## **BC GAS LONG RUN INCREMENTAL COSTS**

1 This long run incremental cost (LRIC) study estimates the  
2 costs associated with serving future gas demand resulting from  
3 new customers attaching to the BC Gas system as well as  
4 increased demand from existing customers.

### **1.0 CONCEPTS AND COMPONENTS**

7  
8 Incremental costs are one of the factors used to design  
9 customer rates. They measure the costs customers are expected  
10 to impose on the gas system over the long-term. The  
11 incremental costs presented here cover both the BC Gas  
12 distribution system as well as upstream gas supply costs.

13  
14 Long run incremental cost estimates in this study are grouped  
15 into three components:

- 16
- 17 • Demand costs
- 18 • Commodity costs
- 19 • Customer costs
- 20

21 The following sections describe the elements and the  
22 procedures used in deriving cost estimates for each component.  
23 The final section provides a summary and conclusions.

### **2.0 DEMAND COSTS**

24  
25  
26  
27 The demand cost component consists of costs associated with  
28 transmission and distribution capacity on the BC Gas system  
29 and the fixed demand costs for gas supply.

#### **2.1 DEMAND COSTS: TRANSMISSION AND DISTRIBUTION SYSTEM IMPROVEMENTS**

3  
4 System improvements include capacity additions to the BC Gas

1 distribution and transmission system that accommodate the  
2 incremental load requirements of new and existing customers.

3  
4 The incremental cost estimate of transmission capacity was  
5 derived from 20 year transmission plans for BC Gas. The  
6 present value of total forecast capital transmission  
7 expenditures over the 20 year forecast period was divided by  
8 the present value of forecast incremental system peak day  
9 demand over that same period. A capital recovery factor was  
10 applied to derive the annual transmission cost of capacity in  
11 \$/peak day GJ. Overhead was added to account for those  
12 operation and maintenance expenditures capitalized into  
13 transmission costs. Derivation of incremental overhead rates  
14 is discussed in Section 5.

15  
16 Estimates for the incremental cost of distribution capacity  
17 were derived from the BC Gas Five Year System Plan. The  
18 capital cost estimates for regions in the interior were  
19 adjusted to account for districts with incomplete Five Year  
20 Plans<sup>1</sup>. Only those projects in the System Plan that were  
21 required for meeting increases in capacity requirements, from  
22 increased loads due to new or existing customers, were used in  
23 the estimation. Replacement projects not associated with  
24 incremental requirements were not included in the analysis.  
25 The annual distribution cost of capacity was calculated in a  
26 similar manner to that used for transmission. Capital  
27 expenditures shown in the five year plan were averaged and  
28 applied to future years<sup>2</sup>. This extrapolation was required to  
29 provide distribution capital costs on a consistent basis with  
30 transmission capital costs and the peak day system forecast.

---

31 <sup>1</sup> System planning budgets in the interior region were increased by 4.4% in each year,  
32 representing the portion of customers residing in areas where 5 year plans have yet to be  
33 completed.

34 <sup>2</sup> System planners at BC Gas indicate that this procedure produces a reasonable proxy of longer  
35 term capital project requirements to meet capacity demand growth.

Table 1 below shows the cost estimates for adding additional transmission and distribution capacity.

Table 1: Transmission and Distribution \$1996 per Peak Day GJ		
	Total	Annual*
Transmission	\$ 298	\$ 35
Distribution	\$ 410	\$ 41
Total T&D	\$ 708	\$ 77

\* Capacity Recovery Factor 10.31%

Total forecast transmission and distribution expenditures together with the associated peak day demand forecast for the BC Gas system are given in Table 2.

<b>Table 2: Transmission &amp; Distribution System Costs and Peak Day Demand Forecasts</b>				
	<b>Capital Costs</b>			<b>Peak Day</b>
	<b>Transmission</b>	<b>Distribution (\$millions)</b>	<b>Total</b>	<b>(TJ)</b>
1996	5.7	9.1	14.8	1,174
1997	7.2	10.7	17.9	1,186
1998	-	3.9	3.9	1,213
1999	7.2	3.5	10.7	1,240
2000	-	10.3	10.3	1,265
2001	6.8	7.5	14.3	1,288
2002	-	7.5	7.5	1,311
2003	10.8	7.5	18.3	1,333
2004	5.9	7.5	13.4	1,354
2005	7.2	7.5	14.7	1,376
2006	-	7.5	7.5	1,397
2007	31.0	7.5	38.5	1,420
2008	-	7.5	7.5	1,437
2009	-	7.5	7.5	1,454
2010	41.2	7.5	48.7	1,470
2011	-	7.5	7.5	1,485
2012	14.0	7.5	21.5	1,501
2013	-	7.5	7.5	1,517
2014	-	7.5	7.5	1,533
2015	-	7.5	7.5	1,549

**2.2 DEMAND COSTS: GAS SUPPLY**

Incremental gas supply costs were determined using the company's Gas Supply Optimization Model (GSOM). Gas supply incremental costs were estimated by assuming that gas demand will be two percent greater than currently forecasted. This

1 change in gas demand results in additional gas supply  
2 requirements, the cost of which is the incremental gas supply  
3 cost. GSOM selects available supply resources to meet  
4 forecast demand requirements. The available supply resources  
5 include contracts for various periods and amounts, space in  
6 underground storage facilities, and peaking facilities such as  
7 LNG. GSOM indicates that for an increase in load, with a  
8 system average load factor, the long term marginal supply  
9 source would be an annual base load supply contract.

10  
11 The demand cost associated with gas supply was separated into  
12 two parts.

13  
14 Most supply resource options chosen by GSOM can be thought of  
15 as serving a dual purpose - meeting peak day demands and  
16 meeting demand on non-peak days. Since the marginal resource  
17 selected by GSOM was long term base load contracts, a method  
18 for deriving a pure peak-related demand cost was required. To  
19 separate pure peak demand costs from the total fixed costs  
20 identified in GSOM, an LNG facility was chosen as a proxy for  
21 the cost of serving needle peak loads. The 2BCF LNG facility  
22 described in the 1995 BC Gas IRP has an associated peak day  
23 cost of \$518/GJ/day. Applying a capital recovery factor  
24 results in an annual cost of capacity of approximately  
25 \$53/GJ/day.

26  
27 The fixed cost (demand charges) of meeting incremental load as  
28 determined by GSOM is \$334/peak day GJ (levelized). When the  
29 cost for LNG peaking is subtracted, the residual demand  
30 component is:

31  
32 
$$\$334 - \$53 = \$281 \text{ GJ/peak day}$$
  
33 
$$\$281/364 \text{ days} = \$0.77/\text{GJ (at 100\% load factor)}.$$

1 This residual demand component is termed here the average  
2 demand.

3

4 **3.0 COMMODITY COSTS**

5

6 The variable gas supply cost was derived from the annual  
7 estimates produced by GSOM. The levelized commodity cost was  
8 estimated to be \$0.95/GJ (\$1996). The winter (November -  
9 March) commodity cost was estimated to be \$1.08/GJ while the  
10 summer (April-October) was \$0.70/GJ.

11

12 **4.0 LONG RUN CUSTOMER CAPITAL COSTS**

13

14 The costs of attaching additional customers to the gas  
15 distribution system includes one time capital expenditures for  
16 meter sets, services and mains. These costs can be attributed  
17 to specific customer rate classes on a per customer basis  
18 using data for typical customer attachments. Table 3 provides  
19 current estimates of customer capital costs for rates 1, 2  
20 and 3.

21

22 The costs given in the table were developed by BC Gas  
23 distribution service engineers and represent typical costs  
24 associated with attaching customers in each class. Attachment  
25 costs for specific customers could vary substantially from  
26 these estimates. The costs shown for services and mains  
27 assume a ratio of 1.2 customers per service to account for  
28 multiple accounts from single services.

Table 3: Meter Set, Service Line and Main Costs per Customer \$1996			
	Rate 1	Rate 2	Rate 3
Meter Set	\$ 346	\$ 477	\$ 3,016
Service	\$ 539	\$ 539	\$ 539
Main	\$ 516	\$ 516	\$ 516
Overhead	\$ 517	\$ 566	\$ 1,503
Total	\$ 1,918	\$ 2,098	\$ 5,574
Annual Cost	\$ 198	\$ 216	\$ 575

\* Capital Recovery Factor 10.31%

Because seasonal and larger industrial customers comprise a heterogeneous group with wide cost variations and no readily identifiable typical customer, customer attachment cost estimates for these industrial customers are not meaningful.

An overhead rate was applied to the total direct costs in each rate class (see Section 5 for a discussion of overheads). It was assumed that future customer attachment costs for meters, services and mains will remain constant in real terms.

#### 5.0 LONG RUN OPERATION AND MAINTENANCE COSTS

Incremental operation and maintenance (O&M) costs were determined using as a base the 1996 approved O&M budget from the 1996-1998 BC Gas Revenue Requirements Application. Incremental O&M costs associated with demand, commodity and customer components, shown in Table 4, were determined using the following approach.

<b>Table 4: Operation &amp; Maintenance Costs (\$1996)</b>	
<b>Demand</b>	
(1) Demand Related O&M	\$ 11,790 (\$000)
(2) System Peak Day (1996)	\$ 1,174 (TJ)
(3) (1)/(2)	\$ 10.04 (\$/peak day GJ)
<b>Commodity</b>	
(1) Commodity Related O&M	\$ 1,178 (\$000)
(2) Total System Throughput	\$ 232,443 (TJ)
(3) (1)/(2)	\$ 0.005 (\$/GJ)
<b>Customer</b>	
(1) Customer Related O&M	\$ 37,298 (\$000)
(2) Total Customers	\$ 704,317
(3) (1)/(2)	\$ 53 (\$/customers)

First, individual budgeted O&M items (BCUC accounts) were evaluated using BC Gas staff expertise to determine what portion of the activity varied either with the number of customers or with additional gas volumes. This variable portion was then assigned as demand, commodity or customer related using allocation factors derived from the FDC study.

The values expressed in \$/GJ peak day, \$/GJ, and \$/customer were applied to the demand, commodity and customer components described in previous sections to arrive at total incremental cost estimates.<sup>3</sup>

---

<sup>3</sup> These O&M cost estimates are included in the summary table (Table 6) in Section 6.

1 Incremental O&M expenditures were also used to determine the  
 2 overhead percentages to apply to transmission, distribution  
 3 and customer related investments in the incremental demand and  
 4 customer cost components. This was done by applying an  
 5 allocation procedure, similar to that described above, on  
 6 those O&M costs which are typically capitalized<sup>4</sup>. Table 5  
 7 below shows the derivation of demand (transmission and  
 8 distribution) and customer (meters, services and mains)  
 9 related overhead rates.

10  
 11 For demand related and customer related components, the  
 12 portion of incremental O&M charged to capital was divided into  
 13 the estimated total incremental direct capital expenditures  
 14 for 1996. Incremental O&M costs were assumed to remain  
 15 constant in real terms throughout the analysis period.  
 16  
 17

Table 5: Overhead Costs (\$1996)	
<b>Demand Related</b>	
(1) O&M Charged to Capital	\$ 2,201,250
(2) Total T&D Capital (1996)	\$ 12,630,264
(3) Overhead Rate (1)/(2)	17%
<b>New Customer Related</b>	
(1) O&M Charged to Capital	\$ 9,822,750
(2) Total Meters et. al. Capital (1996)	\$ 26,600,830
(3) Overhead Rate (1)/(2)	37%

30 <sup>4</sup> O&M costs allocated to overhead were the variable portions of BCUC account items dealing  
 31 with "Charges to capital".

1       **6.0 SUMMARY**

2  
3       Economic theory holds that efficiency is best served when the  
4       price of a product or service reflects marginal costs. The  
5       purpose of this study is to establish estimates of the  
6       marginal cost of providing future gas service to consumers for  
7       the purposes of comparing rates with marginal cost. BC Gas  
8       has built on the LRIC study submitted in the Phase B  
9       Application and has modified the analysis to reflect the  
10       recommendations incorporated in the Commission's decision.  
11       While BC Gas is satisfied with the methodology it has employed  
12       in developing its marginal costs, caution needs to be used in  
13       applying the specific values for rate design purposes.

14  
15       While both FDC and LRIC studies are to some extent subjective  
16       and judgemental, FDC studies are based on historic costs  
17       whereas incremental costs are based on long term forecasts of  
18       the future. Incremental costs are thus subject to  
19       considerable uncertainty. Some of these uncertainties  
20       include:

- 21  
22       • forecasts of well-head gas prices  
23       • forecast capital costs and requirements  
24       • forecasts of gas demand  
25       • Westcoast pipeline system toll forecasts  
26       • the availability of future gas storage  
27       • discount rates  
28       • potential technological improvements

29  
30       These factors influence the precision of the incremental cost  
31       estimates and should therefore be considered when applying the  
32       results to rate design.

33  
34       The following is a summary of the demand, commodity and  
35       customer incremental cost estimates.

1       **6.1 DEMAND COSTS**

2  
3       Table 6 below provides a summary of demand cost estimates for  
4       transmission, distribution, peak day demand and average  
5       demand.  
6

7

8                                   **Table 6: Demand Costs Summary**  
  **(\$1996)**

	(\$/GJ Peak Day)
Transmission*	\$ 40
Distribution*	\$ 47
Peak Day Demand (Supply)	\$ 53
	(\$/GJ)
Avg. Demand Cost	\$0.77

9

10

11

12

13

14

15

16

17                                   \* Includes Operation and Maintenance Costs

18

19

20       The estimates for the value of peak day capacity, including  
21       operation and maintenance related costs, are \$40/GJ peak day  
22       and \$47/GJ peak day for transmission and distribution  
23       respectively. These estimates provide guidance for setting a  
24       price discount for interruptible capacity relative to firm  
25       capacity. At 100% load factor, these figures translate into  
26       a value of \$0.24/GJ (\$87/ 365 days / load factor) for  
27       transportation and distribution service.  
28

29       The peak day supply cost of \$53/GJ peak day represents the  
30       estimated cost of pure demand derived using the cost for a new  
31       LNG facility. The average demand cost of \$0.77/GJ is an  
32       estimate of the incremental cost of average demand capacity  
33       for base load gas supply as derived using the Gas Supply  
34       Optimization Model (GSOM).

1       **6.2   COMMODITY COSTS**

2  
3       Table 7 shows the levelized incremental commodity cost of gas.  
4       This estimate was derived using GSOM and includes related  
5       operation and maintenance costs.  
6  
7

8  
9

13       \* Includes Operation and Maintenance Costs  
14  
15

16       **6.3   CUSTOMER CHARGES**

17  
18       Table 8 provides a summary incremental customer costs,  
19       indicative of the costs of attaching a typical new customer to  
20       the BC Gas system.  
21

22  
23

Table 8: Customer Costs Summary (\$1996)		
Meters, Services & Mains	\$/Customer	
	Per Year	Per Month
Rate 1	\$ 251	\$ 21
Rate 2	\$ 269	\$ 22
Rate 3	\$ 628	\$ 52

24  
25  
26  
27  
28  
29  
30       \* Includes Operation and Maintenance  
31

32       For residential, small commercial and large commercial  
33       customers, these costs do not vary over a wide range of gas  
34       consumption. To the extent that these customer costs reflect  
35       typical fixed costs, the estimates support higher basic  
36       charges for new customers in these markets.

## FULLY DISTRIBUTED COST OF SERVICE STUDY

1 The fully distributed cost (FDC) study performed for purposes  
2 of this rate design application employs, except as noted  
3 herein, the same methodology as that of the FDC study in the  
4 1993 Phase B Rate Design Hearing. The results of that study  
5 were accepted by the Commission in support of the revenue  
6 reallocation between customer classes (Decision dated October  
7 25, 1993, Page 15).

8  
9 As mentioned in BC Gas' evidence during that proceeding, the  
10 basic purpose of a FDC study is to compare the revenue  
11 generated by rates to the cost that a utility incurs in  
12 serving its customer classes. A FDC study is one element  
13 frequently considered in the setting of rates. It is worth  
14 emphasizing, however, that even though it is a useful guide in  
15 this regard, it is not a prescription for rate setting, as  
16 many other factors must also be taken into account.

17  
18 In a manner similar to the general description of the FDC  
19 study in the 1993 Phase B Rate Design Application, the  
20 paragraphs below summarize the procedures employed.

21

### 22 1.0 FULLY DISTRIBUTED COSTING METHODOLOGY

23

24 There is no cost apportionment formula that is perfect from a  
25 theoretical standpoint and, at the same time, practical from  
26 an administrative point of view. The National Association of  
27 Regulatory Utility Commissioners, in its Cost Allocation  
28 Manual, and American Gas Association, in its Gas Rate  
29 Fundamentals, do not specify one method to the exclusion of  
30 all others. There are arguments that can be made for variants  
31 of fully distributed cost, i.e. coincident peak (CP), non-  
32 coincident peak (NCP), average and excess (A&E) and others.

1 As in the 1993 Phase B Rate Design Application, the approach  
2 taken by BC Gas in this application is to set out the findings  
3 under various methods of cost allocation as a basis for  
4 support for the rate design changes proposed. In this way, a  
5 range of costs is developed to illustrate the probable floor  
6 and ceiling for the cost of service.  
7

## 8 **2. CATEGORIES OF COST**

9

10 Approximately 50% of BC Gas' cost of doing business relates to  
11 the cost of natural gas supplies. The remaining 50% of the  
12 cost that BC Gas incurs in serving its customers is for what  
13 can be called "cost of service margin" or "margin". It is the  
14 total cost to serve less cost of gas. The allocation of the  
15 total margin to customer classes is the topic of the material  
16 under this Tab.  
17

18 There are three primary categories of cost causation factors  
19 in utility operations: demand-related cost, customer-related  
20 cost, and commodity-related cost. The first two are called  
21 "standing costs" -- the costs incurred in standing by to serve  
22 customers whenever they apply a load to the system.  
23 Commodity-related costs vary with consumption of energy and  
24 are called "running cost" or the additional cost that is  
25 incurred with the consumption of one more or one less  
26 gigajoule of gas. There are also revenue sensitive costs,  
27 e.g. one percent of revenue in lieu of property taxes on  
28 distribution facilities.  
29

## 30 **3.0 PROCEDURES INVOLVED IN FDC STUDIES**

31

32 BC Gas has followed the traditional three steps in preparing  
33 fully distributed cost of service studies: 1) functional-  
34 ization, 2) classification of function costs into demand,  
35 commodity, and customer-related components, and 3) allocation

1 of these costs to the various rate classes. Functionalization  
2 is the determination of costs by utility functional groups:  
3 gas supply, gas supply administration, transmission,  
4 distribution, marketing and customer accounting.  
5 Classification is the separation of the functional groups into  
6 demand, commodity and customer components by cost causation.  
7 Allocation is the process of apportioning each of the  
8 functionalized and classified cost groups to the various  
9 classes of customers. When possible, costs have been directly  
10 assigned to specific customer classes that caused the cost.  
11 The process starts with the utility's chart of accounts.

12  
13 **3.1 Chart of Accounts**

14  
15 BC Gas maintains its accounting records in accordance with the  
16 uniform system of accounts prescribed by the Commission.  
17 These plant and revenue requirement records are the basic  
18 accounting data source for the fully distributed cost study.

19  
20 **3.2 Functionalization**

21  
22 The functionalization procedure begins with plant and  
23 operating expense accounts. The investment associated with  
24 each facility is assigned to a function, e.g. gas supply, gas  
25 supply administration, transmission, distribution, marketing  
26 and customer accounting. After assigning plant costs  
27 functionally, related expenses usually follows the same  
28 functionalization logic.

29  
30 From this analysis, ratios based on the proportion of gas  
31 plant assigned to each cost of service function are developed.  
32 These plant ratios can be used for the functionalization of  
33 most of the other cost items. This process requires the  
34 assistance of the Company's engineering and accounting

1 personnel to match the plant investment and associated  
2 operating expenses to the proper cost function.

3  
4 **3.3 Classification**

5  
6 In the next step of the FDC, functional cost is divided into  
7 cost causation categories. The three principal categories are  
8 demand-related, commodity-related and customer-related costs.

9  
10 **3.3.1 Demand-Related**

11  
12 The term demand (or capacity) refers to utility service that  
13 must be available upon the customer's demand. Demand related  
14 costs pertain to the peak usage of utility service by the  
15 Company's customers.

16  
17 Storage (LNG), pipeline and compressor costs are assigned to  
18 the demand classification and can be apportioned on the basis  
19 of the relative demands placed on the system by the various  
20 customer classes.

21  
22 **3.3.2 Commodity-Related**

23  
24 A commodity-related cost is the variable cost of gas. Few of  
25 the costs to operate the facilities of BC Gas are variable  
26 with respect to the volume of gas delivered to customers. Gas  
27 supply administration expenses are classified as commodity-  
28 related cost in these FDC studies as a means to apportion the  
29 expenses to all sales and T-service customers.

30  
31 **3.3.3 Customer-Related**

32  
33 At the distribution level, the closer a plant item is  
34 physically located to a customer, e.g. a meter and service  
35 line, the more that particular item can be related to the

1 requirements of that customer. Customer-related costs are  
2 those associated with services, meters, regulators, marketing  
3 and customer accounting. They are directly assigned in  
4 certain cases or are allocated to the customers of a  
5 particular class of service based on customer weighting  
6 factors.

7  
8 A number of different approaches have been used by utilities  
9 to classify distribution mains costs. Sometimes distribution  
10 mains are classified as demand-related, in other FDC studies  
11 a portion of the cost of mains is classified as customer-  
12 related<sup>1</sup>. The latter is the approach most commonly used and  
13 has been employed in this FDC study. The concept of  
14 classifying some portion of the mains as customer-related is  
15 based on the premise that there is some cost incurred to reach  
16 the customer irrespective of the customer's capacity  
17 requirement. At the distribution level, the capacity of  
18 facilities is closely related to the number of customers  
19 connected to those facilities. In the 1993 FDC study,  
20 distribution mains were classified as demand related costs.  
21 In this study, BC Gas has used the zero-intercept method<sup>2</sup> to  
22 classify a portion of mains as customer-related. This method  
23 follows the more commonly used practice in the utility  
24 industry. In the Lower Mainland service area, the customer

34 Global Perspective, Edison Electric Institute, McGraw-Hill Book Company,  
35 pg. 391-393; and Electric Utility Cost Allocation Manual, National  
36 Association of Regulatory Utility Commissioners, 1992, pg. 92-95.

1 -related portion is 20.9%, in the Inland service area it is  
2 24.5% and in the Columbia service area 27.5%.

3  
4 **3.4 Capacity Allocation**

5  
6 Allocation of the functionalized and classified costs among  
7 the various classes of customers is the third step of the FDC  
8 process. As mentioned earlier, there are various methods that  
9 are used in this process. Three of the more commonly used  
10 methods have been employed in this study. They are the  
11 coincident peak (CP), non-coincident peak (NCP) and the  
12 average and excess (A&E) methods. Each is discussed below.

13  
14 Consistent with the 1993 FDC study, the demand allocators for  
15 the firm industrial captive and bypass customers in the Inland  
16 service area have been weighted by transmission distance in  
17 this study.

18  
19 For purposes of the 1996 study, all load factors used in the  
20 capacity allocation process were reviewed. As a result, the  
21 load factor for Rate Schedule 5, previously estimated at 45%,  
22 has been increased to 65%. All other load factors are close  
23 to those used in the 1993 FDC study, and reflect those used  
24 for the 1996 gas cost flow-through.

25  
26 **3.4.1 Coincident Peak (CP)**

27  
28 The CP method is used in this study to allocate capacity costs  
29 according to the demand imposed on the system by the various  
30 classes of customers during the peak day. The correlation  
31 between very cold weather and the firm system peak loads  
32 imposed on the BC Gas system forms the basis of using the  
33 coincident peak method as a capacity cost allocator. BC Gas  
34 builds its system on the basis of having to deliver gas to firm  
35 customers under extreme cold weather conditions.

1 The coincident peak method assigns the capital required to  
2 provide service during the peak load requirements of its  
3 customers.

4  
5 **3.4.2 Non-coincident Peak (NCP)**

6  
7 Under the NCP method of allocating capacity cost, the maximum  
8 rates of consumption of all customers or classes are added  
9 together irrespective of the time of occurrence to find the  
10 aggregate "non-coincident demand". In the case of BC Gas,  
11 peak day loads for the core customers are forecasted to occur  
12 on the coldest winter day, which for the NCP method is the  
13 same as for the CP method.

14  
15 Industrial loads usually have a heating component to some  
16 extent, but they are more process oriented. Their peak loads  
17 may occur at times other than the coldest day of the year. It  
18 may be necessary to build certain portions of the system large  
19 enough to carry their loads regardless of when the coincident  
20 peak occurs. The NCP capacity cost allocation method is of  
21 assistance under these circumstances since capacity costs are  
22 allocated to each class according to the ratio of the maximum  
23 rate of consumption that each class bears to the aggregate  
24 non-coincident demand of all of the classes.

25  
26 **3.4.3 Average & Excess (A&E)**

27  
28 The A&E method is a two part calculation that takes into  
29 account the average use of the system and the non-coincident  
30 demands that are placed on the system. The method recognizes  
31 the dual service a pipeline system provides - a peak capacity  
32 deliverability service and a continuous throughput service.  
33 The first part of the formula recognizes the average demand of  
34 the system capacity. The second part of the formula  
35 recognizes the excess of non-coincident demand over average
