ppm range. Pd micro-channel membrane purifiers would typically be employed in series with a PSA unit and would be used to remove contaminants (for example, CO) that may damage a fuel cell. Pd micro-channel membranes require a hydrogen partial pressure difference to drive the protons through the Pd metal. Typically, a partial pressure of 160–200 psi is optimal (PE 2012).

Dilute hydrogen poses a significant challenge for membrane technology. For example, if 10% hydrogen is fed into a membrane separator, and 70% recovery is being considered, the outlet composition of the gas would be approximately 3%. This means that to support the flux of the outlet elements of the membrane, the pressure ratio would need to be at least 33:1. So, if ambient-pressure hydrogen is recovered, the pressure of the natural gas would need to be at least 33 atm (500 psia). This is, again, an idealized scenario, and a significantly higher ratio than 33:1 would be needed to provide a driving force.

Membrane technology for transmission pipelines may, however, be a good technology fit. Such pipelines often operate at pressures of about 1,000 psig, which provides sufficient driving force for hydrogen extraction. In such systems, the bulk of the process gas retains its pressure, and only a small amount of repressurization would be required to compensate for any device pressure drop.

Electrochemical Hydrogen Separation (Hydrogen Pumping)

Electrochemical Hydrogen Separation (EHS) is a more elaborate method for bulk hydrogen recovery. It operates on principles in common with fuel cell systems, using fuel cell stacks and passing the process gas across one side of the stack. By applying a current across the stack, hydrogen is atomically dissociated from the process gas and is reassociated into hydrogen on the product side. This process operates with very low differential pressure between the process gas and the product gas. Two technologies are used for electrochemical separation: one is based on Nafion and the other on PBI. Nafion is the more mature technology, but PBI is more desirable because the phosphoric acid conditions provide chemical resistance to sulfur contamination and its lower sensitivity to hydration.

PBI membranes require electrical potential to drive substantial current across the stack. As hydrogen concentration differs across the membrane, it needs to be compensated by applying a voltage. Additional voltage is necessary to drive activation, conduction, and diffusion resistances. In the presence of competing adsorption species such as H_2S and CO, the diffusion resistance can increase significantly. This can, however, be balanced with operation at higher temperature (for example, 356°F [180°C]). The power required for EHS is a strong function of the partial pressure of the hydrogen and the total pressure of the product gas. Similar to fuel cell systems, the overpotential required for pumping hydrogen is penalized due to lower hydrogen concentrations. This is exhibited by dilute hydrogen streams requiring higher potentials than concentrated hydrogen streams. Additionally, resistive losses are proportional to the operating current density of the electrochemical separator. At high current density, more resistive losses are experienced. High current density is nevertheless desirable, as the size of the extraction hardware would be smaller and the purity of the resulting gas would be higher. Hydrogen purity is compromised at low current densities due to a constant rate of impurity diffusion across the membrane. At low current density, the diffusion of impurities such as CH_4 would result in a larger fraction in the product. Temperature is another factor of operation. In PBI systems, CO tolerance is accomplished after about 248°F (120°C); beyond that temperature, any CO content of the feed gas degrades performance as a diluent.

EHS systems operating with PBI function with very small differential pressures. High differential pressures are a cause of acid migration in the membrane, which can inactivate the catalytic surfaces of the membrane. However, such a problem is not a major concern when considering high-pressure pipelines such as transmission or distribution pipelines, which are on the order of 500 to 1,000 psig. Hydrogen would be extracted in such systems via EHS to 500 to 1,000 psig. Subsequent gas polishing may be needed, and could be further accomplished with membrane separation as discussed in the previous section. Gas polishing of this type would have a relatively low pressure drop due to the high partial pressure of the feed gas.

Electrochemical processes operating on phosphoric acid or proton exchange membrane (PEM) platforms require water to operate. Phosphoric acid (in PBI) is more tolerant to dry operation, but in the total absence of water it dehydrates to a solid form that is not ionically conductive. PEMs require even more water to operate as the gas needs to be saturated at the operating temperature and pressure. Addition of water involves a humidification system, while pipeline gases have to be dry. Therefore, a water removal system would be necessary. Additionally, the membranes are susceptible to contamination from sulfur and ammonia. Sulfur is always present; ammonia is rarely seen. In cases of natural gas containing ammonia, an upstream gas separator may be required to remove species such as ammonia and sulfur. Of course, sulfur would also be reinjected in the gas downstream to provide odorization. It is also important to consider that PBI will also produce some phosphoric acid vapors (typically in the form of P_2O_5 or P_4O_{10}). These species are highly corrosive and need to be filtered out of the effluent gasses. This species is relatively easily trapped, however, due to its high reactivity.

It is worth noting the additional potential functionality of proton exchange membranes (PEM). While phosphoric acid cannot support more than 2 psi of differential pressure, PEM systems can operate with differential pressure in excess of 1,000 psi. It is well within the state of the art to operate a PEM when pumping hydrogen from about15 psi to 1,000 psi. This can be advantageous with other upstream bulk separations (for example, PBI or a diffusion membrane system). In such a case, a PEM can operate in two functions:

- Electrochemical compressor
- High-purity filter.

Electrochemical compression can be especially valuable at small scales where cost scaling factors for compressors become prohibitive. Unlike compressors, the scaling factor for electrochemical compression is much more linear with size. And because the membrane has few moving parts and avoids fuel cell degradation drivers (catalyst oxidation and contamination), maintenance costs would likely be low.

Sulfur and Constituent Considerations

In all the above technologies, sulfur and odorants would largely need to be removed before the process gas enters the purification equipment, and a scrubbing or hydrodesulfurization (HDS) application would be required. HDS may be the ideal technology, as hydrogen is already present in the feedstock. This technology offers a high density of sulfur capturing and a very low slip rate from the scrubber. Downstream, the gas would need to be reodorized by reinjection of mercaptans. This can be a significant hurdle. Deodorizing gas with 10% hydrogen and 70% recovery would mean that 33 parts of gas would need to be deodorized to recover 1 part of hydrogen gas. It is thus worth investigating in more detail which system type might have higher tolerance for sulfur. For example, the industry-standard HDS process typically operates at 600°F (316°C). This is not practical in a pipeline application. HDS would need a burner, recuperator, and air cooler, with the burner consuming a significant amount of energy. More practical techniques may include metal-doped carbon, damp iron oxide systems, and methyl diethanolamine (MDEA) for large-scale units.

Another major consideration is double-bonded hydrocarbons (ethylene, propylene), which can readily polymerize on many process surfaces and make impermeable coatings. Such components are present in small concentrations in natural gas, and in some pipeline practices (such as propane peak shaving) they can account for more than 1% of the total gas composition. Injection of propane is also likely in case of hydrogen pipelines as heavy hydrocarbons may be used to increase the gas heat content due to it being lowered by hydrogen (Zachariah-Wolff et al. 2007). This is especially challenging for ambient-temperature sulfur-scrubbing technologies, although they are not a significant problem for polymer membranes or PSA.

Oxygen is another constituent sometimes found in pipelines. It is more of an issue downstream from transmission pipelines. For example, gas appliances at high altitudes such as Denver, Colorado, operate more efficiently when premixed with air to compensate for the lower atmospheric oxygen. In this case, air is mixed in at the city gate and would not affect hydrogen transmission along the main line. Oxygen can also be introduced in rare instances such as peak shaving. For example, this is still encountered in areas in the Northeast during peak demands in cold winters. Again, this is typically performed downstream of any transmission line. As both hydrogen and oxygen react instantly on a catalytic surface, EHS would not be able to operate under such conditions. However, oxygen could also be a benefit by reacting with hydrogen to form water on the membrane surface. This water is beneficial as the membrane needs to be hydrated to operate, but is a hazard due to the associated exothermic reaction. As oxygen injection is a rather rare practice, system selection would be a function of local conditions.

Cost Estimate of Hydrogen Extraction from a Distribution Natural Gas Pipeline

NREL performed a cost estimate of hydrogen extraction from a distribution natural gas pipeline employing PSA units. We used Directed Technologies, Inc.'s (DTI) PSA capital cost estimate (DTI 2011) and H2A (DOE 2012) economic assumptions to develop the extraction cost modeling.

DTI's capital cost estimate for PSA units is based on the N^{th} plant concept, which reflects a mature system that is functionally reliable in the field and has been produced in sufficiently high annual and cumulative quantities as to have a capital cost (and unit cost) close to its asymptotic limit. At low manufacturing volumes, capital costs are high due to relatively time-intensive manufacturing and assembly methods. As the manufacturing rate increases, more efficient production methods become economical, capital cost (per unit output) decreases, and unit cost decreases. At extremely high manufacturing rates, all possible cost improvements have been achieved, and production rates are increased only by replicating process machinery. At those levels, capital cost (per unit output) and unit cost flatten in relation to the manufacturing rate.

The N^{th} plant assumption affects the H2A cost computations in two ways. The primary effect is in the estimated value of plant capital cost. The capital cost used in the H2A computation should not pertain to the initial or "one off" cost of a system, but rather to a relatively mature system produced in high volumes. Blended into the capital cost estimate are factors such as bulk discounts on material costs and low-cost manufacturing and assembly methods. These are made possible by serial production of the systems, efficient and streamlined business operations, and a lower profit margin consistent with a mature product that must be priced competitively.

We assess only the cost of hydrogen extraction here. The other costs (injection cost, hydrogen losses along the pipeline, capital cost increase caused by underutilization during lag-in-demand seasons, analytical costs, etc.) are not accounted for here.

The estimated cost of hydrogen extraction by PSA from a 300-psi pipeline is shown in Figure 15. The hydrogen recovery factor from PSA is assumed to be 80%. For a 10% hydrogen concentration, the extraction cost is \$3.3–\$8.3/kg of hydrogen extracted, depending on the scale of extraction or recovery rate in kg/day, as shown in Figure 15. For a 20% hydrogen concentration, the extraction cost across the same scale of extraction drops to \$2.0–\$7.4/kg. The high cost of hydrogen extraction from a natural gas pipeline is largely due to high capital costs. For example, for a 10% hydrogen pipeline, the capital cost contribution to the levelized cost of hydrogen extraction is 61% (Figure 16), 66% of which is the cost of the compressor (Figure 17). Gas pressure at the PSA exit is about 2 atm (30 psi). If hydrogen is extracted from a pipeline at 300 psi, the separated natural gas has to be recompressed back to the pipeline. Due to low concentrations of hydrogen, the amount of natural gas that has to be recompressed is high and requires a large compressor.

High recompression costs can be avoided if hydrogen is extracted at a pressure-reduction facility so natural gas does not need to be recompressed. Pressure differentials can vary between pressure-reduction facilities, but are often significant at the city gate where transmission lines feed into distribution lines. The hydrogen extraction cost for a 10% hydrogen blend under these circumstances is 6 to 11 times lower (\$0.3–\$1.3/kg of hydrogen extracted) depending on the scale of extraction or recovery rate in kg/day, as shown in Figure 18. These extraction costs were modeled for a pressure drop from 300 to 30 psi. Based on this significant cost reduction, it appears that hydrogen extraction from a natural gas distribution pipeline at a pressure-reduction facility will prove to be a lower-cost option, mostly due to the fact that natural gas exiting the PSA unit would require minimal or no recompression.

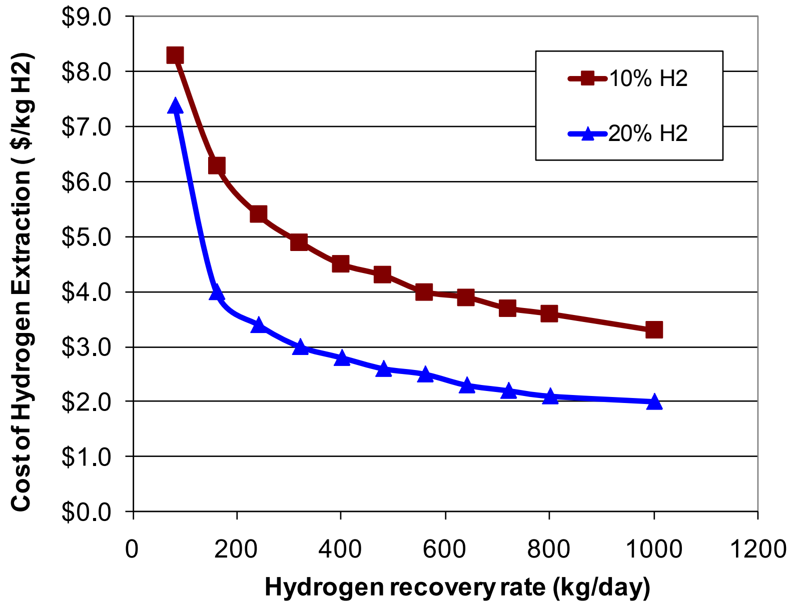

Figure 15. Estimated cost of hydrogen extraction by PSA unit from 300 psi natural gas distribution pipeline (assumed hydrogen recovery factor is 80%).

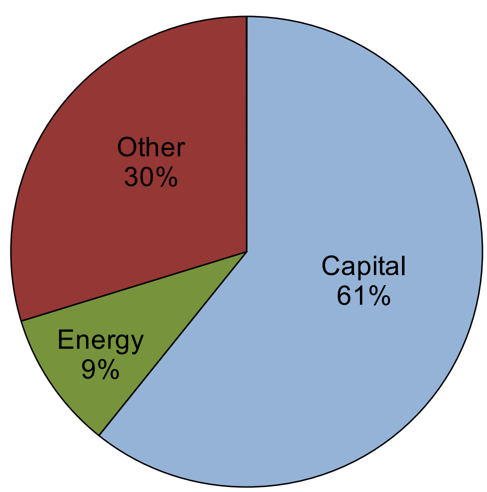

Figure 16. Hydrogen extraction cost breakdown.
Extraction by PSA unit from 300 psi natural gas distribution pipeline with 10% hydrogen added. The hydrogen recovery rate is 100 kg/day and the assumed hydrogen recovery factor is 80%. Cost items in the Other category include labor and O&M.

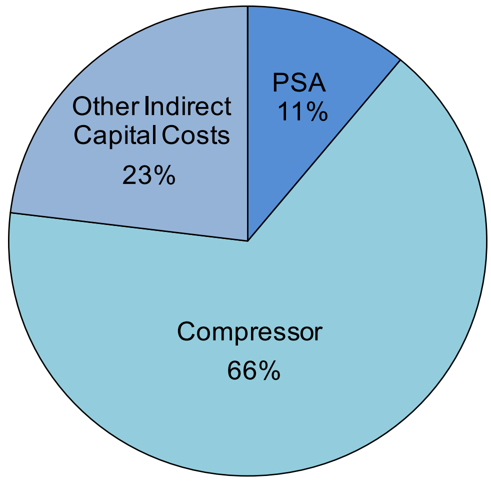

Figure 17. Breakdown of capital cost contribution to the hydrogen extraction cost.
Extraction by PSA unit from 300 psi natural gas distribution pipeline with 10% hydrogen added. The hydrogen recovery rate is 100 kg/day and the assumed hydrogen recovery factor is 80%. Other Indirect Capital Costs include land, engineering and design, and permitting.

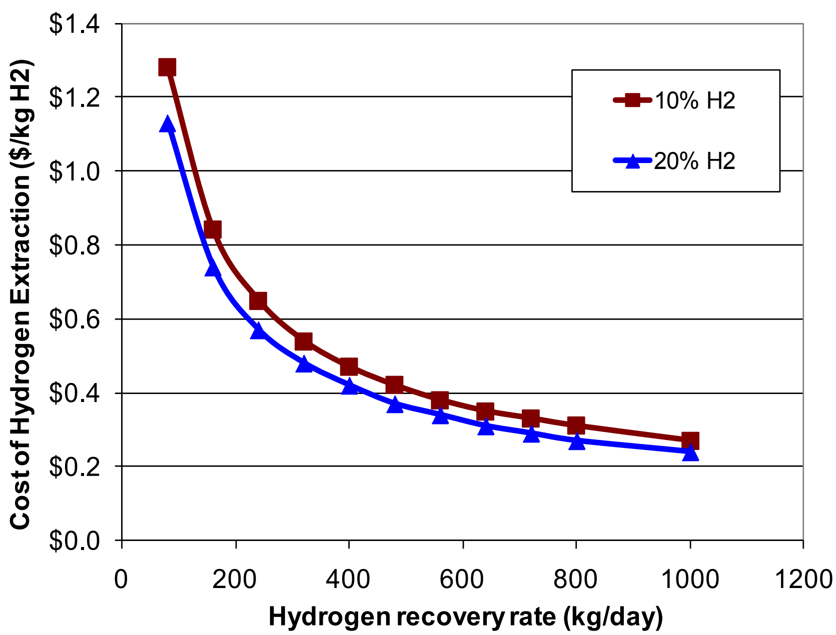

Figure 18. Estimated cost of hydrogen extraction by PSA unit at the pressure-reduction facility (from 300 psi to 30 psi).
Assumed hydrogen recovery factor is 80%.

Summary and Recommendations

Blending hydrogen into natural gas pipeline networks at low concentrations has the potential to increase output from renewable energy production facilities in the near term. In the longer term, blending may provide an economic means of hydrogen delivery when the hydrogen is injected upstream and then extracted downstream for use in fuel cell electric vehicles (FCEVs) or stationary fuel cells. This report reviews several studies of hydrogen blending and provides an assessment specific to the U.S. natural gas pipeline system, included in Appendix A. The implications of hydrogen blending vary with the concentration of hydrogen. Relatively low concentrations of hydrogen, 5%–15% by volume, appear to be feasible with very few modifications to existing pipeline systems or end-use appliances. However, this assessment of feasibility will vary from location to location. Higher concentrations introduce additional challenges and required modifications. Preliminary cost estimates suggest that hydrogen could be extracted economically at pressure regulation stations. For a station with a pressure drop from 300 to 30 psi, we estimate an extraction cost ranging from \$0.3−\$1.3 per kg hydrogen for a 10% hydrogen blend, depending upon the capacity and recovery rate.

This report reviews seven key issues concerning blending hydrogen into natural gas pipeline networks: (1) benefits of blending, (2) extent of the U.S. natural gas pipeline network, (3) impact on end-use systems, (4) safety, (5) material durability and integrity management, (6) leakage, and (7) downstream extraction. These issues are interrelated, but are addressed separately for the sake of clarifying explanation. The first two issues place the concept of blending in context. Issues 3–5 impose restrictions on the acceptable level of hydrogen blending, with requirements for end-use systems imposing the greatest restrictions.

Extensive recommendations for future work to better understand the potential costs and benefits associated with hydrogen blending have been proposed in other studies, particularly in the NaturalHy project funded by the European Commission (Florisson 2012). For additional work on the concept of blending renewable hydrogen into the U.S. natural gas pipeline system, we recommend the following:

1. Research and analysis of the costs associated with modifying U.S. pipeline integrity management systems to accommodate different levels of hydrogen blending.
2. Development of case studies assessing the pipeline system modifications required for specific U.S. regions at multiple hydrogen blend levels.
3. Detailed assessment of the impact of hydrogen blending on U.S. end-use systems, such as household appliances and power production technologies (i.e., engines and turbines).
4. Analysis of hydrogen blending in the near term (e.g., 5−10 years) as a means of economically increasing the output of renewable energy production facilities.
5. Dynamic analysis of the role of natural gas and hydrogen storage in future scenarios where hydrogen blending is prevalent in the U.S. natural gas systems.
6. Analysis of the role of hydrogen blending as a least-cost delivery option in the development of a hydrogen infrastructure for fuel cell electric vehicles.
7. Consideration of hydrogen blending as a strategic option to increase the public benefit derived from the existing U.S. natural gas infrastructure, with a focus on long-term implications for energy supply, energy security, integration of renewable natural gas, and greenhouse gas reductions.

Executive Summary

There is an extensive natural gas pipeline network in the United States. Some studies suggest that it could be a viable solution for the early market to partially use existing natural gas pipelines to deliver hydrogen, mixing it with natural gas in certain proportions, and then separate and purify it for use by an end consumer.

The existing natural gas pipeline networks include the gathering, transmission and distribution pipeline systems. It is considered that hydrogen can be injected into natural gas transmission pipelines and delivered to end users through distribution networks. As hydrogen and natural gas differ significantly in their physical properties, addition of hydrogen to the natural gas pipeline systems must be acceptable in terms of safety and integrity of the network.

In order to assist the development of a delivery go/no-go decision on the use of existing natural gas infrastructure to transport hydrogen from production to end users, GTI performed this literature review for National Renewable Energy Laboratory (NREL) to provide the scientific basis and engineering assessment on some of the aspects related to adding hydrogen in natural gas distribution systems. The scope of this review covers the seven aspects that have been investigated in NaturalHy including "Life Cycle Assessment", "Safety", "Leakage Assessment", "Durability", "Integrity", "End Use" and "Environmental and Macroeconomic Impacts".

In this study, GTI reviewed the available studies related to using the existing natural gas pipeline for hydrogen transportation. The primary focus was on the studies performed by the *NaturalHy Project*. GTI also provided a summary and discussion related to the use of the natural gas network for hydrogen service. This included analysis of the report from the Greenhouse Gas R&D Programme sponsored by the International Energy Agency (IEA) and related results from this study and other publications. The results from this study indicate that adding hydrogen into natural gas has beneficial effects on the environment by reducing greenhouse emissions and air pollutions. But there is not enough information from currently available literature sources to support benefits to the economy and employment.

In addition to the report from the NaturalHy Project, GTI included additional literature sources on material performance in hydrogen environments. GTI provided a scientific basis for assessing the durability and integrity of the existing pipeline infrastructure and potential gas leakage under hydrogen service. The reviewed information finds that there is no major impact from hydrogen on the material integrity under natural gas distribution operating conditions. However, hydrogen leakage through plastic pipe materials and elastomers is much higher than methane, and this may becomes a safety concern in a confined space where accumulation of the gas may increase the likelihood and severity of a fire or explosion.

GTI performed a quantitative risk assessment based on the current natural gas distribution system using the statistical data of US distribution system incidents, together with the survey results on the significant threats in distribution systems provided by utility operators. Using the risk of the system under natural gas service as a baseline, the overall risks at three hydrogen levels (<20%, 20 to 50%, and >50%) were assessed using the results from NaturalHy and other literature sources.

Compared to the current situation with natural gas, the risks present by natural gas distribution systems are increased by adding hydrogen into the system. The impact depends on the hydrogen concentration in the gas mixtures. If less than 20% hydrogen is introduced into the distribution system, the overall risk is not significant, though having hydrogen in natural gas has more impact on the safety in service lines than mains. If the hydrogen level in natural gas increases beyond 20%, the overall risk in service lines can significantly increase and the potential hazards can become severe, while the overall risk in distribution mains still can be moderate up to 50%. For hydrogen level above 50% in natural gas, the risks in both distribution mains and service lines significantly increase, and the overall risk in distribution system becomes unacceptable.

The study of the influence on pipeline integrity by adding hydrogen in the NaturalHy Project focuses on transmission pipelines. It cannot easily be applied to distribution systems because these systems are inherently different from transmission pipelines. The level of hydrogen that is acceptable for transmission pipelines may need to be reassessed for distribution systems in terms of the frequency and severity of fire or explosion in populated areas.

In addition, the hazards arising from gas leakage in a distribution system can be more severe than with transmission pipelines, especially in a confined service area. The integrity management for distribution systems under hydrogen services may require the implementation of a leak detecting or monitoring device or sensor. Currently, there is no available odorant for hydrogen, and this remains a gap to be further investigated.

It is likely that the maintenance costs for distribution systems under hydrogen service will be increased due to the needs for increased inspection frequency and leak detection. Since there is no existing integrity program for distribution system (although a new federal mandate is just being implemented), it is difficult to determine the stepwise maintenance cost of adding hydrogen.

Currently, the membranes used for extracting hydrogen from hydrogen/natural gas mixtures are under development. It is indicated by a recent study that extracting hydrogen from the gas mixture will not adversely affect the downstream gas quality since the Wobbe index and heating value will not be outside statutory requirements.

Electroless plated palladium membranes and carbon molecular sieves (CMS) are two promising technologies that are being considered for further development. Palladium membranes can provide high purity hydrogen, but they are expensive and have to operate at 300ºC. CMS membranes are low cost and can operate at temperatures between 30ºC and 90ºC, but the maximum hydrogen content obtained using CMS membranes is 98%. The most promising future technique would be a hybrid separation system consisting of both palladium and CMS membranes.

Introduction

Hydrogen is considered as an important energy carrier in the future for sustainable, reliable and cost-effective energy. As an energy carrier, hydrogen will provide a secure energy supply by utilizing locally available energy resources such as wind, solar, biogas, nuclear, etc.

One of the main barriers to moving towards a hydrogen economy is developing a reliable and cost-effective hydrogen delivery system. Compared with trucks and trains, pipeline transportation and distribution systems are considered as a safe, environmentally friendly and cost effective way to move hydrogen from its production location to its end users. However, the cost to construct a new widespread pipeline system for hydrogen delivery is huge and it may take decades to complete.

A cost effective transitional hydrogen delivery system would be to use the existing natural gas pipeline network, which offers advantages such as being: (a) widely spread and interconnected, (b) very high capacity, (c) well developed maintenance and control structure, (d) well established safety procedures, (f) well established grid management and operation strategies, and (g) broad acceptance by the public.

Because the physical and chemical properties of hydrogen are quite different from natural gas, the existing natural gas pipeline system is not suitable for delivery of pure hydrogen without significant modifications. However the existing natural gas pipeline system may be able to be used for co-transporting hydrogen with natural gas (i.e., a mixture) with no or minor modifications of the pipeline design, operation, and maintenance. This hydrogen/natural gas mixture could then be used in end user's systems, given appropriate modifications of the appliances, or could be used as pure hydrogen by developing devices to extract hydrogen selectively from the mixture.

Existing natural gas pipeline networks are made up of the gathering, transmission, and distribution pipeline systems. Hydrogen would be injected into natural gas transmission pipelines and delivered to end users through distribution networks.

GTI performed a literature review for the National Renewable Energy Laboratory (NREL) to provide the scientific basis and engineering assessment on the potential for adding hydrogen to natural gas distribution systems. The review is broken down into seven (7) subtasks:

- **Task 4.1: Life Cycle Assessment:**

  The review in this task includes the major natural resource inputs and environmental outputs, socio-economic assessments of employment and economic costs for: (a) current natural gas and related energy systems, (b) transitional natural gas/hydrogen systems, and (c) future complete hydrogen systems.

- **Task 4.2: Safety**

  Review the impact of adding hydrogen on safety and the conditions under which the risk in natural gas pipeline systems is acceptable for transporting hydrogen in natural gas.

- **Task 4.3: Leakage Assessment**

  Review the gas leakage from the pipeline system and the effect that the addition of hydrogen might have on this leakage.

- **Task 4.4: Durability:**

  Review the durability of pipeline materials under hydrogen service at the operating conditions and potential hydrogen levels to be introduced into the system. Indentify potential concerns for pipeline safety and integrity from the impact of hydrogen on material durability.

- **Task 4.5: Integrity:**

Review the potential impact of hydrogen on pipeline integrity. Also review the suitability of current integrity management program (IMP) for hydrogen service and the maintenance cost under hydrogen service. The distribution system is the focus of this task. The current situation of integrity management for distribution pipelines and the issues that may arise with adding hydrogen in natural gas are addressed in the review.

- **Task 4.6: End use:**

Review the development of membranes for the efficient separation of hydrogen from a hydrogen/natural gas stream and the effect on the downstream gas quality after removal of hydrogen.

- **Task 4.7: Impacts:**

Review the environmental and macroeconomic benefits of using the existing natural gas network to transport hydrogen.

Overview – Natural Gas Distribution System in US

US Natural Gas Pipeline Infrastructure

The natural gas delivery pipeline infrastructure is divided into gathering, transmission, and distribution systems, see Figure 1. The distribution system consists of mains, service lines and meter set assemblies which comprise meters, regulators and other installations.

Transmission pipelines are typically linear systems that transport gas over a relatively long distance. These systems have relatively few connections on the main lines.

Distribution pipeline systems are arranged in a network to fit geographical configurations of the service area. There are many connections to the main lines. Networks can be designed in branch or tree configurations, be redundant or supplied by a single feed. Because of the interconnections, each section of pipe could receive its gas flow from more than one direction. A distribution system can be subdivided into pressure districts, where each district is operated at its own pressure level to ensure an adequate and reliable supply of gas to the area's customers.

Comparison of Transmission and Distribution Systems

Transmission pipelines traverse long distances and have few branch connections, predominately located in Class 1 and Class 2 locations as defined in 49 CFR Section 192.5. They are generally large diameter (up to 48″) pipes and nearly 100% of the pipes are steel. Transmission pipelines typically operate at pressure levels between 600 psig (41.4 bar) and 1200 psig (82.7 bar), and in some cases up to 2000 psig (137.9 bar) and the stress levels mostly exceed 20% of the specified minimum yield strength (SMYS) of the steel pipes. Over 96% of the total transmission mileage is wrapped/coated steel pipe that is cathodically protected. Approximately 3% of the total transmission mileage is bare steel with and without cathodic protection. Failure of transmission pipelines usually occur as a catastrophic rupture of the pipeline, caused by the high pressure of the contained gas.

Distribution pipelines are generally small in diameter (as small as 5/8″) and are constructed of several kinds of materials including a significant percentage of plastic pipes. Distribution pipelines also have frequent branch connections for service lines to individual customers. The dominant cause of distribution incidents is excavation damage with third party damage being the major contributor to these incidents. Distribution pipeline failures almost always involve leaks, rather than ruptures because the internal gas pressure is much lower than for transmission pipelines.

Both distribution and transmission facilities are subjected to a variety of periodic inspections mandated by 49 CFR Part 192, see Table 1. The requirements are similar for both transmission and distribution systems with some exceptions. Odorants are required for distribution pipelines and transmission pipelines in populated areas.

Piping Materials of Distribution Network

Department of Transportation (DOT) 2007 Annual Distribution Data shows the piping materials used to construct mains and service lines in distribution networks (Figure 2 and Table 2). The natural gas distribution system in the US includes 1,201,000 miles of distribution mains and 64,804,000 service lines. Steel and polyethylene plastic pipes are the dominant piping materials in distribution systems. The majority of the steel pipes in distribution mains and service lines are coated and cathodically protected.

Historically, distribution mains were primarily made of carbon steel pipe. Since the 1970s, a larger portion of the gas distribution main lines have been made of plastic, mostly polyethylene (PE) and sometimes polyvinyl chloride (PVC). PE pipes are increasingly being used to construct distribution pipelines and replace the aging iron and steel pipes in the low-pressure distribution system because of lower construction and maintenance costs.

As shown in Table 2 and Figure 2, distribution mains are almost evenly divided between steel and polyethylene pipes which account for 47% and 48% respectively. Typical steel grades for the main distribution pipeline include A, B, X42, and X46, see Table 3 for their material properties [10]. Cast iron (CI) and wrought iron (WI) pipes only accounts for 3% of the mains. Many of the cast iron systems were installed over fifty years ago when they were originally used to transport town gas. These lines have been operated for many decades at pressures from 0.25 psig (17.2 mbar) to 60 psig (4.1 bar). There is also a small amount of ductile iron (828 miles) and copper pipes (36.5 miles) used for distribution mains. In addition to polyethylene pipes, PVC and Acrylonitrile Butadiene Styrene (ABS) are the other two plastic pipes used in distribution mains, accounting for 1.8% and 0.2% respectively.

Distribution service lines are primarily made of polyethylene (63%) and steel (33%). The remainder consists of small percentages of copper (1.73%), cast and wrought iron (0.17%), PVC (0.4%), ABS (0.02%) and ductile iron pipes (0.001%). About 1.96% of the total service line pipes are not identified.

The sizes of the typical distribution pipes are between 1.5" and 8" for mains and 0.5" to 2" for service lines. The distribution of the pipe size for steel and PE pipes in distribution mains and service lines is plotted in Figure 3 and Figure 4 respectively. A small percentage of distribution mains and services have a larger diameter pipe, typically for commercial and industrial application.

Elastomeric Sealing Materials in Distribution Network

Elastomers have been used as mechanical coupling seals and gaskets, meter and regulator diaphragms, boots, O-rings, flange seals, valve seats, etc. There are many types of elastomers and the formulation varies with the application. Table 4 lists the type of elastomers that have been used in natural gas distribution systems. Butadiene-Styrene (SBR) and Butadiene-Acrylonitrile (NBR) are the two major elastomers that have been used as gasket, O-ring, diaphragms, flange and quad seals in natural gas industry.

Failure of elastomers could result in leaks. The major failure of elastomers comes from the chemical reaction between the elastomers and chemicals or the adsorption/permeation of the chemicals by the elastomers. This attack results in swelling and softening with a reduction of their tensile strength. The temperature and concentration of the chemical medium determines the degree of deterioration. The absorption and desorption of a gas medium during the change of gas compositions may result in permanent damage of the elastomers.

Some elastomers can be degraded in outdoor conditions when they are exposed to sunlight, ozone, and oxygen. This type of degradation can cause surface cracking, discoloration, significant loss of tensile strength, elongation and other rubbery properties.

Pure mechanical damage is not a frequent failure mode of elastomers. Most mechanical damage occurs as a result of chemical deterioration of the elastomer. When the elastomer is chemically deteriorated, it is more susceptible to mechanical damage. Elastomers become brittle when cooled below their glass transition temperature, and this can lead to brittle fracture of the elastomers.

Operating Pressure of Distribution Network

Distribution pipelines typically operate at pressures ranging from 0.25 psig (17.2 mbar, gas delivered directly to customers without any additional reduction in pressure) to 60 psig (4.1 bar) and sometimes up to 100 psig (6.9 bar). A few distribution pipelines operate at higher pressures of up to 400 psig (27.6 bar high pressure distribution pipelines). The stress levels of the steel pipes in distribution system are normally less than 10% of the ***Specified Minimum Yield Strength*** (SMYS).

Typical Failure Mechanism of Distribution Pipelines

Distribution pipeline incidents typically result in a leak instead of a rupture due to their relatively low operating pressures and the correspondingly lower operating stress. The primary safety concern is that if a leak goes undetected and the gas collects in a confined space, it can eventually ignite and causing an explosion. The total numbers of the leak incidences in distribution systems from the DOT 2007 annual report are summarized in Table 5. The data are plotted as a function of failure mode in Figure 5 .

The exceptional case for distribution systems is "brittle-like cracking" in certain types of plastic pipe, which relates to crack initiation in the pipe wall, followed by stable crack growth, and eventual gas leak. Although significant cracking may occur at points of stress concentration, and near improperly designed or installed fittings, small brittle-like cracks may be difficult to detect until a significant amount of gas leaks out of the pipe and potentially migrates into an enclosed space. Premature brittle-like cracking requires relatively high localized stress intensification that may be the result of geometrical discontinuities, excessive bending, improper fitting assemblies, and/or dents and gouges.

Locations of Distribution Infrastructure Facilities

Distribution facilities are primarily located in populated areas. Distribution lines do not follow class locations, but the majority of the lines would fall into Class 3 and Class 4 locations under transmission class location definitions.

Distribution piping is frequently located in congested urban areas, typically under pavement in streets, highways and other public right-of-ways or utility easements.

Safety Records

The incident data in the Office of Pipeline Safety (OPS) database reported by operators for the period of 1990 through 2002 are summarized in Table 6 showing the causes of transmission and distribution incidents. During the period, there were a total of 957 transmission pipeline incidents and 1579 distribution incidents. The causes of incidents are classified into five major categories:

1. Corrosion
2. Outside Forces
    - First or second party damage;
    - Third party damage;
    - Earth movement (landslide/washout, subsidence, frost heave, earthquake, etc.);
    - Lightning or fire; and
    - Other
3. Construction Operating Error
4. Accidently Caused by Operator
5. Other

Outside force is the predominant cause of incidents for transmission and distribution pipelines, but it is more significant in distribution (60.4% of total incidents and 46.6% of serious incidents) than for transmission (39.8% of total incidents and 36.9% of serious incidents). Corrosion is a much more significant cause in transmission pipelines (23.4%) than in distribution pipelines (3.7%). The other category is a significant cause in both transmission (22.3%) and distribution (23.9%) pipelines. No additional information is available to further determine the cause of these "other" incidents.

Figure 6 shows the serious incidents categorized by system part in the distribution systems reported to OPS from 1990 to 2002. Most of the serious incidents are associated with the mains, followed by services, meter set assemblies and a category termed "Other" and "No Data".

The incident causes also vary with material of construction. Figure 7 shows the serious incidents categorized by construction materials in mains. The serious incidents in mains are primarily from polyethylene plastic pipes, steel, and cast iron pipes. These three materials are the most common pipe materials in distribution systems. Corrosion is an issue with steel systems, less so with cast iron and not at all with polyethylene. Third party damage is the dominant outside force category with all materials, but cast iron is subject to a higher proportion of incidents from earth movement.

The principal materials of construction for service lines are steel and polyethylene plastic. Other materials make up such a small percentage of the piping and are considered negligible. As shown in Figure 8, outside force is the largest cause of serious incidents in service lines, 54% and 76% for steel and polyethylene service lines respectively.

The dominant causes of failure for meter set assemblies are outside forces and “other”, with third party damage comprising most of the outside forces. No corrosion related serious incidents were reported for meter set assemblies during the study period from 1990 to 2002 [27].

Task 4.1 – Life Cycle Assessment

Hydrogen is considered an important energy carrier for a sustainable energy future. Developing a reliable hydrogen delivery system would remove one of the main economic barriers of a hydrogen economy. Pipeline transportation and distribution systems are cost effective ways to move hydrogen from its production location to its end users. There is a potential to transport hydrogen using the existing natural gas pipeline network. The potential benefits of adding hydrogen to natural gas have been addressed in the "NaturalHy Project-Work Package 1" through life cycle and socio-economic assessment.

This study was lead by *University of Loughborough*, and participants included by *COGEN Europe***;** *ECN - the Energy Research Centre; Instituto de Soldadura e Qualidade (ISQ); Planungsgruppe Energie und Technik GbR (PLANET); SAVIKO Consultants ApS;* and *Technische Universität Berlin.*

Life Cycle and Socio-Economic Assessment Literature [1]

The complete life cycle consists of:

- The production of natural gas, related fuels, and hydrogen;
- The construction, operation, maintenance and decommissioning of relevant networks, and
- The utilization of natural gas, related fuels, natural gas/hydrogen mixtures and pure hydrogen.

The life cycle assessment concentrated on primary energy inputs relevant to energy resource depletion, green house gas emissions associated with global climate change, and other gaseous, liquid and solid emissions related to acidification, ozone depletion and eutrophication. Social-economic assessments address direct and indirect job creation, maintenance, and the internal economic costs.

A literature review was performed in this study to examine the existing work on relevant life cycle and socio-economic assessment. In total, 214 references were identified and 172 reviews were conducted. The coverage by technology and type of assessment is extremely diverse. Table 7 lists the technology areas in the literature database.

The references on employment are very limited. Most of the studies were completed during the 1970's and early 1980's and are currently considered outdated.

Standard Procedures for Life Cycle and Socio-Economic Assessment [2]

Standard procedures were established for calculating various environmental impacts, economic costs and employment implications of existing and possible future energy systems. The variables determined in the procedure for calculation include:

- Primary energy inputs as indicator of energy resource depletion;
- Greenhouse gas emissions associated with global climate change (carbon dioxide, methane and nitrous oxide);
- Pollutants affecting urban air quality (sulfur dioxide, oxides of nitrogen, and particulate);
- Internal economic costs; and
- Direct and indirect jobs in the European Union.

The calculations for the existing natural gas network were used as a baseline scenario for comparison against the intermediate scenario with addition of hydrogen:

1) **Baseline Scenario**
    - Natural gas supply

- Natural gas network construction
- Natural gas network operation
- Natural gas network decommissioning

2) Intermediate Scenario

- Adjustment on gas leakage by adding of hydrogen
- Adjustment on Integrity Management Program for transporting hydrogen/natural gas mixture
- Hydrogen separation technologies
- Effect of hydrogen on end-user appliances
- Hydrogen production from different hydrogen generation technologies include:
  - Natural gas reforming without Carbon Capture and Storage (CCS);
  - Natural gas reforming with CCS;
  - Coal gasification with CCS;
  - Nuclear Power electrolysis;
  - Biomass; and
  - Wind power electrolysis.

Overall Benefits of Adding Hydrogen to Natural Gas [2]

The results from the calculation indicate some benefits of adding hydrogen to natural gas:

1) Significant reduction of greenhouse gas emissions if hydrogen is produced from biomass, wind power, and nuclear power
2) Some advantage on greenhouse gas emissions with hydrogen production from fossil fuels with CCS, but no benefits for decreasing primary energy demand or energy resource depletion
3) Potential benefits of selective extraction of hydrogen (this depends on the performance of the separation technology and the subsequent use of the hydrogen and the residual gas)
4) Potential benefits on improving air quality by reducing sulfur dioxide, oxides of nitrogen and particulate emissions if hydrogen is used in transportation and displaces conventional diesel fuel
5) Potential benefit on "greening" natural gas if the hydrogen/natural gas mixture is used directly in existing appliances for heat production and electricity generation

Summary on Life Cycle and Socio-Economic Assessment

The results from this study clearly support the beneficial effects on the environment from adding hydrogen to natural gas including the reduction of greenhouse emission and the improvement of air quality. However, the published work supported by this study addressed to a lesser degree the economic evaluation and employment aspects, and no concluding remarks were made.

Hydrogen has been acknowledged as an alternative energy carrier in US National Energy Policy, and is considered to be a substitute for petroleum-based fuels in light-duty transportation vehicles. A well-developed hydrogen economy will make use of the lowest cost sources of hydrogen, and central station natural gas and coal are the two lowest cost hydrogen sources, followed by various electrolysis-based systems. This could significantly reduce green house gas emissions if carbon capture and storage technologies are used. Large scale hydrogen production plants will likely be built in the future and a national hydrogen transmission and distribution system would be a cost effective way to distribute large volumes of hydrogen over long distances.

Currently, hydrogen is produced in a number of plants and is used primarily in the manufacture of chemicals and petroleum products. There are approximately 700 miles of hydrogen pipelines in US, which lie in the Gulf Coast region where large hydrogen refineries and chemical plants are concentrated. However, there are natural gas networks throughout the US. By utilizing the existing natural gas network for effective delivery of hydrogen in large volumes, there will be beneficial impacts on the society, economy, and environment.

Task 4.2 – Safety

The existing natural gas pipeline networks are designed, constructed and operated for conveying natural gas. The safety of the pipeline system and the risk posed to the public by the supply and use of natural gas are well understood and considered acceptable. Hydrogen has different chemical and physical properties which may adversely affect the risk presented to the public. The major concerns of the impact on safety, by adding hydrogen in the existing natural gas pipeline systems, include the potential rupture of pipeline by hydrogen and the increased probability of gas ignition, and the risk of fire and explosion hazards in an incidental leakage of a hydrogen/natural gas mixture.

GTI has reviewed the publications from NaturalHy Project and the Greenhouse Gas R&D Programme sponsored by International Energy Agency (IEA). The results from the above studies are used as a basis for ranking the severity of fire and explosion hazards in natural gas distribution systems at different hydrogen levels.

In addition, GTI performed a quantitative risk assessment based on the current US natural gas distribution system for conveying hydrogen containing natural gas. The risk factors for the existing distribution systems operated with natural gas was defined with: (a) the statistical data of the fatal incidents occurring in US distribution systems from 1990 to 2002 together with, (b) the survey results on the significant threats in distribution systems provided by utility operators. The overall risks for natural gas service are used as a baseline to compare the risks when hydrogen is added into natural gas distribution systems. The overall risk in distribution systems is assessed at three hydrogen levels that have been investigated in the NaturalHy project and other related research programs.

Risk Assessment by NaturalHy Project (Work Package 2) [3]

The potential risks of transporting hydrogen using the existing natural gas pipeline network have been investigated by "NaturalHy Project in Work Package 2". This work was led by *Loughborough University*, and *Leeds University, CEA, Shell Hydrogen, UK HSE,* and *National Grid participated also.*

The risk is a combination of the likelihood and the consequence (hazard) of an incident. The data and results from NaturalHy Project Work Package 3 and 4 on the durability and integrity of natural gas pipeline for transporting hydrogen/natural blends were used to aid the re-evaluation of the failure frequency of pipelines under hydrogen services. Laboratory scale and large scale experiments were developed to examine the consequence of fire and explosion situations pertinent to hydrogen/natural gas mixtures. Simple and Computational Fluid Dynamic (CFD) models were developed and validated using the experimental data, and the models were used to assess the impact of different level of hydrogen on the severity of the hazards which may arise from a wide range of accident scenarios.

The Impact on the Likelihood of Incident by Adding Hydrogen:

Failure frequency of pipelines is unchanged compared to that of natural gas pipelines with up to 50% hydrogen addition when an appropriate integrity management system is in place. The ignition probability is higher for hydrogen and natural gas mixtures due to the significant reduction in the minimum energy required for ignition and the increase in the upper flammability limit.

The Impact on the Consequence of an Incident by Adding Hydrogen:

The gas buildup behavior is similar in nature to natural gas. The concentration of the gas buildup is slightly higher with hydrogen addition of up to 50% in natural gas, but gas build up concentration significantly increase at hydrogen level above 50%, especially when the hydrogen addition is larger than 70%.

In a vented explosion, 20% hydrogen addition made little difference on the explosion severity, but 50% or higher hydrogen additions will increase the severity.

In an event of gas buildup in a confined space, the explosion severity increases moderately up to 30% hydrogen addition, but it significantly increases for 40% or more hydrogen addition. Fire hazard slightly decreases with hydrogen addition.

Risk Assessment:

A risk assessment tool (LURAP) was produced, based on the analysis of likelihood and consequence, to calculate the risk at different levels of hydrogen in natural gas. It was found that adding hydrogen in the natural gas pipeline increases the risk to an individual at location near the pipeline, but decreases the extent of the hazardous region.

In addition, the risk assessment of the expected background level leakage from the pipeline network indicates that the level of leakage overall is very small and poses no hazard from a safety standpoint.

Overall Safety Effect by Adding Hydrogen to Natural Gas Network (Greenhouse Gas Programme, IEA [11])

The potential change of gas properties by adding hydrogen up to 25% in natural gas and the resulting impact on the hazards have been assessed relative to the use of standard natural gases in this study, and the results are summarized in Table 8. Based on this assessment, adding hydrogen up to 25% increases the explosion risk in a confined room and the probability of a fire. It is concluded in this study that the use of hydrogen blended natural gas under well regulated circumstances should not increase the risk of explosions in comparison to those with unblended natural gas.

Risk Assessment for US Natural Gas Distribution Systems under Hydrogen Service

The potential risks posed to the public by natural gas distribution pipelines are generally assessed by the probability of pipeline failure and the consequence of the failure, i.e.:

$$Risk = Probability * Severity \tag{1}$$

The major failure mode in natural gas distribution pipelines is by leak, and the statistical data published by DOT in the 2007 annual report are categorized into eight failure modes for the leak incidences (see Table 5):

1) Corrosion

Leak resulted from corrosion is one of the failure modes in distribution system. It includes the external corrosion from bare steel pipes, coated/wrapped steel pipes and cast iron pipes, and internal corrosion. The leak from corrosion defects in distribution system can result in the gas buildup in a confined area and create a hazard of fire or explosion.

2) Material Defect

Manufacture related defects are one type of material defects for pipes. These include defective materials, pipe, pipe seam or piping components, etc. The other type of defects are related to construction, such as defective pipe girth welds, defective fabrication welds, stripped threads, broken pipes or couplings for steel pipe, and defective fusion, installation error, and improper back fill for plastic pipes.

This type of failure can result in slow release of gas and will pose fire or explosion hazard if the leak occurs in a confined space.

3) Natural Force

Natural force includes the forces that are applied to the pipeline from earth movement in the event of landslide/washout, subsidence, frost heave, earthquakes, etc. Natural force can result in severe damage of the pipeline and significant release of gas.

4) Excavation Damage

This is the damage of pipes during excavation which normally result in a leak or in rupture of the pipeline.

5) Other Outside Force

This is the damage from the outside force other than natural force or excavation.

6) Equipment Malfunction

This failure results from equipment malfunction, such as gasket or O-ring failure, control/relief equipment malfunction, seal failure, piping component failure, etc.

7) Operation

This is the failure from incorrect operations, e.g., the operator doesn't follow correct operational procedure.

8) Other

This includes the failure modes that don't fall into any of the above categories.

Table 5 and Figure 5 show the percentage of the leak incidents from each failure mode in distribution mains and service lines. Corrosion and excavation are the two frequent leak incidents. In view of adding hydrogen into the distribution system, the likelihood of each failure mode will not be significantly changed. However, the possibility and severity of a fire or explosion can be increased by the presence of hydrogen in natural gas.

The hazards of fire or explosion in natural gas distribution systems are ranked into six levels (no hazard (0), minor (10), minor to moderate (20), moderate (30), moderate to severe (40) and severe (50)) based on the risks posed to the public by pipeline failure, see Table 9. For each category of pipe materials in distribution main and service lines, the hazards are assessed on the eight failure modes based on the incident data from OPS database and the survey results on the significance of the threats in natural gas distribution pipelines provided by utility operators (see Task 4.5) [27].

The risk factors for the five material categories are defined using the ranking in Table 9 for each failure mode and shown in Table 10 and Table 11 for distribution mains and service lines respectively. The last column in Table 10 and Table 11 is the overall risk factors for each failure mode presented by natural gas, and it is calculated by the sum of the risk factor of each type of material times the percentage of this type of material in the system, i.e.:

$$RF_{Overall} = \sum_{(i=1 \text{ to } 5)} [RFi * Pi] \tag{2}$$

$RF_{overall}$: the overall risk factor

RF_i: risk factor for each material category (total of five categories)

P_i: percentage of each type of material in distribution mains or service lines

The overall risks for each failure mode in Table 10 and Table 11 are further assessed for hydrogen/natural gas mixture at three hydrogen levels (< 20%, 20 to 50% and > 50%). These three levels are identified based on the studies in NaturalHy and other literature sources that have investigated the influence of hydrogen concentration on the occurrence of fire or explosion by hydrogen/natural gas mixtures and the severity of the hazards.

In distribution mains, most of the pipelines are considered as in the vented condition. Adding hydrogen in the natural gas will increase the gas buildup near the pipeline, but the change of gas buildup behavior is slight for hydrogen up to 50%. The hazard resulted from slow release of gas, such as the gas leak from corrosion or manufacture defects are not significantly increased by adding up to 20% hydrogen in natural gas, but it will be significantly increased at higher hydrogen level, especially above 50% hydrogen. In the case of pipeline failure by outside forces such as excavation damage or natural force, the explosion hazard is increased with the presence of hydrogen, and the risk factor is significantly increased at hydrogen level above 50%. Table 12 and Table 13 show the influence of hydrogen on the risk factor (for mains and services respectively) of each failure mode and the overall risks at the three levels of hydrogen concentration. The overall risk calculated using Equation (1) indicates that the overall risk in distribution mains is increased by adding hydrogen in natural gas. The increase of the risk is moderate by adding up to 50% hydrogen, but the increase becomes significant when more than 50% hydrogen is added.

On the contrary to distribution mains, many of the pipelines in distribution services are in the confined space, such as within the building area. The leaked gas cannot be vented quickly and the gas buildup in the confined space will increase the possibility of a fire or explosion. Adding hydrogen in natural gas increases the risk factors for all the failure modes in service pipelines. The overall risk is significantly increased at all hydrogen levels, and it becomes severe at hydrogen levels above 20% as shown in Table 13.

Summary and GTI's Concluding Remarks on Safety

GTI performed a quantitative risk assessment on US natural gas distribution systems for carrying hydrogen containing natural gas. The risk analysis is based on the research findings from NaturalHy and other studies related to the influence of hydrogen on the potential risks posed to the public by transporting hydrogen in the existing natural gas network. The statistical data of the fatal incidents occurring in US distribution systems from 1990 to 2002 together with the survey results on the significant threats in distribution systems were used to define the baseline risk factor for each failure mode under natural gas service. The influence of hydrogen were assessed based on the research findings from NaturalHy and other studies, and the risk factors defined for each failure mode at three hydrogen levels that have been investigated in the literature.

Compared to the current situation with natural gas, the risks present in natural gas distribution systems are increased by adding hydrogen into the system. The impact depends on the hydrogen concentration in the gas mixtures. If less than 20% hydrogen is introduced into distribution system, the overall risk is not significant. But the service lines are more critical than distribution mains because they are mostly installed in the confined spaces. In this case, adding hydrogen in the gas increases the explosion risk in the event of a gas leak. If the hydrogen level in natural gas increases beyond 20%, the overall risk in service lines can significantly increase and the potential hazards can become severe, while the overall risk in distribution mains still can be moderate up to 50%. For hydrogen level above 50% in natural gas, the risks in both distribution mains and service lines significantly increase compared to the situation with natural gas, and the overall risk in distribution system becomes unacceptable.

Task 4.3 – Leakage Assessment

Because of the smaller molecular size of hydrogen, the leakage rate of hydrogen though pipe wall and joints may be larger than methane, and result in economic and safety concern of the total loss of gas. GTI has reviewed the publications from NaturalHy Project which mainly focus on the permeability of plastic pipe materials including polyethylene (PE) and polyvinyl chloride (PVC). GTI also reviewed the report from IEA Greenhouse Gas R&D Programme and other relevant information for gas leakage in the natural gas distribution pipeline under hydrogen services.

Assessment of Permeation Loss by NaturalHy Project (Work Package 3) [3, 18]

Permeation loss of gas from plastic pipes has been investigated by "NaturalHy Project in Work Package 3". This work was performed by Gaz de France. In this investigation, real pipes and assemblies were tested at the operating temperatures and pressures with hydrogen/methane mixture in order to more precisely evaluate the permeation of hydrogen through the plastic pipe in the natural gas distribution network.

Three different PE grades (PE 63, PE 80, and PE 100) in the diameter range from 20 mm (0.79") to 200 mm (7.87") with pressure between 14.5 psig (1 bar) and 174 psig (12 bars) or over and temperatures in the range from 5ºC to 25ºC. These represent commonly used polyethylene materials and pipe sizes in the natural gas networks and typical operating conditions. Pure methane and hydrogen/methane mixture containing 10% hydrogen were used in the tests to investigate the permeation behavior of hydrogen/natural gas mixture compared to natural gas. Table 14 shows the permeation coefficient of hydrogen and methane from a test under 58 psig (4 bar), 116 psig (8 bar) and 174 psig (12 bar) with a 32 mm (1.26″) PE 80 pipe. The calculated gas loss based on the experimental data at the test pressures is also included in this table. The results from this study are summarized in the follow [18]:

- There is an incubation time for methane to diffuse through the pipe, while the incubation time for hydrogen is close to zero.
- The permeation rate of methane and hydrogen increases with the increase of the internal pressure.
- The permeation coefficient of hydrogen is 4 to 5 times greater than that of methane in the hydrogen/methane mixture, even if the hydrogen partial pressure is lower by an order of magnitude than that of methane in the mixture.
- The absolute values of methane loss calculated for three type of PE piping materials are far lower than the extrapolated data.
- The aging of the pipes seems to have no significant influence on the permeation coefficients in these experimental conditions.

One type of PVC (PVC-CPE) was also included in this study, and the calculated hydrogen leakage rate from PE and PVC pipes at 2.9 psig (200 mbar) distributing 100% H_2 are [8]:

- PE100: 5.0 liter/km/day, and
- PVC: 13.2 liter/km/day

The leakage rate of methane and hydrogen calculated from PE disc samples under a mixture of 80% natural gas and 20% hydrogen at 58 psig (4 bar) are [8]:

- Methane: 1.1 liter/km/day, and
- Hydrogen: 2.3 liter/km/day

Additional Information on Leakage Assessment

In addition to the gas leakage study in NaturalHy project, GTI also reviewed the report from IEA Greenhouse Gas R&D Programme [11] and other relevant information [13, 18, 19, 29] about hydrogen leakage in natural gas distribution systems.

Gas Leakage from Steel or Ductile Iron Systems [19]:

The leakage in steel and ductile iron systems mainly passes through the threads or the mechanical joints. The leakage measurements carried out by GTI on gas distribution systems indicated that the volume leakage rate for hydrogen is about a factor of three higher than for natural gas.

Gas Leakage from Plastic Pipes and Elastomers [11, 13, AGA handbook]

Leakage Assessment by IEA Greenhouse Gas Programme [11]

The permeation coefficient of hydrogen in several plastic pipes was determined by experimental measurements in this study. The experimental data and the literature data are summarized in Table 15 [11]. A calculation of the total loss of hydrogen was performed in this study based on the experimental data of a representative material from the Dutch grid. The estimated gas loss is 26×10^3 m^3 (918,182 Ft^3) per year when 17% hydrogen is adding into this gas distribution system. This amount of gas loss only represents 0.0005% of the hydrogen transported. Thus the gas loss due to the hydrogen permeation is considered as negligible and will not create a significant problem.

Estimation of Gas Loss for US Distribution Network

The majority of the plastic pipes used in US natural gas distribution systems are polyethylene pipes including medium density polyethylene (MDPE) and high density polyethylene (HDPE). There are also small percentage polyvinylchloride pipes. These materials are similar to those used in European natural gas distribution system, but with different material designation system.

The permeation coefficient of hydrogen and methane in the typical plastic pipe and elastomeric materials that have been used in US distribution systems are summarized in Table 16 [13, 29]. The hydrogen permeation coefficient in the US grade plastic pipe materials are very close to those published by IEA's study [11]. It appears the permeation coefficient of hydrogen is about 5 to 6 times of that of methane in the plastic pipes. The hydrogen permeation coefficient is even higher in elastomers, especially in natural rubber and Buna S, which are 26 and 21 times of that in HDPE.

Because the plastic pipes have much larger surface area than the seals, the gas leakage rate is calculated with plastic pipes to estimate the amount of gas leakage in the entire gas distribution system. The gas leakage rate (V) through plastic pipes can be calculated using the permeation coefficient (P) [30]:

$$V=P*(A/t)*\Delta p \qquad (3)$$

A: the surface area of pipe

t: pipe wall thickness

Δp: the pressure difference between internal and external surface of pipe

High density polyethylene is used as an example for this calculation with a pipe diameter of 1″ and wall thickness of 0.1″ which is a representative pipe dimension in the distribution system. Table 17 shows the calculated hydrogen and methane leakage rate at the typical distribution operating pressures (60 psig (4.1 bar), 3 psig (210 mbar), and 0.25 psig (17.2 mbar)) with various hydrogen concentrations of hydrogen/methane mixtures. The gas leakage data are also plotted vs. the hydrogen content at the operating pressures in Figure 9. The total volume of gas loss of hydrogen and natural gas increases by adding hydrogen due to the higher permeation rate of hydrogen. The total gas loss from a gas mixture containing 20% hydrogen is about double the gas loss from a pure methane, but the amount of gas loss with this hydrogen content from a 1″ HDPE pipe at low pressure (3 psig (210 mbar) and 0.25 psig (17.2 mbar)) is not significant (5.3 ft^3/mile/year and 0.4 ft^3/mile/year at 3 psig and 0.25 psig respectively).

Since the service lines normally operate at 3 psig (210 mbar) or 0.25 psig (17.2 mbar), the total gas loss from service lines is negligible compared to that from distribution mains which operate at 60 psig (4.1 bar) or higher. The estimated total gas loss in the distribution systems at different hydrogen levels in the gas mixture is shown in Figure 10 using 60 psig (4.1 bar) as a representative operating pressure and the mileage for PE pipes with the size less than 2″ diameter which accounts about 69% of the total plastic pipes in distribution system. The gas leakage rates obtained from experimental measurements in NaturalHy are also included in this plot. For pure methane, the gas loss calculated from NaturalHy experimental data is close to the calculation from AGA handbook. However, for the gas mixture containing 10% hydrogen, the gas loss calculated based on NaturalHy experimental data is only half of that based on the permeation coefficient from AGA handbook. The total gas loss for the gas mixture containing 20% hydrogen is about 40 million cubic feet per year, and it is about double the total gas loss from pure methane, but this amount is still not significant from the economy point of view.

Summary and GTI's Concluding Remarks on Gas Leakage

It has been indicated by the research studies and literature data that hydrogen is more mobile than methane in many polymer materials including the plastic pipes and elastomeric seals used in natural gas distribution systems. There is almost zero lag time for hydrogen to penetrate the pipe wall, and the permeation rate of hydrogen is 4 to 5 times faster than methane through the typical pipes used in natural gas distribution.

The permeation coefficient of hydrogen is even higher through most of the elastomeric sealing materials that are used in natural gas distribution systems. Natural rubber and Buna S (SBR) have less sealing ability to hydrogen compared to the other elastomers.

Since plastic pipes have much larger surface area compared to the seals, a typical polyethylene pipe used in natural gas distribution system is used to estimate the gas loss through pipe wall at the general operating pressures. The calculation based on the literature data of the permeation coefficient of hydrogen and methane in the polyethylene pipe (PE 3608 or PE 4710) indicates that the majority of the gas loss is from the pipes in distribution mains which operate at 60 psig (4.1 bar) or higher. The gas loss from the total of 414,830 mile polyethylene pipes with the size less than 2″ in the entire distribution mains is about 40 million cubic feet per year if 20% hydrogen is added into natural gas pipeline system. Though this amount of gas loss is almost double the total gas loss when the systems deliver only natural gas, it is still considered insignificant from the economic point of view. In addition, adding hydrogen in natural gas can slightly reduce the leakage of methane into the environment which is beneficial for greenhouse gas reduction.

The hydrogen permeation coefficient from literature data is higher than that from the experimental measurements in NaturalHy project, especially at lower pressure. This phenomenon is reasonable because the literature data is measured in pure hydrogen and thin polymer films. It is most likely that hydrogen is less mobile in a low concentration hydrogen/methane mixture because the activity of hydrogen is much lower compared to pure hydrogen. Further, the plastic pipe has a much thicker wall and denser structure than the thin film which will increase the resistance for hydrogen to penetrate. Thus, the gas loss based on literature data may over estimate the gas loss from a pipeline system containing low concentration of hydrogen, especially at low operating pressures, e.g. 3 psig (210 mbar) or 0.25 psig (17.2 mbar). In order to obtain a more accurate estimation of the gas loss in the distribution system, it is necessary to perform further investigations testing pipes under general distribution operating pressures and at hydrogen concentrations that are typical of what will be used for blending hydrogen into natural gas pipeline systems.

The amount of gas loss from service lines is negligible from the economic point of view, but gas leaking in a confined space may increase hydrogen concentrations to levels that may become a threat from the safety standpoint. This is the same for elastomeric seals which have higher permeation rates for hydrogen. The accumulation of leaked gas over time may present a safety concern in a confined space where there are many sealed joints. This issue has not been well studied in NaturalHy and the other investigations, and remains a gap for the risk assessment.

It is important to obtain further understanding on hydrogen permeation behavior in plastic pipes and elastomeric materials under the expected operating conditions for hydrogen services. Further investigation should be performed on the existing pipe and seal materials as well as newly developed materials that can be used as a replacement for current materials. This will provide a basis to accurately estimate the gas leakage through pipes and seals, and in particular to determine if the leakage in a confined space over time will present a safety risk and if it is required to implement a leak detection/monitoring device.

Task 4.4 – Durability

It is well known that hydrogen damage is one of the concerns for many metallic piping materials. The occurrence and the severity of hydrogen damage on metallic materials depend on the type of materials, hydrogen concentration and the operating parameters. It is crucial to understand the acceptable hydrogen level that can be blended into natural gas without negatively impacting the lifetime of the infrastructure.

Since hydrogen is the smallest element, it has a greater tendency than natural gas to leak through valves, seals, gaskets and pipes. The accumulation of hydrogen in a confined space may create safety concerns. Gas meters record the volumetric quantities of the gas supplied. Adding hydrogen into natural gas changes the gas properties. Therefore, it is necessary to quantify the deviation of the gas meter when measuring hydrogen/natural gas mixtures at various hydrogen levels.

The above issues relate to material degradation. Leakage and meter accuracy were investigated in the NaturalHy Project-Work Package 3. The aim of this investigation was to develop sufficient knowledge for establishing hydrogen level in the blends, estimating the lifetime for different natural gas networks, identifying and removing bottlenecks for transporting hydrogen in the natural gas network and developing operational guidelines. The goal of the NaturalHy Project is to determine the feasible conditions under which hydrogen produced from a centralized production site can be injected into high pressure transmission pipelines and deliver to end users through distribution networks. Under this scenario, the durability of pipeline materials in distribution network is less of a concern than transmission pipelines because distribution pipelines operate at much lower pressure levels. Thus, hydrogen degradation of metallic components in natural gas distribution systems was not studied in the NaturalHy Project based on the hypothesis that the integrity of metallic components in low pressure distribution systems will not be significantly impacted at the hydrogen levels that are acceptable for high pressure transmission pipe.

In view of the long term goal of the US to use hydrogen as a sustainable energy carrier, hydrogen produced from the satellite, local production sites, will play a role in the hydrogen economy, especially in utilizing renewable energy such as wind and solar. In this scenario, hydrogen is most likely to be blended into natural gas distribution networks directly and the hydrogen level in natural gas determined from the pipeline materials and operating conditions for transmission pipelines could be conservative. A beneficial improvement can be made on the productivity of hydrogen delivery and recovery of hydrogen from gas mixture at end users if higher levels of hydrogen can be injected directly into natural gas distribution systems without adversely impacting pipeline integrity.

In order to provide a comprehensive point of view on the impact from hydrogen on distribution pipeline materials, GTI included other literature sources on materials degradation, hydrogen leakage and gas meter accuracy with hydrogen/natural gas. In addition, GTI performed a thorough review of the pipeline materials using the distribution pipeline data published by DOT and the GTI literature sources. By integrating the literature information with the pipeline materials and operating conditions in the natural gas distribution system, GTI assessed the durability of the US natural gas distribution infrastructure for transporting hydrogen/natural gas mixtures.

Durability (NaturalHy Projects-Work Package 3) [8, 17, 18]

This investigation was led by GDF SUEZ, with participation by Commissariat à l'Energie Atomique, CMI, CSM, DBI-GUT, DEPA, Ecole Nationale des Ingénieurs de Metz, GASUNIE, Institut Français du Pétrole, IGDAS, ISQ, STATOIL, TNO, TOTAL and TUBITAK.

In this project, the effects of hydrogen on the durability of the materials and components used in the natural gas transmission and distribution network, as well as the end user devices were studied.

Hydrogen Affect on the Initiation and Growth of Defects in Transmission Pipelines

This work focused on the hydrogen embrittlement of steel pipes used for high pressure natural gas transmission pipeline, and the crack growth from the existing defects, such as corrosion defects and sharp defects in the welds. It is concluded in this study that adding up to 50% hydrogen into the natural gas transmission pipelines may not cause catastrophic failure. The acceptable hydrogen level depends on the type of steel used for high pressure pipeline.

Because distribution system operate at much lower pressure than transmission pipeline and are built with lower grade steels, no additional studies were performed in NaturalHy to evaluate the risk of hydrogen embrittlement on distribution steel and other metallic pipes. Additional review and evaluation by GTI on the integrity impact from adding hydrogen on distribution pipes are included in the next section.

Hydrogen Permeation in Plastic Pipes in Distribution Network

This work has been reviewed in Task 4.3, and the main conclusion is that permeation of hydrogen through the walls of PE pipes is 4-5 times faster than methane. Nonetheless, the gas permeation loss is still very small and acceptable from a safety, economy and environmental point of view.

Aging of Plastic Pipes in Hydrogen/Natural Gas Blends

Aging of PE pipe materials was tested with laboratory samples and it was concluded that aging effect of hydrogen on PE pipe materials is not significant. But aging of the other polymer materials such as PVC, ABS and the elastomeric sealing materials was not reported in this study.

The Reliability of Gas Meters for Hydrogen Services

Three gas meters with polymer membranes manufactured by Gallus (France), Dresser (Italy) and Elster (Germany) were tested with two gas mixtures (100% methane and 50% hydrogen and 50% methane). The test results on Dresser meter show a positive change, while the test results on Gallus and Elster meters show a negative change in 50% hydrogen/methane mixture compared to 100% methane. But the gaps are less than 2% for all the tested meters and they all decreases at lower flow rate.

Additional Information for the Durability of Pipeline Materials under Hydrogen Services

In addition to the durability studies published by the NaturalHy Project, GTI include additional literature sources related to the effect from hydrogen on pipeline materials and equipments. They are used as supplemental information to provide a comprehensive point of view in terms of the impact from hydrogen on the distribution systems and the basis to assess the potential risks imposed to the system in the presence of different levels of hydrogen in natural gas.

Hydrogen Damage of Metals

Hydrogen damage is a form of environmentally assisted failure that results most often from the combined action of hydrogen and residual or applied tensile stress. The failure includes cracking, blistering, hydride formation and loss in tensile ductility and it has been generally called hydrogen embrittlement (ASM Vol. 13a). In general, the hydrogen damage occurs at a stress level below those typically experienced for a particular metal in an environment without hydrogen. It is affected by hydrogen pressure, purity, temperature, stress level, strain rate, and material microstructure and strength.

The specific types of hydrogen damage have been categorized in ***ASM Handbook Vol. 13A***, see Table 18. This table includes the materials that are susceptible to hydrogen damage, the various types of hydrogen damage, the source of hydrogen and the typical conditions for the occurrence of failure. The first three classes are grouped together and designated hydrogen embrittlement. It appears that the conditions for hydrogen damage on iron or copper do not apply to natural gas distribution system, thus there should be no concern of hydrogen damage on iron and copper pipes in the distribution system. Though hydrogen embrittlement is a potential concern for steel pipe, this effect varies with the steels. In general, high-strength steel (>100 ksi yield strength) are more susceptible to hydrogen induced cracking, while low-strength steel is only subjected to loss in tensile ductility.

Hydrogen Impact on Steel Linepipe

Hydrogen Embrittlement of Steel Pipe [11]

Many steels are prone to hydrogen embrittlement, which is the type of brittle fracture at a sustained load below the yield strength when materials are exposed to hydrogen. High pressure transmission steel pipeline is more of a concern due to the higher stress from the operating pressure and the higher strength of pipeline material, especially the new natural gas pipeline construction. Hydrogen concentration and operating pressure are the most critical factors to cause hydrogen embrittlement.

The steel grades (API 5L A, B, X42 and X46) used in natural gas distribution pipeline are relatively low strength steels. The predominant hydrogen damage for low strength steels is loss of tensile ductility or blistering, but they usually fail in a ductile mode instead of catastrophic brittle fracture in hydrogen environment. The severity of the hydrogen damage depends significantly on the hydrogen concentration and operating pressure.

Hydrogen Assisted Fatigue [13]

Carbon and low alloy steels show accelerated fatigue crack growth and degradation in fatigue endurance limits when expose to hydrogen even at relatively low pressures. The accelerated fatigue crack growth is more pronounced at ambient temperatures and becomes less severe at elevated temperatures. The presence of hydrogen reduces the threshold cyclic stress intensity factor (ΔKth) as well as fatigue life, thus fatigue cracking will be a concern if the pipeline experiences pressure fluctuations.

Enhanced Crack Growth on Existing Defects [11]

Crack growth from existing defects may be enhanced by the addition of hydrogen due to the reduced ductility of steel, and fluctuation of the operating pressure in the pipeline may accelerate this effect.

At low and medium pressures (< 290 psig (20 bar)) in distribution systems, the pipeline will be far less susceptible to hydrogen enhanced crack growth due to the relatively low operating tensile strength compared to the design strength. There is a long history of the successful transportation of “pure” hydrogen at pressures below 290 psig (20 bar) across the world, no operational problems occurring over many decades. Town gas, which contains hydrogen, also has been transported historically in gas distribution pipelines.

Welding Requirements for Hydrogen Services [13]

The welds should be defect free and the weld heat affected zones must match the mechanical and toughness properties of the linepipe. The hardness levels in the weld and weld heat affected zone must be controlled to avoid hard spots to ensure the adequate toughness for hydrogen containing environment.

Hydrogen Impact on Non-Metallic Materials

Compatibility of Polymer Materials with Hydrogen [13]

The degradation of polymer materials in normal environmental conditions includes UV irradiation, chemical attack and thermal breakdown. With respect to the investigation of the polyethylene pipeline for hydrogen service, no degradation by pure hydrogen has been reported. Little or no interaction between hydrogen gas (or any non-polar gas) and polyethylene should be expected [30]. In addition, hydrogen alone does not provide radicals that can cause polymer breakdown. Most of the elastomers are also compatible with hydrogen. Table 19 lists the major plastic and elastomeric materials used in natural gas pipeline and their compatibility to hydrogen.

Though pure hydrogen dose not promote the degradation of polymer materials, some contaminants in hydrogen gas may be harmful to pipeline materials, and the degradation depends on their concentration.

Hydrogen Permeability in Plastics [11]

This has been reviewed in Task 4.3. In plastic pipe systems, hydrogen diffuses faster than methane through the plastic pipe wall, but the total loss of hydrogen is considered insignificant from the economic standpoint.

Impact of Hydrogen on the Durability of Gas Meters [11]

The influence of hydrogen addition was measured for leather and plastic diaphragm gas meters in Polman's study [11]. The deviations in gas metering were determined with natural gas and 17% hydrogen/natural gas mixture at five different flows from 0.013 to 5 m^3/h. For the two types of gas meters, the deviations observed were lower than 0.1%. This deviation can be regarded as negligible considering the calibration standards stating a maximum deviation of 4% for recalibration and repeatability within 0.2%.

This study also examined the required capacity of gas meters for measuring hydrogen/natural gas mixtures. The results indicated that for mixtures up to 17%, the required capacity is not affected by adding hydrogen in natural gas.

It is concluded in this study that the gas meters used in natural gas distribution systems are not expected to be changed.

Summary and GTI's Concluding Remarks on Durability

Impact of Hydrogen on the Durability of Metallic Pipes in Distribution Systems

The metallic pipes in US distribution systems are primarily made of relatively low strength steel, typically API 5L A, B, X42 and X46 in distribution mains. The major hydrogen damage of these steels in a hydrogen containing environment is loss of tensile strength or blistering which strongly depends on the hydrogen content in the environment. They normally fail in ductile mode, and are not the type of steels that are susceptible to hydrogen induced brittle cracking.

In addition, the operating pressure in distribution system is normally less than 250 psig (17.2 bar), and the stress level in most of the steel pipes, generated by operating pressure, is less than 20% SMYS. Under this stress level, the potential risks for the low strength steel pipes in distribution system are low considering the failures by hydrogen (hydrogen induced stress cracking, hydrogen enhanced fatigue cracking or hydrogen enhanced crack growth from the existing defects) which are the major integrity concerns for high pressure transmission pipelines transporting hydrogen.

For the other metallic pipes, including ductile iron, cast and wrought iron, and copper pipes, there is no concern of hydrogen damage under general operating conditions in natural gas distribution systems.

Impact of Hydrogen on the Durability of Plastic Pipes and Elastomers in Distribution Systems

There is no major concern on the hydrogen aging effect on PE or PVC pipe materials. Most of the elastomeric materials used in distribution system are also compatible with hydrogen. There is very small amount of ABS pipes in distribution mains (0.2%) and service lines (0.02%). No investigation on the aging and permeability of this pipe material has been performed. Since this material only takes very small portion in the distribution pipes, and also it is not the pipe material to be used for new construction, the unknown performance from ABS will not significantly affect the overall performance for the plastic pipes in distribution system. If ABS is of direct concern, targeted testing could be conducted. Therefore, it can be concluded that material aging by hydrogen is not a major concern on the durability of the polymer materials in natural gas distribution systems.

One remaining durability gap that needs to be addressed is the potential contaminants in hydrogen gas that may be introduced into the network. The specification for the purity level of the hydrogen gas to be transported by natural gas pipelines has not been determined.

Impact of Hydrogen on the Durability of Gas Meters

The deviation of a gas meter with hydrogen/methane mixtures varies with the manufacture's detail of the meter design, e.g., Dresser meter show a positive change while those from Gallus and Elser show a negative change. Nonetheless, the deviation is acceptable based on the requirement for recalibration (<4%) when they are measuring a gas mixture containing less than 50% hydrogen. The meters may not need to be "tuned" under the potential hydrogen levels (<50%) in natural gas pipeline that are transporting hydrogen/natural gas mixtures.

Task 4.5 - Integrity

There are always existing defects in the pipe materials or welds. The current integrity management for natural gas pipeline systems is based on the operating conditions for transporting natural gas. Adding hydrogen into the pipeline network changes the pipeline operating environment, which may accelerate crack propagation or fatigue failures from the existing defects, and thus adversely impacts pipeline integrity. There may be certain defects which are acceptable under current integrity management criteria which will become critical due to the material property change in hydrogen containing environments.

In the US, the Pipeline and Hazardous Materials Safety Administration (PHMSA) has implemented integrity management requirements for hazardous liquid and gas transmission pipelines, but no similar requirements currently exist for gas distribution pipelines. In 2009, PHMSA published the final rule effective on Feb. 12, 2010 to establish integrity management requirements for gas distribution pipeline systems. The operators are given until August. 2, 2011 to write and implement the integrity program for distribution pipeline systems.

The investigations of the suitability of current integrity programs for hydrogen services have been focused on the natural gas transmission pipelines. The integrity concern in the medium to low pressure distribution system is considered a lower risk compared to high pressure transmission pipeline assuming that the hydrogen level that is acceptable to high pressure transmission pipeline will not create a significant threat to distribution systems which operate at much lower pressures.

Because the natural gas distribution systems are different from transmission pipelines and they are constructed with a large variety of materials and operated with varied pressures and other conditions, it is not appropriate to simply apply the integrity program for transmission pipelines to distribution systems. In order to assess the potential risks of adding hydrogen to the distribution systems, GTI performed a review on the natural gas distribution systems (see the section ***"Overview-Natural Gas Distribution System in US"***) and the potential fourteen threats in the distribution systems which have been identified by the ***American Gas Foundation*** through the survey of a group of utility operators [27]. Each of the threats has been reevaluated by GTI for the conditions under which the systems transport hydrogen/natural gas mixtures. The integrity investigation from the NaturalHy Project is used as a basis to identify the risk to the integrity of distribution systems.

Integrity Management Program for Transporting Hydrogen/Natural Gas Mixtures [4,5,6]

The needs to upgrade current Integrity Management Program (IMP) for transporting hydrogen/natural gas mixtures were investigated in "NaturalHy Project Work Package 4". The aim of this project is to provide a specification for an Integrity Management Tool (IMT) that allows the operator to modify the existing IMP for hydrogen service. The cost of the new IMP was also evaluated in this study.

This work was led by *DBI-GUT*, with participation by *TNO Science & Industry, Computational Mechanics BEASY, GDF SUEZ, PII Ltd., Istanbul Gas Distribution Co. Inc. (IGDAS), N.V. Nederlandse Gasunie, Instituto de Soldadura e Qualidade (ISQ), Turkish Scientific and Technical Research Council (TUBITAK), StatoilHydro and Total.*

Defects in Natural Gas Pipeline Systems and the Potential Impact by Hydrogen

The acceptable defects in the natural gas pipeline systems are defined in the current integrity program by the number, type, distribution and the shape of the defects. The aspects to be concerned with for hydrogen services is the stress generated at a defect and the rate at which the defect can propagate if the stress is over the critical value for crack propagation. Blunt defects, like corrosion, will not generate relatively large stresses. However, sharp defects, like cracks, can cause significant stress and under typical pipeline fatigue loads hydrogen can accelerate crack growth. In general, crack and crack like defects are considered to be more critical than corrosion defects when hydrogen is introduced.

Impact of Hydrogen on the Defect Criticality

A clear impact on the acceptable initial crack size was observed especially for axial defects. The critical size of the defects can be back calculated with an assumed design life based on the knowledge of crack growth rate in a specific environment. The effect of hydrogen on the defect criticality is minor under the selected assumptions in the hydrogen/natural gas mixtures with up to 50% hydrogen. A tool was developed to calculate the probability that a pipeline will fail or a defect will lead to a pipeline failure and the failure rate.

Inspection/Monitoring Tools and Inspection Intervals

The current inspection tools were investigated for their abilities to identify the critical defects under hydrogen services. The modified pipeline inspection tools (MFL, TRIAX, and EMAT) can be applied to find critical defects when transporting hydrogen/natural gas. The inspection interval can be determined for different hydrogen concentrations, loads and geometries of pipeline and defects based on the in-line inspection and probability of failure (POF) calculation results. The expected inspection intervals will be shortened for transporting hydrogen/natural gas mixture, especially for higher hydrogen concentrations. Improvement of the in-line inspection tools of their reliability and sensitivity to identify critical cracks will be beneficial to lowering the probability of failure.

Cathodic Protection (CP) Integrity Management

A prototype of an integrated remote monitoring system has been proven feasible for coated pipelines. This system includes data collection system and a modeling tool to provide a real time display of the CP protection levels along the pipeline. The benefit of using this remote monitoring system is to manage the pipeline integrity in the presence of hydrogen with reduced cost.

Repair Methods

Three currently applied repair procedures have been investigated to determine if they can be used for pipeline repair under hydrogen service. The focus was on the pipeline load and the effect of hydrogen on welding activities. Clock Spring, Metallic Sleeve and Weld Deposit can be used to repair the pipelines that co-transport hydrogen and natural gas, but the performance will be slightly reduced in some cases.

Cost of the Integrity Management for Hydrogen Service

The cost of the integrity management is strongly dependent on the individual circumstances including hydrogen concentration, defect distribution, material properties, loads and integrity targets. The potential increase of the total cost will be less than 10% for the inspection and repair costs on corrosion and cracks if: (a) the hydrogen concentration is less than 50% of the natural gas blend, (b) with the maximum operation pressure of 957 psig (66 bars), and (c) the design life of the system is 50 years or less.

Additional Information for Distribution Pipeline Integrity under Hydrogen Services

Major Threats to Distribution Infrastructure

The threats are classified in ASME Standard B31.8S (Managing System Integrity of Gas Pipelines) as:

1) Time Dependent Threat
    - External corrosion
    - Internal corrosion
    - Stress corrosion cracking (SCC)
2) Stable Threat
    - Manufacturing related (e.g., defective pipe seam or defective pipe)

- Construction related (e.g., defective pipe girth weld, wrinkle bend or buckle, etc.)
- Equipment related (e.g., gasket or O-ring failure, control/relief equipment malfunction, etc.)

3) Time Independent
   - Third party/Mechanical damage
   - Incorrect operations (incorrect operation procedure)
   - Weather related/outside force (cold weather, lightening, heavy rains or floods, earth movements)

The above threats are defined primarily for natural gas transmission system which operate at high pressure and are constructed predominantly with high strength steels which are coated, wrapped or bare. The materials found in distribution pipeline systems are predominantly steel or polyethylene, with some cast iron, wrought iron, other plastics and copper. Some of the threats to transmission pipelines are not applicable to distribution systems. For example, the threat of stress corrosion cracking is not typically a threat to the distribution infrastructure because it is the cracking of a pipeline from the combined influence of tensile stress, a corrosive environment, and a susceptible material. The distribution pipelines do not operate at pressures high enough to produce the stress necessary to create an environment that could include stress corrosion cracking.

With the different materials taken into account, and in view of the incident causes, the nine threats defined for transmission pipelines were expanded to the following fourteen categories of threats for distribution systems which are prioritized in Table 20 [27]. Unlike transmission pipelines, the top two threats to distribution pipelines are the weather-related outside force damage on cast iron and excavation/mechanical damage instead of the time dependent threats from corrosion (external corrosion, internal corrosion or stress corrosion cracking) posed to transmission pipelines. This is because the distribution pipelines are mostly buried in the highly populated area and are frequently subjected to outside force damage.

For the fourteen threats present for natural gas distribution systems, the likelihood of any threat will not be significantly affected by having hydrogen added in the system, but the severity of the hazard may be increased by hydrogen in the case leaking occurs as a result of an incident.

The integrity program may need to be tightened in the future when hydrogen is added to the distribution system. For example, one may need to shorten the inspection intervals to minimize the possibility of pipeline failure, or to implement leak detection or monitoring device for hydrogen. Currently there is no available odorant for hydrogen, and this may require the development of a new odorant. This may lead to a potentially increase of the maintenance cost for the utilities. Since there is no existing integrity program for distribution system (DIMP is just being introduced in the U.S.), the affect on maintenance cost by adding hydrogen cannot be determined.

Summary and GTI's Concluding Remarks on the Integrity under Hydrogen Services

Conclusions in NaturalHy Project on Transmission Pipeline Integrity

The studies on integrity in NaturalHy project is focused on high pressure transportation pipelines. This study concludes that hydrogen can be transported by the existing natural gas pipeline with small adaptations of the current Integrity Management Program. The necessary adaptations depend on the hydrogen concentration and the operating conditions of the individual pipeline. The modifications of current integrity program is considered insignificant if hydrogen in the pipeline is less than 50%, but it requires a detailed investigation for each case and corresponding modification on the upper limitation of hydrogen concentration.

GTI’s Comments on Distribution Integrity

The threat of hydrogen addition on distribution integrity has been considered smaller when compared to transmission pipelines. It should be noted that the natural gas distribution systems are very different from transmission pipelines, and it is not possible to simply apply the integrity program for transmission pipeline to distribution systems. One of the important differences of distribution systems from transmission pipelines is the locations, i.e., the distribution pipelines are in populated areas. The level of hydrogen that is acceptable for transmission pipeline may need to be reassessed for distribution systems in terms of the frequency and severity of fire or explosion in the populated area. In addition, the gas leakage in a distribution system is more severe than transmission pipeline, especially in a confined service area. The integrity management for distribution systems under hydrogen services may require the implementation of leak detecting/monitoring devices or sensors. Currently, there is no available odorant for hydrogen, and this becomes an area for further investigation.

It is likely that the maintenance cost for distribution system under hydrogen service will be increased due to the need for increasing inspection frequency and leak detection.

Task 4.6 - End Use-Hydrogen Separation

One of the challenge for using the existing natural gas network to distribute hydrogen is to separate hydrogen from the mixtures at the end use. Currently, pressure swing adsorption (PSA) is the mature technology used in refineries to produce high purity hydrogen. However, this technology requires large scale units which work best with high levels (normally larger than 50%) hydrogen in the mixtures. A smaller scale separation is desired to extract hydrogen from the hydrogen-natural gas mixtures which contains lower levels of hydrogen (mostly likely below 25%) under typical natural gas pipeline conditions. In addition, the purity of the hydrogen extracted from hydrogen-natural gas mixtures has to match the requirements in the specific application.

Hydrogen-selective membranes are commonly seen as the promising technology for the recovery of hydrogen from the feed stream with a low (<30%) hydrogen concentration. The NaturalHy project has focused on developing advanced hydrogen selective membranes for the separation of hydrogen from natural gas/hydrogen mixtures in "Work Package 5 (Task 5.3-5.7)".

This work was led by *University of Oxford*, and with participation by the *Norwegian University of Science and Technology (NTNU)* and *Compagnie Europeenne des Technologies del'Hydrogene (CETE).* The objects of this work include:

- Developing membranes to recover hydrogen from hydrogen/natural gas mixtures;
- Investigating the physical properties of the remaining stream and methods to re-establish the gas quality; and
- Performing a cost analysis of the membrane system vs. the commercial PSA systems.

In general, membranes are classified into two major types: dense membranes (e.g., metallic membranes) and microporous membranes (e.g., carbon molecular sieves). Both types of membranes have been investigated in NaturalHy project.

Development of High Selectivity Palladium-Based Membranes

Palladium membranes are the most used technology to recover hydrogen from gas streams with a low hydrogen concentration. In order for these membranes to function efficiently, the entire gas feed stream must be heated to temperatures higher than 350ºC. Currently, the commercially available palladium membranes are conventionally "thick" tubular membranes and are very expensive. The object of NaturalHy project is to develop ultra-thin palladium-alloy membranes supported on porous ceramic substrates to achieve coherent, defect-free membranes. One of the processes that can produce a three micrometer thick membrane is electroless plating of palladium onto a porous alumina substrate. The other technology is to deposit thin palladium/silver alloy membranes onto smooth uniform substrates. These membranes operate at 300ºC with good hydrogen flux, high recovery and 100% selectivity for hydrogen. The results from this investigation indicate:

- Electroless plating of palladium onto a porous alumina substrate can produce the membranes that meet or exceed 2010 US DOE targets for membrane hydrogen flux at 400ºC.
- Depositing thin palladium alloyed with silver and copper is not successful because the manufacturing defects in the ceramic support give rise to pin-hole leaks and mechanical problems.
- Magnetron vacuum sputtering is a potential alternative technique, but the challenge is to use perfectly smooth surfaces such as silicon wafers and polymers as the forming surface and then remove of the deposited membrane.

Development of Carbon-Based Membranes

Though palladium membranes are promising for recovery of hydrogen from feed streams with a low (<30%) hydrogen, these membranes have to be heated to temperatures higher than 350ºC in order to function efficiently. This temperature requirement increases the cost and energy input. Carbon-based membranes are able to separate hydrogen at lower or ambient temperature, however the efficiency with respect to flux and selectivity vary depending on temperature and pressure.

Two types of new carbon-based membrane materials suitable for the recovery of hydrogen from hydrogen/natural gas mixtures have been investigated in this project.

Carbon Molecular Sieves (CMS)

Carbon molecular sieves are formed by carbonization (pyrolysis) of a polymeric precursor at temperatures between 400 and 800ºC. This is usually preformed under vacuum or an inert gas such as nitrogen using cellulose derived from plentiful wood pulp which is cheap and abundant.

Periodical regeneration of carbon membranes can recover hydrogen permeation properties and is beneficial to improve long-term performance of the membranes. A regeneration technique that can be applied on-stream while the membrane is in operation has been developed.

The results from this investigation indicate that the CMS sieves can effectively recover hydrogen from the pipeline networks that transport hydrogen/natural gas blends. It provides a greater permeability and better selectivity (up to 98%) than conventional polymer membranes and operates at temperatures between 30ºC and 90ºC. Further development is ongoing to develop larger scale membrane modules and perform lifetime testing.

A Mixed Matrix (MM) Material

The development of the MM-membrane did not provide successful results and the development of this membrane was terminated in this project.

Development of Hybrid Membrane Separation System

It is most likely that the beneficial characteristics from metallic and carbon based membranes can be combined by producing a hybrid membranes to provide an increase in efficiency and flexibility together with lower cost. A carbon based membrane can be used as at the first stage to achieve higher hydrogen content (up to 98%) at almost room temperature and then followed by a palladium membrane for final purification of hydrogen. A hybrid separation system is proposed for further development, see Figure 11.

Summary on Hydrogen Separation Technologies

Electroless plating of palladium and carbon molecular sieves are the two technologies that can be further developed for hydrogen separation from hydrogen/natural gas blends transported by a natural gas pipeline network. A Palladium membrane can provide high purity hydrogen, but is expensive and has to operate at 300ºC. A CMS membrane is low cost and can operate at temperature between 30ºC and 90ºC, but the maximum hydrogen content obtained using a CMS membrane is 98%.

The most promising technique in the future would be a hybrid separation system. This could be constructed by combining palladium and CMS membrane technology. The cost analysis performed in this study indicates that the hybrid system including ancillaries is potentially cheaper than separation by PSA. Small scale PSA systems are under development, but it is problematic for PSA to separate hydrogen from streams with hydrogen content less than 40%, an additional PSA or a CMS membrane can be used in the first stage to concentrate the hydrogen level in the feed.

The analysis performed in this study also shows that the downstream gas quality will not be adversely affected since the Wobbe index and heating value will not be outside the statutory requirements.

Task 4.7 – Impacts (Environmental and Macroeconomic Benefits)

The impact from adding hydrogen into natural gas systems was assessed in "NaturalHy Project Work Package 1". The review of this study by GTI is included in Task 4.1, and below is a summary of the major impacts on environmental and macroeconomic benefits from adding hydrogen in natural gas:

1) Significant reduction of greenhouse gas emissions if hydrogen is produced from biomass, wind power, and nuclear power.
2) Some advantage on greenhouse gas emissions with hydrogen production from fossil fuels with CCS, but no benefits for decreasing primary energy demand or energy resource depletion.
3) Potential benefits of selective extraction of hydrogen (this depend on the performance of the separation technology and the subsequent use of the hydrogen and the residual gas).
4) Potential benefits on improving air quality by reducing sulfur dioxide, oxides of nitrogen and particulate emissions if hydrogen is used in transportation and displaces conventional diesel fuel.
5) Potential benefit on "greening" natural gas if the hydrogen/natural gas mixture is used directly in existing appliances for heat production and electricity generation.

Conclusions

GTI reviewed the studies performed by the *NaturalHy* Project on using natural gas network for hydrogen services. The scope of this review covers the seven aspects that have been investigated in NaturalHy including “Life Cycle Assessment”, “Safety”, “Leakage Assessment”, “Durability”, “Integrity”, “End Use” and “Environmental and Macroeconomic Impacts”. In addition to the reports and publications from the NaturalHy Project, GTI included the report published by the Greenhouse Gas R&D Programme sponsored by International Energy Agency (IEA) and other related publications in this review to develop a comprehensive understanding of the major benefits and limitation of using the existing natural gas network for transporting hydrogen.

The aim of this review was to provide a scientific basis and engineering assessment of the potential impact from hydrogen on the US natural gas distribution infrastructure when hydrogen is blended into the natural gas network. The conclusions of this review not only include the summary of the findings and conclusions from the research investigations, but also include GTI’s comments made for US distribution system by integrating the research findings with the particular conditions for the distribution infrastructure. The main conclusions of the seven tasks are summarized below:

1) Task 4.1 Life Cycle Assessment

The life cycle assessment in the NaturalHy project supports the beneficial effects on the environment by adding hydrogen to natural gas, which include the reduction of greenhouse emission and improving the air quality. However, there is not enough information in this study to support that there is a benefit from the standpoint of economy and employment. No concluding remarks were made in this aspect.

2) Task 4.2 Safety

The research findings indicate that the probability of ignition and the severity of explosion of pipeline systems are increased by adding hydrogen. The risk increased by blending hydrogen into natural gas pipeline systems is related to the hydrogen levels in the gas mixtures, and the increase is slight for hydrogen addition up to 20%.

GTI performed a quantitative risk assessment on US natural gas distribution systems for carrying hydrogen containing natural gas. Compared to the current situation with natural gas, the risks in natural gas distribution systems are increased by adding hydrogen into the system. The assessment results indicate that the risks in distribution mains and service lines are different, especially at higher levels of hydrogen in the system.

If less than 20% hydrogen is introduced into distribution system, the overall risk is not significant for both distribution mains and service lines, but the service lines are more impacted than mains because they are mostly in confined spaces.

If the hydrogen level in natural gas increases beyond 20%, the overall risk in service lines can significantly increase and the potential hazards can become severe, while the overall risk in distribution mains still can be moderate at up to 50% hydrogen.

For hydrogen level above 50% in natural gas, the risks in both distribution mains and service lines significantly increase compared to the situation with natural gas, and the overall risk in distribution system becomes severe.

3) Task 4.3 Leakage

Hydrogen is more mobile than methane in many polymer materials including the plastic pipes and elastomeric seals used in natural gas distribution system. The permeation coefficient of hydrogen is higher through most of the elastomeric sealing materials vs. plastic pipe materials. But the plastic pipes have much larger surface area compared to the seals. Therefore, the leaks through pipe walls accounts for the major gas loss in the systems.

A calculation based on the literature data for the permeation coefficient of hydrogen and methane in the polyethylene indicates that the majority of the gas loss is from the pipes (pipe wall) in distribution mains which operate at 60 psig (4.1 bar) or higher. The gas loss from the total of 414,830 miles of polyethylene pipes with the sizes less than 2″ in the entire distribution mains is about 40 million cubic feet per year if 20% hydrogen is added into natural gas pipeline system. Though this amount of gas loss is almost double the total gas loss when the systems deliver only natural gas, it is still considered insignificant from the economic point of view. Furthermore, this calculation may over estimate the gas loss because the permeation coefficient in the literature is considered larger than the experimental measurements using pipe test under actual operating pressures, especially at lower pressure. Further investigation may be necessary for accurately quantifying the gas loss.

The amount of gas loss from service lines is negligible from the economy point of view, but the gas loss into a confined space may increase hydrogen concentration to levels that may become a threat from the safety standpoint. In addition, the gas leak from the elastomeric seals at the joints in service lines may increase the risk in confined spaces.

Further investigation on the pipe and seal materials can provide a basis to accurately estimate the gas leakage through pipes and seals in order to determine if the leakage in a confined space, over time, will present a safety risk and if it is required to implement a leak detection/monitoring device.

4) Task 4.4 Durability

The metallic pipes in US distribution systems are primarily made of low strength steel, typically API 5L A, B, X42 and X46 in distribution mains. They are not the type of steels that are susceptible to hydrogen induced brittle cracking. In addition, at the stress level generated in natural gas distribution system, hydrogen induced failures are not major integrity concerns for the steel pipes in distribution system.

For the other metallic pipes including ductile iron, cast and wrought iron, and copper pipes, there is no concern of hydrogen damage under general operating conditions in natural gas distribution systems.

There is no major concern on the hydrogen aging effect on PE or PVC pipe materials. Most of the elastomeric materials used in distribution system are also compatible with hydrogen.

The deviation of a gas meter with hydrogen/methane mixtures varies with the manufacture's detail of the meter design. Nonetheless, the deviation is acceptable based on the requirement for recalibration (<4%) when they are measuring a gas mixture containing less than 50% hydrogen. The meters may not need to be tuned under the potential hydrogen levels (<50%) in natural gas pipeline that are transporting hydrogen/natural gas blends.

One of the remaining gaps needs to be addressed for the durability issues is the potential contaminants in hydrogen gas that may be introduced into the network.

5) Task 4.5 Integrity

In the NaturalHy Project and some other research programs, the focus on the integrity issues has been on the transmission pipelines because of the concerns of high operating pressures (up to 2000 psig (138 bar)) and the pipeline steels that are subject to hydrogen induced cracking. It is concluded in the NaturalHy Project that hydrogen can be transported by the existing natural gas pipeline with small adaptations of the current Integrity Management Program. The necessary adaptations depend on the hydrogen concentration and the operating conditions of the individual pipeline. The necessary modifications are not significant with up to 50% hydrogen addition, but a detailed investigation for every case is mandatory and the upper limitation on hydrogen concentration may be reduced.

It should be noted that the natural gas distribution systems are very different from transmission pipelines, and it is not possible to simply apply the integrity program for transmission pipelines to distribution systems. One of the important differences of distribution systems from transmission pipeline is the locations of these systems. The level of hydrogen that is acceptable for transmission pipeline may need to be reassessed for distribution systems in terms of the frequency and severity of fire or explosion in a highly populated area.

In addition, the hazards arising from gas leakage in a distribution system may be more severe than in transmission pipelines, especially in a confined service area. The integrity management for distribution systems under hydrogen services may require the implementation of leak detecting or a monitoring device or sensor. Currently, there is no available odorant for hydrogen, and this becomes an area for further investigation.

It is likely that the maintenance cost for distribution systems under hydrogen service will be increased due to the need for increasing inspection frequency and implementing leak detection.

6) Task 4.6 End Use Hydrogen Separation

Electroless plating of palladium membranes and carbon molecular sieves are the two technologies that can be further developed for hydrogen separation from hydrogen/natural gas blends transported by a natural gas pipeline. Palladium membranes can provide high purity hydrogen, but they are expensive and have to operate at 300ºC. CMS membranes are low cost and can operate at temperature between 30ºC and 90ºC, but the maximum hydrogen concentration obtained using CMS membranes is 98%.

The most promising technique is to making a hybrid separation system by combining palladium and CMS membranes. The cost analysis performed in this study indicates that the hybrid system, including ancillaries, is potentially cheaper than separation by PSA.

Small scale PSA systems are also under developments that include an additional PSA or a CMS membrane in the first stage to concentrate the hydrogen level in the feed.

Downstream gas quality will not be adversely affected since the Wobbe index and heating value will not be outside the statutory requirements.

7) Task 4.7 Environmental Impact

Adding hydrogen in natural gas can significantly reduce greenhouse gas emissions if hydrogen is produced from biomass, wind power and or nuclear power. There are also some advantages related to greenhouse gas emissions with hydrogen production from fossil fuels with CCS, but hydrogen from this source has no benefits for decreasing primary energy demand or energy resource depletion.

Adding hydrogen in natural gas also has the potential benefits of improving air quality by reducing sulfur dioxide, oxides of nitrogen and particulate emissions if hydrogen is used in transportation and displaces conventional diesel fuels. It could also green natural gas if the hydrogen/natural gas mixture is used directly in existing appliances for heat production and electricity generation.

Table 8. Effect of Hydrogen Addition in Natural Gas on Gas Properties and Hazards*

Properties/Phenomena	Effect of Hydrogen Addition	Main Hazardous Hazards					
		Rupture	Explosion	Fire	Burns	Suffocation	Poisoning
Density	Lower					x	
Viscosity	Lower					x	
Velocity of Dispersion	About the same		x	x		x	
Hydrogen Component	Higher	x					x
Household Gas Pipe Leak Rate	Higher		x	+		x	
Lower flammability limit	About the same level		x	x			
Higher Flammability Limit	Higher		+				
Flammability Range	Wider		x				
Detonability Range	Wider		x				
Explosive Energy/Volume	Lower		x	x			
Explosive Energy/Mass	Higher		x	x			
Minimum Energy for Ignition	Lower		x	x			
Auto Ignition Temperature	Lower		x	+			
Uncontrolled Ignition	Easier		x	x			
Severity of Explosive Damage	Lower		x				
Explosion Risk in Confined Room	Higher		+				
Explosion Risk in unconfined Room	Lower		-				

Note:

*: Table from IEA report "Reduction of CO_2 Emissions by Adding Hydrogen to Natural Gas" [11]

×: hazard exists but unchanged by presence of hydrogen up to 15%

+: hazard increases by presence of hydrogen

-: hazard reduces by presence of hydrogen

Table 9. Ranking of the Hazards in Natural Gas Distribution Systems*

Significance of Hazard	Ranking Assigned
Severe	50
Moderate to Severe	40
Moderate	30
Minor to Moderate	20
Minor	10
None	0

Note:
*: The severity of the hazards is ranked with the numerical system generally used for risk assessment.

Table 10. The Risk Factor [a] for Pipe Material Categories and the Overall Risk Factor [b] at Each Failure Modes in Distribution Mains

Failure Mode	Pipe Material Categories and Their Percentage in Distribution Mains					
	Steel	Cast Iron	PE	Other Plastics	Other	Overall Risk Factor
	46.55%	3.14%	48.12%	2.06%	0.13%	
Corrosion	50	40	0	0	10	**24.54**
Material Defect	30	10	40	30	10	**34.16**
Natural Force	30	50	20	20	10	**25.58**
Excavation	50	50	50	50	50	**50.00**
Other Outside Force	10	10	10	10	10	**10.00**
Equipment	30	30	30	30	30	**30.00**
Operation	30	30	30	30	30	**30.00**
Other	10	10	10	10	10	**10.00**
Total	240	230	190	180	160	**214**

Note:

a: The hazard severity for each pipe material category was assessed at each failure mode by GTI based on the engineering experiences and the reported incident data in natural gas distribution system from 1990 to 2002 in AGF report "Safety Performance and Integrity of the Natural Gas Distribution Infrastructure" [27]. The risk factor for each material category in this table is assigned with the numerical definition of the hazard severity defined in Table 9.

b: The overall risk factor for each failure mode is calculated by the sum of the risk factor of each material category times the percentage of this material in distribution mains, see Equation (2).

Table 11. The Risk Factor [a] for Pipe Material Categories and the Overall Risk Factor [b] at Each Failure Modes in Service Lines

Failure Type	Pipe Material Categories and Their Percentage in Service Lines					
	Steel	Cast Iron	PE	Other Plastics	Other	Overall Risk Factor
	32.68%	0.17%	63.05%	0.42%	3.69%	
Corrosion	50	40	0	0	10	**16.77**
Material Defect	30	10	40	30	10	**35.53**
Natural Force	30	50	20	20	10	**22.95**
Excavation	50	50	50	50	50	**50.00**
Other Outside Force	10	10	10	10	10	**10.00**
Equipment	30	30	30	30	30	**30.00**
Operation	30	30	30	30	30	**30.00**
Other	10	10	10	10	10	**10.00**
Total	240	230	190	180	160	**205**

Note:

a: The hazard severity for each pipe material category was assessed at each failure mode by GTI based on the engineering experiences and the reported incident data in natural gas distribution system from 1990 to 2002 in AGF report "Safety Performance and Integrity of the Natural Gas Distribution Infrastructure" [27]. The risk factor for each material category in this table is assigned with the numerical definition of the hazard severity defined in Table 9.

b: The overall risk factor for each failure mode is calculated by the sum of the risk factor of each material category times the percentage of this material in service lines, see Equation (2).

Table 12. Risk Assessment for Distribution Mains at Three Hydrogen Levels

Failure Mode	Probability [a] (%)	Risk Factor				Overall Risk			
		NG [b]	< 20% H_2 [c]	20 to 50% H_2 [c]	>50% H_2 [c]	NG [b]	<20% H_2 [c]	20 to 50% H_2 [c]	>50% H_2 [c]
Corrosion	36.42	24.54	29.54	29.54	44.54	8.94	10.76	10.76	16.22
Material Defect	6.98	34.16	39.16	39.16	54.16	2.38	2.73	2.73	3.78
Natural Force	8.47	25.58	35.58	35.58	45.58	2.17	3.01	3.01	3.86
Excavation	15.39	50.00	60.00	70.00	70.00	7.69	9.23	10.77	10.77
Other Outside Force	1.86	10.00	15.00	15.00	30.00	0.19	0.28	0.28	0.56
Equipment	6.75	30.00	35.00	35.00	50.00	2.02	2.36	2.36	3.37
Operation	2.53	30.00	35.00	35.00	50.00	0.76	0.89	0.89	1.27
Other	21.60	10.00	15.00	15.00	30.00	2.16	3.24	3.24	6.48
Total	100.00	214	264	274	374	26	33	34	46

Note: The calculation of "Risk Factor" was performed by GTI

a: The probability of each failure mode is the statistical data of the leak incidents in distribution mains from DOT 2007 annual report [25], see Table 5.

b: The baseline risk factor for each failure mode in natural gas distribution mains, see Table 10.

c: The risk was assessed by GTI for each failure mode at different hydrogen levels in natural gas distribution mains compared with the baseline risk with natural gas. The risk factor at each level of hydrogen is calculated by adding the baseline risk factor with the increase of risk factor (ΔRF) at this hydrogen level, which is defined as below:

ΔRF=5: minor increase

ΔRF=10: minor to moderate increase

ΔRF=20: moderate to significant increase

Table 13. Risk Assessment for Distribution Services at Three Hydrogen Levels

Failure Mode	Probability [a] (%)	Risk Factor				Overall Risk			
		NG [b]	< 20% H_2 [c]	20 to 50% H_2 [c]	>50% H_2 [c]	NG [b]	< 20% H_2 [c]	20 to 50% H_2 [c]	>50% H_2 [c]
Corrosion	21.64	16.77	26.77	26.77	36.77	6.11	9.75	9.75	13.39
Material Defect	11.16	35.53	45.53	45.53	55.53	2.48	3.18	3.18	3.88
Natural Force	3.40	22.95	42.95	42.95	42.95	1.94	3.64	3.64	3.64
Excavation	24.90	50.00	70.00	90.00	100.00	7.69	10.77	13.85	15.39
Other Outside Force	3.95	10.00	20.00	20.00	30.00	0.19	0.37	0.37	0.56
Equipment	12.71	30.00	40.00	40.00	50.00	2.02	2.70	2.70	3.37
Operation	2.57	30.00	40.00	40.00	50.00	0.76	1.01	1.01	1.27
Other	19.66	10.00	20.00	20.00	30.00	2.16	4.32	4.32	6.48
Total	100.00	205	305	325	395	23	36	39	48

Note: The calculation of "Risk Factor" was performed by GTI

a: The probability of each failure mode is the statistical data of the leak incidents in service lines from DOT 2007 annual report [25], see Table 5

b: The baseline risk factor for each failure mode in natural gas service lines, see Table 11.

c: the risk was assessed by GTI for each failure mode at different hydrogen levels in natural gas service lines compared with the baseline risk with natural gas. The risk factor at each level of hydrogen is calculated by adding the baseline risk factor with the increase of risk factor (ΔRF) at this hydrogen level, which is defined as below:

ΔRF=5: minor increase

ΔRF=10: minor to moderate increase

ΔRF=20: moderate to significant increase

ΔRF=40: significant increase

ΔRF=50: significant increase at higher degree

Table 14. The Permeation Coefficient and the Calculated Gas Loss from a 32 mm (1.26″) PE80 Pipe Under the Pressures of (58 psig (4 bar), 116 psig (8 bar) and 174 psig (12 bar))*

Gas	Pressure (psig)	Time-Lag (day)		Permeation Coefficient ($\times 10^{-3}$ ft^3-mil/ft^2/day/psig)		Gas Loss (ft^3/mile/year)		
		CH_4	H_2	CH_4	H_2	CH_4	H_2	Total
Pure CH_4	58	6.46	NA	0.18	0	54.07	NA	54.07
90% CH_4 + 10% H_2	58	4.31	0	0.09	0.34	25.90	10.59	36.49
	116	6.39	0	0.12	0.50	67.03	31.04	98.07
	174	5.69	0	0.12	0.52	101.91	48.54	150.45

Note:

*: The original data in this table are from the experimental test results in the paper of "Evaluation of the Permeability to CH_4 and H_2 of PE Currently Used in Gas Distribution Networks" [18], and are converted to the English unit.

Table 15. Permeation Coefficient (10^{-3}×ft^3-mil/ft/day/psig) of Hydrogen Gas for Plastic Pipe Materials at 20°C*

Material	Experiment	Literature
PE80	1.50	1.99
MDPE	1.63	1.10
PE100	1.46	0.00
PEXa	3.37	0.00
PVC	0.91	0.69
Ductile PVC	0.97	0.00

Note:

*: The original data in this table are from IEA report "Reduction of CO_2 Emissions by Adding Hydrogen to Natural Gas" [11], and they are converted to the English unit.

Table 16. Permeation Coefficient ($10^{-3}\times ft^3$-mil/ft/day/psig) of Hydrogen in Plastic Pipe and Elastomeric Materials

Material	Hydrogen	Methane
MDPE (PE2708) [a]	1.43	0.29
HDPE (PE3608) [a]	1.09	0.16
HDPE (PE4710) [a]	1.09	0.16
PVC [a]	0.95	NA
Natural Rubber [b]	28.39	NA
Butyl Rubber [b]	4.27	NA
Buna S (SBR) [b]	23.02	NA
Neoprene (CR) [b]	7.67	NA
Buna N (NBR) [b]	9.12	NA

Note:

a: Data are from "AGA Handbook: Plastic Pipe Manual for Gas Service" [29]

b: Data are from EIA report "Hydrogen Transportation Pipeline" [13]

Table 17. The Calculated Gas Loss Rate (ft^3/mile/year) Based on Literature Data for HDPE Pipes at the Operating Pressures of 60 psig, 3 psig and 0.25 psig*

Hydrogen Content	At 60 psig			At 3 psig			At 0.25 psig		
	H_2	CH_4	Total	H_2	CH_4	Total	H_2	CH_4	Total
0%	0.0	49.4	49.4	0.0	2.5	2.5	0.0	0.2	0.2
10%	32.9	44.5	77.4	1.6	2.2	3.9	0.1	0.2	0.3
20%	65.9	39.5	105.4	3.3	2.0	5.3	0.3	0.2	0.4
50%	164.7	24.7	189.4	8.2	1.2	9.5	0.7	0.1	0.8
100%	329.3	0.0	329.3	16.5	0.0	16.5	1.4	0.0	1.4

Note: The calculation was performed by GTI.

*: The data in this table are calculated by Equation (2) using the permeation coefficient data in Table 16 from "AGA Handbook: Plastic Pipe Manual for Gas Service" [29].

Table 18. Classification of Hydrogen Degradation of Metals*

Type of Damage	Hydrogen Embrittlement			Hydrogen Attack	Blistering
	Environment Embrittlement	Stress Cracking	Loss in Tensile Ductility		
Typical Materials	Steels, nickel-base alloys, metastable stainless steel, titanium alloys	Carbon and low-alloy steels	Steels, nickel-base alloys, Be-Cu bronze, aluminum alloys	Carbon and low-alloy steels	Steels, copper, aluminum
Hydrogen Source	Gaseous H_2	Thermal processing, electrolysis, corrosion	Gaseous H2, internal hydrogen from electrochemical charging	Gaseous	Hydrogen sulfide corrosion, electrolytic charging, gaseous
Typical Conditions	10^{-10} to 10^{4} gas pressure	0.1 to 10 ppm total hydrogen content	0.1 to 10 ppm H_2 of gas pressure exposure	Up to 15 ksi	Hydrogen activity equivalent to 3-15 ksi
	Observed at -150 to 1290°F Most severe at 70°F	Observed at -150 to 210°F Most severe near 70°F	Observed at -150 to 1290°F	400-1100°F	30-300°F
	More severe at low strain rate	More severe at low strain rate	Strain rate important		

Type of Damage	Shatter Cracks, Flakes, Fisheyes	Micro-Perforation	Degradation in Flow Properties	Metal Hydride Formation
Typical Materials	Steels (forgings and castings)	Steels (compressors)	Iron, steels, nickel-base alloys	Vanadium, Niobium, Tantalum, Titanium, Zirconium, Uranium
Hydrogen Source	Water vapor reacting with molten steel	Gaseous hydrogen	Gaseous or internal hydrogen	Internal hydrogen from melt; corrosion, electrolytic charging, welding
Typical Conditions	Precipitation of dissolved ingot	30-125 ksi	1-10 ppm hydrogen content at 70°F for iron or steels	15-15,000 psig gas pressure
	Cooling	70-210°F	Up to 15 ksi gaseous hydrogen at T > 0.5 melting point for various metals	Hydrogen activity must exceed solubility limit near 70°F

Note:

*: Table from ASM Handbook Vol. 13A (Hydrogen Damage) [28]

Table 19. Hydrogen Compatibility of the Plastics and Elastomers Used in Natural Gas Pipeline*

Polymers	Compatibility
Polyethylene	Good
Polyvinyl Chloride	Good
Natural Rubber	Fair
Butyl Rubber	Good
Silicone Rubber	Fair
Neoprene (CR)	Good
Buna S (SBR)	Good
Viton	Good
Buna N (NBR)	Good

Note:

*: Data from EIA report "Hydrogen Transportation Pipelines" [13] and PPI report "Chemical Resistance of Thermoplastics Piping Materials" [31]

Table 20. Operator Perceptions on Threat Significance*

Threat Priority	Threat	% of Respondent
1	Outside Force/Weather Cast Iron Pipe	90
2	Excavation/Mechanical Damage	87
3	External Corrosion Bare Steel Pipe	86
4	External Corrosion (Graphitization) Cast Iron Pipe	71
5	External Corrosion Coated & Wrapped Pipe	69
6	Construction-Related Defects Plastic Pipe	57
7	Outside Force/Weather Steel Pipe	49
8	Construction-Related Defects Steel Pipe	48
9	Incorrect Operations & Operator Error	35
10	Equipment Malfunction	35
11	Manufacture-Related Defects Plastic Pipe	30
12	Outside Force/Weather Plastic Pipe	26
13	Internal Corrosion	22
14	Manufacture-Related Defects Plastic Pipe	22

Note:

*: Table from AGF report "Safety Performance and Integrity of the Natural Gas Distribution Infrastructure" [27]. The identified threats in natural gas distribution systems are prioritized in this table according to the response from the survey performed by AGF with the utility operators. The higher priority is given to the threat accepted by more respondents.

END OF TABLE

Environmental benefits and safety

Cleaner fuel for cleaner air

Converting your fleets and vehicles to natural gas not only helps the province meet its greenhouse gas emissions reduction goals, but also helps improve air quality[1] in the communities you serve.

- Natural gas burns cleaner than gasoline or diesel, which can result in less pollution and greenhouse gases.[2]
- Carbon dioxide (CO2) emissions, the principal greenhouse gas that contributes to global warming, are reduced by 15 to 25 per cent.[2,3]
- Natural gas vehicles emit virtually no particulate matter, the harmful microscopic component of air pollution that penetrates deeply into the lungs.[4]

With renewable natural gas (or biomethane), you can reduce the environmental impact of your operations even further. It costs a little extra, but can help to significantly reduce the greenhouse gas emissions created by your fleet. Learn more about renewable natural gas.

The safe choice[5]

With many built-in safety features, natural gas vehicles have a track record of safe operation.

A sealed system and thorough testing for extreme temperature and stress conditions ensures on-vehicle fuel storage systems do not leak. But in the event of a fuel leak, these systems are designed to automatically shut down. A sealed system is also created between the fuel dispenser and vehicle during refuelling. Fuel will not flow unless the fuel dispenser is properly connected to the vehicle, which helps reduce the risk of fuel leaks.

Other safety features

Fuelling site contamination is virtually eliminated with above ground fuel storage tanks for both compressed natural gas (CNG) and liquefied natural gas (LNG) stations. If there is a leak, the fuel will rise into the atmosphere so there is no risk to soil or groundwater. In the event of an LNG leak, the fuel could pool, so containment structures are used around LNG tanks to contain any leaked fuel. The LNG will then change from a liquid to a gas and vent into the atmosphere. Monitoring systems are also used to monitor fuelling station conditions 24 hours a day.

Local businesses capture emissions and save energy through FortisBC pilot program

November 20, 2017

New carbon capture technology introduced for commercial heating systems

SURREY, BC – As part of FortisBC's commitment to providing innovative energy solutions to its customers, the company today announced a new pilot program for businesses. The program uses first in the world carbon capture technology to decrease greenhouse gas (GHG) emissions and save energy.

The technology, produced by CleanO2 Carbon Capture Technologies (CleanO2), reduces the energy usage of commercial boilers that use natural gas and captures and converts carbon dioxide (CO2) into a usable byproduct. This results in cost savings for the commercial business as well as a reduction in GHG emissions.

"FortisBC embraces progressive and sustainable technologies for the benefit of all of our customers. By developing this pilot program, businesses have access to new technology which aligns with broad policy goals for carbon reduction," said Jason Wolfe, director of energy solutions at FortisBC. "New technologies are becoming increasingly important in the move to be more efficient in our energy usage, reducing emissions, all while ensuring customers have access to affordable energy choices such as natural gas."

The carbon capture unit will have an impact on GHG emissions for commercial customers. Organizations that have signed on to the six-month pilot program include Cadillac Fairview Richmond Centre and Blue Horizon Hotel. Both of these businesses embrace creating a more sustainably conscious future for their customers.

"Technologies like carbon capture are the way of the future in terms of reducing emissions and saving energy," said Jaeson Cardiff, CEO of CleanO2. "Our units decrease energy consumption by up to 10 per cent depending upon the boiler size. In addition, our units remove CO2 from flue gas thereby reducing GHG emissions."

The carbon capture unit captures carbon from flue gas to turn it into sodium carbonate, also known as soda ash, a versatile mineral used to make pharmaceuticals, manufacture glass as well as soap. According to CleanO2, the unit can create up to 6.7 tons of soda ash per year and operate for up to 25 years.

The pilot program was developed to assist in advancing the technologies to commercialization and acceptance in the market.

For more information on the pilot program and carbon capture technology, contact: energysolutions@fortisbc.com.

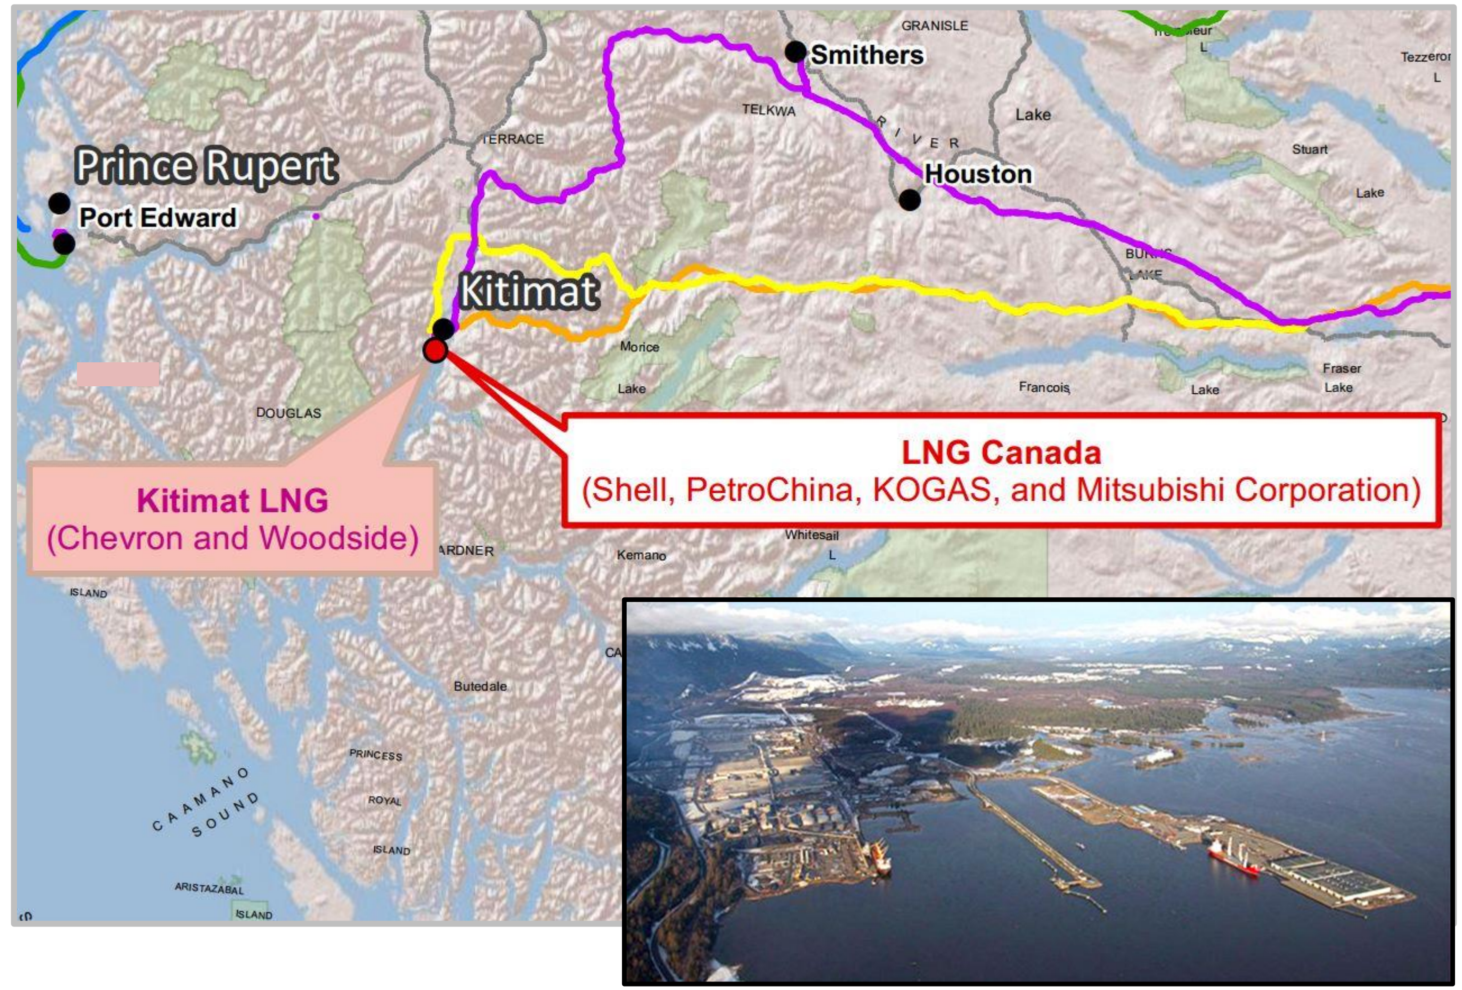
FortisBC Energy Inc. is a regulated utility focused on providing safe and reliable energy, including natural gas, propane and thermal energy solutions. FortisBC Energy Inc. employs almost 1,800 British Columbians and serves approximately 994,000 customers in 125 B.C.

communities. FortisBC Energy Inc. is indirectly, wholly owned by Fortis Inc., the largest investor-owned distribution utility in Canada. FortisBC Energy Inc. owns and operates approximately 48,700 kilometres of natural gas transmission and distribution pipelines. FortisBC is a subsidiary of Fortis Inc., a leader in the North American regulated electric and gas utility industry. For further information visit www.fortisinc.com.

LNG Canada Export Terminal

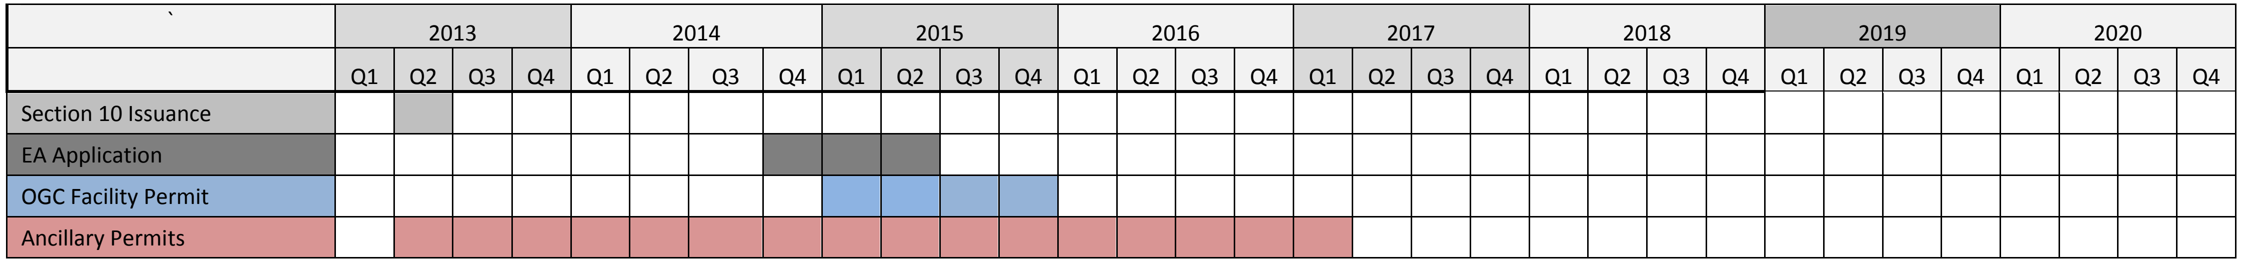
Proponent(s): LNG Canada
Related Infrastructure: Coastal GasLink Pipeline (TransCanada)

LNG Canada, a joint venture company comprised of Shell Canada Energy (an affiliate of Royal Dutch Shell plc – 50%), affiliates of PetroChina Company Ltd. (20%), Korea Gas Corporation (KOGAS) (15%), and Mitsubishi Corporation (15%), is proposing to build an LNG export terminal in Kitimat. The facility will consist of LNG liquefaction and storage facilities, marine terminal facilities, two cryogenic LNG transfer pipelines and supporting facilities and infrastructure. Initially two LNG processing units (called "trains") with capacity to produce 6.5 MTPA each of LNG will be built, with an option to expand the facility to four trains in the future, for a total estimated production capacity of 26 MTPA.



OGC PROJECT OVERVIEW	
Number of authorizations anticipated	15
Number of applications approved to date	14
Number of authorizations in review	1
Number of First Nations involved	1

Gantt Chart



Milestone Dates

NEB	**2016 (Q2)**	Export Licence approved (40 years)
	Current Status Project currently delayed.	
EAO	**2014 (Q4)**	EA Application Start Date
	June 17, 2015	EA Application Completion Date
	LNG Facility Permit issued Dec 22, 2015	
BCOGC	**2015 (Q1)**	BCOGC Application Start Date
	Dec 22, 2015	BCOGC Application Approval Date
	FID decision delayed due to 'global industry challenges'	
Project Start *	**TBD**	Expected Construction Start *(requires FID)*
	TBD	Expected Leave-to-Open Date

Additional notes

- Located on private land, incorporating the former Methanex industrial site.
- On Nov 4, 2014, LNG Canada and BC Hydro signed a power agreement that would see the proponent use electricity for a portion of the power needed to run the facility. The remaining power requirements would be natural –gas generated.
- Proposed LNG infrastructure in vicinity: Kitimat LNG Terminal (Chevron/Woodside)

**Project Start dates are contingent on all necessary approvals being met and are subject to change.*

Appendix E

POTENTIAL GHG EMISSIONS REDUCTION PATHWAYS

APPENDIX E: POTENTIAL GHG EMISSIONS REDUCTION PATHWAYS

1.1 Context

FEI prepared this appendix within the context of a 20-year vision by broadening assumptions beyond the analysis presented in the body of the 2017 LTGRP in order to show the potential contribution that emerging initiatives and technologies could make to long term GHG emissions abatement. Stakeholders have supported including such an appendix in order to better illustrate that pathways to a lower carbon future do exist that include, and may be better enabled by, the use of natural gas and natural gas infrastructure. Aspects of this examination of emerging initiatives and technologies remain speculative at this time. The likelihood of any particular initiative or technology in this appendix developing to the full extent discussed in the appendix remains unknown. FEI recognizes that limited BC-specific data may exist about emerging initiatives and technologies. As a result, this appendix is based on broad and, where applicable, public assumptions. For those initiatives and technologies about which information is available, FEI has utilized such information in its examination. For initiatives and technologies that are less well documented, FEI presents high level discussions only and plans to refine these in future LTGRP submissions when the required input data improves.

1.2 Inputs

1.2.1 ANNUAL DEMAND IMPACT

This appendix uses FEI's annual demand forecast from Section 3 of the 2017 LTGRP. The examination in this appendix uses the 2015 base year as its starting point. In this annual demand forecast, increases in natural gas annual demand result in GHG emissions increases (represented as negative reductions). Decreases in annual demand reduce GHG emissions. FEI's examination in this appendix presents results for the Reference Case and the Global Growth & Carbon Step Change scenario. As outlined in Section 8 of the 2017 LTGRP, the alternate future scenarios of the annual demand forecast include varying levels of natural gas displacement by low carbon thermal energy and electricity. The examination in this appendix does not change these scenario-specific displacement levels.

1.2.2 C&EM IMPACT

This appendix maintains the annual demand energy savings results from Section 4 of the Application. C&EM GHG emissions impacts are calculated via the same method as in Section 8 of the Application.

As informed by the BC CPR, the 2017 LTGRP C&EM analysis method used in Section 4 of the Application already pursues all cost effective demand-side measures. Drawing on the BC CPR analysis, Section 4 of the Application indicates that C&EM energy savings may potentially be increased by increasing C&EM incentive levels from the assumed values. However, estimated total C&EM programming expenditures are more sensitive to such an increase than forecast C&EM energy savings.

1.2.3 RNG IMPACT

This appendix assumes four speculative maximum RNG levels to be achieved by 2036. The first level assumes that FEI will reach its maximum allowance under the GGRR (5 percent of FEI's 2015 non-bypass annual demand, or approximately 8.88 million GJ at up to $30 per GJ energy supply cost) by 2036. The second through fourth levels assume that new technologies, such as cellulosic biogas, will expand the maximum attainable RNG supply up to approximately 94 million GJ by 2036. These levels are based on industry research into potentially available RNG supply and do not account for potential competition for RNG feedstock from non-RNG end uses. The second through fourth levels represent between approximately 25 and 46 percent of FEI's forecast 2036 Reference Case annual demand.

For each maximum level, the examination assumes that RNG annual demand will increase at a constant annual rate from the 2017 LTGRP's forecast 2017 levels to the assumed speculative maximum levels. The examination does not account for potential operational, technical, or safety constraints that may limit FEI's ability to mobilize, inject, or transport RNG in its pipeline system.

This appendix uses the same method for calculating emissions reductions from the RNG initiative as the main body of the Application. As outlined in Section 8 of the Application, this method is conservative because it does not account for avoided landfill methane emissions that are diverted as a result of the RNG initiative. Avoided landfill methane emissions could result in approximately 6 to 12 times additional avoided GHG emissions that FEI currently does not use in its calculated emissions reductions.

1.2.4 POWER-TO-GAS IMPACT

This examination assumes that electrolysers generate hydrogen which is injected into the FEI gas supply. For simplicity, this appendix exclusively applies BC Hydro's average electricity GHG emissions factor for calculating GHG emissions reductions.[1] FEI calculates GHG emissions reductions by comparing the natural gas emissions factor with the emissions factor of BC Hydro electricity, after scaling the electricity emissions factor to account for an assumed 70 percent electrolyser efficiency (based on the nominal hydrogen production efficiency of common

[1] Applying average grid electricity to electrolysis is likely to underestimate potential GHG emissions reductions from power-to-gas. Power-to-gas electrolysers are likely to be driven by marginal electricity and the energy and emissions policy environment encourages marginal electricity generation to be renewable. As such, the marginal electricity emissions factor is likely to be lower than the average grid electricity emissions factor.

industrial electrolysers).[2] This examination does not account for any electric generation, transmission, or distribution losses. Power-to-gas could represent a value-added product for the BC electricity sector. Hydrogen could be produced at times of surplus electricity on the grid, such as during the spring freshet or during periods of high renewable (e.g. wind) generation.

Industry research reflects a broad range of potential maximum power-to-gas levels among the natural gas supply to be viable without significantly increasing risks to end-use appliances, public safety, or the durability and integrity of the existing pipeline networks. These levels approximately extend from 5 percent to 15 percent by volume and depend on the specific infrastructure and end-use characteristics of each jurisdiction which can vary significantly.[3] This appendix assumes two maximum power-to-gas levels: (1) 5 percent of 2036 forecast scenario annual demand by 2036, and (2) 15 percent of 2036 forecast scenario annual demand by 2036. The examination assumes a linear increase from zero percent in 2015 to the assumed maximum levels. This does not account for potential supply limitations of hydrogen or its feedstock materials or for knock-on GHG emissions changes in upstream sectors. This appendix also does not account for any potential BC-specific operational, technical, or safety constraints that may limit the injection, pipeline transport, or end use of power-to-gas supply. The higher of the two power-to-gas levels assumes that technology advances, such as the ability to cost effectively generate synthetic methane from hydrogen, will reduce potential constraints associated with localized concentrations of hydrogen for pipeline injection, pipeline transport, or end-use consumption.

At the assumed electrolyzer efficiency, the two assumed power-to-gas levels would require approximately 4,016 and 12,049 GWh of electric energy, respectively, in the Reference Case in 2036. For comparison, the 2017 LTGRP Lower Bound scenario indicates natural gas load defection and suggests a forecast increase of annual electric load of approximately 17,226 GWh by 2036.

1.2.5 NGT IMPACT

This appendix uses the same NGT GHG emissions reduction analysis method as Section 8 of the Application but splits the NGT impact into a domestic and an international category based on the current boundaries of the BC GHG emissions inventory. For marine bunkering, this means that coastal and trans-Pacific vessels are reported in the international category; only short sea vessels accrue to the domestic category. The international category thus represents GHG emission reductions from converting to LNG coastal and trans-Pacific marine vessels only.

International marine bunkering is a significant source of GHG emissions. However, according to the United Nations Framework Convention on Climate Change, this source of emissions does not fall under any one country's emissions inventory. LNG-bunkered marine vessels can reduce

[2] Appendix D-31: http://www.electrochemsci.org/papers/vol7/7043314.pdf.
[3] Appendix D-32: https://energy.gov/sites/prod/files/2014/03/f11/blending_h2_nat_gas_pipeline.pdf.

their carbon intensity by approximately 20 percent when compared with traditional bunkering fuels.[4] Emissions from shipping activities not included in the provincial GHG inventory amount to about 70 million metric tonnes of CO_2e per year, which is greater than the combined 64 million metric tonnes of CO_2e per year that the entire Province of BC emits per year.

1.2.6 OTHER EMERGING TECHNOLOGIES

Additional emerging technologies do exist which may provide further opportunities for GHG abatement but this examination excludes these technologies as insufficient data is available at this point. The following two examples illustrate this additional GHG abatement potential:

- End-use carbon sequestration, such as the CleanO2 technology for commercial heating systems that FEI supports via a pilot program announced on November 20, 2017, may enable GHG abatement without changing the carbon intensity or annual demand of natural gas;[5] and
- End-use appliance efficiency advancements, such as natural gas-fired heat pumps, may increase the efficiency of natural gas end-use appliances beyond 100 percent.

Together, such additional emerging technologies may enable initiatives which may significantly impact GHG emissions beyond the opportunities quantified in this appendix.

1.2.7 ADDITIONAL CONSIDERATIONS

Some of the emerging initiatives and technologies discussed in this appendix may have non-GHG benefits which are not quantified in this appendix. Some emerging initiatives and technologies may reduce air emissions other than GHG. As outlined in Section 2 of the Application, NGT reduces emissions of Particulate Matter (PM) and Nitrous Oxides (NOx) which have harmful health impacts. Some emerging initiatives and technologies may have wider non-energy benefits. For example, RNG may create an economic use for agricultural waste products.

1.3 Results

Table E-1 below summarizes the speculative pathways resulting from the examination in this appendix. These pathways do not account for all interactive effects. For example, RNG or power-to-gas are not assumed to displace higher carbon emitting transportation fuels even though this would have greater GHG abatement impacts than displacing higher emitting

[4] Appendix D-33: https://www.fortisbc.com/NaturalGas/Business/NaturalGasVehicles/Environmentalbenefitsandsafety/Pages/default.aspx.

[5] Appendix D-34: https://www.fortisbc.com/MediaCentre/NewsReleases/2017/Pages/20171120-Local-businesses-capture-emissions-and-save-energy-through-FortisBC-pilot-program.aspx.

transportation fuels with conventional natural gas (using RNG to displace higher emitting transportation fuels could reduce emissions by approximately 80 percent).

For illustration and as encouraged by stakeholders, FEI assumes hypothetical GHG reduction targets for two summary categories: (1) Stationary Combustion Sources & Industrial Processes and Product Use, and (2) Transport. BC currently does not allocate its legislated GHG emissions reduction targets to specific sectors. FEI also does not create or assign GHG emissions reduction targets but simply conducts activities which realize opportunities for emissions reductions. The 2030 reduction target is based on the Government of Canada's 2017 Nationally Determined Contribution under the Paris Agreement (reducing GHG emissions by 30 percent from 2005 until 2030). When applied to BC's economy-wide GHG emissions, this calculates to a reduction of approximately 26 percent from 2014 until 2030. For the 2036 target year, this appendix uses the target from Section 8 of the Application.

For the first summary category, FEI applies the respective 2030 and 2036 emissions reduction percentage targets to its 2015 base year annual demand. This yields reductions of 26 and 45 percent, respectively, and thus assumes that FEI's annual demand will bear an equal reductions burden as other sectors of the BC economy. For the second summary category, FEI discounts BC's assumed hypothetical economy-wide emissions reduction targets in two successive steps. First to 38.4 percent to account for the ratio of the Transport category to total BC emissions as reported in the 2014 BC GHG emissions inventory, and second, to 45.66 percent to account for the ratio of heavy-duty diesel vehicles, railways, domestic navigation and off-road diesel to total Transport category emissions. This yields the emissions reductions that apply from the assumed hypothetical 2030 and 2036 targets to the total domestic market that is theoretically addressable by FEI's NGT initiative. Nevertheless, emissions in this theoretically addressable market may be reduced by a combination of FEI and non-FEI initiatives.

In the first summary category, combining the annual demand and C&EM impacts with four potential RNG and two potential power-to-gas GHG abatement opportunity levels creates eight different pathways per 2017 LTGRP scenario and target year. To illustrate the range of emissions reduction opportunities across these pathways, each target year in Table E-1 totals the reduction opportunities for the top and the bottom of the pathway opportunity range. The top of the pathway opportunity range overshoots the assumed hypothetical 2030 and 2036 emissions reduction targets, whereas the bottom of the pathway range does not contribute sufficient emissions reductions to equal the assumed hypothetical targets. For each target year in Table E-1, blue field highlighting indicates the minimum RNG opportunity level required for a pathway with the lower power-to-gas opportunity level to meet or overshoot the respective assumed emissions reduction target. Orange field highlighting indicates the minimum RNG opportunity level required for a pathway with the higher power-to-gas opportunity level to meet or overshoot the respective assumed emissions reduction target.

In the second summary category, FEI's domestic emissions reduction pathways alone do not contribute sufficient GHG emissions reductions to equal the assumed hypothetical reductions target. As noted above, the target for this category represents the total addressable market and emissions reductions targets for this market may be met by a combination of FEI and non-FEI initiatives. Additionally, GHG abatement in this category would increase if FEI were to capture a larger proportion of the potential eligible market than assumed in the annual demand forecast from Section 3 of the Application (i.e. 4 and 15 percent of the potential eligible CNG market domestically across the Reference Case and Global Growth & Carbon Step Change scenarios, respectively). This effect would be compounded by fully accounting for interactive effects between categories to enable displacing higher carbon transportation fuels with RNG and power-to-gas. FEI's Global Growth & Carbon Step Change international pathway offers significantly more GHG emissions reductions than indicated by the assumed hypothetical domestic targets. Since climate change represents a global challenge, GHG emissions reductions should be valued as a solution to this challenge no matter which jurisdiction these reductions accrue to for reporting purposes.

Investment in the emerging activities examined in this appendix may cause upward pressure on FEI's rates but such upward pressure may be offset by maintaining or increasing delivered energy amounts via these activities. The impact of NGT on projected delivery rates discussed in Section 8 of the Application illustrates this effect. In contrast, reducing energy amounts delivered by FEI's infrastructure in order to achieve GHG emissions abatement would cause upward pressure on rates without any compensating effect. As outlined in Section 8 of the Application, by continuing to serve BC's thermal energy needs with natural gas, FEI will help to curb increases in electricity demand that would otherwise be caused by gas-to-electric fuel switching in either new or existing buildings. While this electric load avoidance would not eliminate emissions in BC, it would preserve more of BC's clean electricity for potential other end uses, such as power-to-gas or export to other jurisdictions within the electricity trading region. Electricity exports and power-to-gas could economically benefit British Columbians. Electricity exports may also result in greater emissions reductions by displacing coal or natural gas fired electricity generation currently in use in other jurisdictions within the electricity trading region.

Table E-1: Speculative Emissions Reduction Results

	Potential GHG Emissions Reduction Pathways	Forecast Emissions Reductions ($MtCO_2e$, 2015 Base)	
		Reference Case	Global Growth & Carbon Step Change
	1. Stationary Combustion Sources & Industrial Processes and Product Use		
2030	Annual Demand Impact	-0.3	-0.3
	C&EM	0.7	0.6
	RNG at GGRR Cap (2036)	0.3	0.3
	Cellulosic RNG at 51 million GJ (2036)	1.8	1.8
	Cellulosic RNG at 84 million GJ (2036)	2.9	2.9
	Cellulosic RNG at 94 million GJ (2036)	3.3	3.3
	Power-to-Gas at 5% of 2036 Demand by 2036	0.3	0.3
	Power-to-Gas at 15% of 2036 Demand by 2036	1.0	1.0
	Total - Bottom of Range	**1.0**	**0.9**
	Total - Top of Range	**4.6**	**4.6**
	Assumed Domestic Reductions Target	**2.5**	
2036	Annual Demand Impact	-0.5	0.1
	C&EM	0.8	0.7
	RNG at GGRR Cap (2036)	0.5	0.5
	Cellulosic RNG at 51 million GJ (2036)	2.6	2.6
	Cellulosic RNG at 84 million GJ (2036)	4.3	4.3
	Cellulosic RNG at 94 million GJ (2036)	4.8	4.8
	Power-to-Gas at 5% of 2036 Demand by 2036	0.5	0.4
	Power-to-Gas at 15% of 2036 Demand by 2036	1.4	1.3
	Total - Bottom of Range	**1.2**	**1.7**
	Total - Top of Range	**6.5**	**6.9**
	Assumed Domestic Reductions Target	**4.5**	
	2. Transport		
2030	NGT - Domestic	0.2	0.3
	NGT - International	1.4	10.7
	Total - Domestic	**0.2**	**0.3**
	Total - International	**1.4**	**10.7**
	Assumed Domestic Reductions Target	**2.9**	
2036	NGT - Domestic	0.3	0.5
	NGT - International	1.9	14.4

	Total - International	**1.9**	**14.4**
	Assumed Domestic Reductions Target	**5.1**	

1.4 FEI's role in global GHG emissions reductions

Reducing net global GHG emissions is the preeminent objective to mitigate global climate change. FEI is undertaking actions that can achieve net GHG emission reductions outside of

BC. Two important pathways are LNG exports to countries to substitute for more carbon intensive fuels and LNG bunkering for international marine shipping. While these actions will not drive reductions to achieve BC's domestic targets, the scope of BC's emissions reductions activities should be broadened so as to recognize the role FEI can play in helping to reduce global GHG emissions.

1.4.1 LNG EXPORTS

Recent analysis conducted by the International Energy Agency (IEA) in 2017 concludes that LNG exports to China and India from North America are a key component of a global energy transition to limit global warming to two degrees Celsius above pre-industrial levels. According to the IEA's Sustainable Development Scenario (SDS), natural gas becomes the single largest fuel supply at 25 percent of global energy consumption. While absolute gas consumption declines in most of the developed world, it increases over threefold in China and fourfold in India. Natural gas is used to decarbonize power, industry, buildings and transport, substituting for coal and oil consumption. Importantly, gas consumption is 30 percent higher in India and 10 percent higher in China in the SDS compared to the New Policies Scenario reference case. This means that increased gas consumption becomes *more* important as a CO_2 abatement option as each of these countries drives to reduce emissions in line with the goal to limit global warming to two degrees above pre-industrial levels.

In the SDS, LNG exports satisfy most of the new demand for natural gas in these countries. As a result, global LNG trade more than doubles currently traded volumes by 2040. LNG exports from North America to China grow to 150 billion cubic meters by 2040 (approximately double Canada's current gas exports to the US).

LNG exports from BC are well-positioned to reduce GHG emissions. BC's 0.16 tonnes of CO_2 per tonne of LNG intensity target is the lowest in the world. BC's gas reserves in the Montney basin have low formation CO_2. Further, low GHG emissions intensity electricity, cooler climate, and proximity to China all serve to increase the emissions reduction potential of BC natural gas abroad. FEI's Tilbury Phase 1A liquefaction facility is powered by electricity and is anticipated to be one of the cleanest LNG facilities in the world.

Pinpointing the total CO_2 abatement from increased natural gas consumption in export markets requires decomposition analysis with detailed data. A speculative estimate of the total reduction potential can be quantified using high-level IEA data in the World Energy Outlook. Assuming a direct one-to-one substitution of natural gas energy for coal in power generation and other end-use applications, the abatement potential of natural gas substitution is sizeable. Natural gas produces three million tonnes less CO_2 emissions than coal per million tonnes of oil equivalent (Mtoe). In the SDS, natural gas consumption in the non-power end-use sectors increases by 218 Mtoe (259 billion cubic meters) between 2015 and 2040. This means that, assuming direct substitution for coal, natural gas may abate over 600 million tonnes of CO_2 emissions across the non-power end-use sectors. In the power sector, every TWh of natural gas generation that displaces coal reduces emissions by 0.8 million tonnes of CO_2.[6] In the SDS, natural gas power generation increases by 745 TWh from 2015 to 2040. As such, natural gas utilization may abate over 500 million tonnes of CO_2 by 2040.

Taken together, 150 billion cubic meters of exports from North America that substitute for coal consumption could reduce CO_2 emissions by an estimated 400 million tonnes - over 6 times greater than BC's total 2014 emissions.[7] 30 billion cubic meters of natural gas exports would account for approximately 20 percent of forecast total North American exports and would require approximately 23 million tonnes per annum (MTPA) of LNG export capacity. Large LNG export projects proposed in BC, such as LNG Canada, range around 26 MTPA.[8] If BC facilities exported 23 MTPA of LNG to China for coal substitution, associated forecast downstream emissions reductions would be in the order of approximately 80 million tonnes annually (BC's total 2014 GHG emissions are approximately 64 million tonnes).

1.5 Conclusion

The size of the opportunity presented by the potential GHG emissions reduction pathways in this appendix supports investments into further analysis and development of these pathways. FEI will continue monitoring and will, where appropriate, support emerging initiatives and technologies such as the ones discussed in this appendix. FEI emphasizes that, once more specific information becomes available, it will be important to compare on an equal footing the potential pathways discussed in this appendix to alternative GHG emissions abatement pathways, such as domestic electrification.

6 Assuming emissions factors for gas and coal without significant deployment of carbon capture and storage.
7 Assuming natural gas exports are proportionately spread to all major gas consuming sectors in China.

Appendix F

GLOSSARY OF TERMS AND ACRONYMS

APPENDIX F – GLOSSARY OF TERMS AND ACRONYMS

Acronym or Term	Definition
ACP	Annual Contracting Plan
AECO/NIT	Alberta Energy Company/Nova Inventory Transfer - refers to an important storage and exchange point for Canadian natural gas. AECO/NIT is commonly used to refer to the benchmark pricing index for the Alberta natural gas marketplace.
AFUDC	Allowance for funds used during construction - an allowance for the cost of debt and equity funding of capital projects before they are completed and placed into service and included in rate base; the AFUDC recorded for a project is added to the overall project cost.
AIP	Asset Investment Planning
Annual demand	The cumulative daily demand for natural gas over an entire year.
BC	British Columbia
BC CPR	A recent Conservation Potential Review (CPR) conducted jointly by multiple British Columbia utilities.
Bcf	one billion cubic feet
Bcf/d	one billion cubic feet per day
BCH	British Columbia Hydro and Power Authority (BC Hydro)
BCUC	British Columbia Utilities Commission, or Commission - the BCUC is the provincial body regulating utilities in British Columbia.
BP	BP Energy Marketing & Trading – a subsidiary of the BP p.l.c. group of companies.
BTU	British Thermal Units
Burrard Thermal	Burrard Thermal Generating Station (BC Hydro)
CAPP	Central Appalachian
CCE	Cost of Conserved Energy - a standard method for expressing cost-benefit test results for energy efficiency initiatives in dollars per unit of energy savings. Electric utilities use the CCE to express the net cost of saving one unit of utility-supplied energy. In the 2017 LTGRP, FEI uses the CCE to express in dollars per GJ the UCT results; thus the CCE represents annualized and, where applicable, discounted UCT costs divided by annual energy savings.
CEA	*Clean Energy Act*

Acronym or Term	Definition
C&EM	Conservation and Energy Management
CEO	Conservation Education, and Outreach
CGA	Canadian Gas Association
CHBA	Canadian Home Builders' Association
CIAC	Contributions in aid of construction
CLP	Climate Leadership Plan
CLT	Climate Leadership Team
CNG	Compressed natural gas
Commission	*see British Columbia Utilities Commission, BCUC*
CO_2e	Carbon dioxide-equivalent - a unit to express an amount of greenhouse gas emission in terms of carbon dioxide (CO_2) based on the relative global warming potential of each gas. Commonly expressed in million tonnes, i.e. $MtCO_2e$.
CPCN	Certificate of Public Convenience and Necessity - a certificate obtained from the British Columbia Utilities Commission under Section 45 of the *Utilities Commission Act* for the construction and/or operation of a public utility plant or system, or an extension of either, that is required, or will be required, for public convenience and necessity.
Core	A category of FEI customers rely on FEI to both procure their gas supply and also deliver this supply to their meters in a non-interruptible manner. This includes Rate Schedules 1, 2, 3, 4, 5, and 6.
COV	City of Vancouver
CPR	Conservation Potential Review - a comprehensive economic analysis of energy conservation potential that looks at where energy savings opportunities exist (*also see BC CPR*)
CTS	Coastal Transmission System
Daily demand	The amount of natural gas consumed by the Utilities' customers throughout each day of the year.
Demand forecast	A prediction of the demand for natural gas into the future for a given period and under a specified set of expected future conditions.
DES	District Energy System
DHW	Domestic Hot Water

Acronym or Term	Definition
DSM	Demand side management - commonly defined as any utility activity that modifies or influences the way in which customers utilize energy services.
DSM Regulation	Demand-Side Measures Regulation – one of the regulatory instruments that govern utility demand-side measure programs in BC.
Design day, or design hour demand	The maximum expected amount of gas in any one day or hour required by customers on the utility system. Since core customers' demand is primarily weather dependent, design-day or design-hour demand is forecasted based upon a statistical approach called Extreme Value Analysis, which provides an estimate of the coldest day weather event expected with a 1-in-20-year return period. For transportation customers, the design-day is equivalent to the firm contract demand (*also see Peak day*).
DLE	Diesel litre-equivalents
ECA	Emission Control Areas – in marine shipping
EEC	Energy Efficiency and Conservation
EECAG	Energy Efficiency and Conservation Advisory Group
EERS	Energy Efficiency Resource Standards – regulations which require public utilities to demonstrate annual energy savings as a percentage of their total load.
EDI	Electronic data interchange contract – a contract based on a standard protocol for exchanging operational data between natural gas dispatch centers.
EF	Energy Factor or Efficiency Factor
EGH	EnerGuide for Houses
EGP	FEI's Eagle Mountain to Woodfibre Gas Pipeline Project
EIA	Energy Information Administration (U.S.) - a division of the U.S. Department of Energy that provide statistics, data and analysis on resources, supply, production, consumption of energy.
EMAT	Electro-Magnetic Acoustic Transducer – a type of advanced in-line inspection technology for pipelines.
EPA	United States Environment Protection Agency
FBC	FortisBC Inc.
FEED	Front End Engineering Design
FERC	Federal Energy Regulatory Commission

Acronym or Term	Definition
FEI	FortisBC Energy Inc.
FEVI	FortisBC Energy (Vancouver Island) Inc.
FEW	FortisBC Energy (Whistler) Inc.
FID	Final investment decision
Firm Transportation	A category of FEI customers who procure their own gas supply but rely on FEI to deliver this supply to their meters in a non-interruptible manner. This includes Rate Schedules 23, 25, and the contracted firm delivery component of Rate Schedule 22 (including 22A and 22B) and other special Rate Schedules.
GDP	Gross Domestic Product
GGRR	Greenhouse Gas Reduction (Clean Energy) Regulation
GGRA	*Greenhouse Gas Reduction Targets Act*, sometimes also referred to as GGRTA
GHG	Greenhouse gas
GHGI	Greenhouse gas intensity
GJ	Gigajoule - a unit of energy equivalent to one billion joules. One joule of energy is equivalent to the heat needed to raise the temperature of one gram (g) of water by one degree Celsius (ºC) at standard pressure (101.325 kPa) and standard temperature (15ºC).
GLJ	GLJ Petroleum Consultants Ltd. - a private petroleum industry consultancy serving clients who require independent advice relating to the petroleum industry, including the preparation of natural gas and oil price forecasts on a quarterly basis.
GSA	General Electric Company Smallworld GeoSpatial Analysis tool
GTN	Gas Transmission Northwest LLC
GWh	Gigawatt hour - a unit of energy equal to one million kilowatt hours
HDD	Heating degree day - a measure of the coldness of the weather experienced. The number of heating degree days for a given day is calculated based on the extent to which the daily mean temperature falls below a reference temperature, 18 degrees Celsius.
HFO	Heavy fuel oil
HP	Horsepower
HPDI	High pressure direct injection

Acronym or Term	Definition
Huntingdon-Sumas	Gas flow regulating stations on either side of the British Columbia /Washington state (U.S.) border through which much of the regional gas supply is traded.
I-5 Corridor	The natural gas regional market area served by infrastructure located along Interstate-5 in the northwestern U.S. The I–5 corridor includes B.C.'s Lower Mainland and Vancouver Island, Western Washington and Western Oregon.
IEA	International Energy Agency
IFO	Intermediate fuel oil
IG	Island Generation (BC Hydro) - a cogeneration plant located at Elk Falls, Campbell River that supplies electricity and thermal energy on Vancouver Island.
IGC	Island Gas Connector Project - a natural gas pipeline to serve a proposed liquefied natural gas facility on southern Vancouver Island called Malahat LNG.
ILI	In-line inspection
IMO	International Maritime Organization – a specialized agency of the United Nations responsible for regulating shipping.
IP	Intermediate pressure
IRP	Integrated resource plan - a document that details the resource planning process and outcomes that guide a utility in planning to serve its customers over the long term. *(also see LTRP.)*
IRR	Internal rate of return
IT	Information technology
ITS	Interior Transmission System
JPS	Jackson Prairie Storage
km	Kilometer
KORP	Kingsvale Oliver Reinforcement Project
kPa	Kilopascal - a metric measurement unit of pressure. Gauge pressure is often given in units with a 'g' appended, e.g. 'kPag'.
kW	kilowatt (a unit of energy equal to one thousand watts) - the commercial unit of measurement of electric power. A kilowatt is the flow of electricity required to light ten 100-watt light bulbs.

Acronym or Term	Definition
kWh	Kilowatt hour (equal to one thousand watts used for a period of one hour) - the basic unit of measurement of electric energy. On average, residential customers in B.C. use about 10,000 kWh per year.
LMIPSU	Lower Mainland Intermediate Pressure System Upgrade Project
LMSU	Lower Mainland System Upgrade Project
LNG	Liquefied Natural Gas - natural gas stored under low temperature, which turns to liquid form. Approximately 600 times as much natural gas can be stored in its liquid state than in its typical gaseous state; however, specialized storage facilities must be constructed.
Load	The total amount of gas demanded by all customers at a given point in time.
LTERP	Long Term Electric Resource Plan – FortisBC Inc.'s LTERP examines future demand and supply resource conditions over the next 20 years and recommends actions needed to ensure customers' energy needs are met over the long term *(also see IRP)*.
LTRP	Long Term Resource Plan – FEI's LTRP examines future demand and supply resource conditions over the next 20 years and recommends actions needed to ensure customers' energy needs are met over the long term. In 2017, FEI uses LTGRP to distinguish the FEI IRP from the FBC IRP *(also see IRP)*.
LTSP	Long Term Sustainment Plan - an asset management process/planning approach that assists in creating and supporting long term asset replacement plans and capital expenditures.
MDO	Marine diesel oil
MFO	Marine fuel oil
MGO	Marine gas oil
mm	Millimeter
MMBtu	one million British Thermal Units
MMcf/d	one million cubic feet per day
MMscfd	one million standard cubic feet per day, sometimes also mmscfd
MOP	Maximum operating pressure
Mtoe	one million tonnes of oil equivalent
MTPA	one million tonnes per annum
MTRC	Modified Total Resource Cost - a modification to the Total Resource Cost test that is set out in the B.C. Demand-side Measures Regulation to recognize the environmental value of energy conservation.

Acronym or Term	Definition
MW	Megawatt - a unit of power equal to one million watts or one thousand kilowatts, commonly used to measure both the capacity of generating stations and the rate at which electric energy can be delivered.
NEB	National Energy Board
NEBC	Northeast British Columbia
NGT	Natural gas for transportation
NGTL	Nova Gas Transmission Ltd.
NGV	Natural gas vehicles
Normal demand, *also called* **annual demand**	When considering historical normal demand, this is the actual demand experience that has been adjusted to account for weather that has been colder/warmer than normal, i.e. the expected demand during a year of normal weather conditions. When considering forecast normal demand, this is the expected demand under normal weather conditions. Normal weather conditions are based on a rolling 10-year average of heating degree days experienced during each of the 10 years.
NOx	Nitrogen oxides - a form of atmospheric pollutants that are regulated in many jurisdictions.
NPCC	Northwest Power and Conservation Council
NPCC Plan	Northwest Power and Conservation Council Seventh Power Plan
NPS	Nominal Pipe Size – a North American set of standard pipe sizes.
NRCan	Natural Resources Canada
NRES	Neighborhood renewable energy systems – according to the City of Vancouver, a district energy system that runs on renewable energy sources.
NWGA	Northwest Gas Association - a trade organization of the Pacific Northwest natural gas industry. Its members include six natural gas utilities, including FortisBC, serving communities in Idaho, Oregon, Washington and British Columbia, and three interstate pipelines that move natural gas from supply basins into and through the region.
NW Natural	Northwest Natural Gas Company
NWP	Northwest Pipeline
NWIW	Northwest Innovation Works, Inc. – also referred to as NW Innovation
NYMEX	New York Mercantile Exchange
OEM	Original Equipment Manufacturer

Acronym or Term	Definition
PBR	Performance Based Ratemaking or PBR, also frequently called incentive regulation - an approach to determining a utility's rates or revenue requirements that includes incentives for the utility to achieve greater levels of efficiency in managing and operating its utility system, while maintaining (or in some cases improving) its customer service quality. Depending on the desired objectives, PBR can be narrowly focused on a particular aspect of utility service or more broadly based encompassing many aspects of the utility's operations.
PEC	Pacific Energy Corporation
Peak day, peak demand, peak day demand	The maximum expected amount of gas in any one day or hour required by customers on the FEI system. Since Core customers' demand is primarily weather dependent, design-day or design-hour demand is forecasted based upon a statistical approach called Extreme Value Analysis, which provides an estimate of the coldest day weather event expected with a 1 in 20 year return period. For transportation customers, the design-day is equivalent to the firm contract demand (*also see: design day*).
PHF	Peak Hour Factor – the ratio of peak hour consumption to peak day consumption
PI	Prediction Intervals
PJ	Petajoule - a unit of energy equal to 1,000 terajoules or 10^6 gigajoules
PM	Particulate matter – the sum of all solid and liquid particles suspended in the atmosphere; most PM particles form as a result of chemical reactions between pollutants.
PNG	Pacific Northern Gas – a British Columbia natural gas utility with a service territories in Northern British Columbia.
PNW	Pacific Northwest - a region that is commonly referred to as the three northwestern states of Washington, Oregon, Idaho and the Province of B.C.
Posterity	Posterity Group
PRMP	Price Risk Management Plan
PSE	Puget Sound Energy
Psig	Pounds per square inch gauge - a measurement of pressure.
QUEST	Quality Urban Energy Systems of Tomorrow
Rate volatility	The amount to which natural gas rates fluctuate and the frequency of those fluctuations.

Acronym or Term	Definition
Resources	The demand side and supply side means available to meet forecasted energy needs. Examples of supply-side resources within the context of resource planning are pipeline looping, compression and storage.
REUS	Residential End Use Study
RIB	Residential Inclining Block rate (BC Hydro)
RNG	Renewable natural gas
ROW	Right of way
RPAG	Resource Planning Advisory Group
RPS	Renewable Portfolio Standard – a form of regulation requiring a specified percentage of energy/fuel provision to contain renewable energy/fuel.
RRA	Revenue Requirement Application
SCC	Stress Corrosion Cracking
SCP	Southern Crossing Pipeline
SCGT	Simple cycle gas-fired turbine – typically for electricity generation.
SDS	Sustainable Development Scenario – a forecast scenario developed by the International Energy Agency in 2017.
Shut in	A pipeline "shut in" refers to removing a pipeline from service.
SOx	Sulfur oxides – a form of atmospheric pollutants that are regulated in many jurisdictions.
TAC	British Columbia Conservation Potential Review (*see BC CPR*) Technical Advisory Committee – a group of members of the public with significant interest, stake, and experience in determining energy conservation potential in BC; this group provides input and feedback during development of the BC CPR.
Tcf	one trillion cubic feet
TBO	Transportation-by-others – a type of arrangement for pipeline transport whereby one pipeline becomes the shipper on another pipeline system; these arrangements provide additional market access to one pipeline by leasing space on another pipeline.
TD	TD Securities – an affiliate of Toronto-Dominion Bank.
TEDI	Thermal energy demand intensity – an engineering metric for measuring thermal energy transmission through a building envelope.
TJ	Terajoule - a unit of energy equal to 1,000 gigajoules.

Acronym or Term	Definition
TJ/d	Terajoules per day
TP	Transmission pressure
Traditional Annual Method	FEI's traditional time-series based method for forecasting annual energy demand.
Traditional Peak Method	FEI's longstanding and well-established method for forecasting peak energy demand.
TransCanada	TransCanada PipeLines Limited
TRC	Total Resource Cost - a standard cost-benefit test for energy efficiency initiatives that compares the present value of all costs of efficiency for all members of society with the present value of benefits in order to assess the impacts of a portfolio of energy efficiency initiatives on the economy at large.
TSA	Transportation Service Agreement
TWh	Terawatt hour - a unit of energy equal to one billion kilowatt hours
UCA	*Utilities Commission Act*
UBCM	Union of BC Municipalities
UDI	Urban Development Institute
UPC	Use per customer
UPC_{peak}	Peak hour use per customer
UCT	Utility Cost Test - a standard cost-benefit test for energy efficiency initiatives that compares the present value of all costs of efficiency for the utility which offers an energy efficiency program with the present value of benefits in order to assess the impacts of a portfolio of energy efficiency initiatives on the utility specifically.
US	United States
Utilities	*see Fortis Energy Utilities (FEU)*
V2	A specific compressor location on FEI's Vancouver Island Transmission System based on FEI's classification for such compressor locations.
VI	Vancouver Island
VIGJV	Vancouver Island Gas Joint Venture - a joint venture of industrial customers (primarily large mills) on Vancouver Island who contract for transportation services as a single entity.
VITS	Vancouver Island Transmission System, also referred to as VI Transmission System

Acronym or Term	Definition
VPP	Volumetric Production Payment – a tool for managing longer term gas market price risk where the buyer pays an up-front lump sum payment to a gas producer in exchange for specific volumes delivered over the term of the agreement (possibly up to 20 years).
WCSB	Western Canadian Sedimentary Basin
Westcoast	Westcoast Energy Inc.
WLNG	Woodfibre LNG Ltd.
Woodfibre LNG Project	A small scale LNG export and processing facility proposed by WLNG on the site of the formed Woodfibre pulp mill near Squamish.
ZEEA	The avoided cost of gas value stream defined for the MTRC test – the ZEEA is informed by BC Hydro’s long run marginal cost for procuring renewable electricity.

ORDER

WHEREAS:

A. On December 14, 2017, FortisBC Energy Inc. (FEI) filed its 2017 Long Term Gas Resource Plan (Application) pursuant to section 44.1(2) of the *Utilities Commission Act,* for acceptance by the British Columbia Utilities Commission (Commission). FEI is not seeking approval of any particular elements identified within the plan;

B. By Order G-XX-18 dated (Month Day], 2018, the Commission established a written hearing process and a regulatory timetable with two rounds of information requests to review the Application; and

C. The Commission has reviewed the Application.

NOW THEREFORE the Commission orders as follows:

1. The Commission accepts the FortisBC Energy Inc. 2017 Long Term Gas Resource Plan to be in the public interest pursuant to subsection 44.1(6) of the *Utilities Commission Act.*

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of (Month Year).

IN THE MATTER OF
the *Utilities Commission Act*, RSBC 1996, Chapter 473

and

FortisBC Energy Inc.
2017 Long Term Gas Resource Plan

BEFORE:
Panel Chair/Commissioner
Commissioner
Commissioner

on Date

ORDER

WHEREAS:

A. On December 14, 2017, FortisBC Energy Inc. (FEI) submitted its 2017 Long Term Gas Resource Plan (2017 LTGRP) to the British Columbia Utilities Commission (Commission) pursuant to section 44.1(2) of the *Utilities Commission Act* (UCA). FEI is not seeking approval of any particular elements identified within the plan;

B. The 2017 LTGRP presents a long term view of how FEI will meet future demand and reliability requirements at the lowest reasonable cost to customers over the next 20 years;

C. The 2017 LTGRP discusses the planning environment; energy demand forecasting; demand side resources; system resource needs and alternatives; gas supply portfolio planning and price risk management and stakeholder engagement. The 2017 LTGRP also includes a 20 year vision for FEI and an action plan;

D. Section 44.1 of the UCA provides that the Commission may establish a process to review a long-term resource plan;

E. The Commission has reviewed FEI's 2017 LTGRP and has determined that a public hearing is appropriate to review the Application and that a written public hearing process should be commenced, a regulatory timetable should be established and a public notice should be issued.

NOW THEREFORE pursuant to section 44.1(6) of the *Utilities Commission Act*, the British Columbia Utilities Commission orders as follows:

1. A written hearing is established for the review of FEI's 2017 LTGRP in accordance with the Regulatory Timetable set out in Appendix A to this order.

2. By no later than January 26, 2018, FEI is to publish the Public Notice, attached as Appendix B to this Order, in the Vancouver Sun newspaper to provide reasonable notice to those parties who may be affected by the plans outlined in FEI's 2017 LTGRP.

3. The Application, together with any supporting materials, will be available for inspection at FEI Office, 16705 Fraser Highway, Surrey, BC, V4N 0E8. The Application and supporting materials also will be available on the FortisBC website at www.fortisbc.com and on the Commission website at www.bcuc.com.

4. Interveners who wish to participate in the regulatory proceeding are to register with the Commission by completing a Request to Intervene Form, available on the Commission's website at http://www.bcuc.com/Registration-Intervener-1.aspx by the date established in the Regulatory Timetable attached as Appendix A to this order and in accordance with the Commission's Rules of Practice and Procedure attached to Order G-1-16.

5. Participants intending to apply for Participant Assistance/Cost Award (PACA) exceeding $10,000 must file a completed PACA Budget Estimate form by [DATE]. PACA applications should be consistent with the Commission's PACA Guidelines and Order G-97-17. Copies of the PACA Guidelines are available upon request or can be downloaded from the Commission's website at http://www.bcuc.com.

DATED at the City of Vancouver, in the Province of British Columbia, this (XX) day of [Month Year].

PUBLIC NOTICE

[Proceeding Name]

On December 14, 2017, FortisBC Energy Inc. filed its 2017 Long Term Gas Resource Plan (2017 LTGRP) for acceptance by the British Columbia Utilities Commission (Commission), pursuant to section 44.1(2) of the *Utilities Commission Act.*

FEI's 2017 LTGRP presents a long term view of how FEI will meet future demand and reliability requirements at the lowest reasonable cost to customers over the next 20 years. The 2017 LTGRP discusses the planning environment; energy demand forecasting; demand-side resources; system resource needs and alternatives; gas supply portfolio planning and price risk management and stakeholder engagement. The 2017 LTGRP also includes a 20 year vision for FEI and an action plan.

HOW TO PARTICIPATE

There are a number of ways to participate in a matter before the Commission:

- **Submit a letter of comment**
- **Register as an interested party**
- **Request intervener status**

For more information, or to find the forms for any of the options above, please visit our website or contact us at the information below.

www.bcuc.com/RegisterIndex.aspx

All submissions received, including letters of comment, are placed on the public record, posted on the Commission's website and provided to the Panel and all participants in the proceeding.

NEXT STEPS

Intervener registration Persons who are directly or sufficiently affected by the Commission's decision or have relevant information or expertise, and that wish to actively participate in the proceeding can request intervener status by submitting a completed Request to Intervene Form by Thursday, February 1, 2018.

GET MORE INFORMATION

All documents filed on the public record are available on the "Current Proceedings" page of the Commission's website at www.bcuc.com.

If you would like to review the material in hard copy, or if you have any other inquiries, please contact Laurel Ross, Acting Commission Secretary, at the following contact information.
